

8th INTERNATIONAL MULTIDISCIPLINARY SCIENTIFIC SYMPOSIUM

UNIVERSITARIA SIMPRO 2018

11-13 OCTOBER 2018, PETROȘANI

CONFERENCE PROCEEDINGS

Editor: Roland Iosif MORARU

E-editors: Csaba LORINȚ

Radu ION

DISCLAIMER

This book contains abstracts and complete papers approved by the Conference Reviewers and Committees. Authors are responsible for the content and accuracy.

ORGANIZERS:

UNIVERSITY OF PETROȘANI & NIRD - INSEMEX PETROȘANI

Under the auspices:

ACADEMY OF ROMANIAN SCIENTISTS

ACADEMY OF TECHNICAL SCIENCES OF ROMANIA

MINISTRY OF NATIONAL EDUCATION

GENERAL ASSOCIATION OF ENGINEERS IN ROMANIA, AGIR

In partnership with*:

ALUMNI ASSOCIATION OF THE UNIVERSITY OF PETROȘANI,

AMEROPA GRAINS S.A. ROMANIA, CONSTANȚA

ASSYSTEM TECHNOLOGIES ROMANIA

„AUREL VLAICU” UNIVERSITY OF ARAD

CDPM UNION

CHIMPEX CONSTANȚA

CZESTOCHOWA UNIVERSITY OF TECHNOLOGY

HUNEDOARA COUNTY COUNCIL

LABOUR INSPECTORATE

MOL ROMÂNIA

NATIONAL AUTHORITY FOR SCIENTIFIC RESEARCH

OPOLE UNIVERSITY OF TECHNOLOGY

S.C. GLOBAL CONSULTING S.R.L. TOPOLOVENI

SOCIETATEA NAȚIONALĂ A SĂRII, SALROM

SSM-SIU S.R.L. TÂRGU-MUREȘ

* Alphabetically ordered

COMMITTEE MEMBERS:

ORGANISING COMMITTEE

CONFERENCE CHAIR

Prof. dr. Roland Iosif MORARU, University of Petroșani, ROMANIA

HONORARY PRESIDENT

Prof. dr. Sorin–Mihai RADU, University of Petroșani, ROMANIA

CO-CHAIRS

Assoc. Prof. dr. Codruța DURA, University of Petroșani, ROMANIA

Dr. George Arthur GĂMAN, INCD-INSEMEX Petroșani, ROMANIA

Prof. dr. Eduard EDELHAUSER, University of Petrosani, ROMANIA

MEMBERS

Imola DRIGĂ, ROMANIA, Andreea Cristina IONICĂ, ROMANIA

Iosif DUMITRESCU, ROMANIA, Mihaela TODERAȘ, ROMANIA

Ion DOȘA, ROMANIA, Maria DOBRIȚOIU, ROMANIA

INTERNATIONAL SCIENTIFIC COMITEE

Tatiana ANTIPOVA, Institute of Certified Specialists, Perm, RUSSIA

Umer ASGHER, National Institute of Science and Technology, Islamabad, PAKISTAN

Constantin BACIU, Technical University “Gh. Asachi” of Iași, ROMANIA

Lia Alexandra BALTADOR, “Lucian Blaga”, University of Sibiu, ROMANIA

Radian G. BELU, Southern University and A&M College, Baton Rouge, U.S.A.

Daniel BREAZ, “1 Decembrie 1918”, University of Alba-Iulia, ROMANIA

Daniela BUZOIANU, University of Oil and Gasses, Ploiești, ROMANIA

Amir CAUSEVIC, University of Sarajevo, BOSNIA-HERZEGOVINA

Lucian-Ionel CIOCA, “Lucian Blaga” University of Sibiu, ROMANIA

Mihai Pascu COLOJA, University of Oil and Gasses, Ploiești, ROMANIA

Doru Costin DARABONT, NIRD-INCDPM Bucharest, ROMANIA

Predrag DASIC, High Technical Mechanical School of Professional Studies Trstenik, SERBIA

Anca DRĂGHICI, “POLITEHNICA” University of Timișoara, ROMANIA

Carsten DREBENSTEDT, TU Bergakademie, Freiberg, GERMANY

George Artur GĂMAN - NIRD INSEMEX Petroșani, ROMANIA

Emilian GHICIOI, NIRD INSEMEX Petroșani, ROMANIA
Janusz GRABARA, Czestochowa University of Technology, POLAND
Valentin RĂILEAN, IMI-NOVA, MOLDOVA
Claudiu KIFOR, “Lucian Blaga” University of Sibiu, ROMANIA
Karoly KOCSIS, College of Sciences, Mackay School of Earth Sciences and Engineering,
University of Nevada, Reno, USA
Gábor LADÁNYI, University of Miskolc, HUNGARY
Omar LANCHAVA, Georgian Technical University, GEORGIA
Ramona LILE, „Aurel Vlaicu” University of Arad
József MOLNÁR, University of Miskolc, HUNGARY
Mariana NAGY, „Aurel Vlaicu” University of Arad
Sonia PAVLOVICI-VESELINOVICI, University of Niš, SERBIA
Daniel PUPĂZAN, NIRD INSEMEX Petroșani, ROMANIA
Elena Cristina RADA, Università dell’Insubria di Varese, ITALY
Marco RAGAZZI, Università degli Studi di Trento, ITALY
Krzysztof KRAUZE, AGH University of Science and Technology, POLAND
Abd alBadi Mohammed Mahmoud SALEM, AinShams University, Cairo, EGYPT
Biplap Xanthi SENGUPTA, Kharagpur Indian Institute of Technology, INDIA
Semion SHKUNDIN, University NITU "MISIS" Moscova, RUSSIA
Krysztyna SKIBNIEWSKA, University of Warmia and Mazury in Olsztyn, POLAND
Vincenzo TORRETTA, Università dell’Insubria di Varese ITALY
Lyuben TOTEV, University of Mining and Geology “Ivan Rilski”, Sofia, BULGARIA
Dumitru ȚUCU, “POLITEHNICA” University of Timișoara Timișoara, ROMANIA
Jean-Jacques WAGNER, IUT de Belfort-Montbéliard, FRANCE
Janusz WIELKI, Politechnika Opolska, POLAND

NATIONAL SCIENTIFIC COMMITTEE

Ioan BUD – Universitatea Tehnica Cluj Napoca, Centrul de Nord, Baia Mare

Prof. dr. ing. Sabina IRIMIE – Universitatea din Petroșani

Prof. dr. mat. Wilhelm W. KECS – Universitatea din Petroșani

Prof. dr. ing. Maria LAZĂR – Universitatea din Petroșani

Prof.dr.ing. Monica LEBA – Universitatea din Petroșani

Prof. dr. ec. Mariana MAN – Universitatea din Petroșani

Prof. dr. ing. Gheorghe MANOLEA – Universitatea din Craiova

Prof.dr.ing. Dan Codrut PETRILEAN – Universitatea din Petroșani

Conf.dr.ing. Gabriel BĂBUȚ – Universitatea din Petroșani

Conf.dr. Gabriela DUMBRAVĂ – Universitatea din Petroșani

Conf. dr.ing.Csaba LORINȚ – Universitatea din Petroșani

Conf.dr.ing. Ioel VEREȘ – Universitatea din Petroșani

Șef lucr. dr.ing. Ladislau RADERMACHER – Universitatea din Petroșani

Lector.dr. Mihaela SCHMIDT – Universitatea din Petroșani

ADVISORY BOARD

Nicolae DIMA, ROMANIA, Nicolae ILIAS, ROMANIA

Dumitru FODOR, ROMANIA, Mircea GEORGESCU, ROMANIA

Iozsef KOVACS, ROMANIA, Andrei MAGYARI, ROMANIA

Emil POP, ROMANIA, Dorel ZUGRAVESCU, ROMANIA

SECRETARIES OF SESSIONS

Assoc. Prof. dr.eng. Larisa FILIP

CONTENTS

SECTION 1.		
ADVANCES IN SAFETY SCIENCE AND OCCUPATIONAL RISK MANAGEMENT		
1	Guram Abashidze, Nicolae Ilias, Roland Moraru, David Tsverava <i>THE POSSIBILITY OF SAFETY IMPROVEMENT THROUGH EXOGENOUS FIRE PREDICTION IN MINE WORKINGS AND TRANSPORT TUNNELS</i>	21
2	Omar Lanchava, Nicolae Ilias, Giorgi Nozadze, Sorin Radu <i>HEAT AND HYGROSCOPIC MASS EXCHANGE MODELING FOR SAFETY MANAGEMENT IN TUNNELS OF METRO</i>	27
3	Giorgi Nozadze <i>DYNAMICS OF SPREAD OF FIRE-RELATED HARMFUL FACTORS IN METRO TUNNELS DURING A FORCED STOPPAGE OF THE METRO TRAIN</i>	33
4	Nicolae Bancila-Afrim, Roland Iosif Moraru, Lucian - Ionel Cioca, Gabriel Bujor Babut <i>ACCIDENTS AT WORK AMONG INDUSTRIAL PRESSES OPERATORS: ANALYSIS OF STATISTICS IN NORTH-WESTERN REGION OF ROMANIA</i>	39
5	Vlad Mihai Păsculescu, Emilian Ghicioi, Marius Simion Morar, Dragoș Păsculescu, Marius Cornel Șuvar <i>COMPUTATIONAL STUDY FOR IMPROVING THE QUALITY OF SAFETY MEASURES FOR LPG FILLING STATIONS</i>	45
6	Mihaela Laura Bratu, Lucian-Ionel Cioca <i>MANAGERIAL STRATEGIES FOR OPTIMIZING ERGONOMICS IN ORGANIZATIONS, TAILORED TO THE PERSONALITY OF ENGINEERS, TO IMPROVE THE QUALITY OF LIFE AND SECURITY OF EMPLOYEES</i>	51
7	Nicolae Daniel Fiță, Dragoș Păsculescu, Roland Moraru <i>IDENTIFICATION OF RISK SCENARIOS ON CRITICAL INFRASTRUCTURES OF ULTRA HIGH AND VERY HIGH VOLTAGE FOR THE PURPOSE OF RISK ASSESSMENT AND QUALITY IMPROVEMENT OF THE NATIONAL POWER GRID</i>	57
8	Marius Cornel Suvar, Emilian Ghicioi, Laurențiu Munteanu, Vlad Mihai Păsculescu, Gheorghe Daniel Florea, Niculina Sonia Suvar, Aurelian Nicola <i>COMPUTATIONAL STUDY ON THE QUALITY OF THE SUPPRESSION EFFECT OF SPRINKLERS ON BUILDING FIRES SPREAD AND INTERACTION WITH SMOKE LAYERS</i>	63
9	Ilie-Ciprian Jitea, Dragoș Gabriel Vasilescu, Robert Laszlo, Cristian Raul Cioara, Claudia Miron <i>IMPROVING THE QUALITY FOR CLASSIFICATION OF PYROTECHNIC ARTICLES ON THE BASIS OF PYROTECHNIC COMPOSITION CONTENT</i>	69
10	Dragos Gabriel Vasilescu, Robert Laszlo, Attila Kovacs, Cristian Radeanu, Olga Miclea <i>PROSPECTIVE AND EXPLORATORY RESEARCH IN THE QUALITY FIELD OF INDUSTRIAL RISK ASSESSMENT AND ANALYSIS</i>	75
11	Izabella Kovacs, Daniel Pupăzan, Cristian Nicolescu, Alin Irimia, Andrei Gireadă, Cosmin Ilie <i>RESEARCH ON PSYCHOLOGICAL INDICATORS INVOLVED IN RESCUE ACTIVITIES</i>	81
12	Marius Darie, Sorin Burian, Tiberiu Csaszar, Cosmin Colda, Dănuț Grecea <i>CONSIDERATIONS ON LOW CURRENT CIRCUITS PROFICIENCY TESTS WITH EXPLOSIVE GAS MIXTURES</i>	87
13	Cristian Tomescu, Doru Cioclea, Ion Gherghe, Emeric Chiuzan, Marius Morar <i>DETERMINATION OF DANGER, RISK AND FIRE VULNERABILITY PARAMETERS. NUMERICAL SIMULATION IN FIRE EXTINCTION</i>	93
14	Gireada Andrei-Lucian, Găman George Artur, Nicolescu Cristian, Ilie Cosmin, Irimia Alin, Kovacs Izabella <i>RESEARCH ON ESTABLISHING THE PHYSICAL EFFORT OF RESCUERS ACCORDING TO THE ACTIVITY PERFORMED AND TYPE OF RESPIRATION PROTECTION EQUIPMENT</i>	99
15	Alin Irimia, Sorin Burian, Florin Păun, Dan Gabor, Marius Darie <i>TESTING THE TEMPERATURE PROOF OF SELF-CONTAINED BREATHING APPARATUS, BASED ON COMPRESSED AIR</i>	105
16	Sorin Simion, Marius Kovacs, Lorand Toth, Alexandru Simion, Maria Badescu <i>MONITORING WORKER'S EXPOSURE TO PHYSICOCHEMICAL POLLUTANTS TO PREVENT OCCUPATIONAL ILLNESS</i>	109

17	Costica Bejinariu, Diana-Petronela Burduhos-Nergis, Nicanor Cimpoesu, Mihai-Adrian Bernevig-Sava, Stefan-Lucian Toma, Doru-Costin Darabont, Constantin Baci <i>STUDY ON THE ANTICORROSIVE PHOSPHATED STEEL CARABINERS USED AT PERSONAL PROTECTIVE EQUIPMENT</i>	113
18	Diana-Petronela Burduhos-Nergis, Carmen Nejneru, Ramona Cimpoesu, Alin-Marian Cazac, Constantin Baci, Doru-Costin Darabont, Costica Bejinariu <i>ANALYSIS OF CHEMICALLY DEPOSITED PHOSPHATE LAYER ON THE CARABINERS STEEL SURFACE USED AT PERSONAL PROTECTIVE EQUIPMENT</i>	119
19	Cristian Rădeanu, Attila Kovacs, Daniela Rus, Ilie - Ciprian Jitea, Dragos Gabriel Vasilescu <i>INCREASE IN THE SECURITY QUALITY IN USE OF PROFESSIONAL PYROTECHNIC ARTICLES FALLING IN CATEGORY F4</i>	125
20	Cosmin Ilie, Daniel Pupăzan, Cristian Nicolescu, Alin Irimia, Andrei Gireadă, Izabella Kovacs <i>RESEARCHES ON THE DEVELOPMENT OF SPECTROSCOPY TECHNOLOGY USED IN THE PROCESS OF PRESSURE NETWORKS TECHNICAL VERIFICATION</i>	131
21	Daniela Carmen Rus, Emilian Ghicioi, Robert Laszlo, Cristian Rădeanu, Attila Kovacs, Gabriel Vasilescu <i>ASSESSING THE QUALITY SAFETY PERFORMANCE OF THE DEFLAGRATION - DETONATING TRANSIENT BEHAVIOR SPECIFIC TO CLASS 1 HAZARDOUS MATERIALS, ACCORDING TO ORANGE BOOK</i>	137
22	Edward Gheorghiosu, Emilian Ghicioi, Robert Laszlo, Attila Kovacs, Cristian Rădean, Dan Gabor <i>CHECKING THE QUALITY OF THE ELECTRIC IGNITER - PYROTECHNIC ARTICLE OF CATEGORY P1, BY LABORATORY METHODS APPLIED TO DETERMINE THE SENSITIVITY TO ELECTROSTATIC DISCHARGE</i>	141
23	Gheorghe - Daniel Florea, Nicolae - Ioan Vlasin, Zoltan Vass, Bogdan Adrian Şimon, Ligia Ioana Tuhuţ <i>COMPUTATIONAL SIMULATIONS OF THE TRANSPORT AND IGNITION OF METHANE IN ENCLOSED SPACES</i>	145
24	Szollosi- Mota Andrei, Ghicioi Emilian, Prodan Maria, Nalboc Irina, Suvar Sonia <i>DETERMINATION OF FLAMMABILITY PARAMETERS AND BURNING GASES, IN ORDER TO REDUCE RISKS IN THE FIRE OR EXPLOSION TYPE EVENTS</i>	151
25	Dan Gabor, Sorin Mihai Radu, Emilian Ghicioi, Mihaela Paraian, Adrian Marius Jurca, Niculina Vatavu, Florin Paun, Catalin Mihai Popa <i>STUDY OF METHODS FOR ASSESSMENT OF THE IGNITION RISK OF DUST/AIR EXPLOSIVE ATMOSPHERES BY ELECTROSTATIC DISCHARGE</i>	157
26	Niculina-Sonia Şuvar, Emilian Ghicioi, Irina Nălboc, Andrei Szollosi-Moţa, Maria Prodan <i>IDENTIFICATION OF BURNING ACCELERATORS IN INVESTIGATION OF FIRES USING THE INFRARED SPECTROSCOPY METHOD (FTIR)</i>	163
27	Lorand Toth, George Artur Găman, Angelica Călămar, Daniel Pupăzan, Cristian Nicolescu, Izabella Kovacs <i>ELEMENTS OF DISASTER MANAGEMENT AND FIRST AID</i>	169
28	Anisoara Corabieru, Elena Mihalache, Mihai - Adrian Bernevig - Sava, Nicoleta - Monica Lohan <i>PIPE MANUFACTURING PROCESS NOISE AND VIBRATION DETERMINATION CASE STUDY</i>	175
29	Doru Costin Darabont, Costica Bejinariu, Constantin Baci, Mihai-Adrian Bernevig-Sava <i>MODERN APPROACHES IN INTEGRATED MANAGEMENT SYSTEMS OF QUALITY, ENVIRONMENTAL AND OCCUPATIONAL HEALTH AND SAFETY</i>	181
30	Paul Ciubotariu - Ana, Mihai - Adrian Bernevig - Sava, Nicoleta - Monica Lohan, Costică Bejinariu <i>STUDY ON INCREASING THE THERMAL PROTECTION OF HIGH-TEMPERATURE HELMETS USED BY FIREFIGHTERS</i>	185
31	Mihai-Adrian Bernevig-Sava, Doru Costin Darabont, Nicoleta Monica Lohan, Elena Mihalache, Costica Bejinariu <i>SELECTION AND VERIFICATION OF PERSONAL PROTECTIVE EQUIPMENT IN THE CONTEXT OF CURRENT LEGAL REQUIREMENTS</i>	191
32	Constantin Baci, Costica Bejinariu, Doru Costin Darabont, Anisoara Corabieru, Mihai-Adrian Bernevig-Sava <i>OCCUPATIONAL SAFETY AND HEALTH AUDIT BETWEEN THEORY, LEGAL REQUIREMENTS AND PRACTICE</i>	195

33	Andrian Batugin, Konstantin Kolikov, Alexander Ivannikov <i>TRANSFORMATION OF THE GEODYNAMIC HAZARD MANIFESTATION FORMS IN MINING AREAS</i>	199
34	Florina Luminita Besnea, Stefan-Irinel Cismaru, Nicu-George Bizdoaca <i>OPERATING ENVIRONMENT IN AUGMENTED REALITY MAINTENANCE APPLICATIONS</i>	205
35	Joanna Tabor <i>APPLICATION THE FUZZY TOPSIS METHOD TO ASSESS AND SELECT A CONTRACTOR FROM THE POINT OF VIEW OF OCCUPATIONAL SAFETY MANAGEMENT</i>	209
36	George Danko <i>LIMITATIONS AND ERROR MITIGATION FOR MINE CLIMATE MODELS WITH NO THERMAL HISTORY COMPONENT</i>	215
37	Zerbes Mihai-Victor, Cioca Lucian-Ionel, Neamu Vasilica-Silvia <i>DEVELOPING A MODEL OF OCCUPATIONAL HEALTH PROGRAM</i>	221
38	Zerbes Mihai-Victor, Cioca Lucian-Ionel, Neamu Vasilica-Silvia <i>OCCUPATIONAL HEALTH PROGRAMS AND WORKPLACE ABSENTEEISM</i>	227
39	Bianca Cirjaliu, Anca Mocan, Boatca Maria - Elena, Anca Draghici <i>A PROPOSE APPROACH FOR CONTINUOUS IMPROVEMENT USING ERGONOMICS AND QUALITY MANAGEMENT KNOWLEDGE AND METHODOLOGIES</i>	233
40	Alin Gaureanu, Anca Draghici, Hugo Weinschrott <i>INCREASING THE QUALITY OF OCCUPATIONAL SAFETY AND HEALTH IMPLEMENTATIONS THROUGH AWARENESS TRAINING FOR THOSE INVOLVED IN IMPLEMENTING THE SAFETY OBSERVATION REPORT</i>	239
41	Nicoleta Craciun, Alina Trifu <i>REDUCING THE RISK OF SLIPPING ON ICE BY SELECTING APPROPRIATE PROTECTIVE FOOTWEAR</i>	245
42	Gabriel Bujor Băbuț, Roland Iosif Moraru <i>MANAGING THE ACTIVITIES OF AUTHORIZATION TO PRACTICE TRADES AND PROFESSIONS IN TERMS OF SAFETY AND HEALTH AT WORK</i>	251
43	Gabriel Bujor Băbuț, Roland Iosif Moraru, Popescu Stelea Mihai, Babut Andrada Denisa <i>IMPROVING DRAINED GAS QUALITY PARAMETERS THROUGH OPTIMAL MANAGEMENT OF METHANE DRAINAGE SYSTEMS</i>	257
44	Georgeta Buica, Antonov Anca Elena, Constantin Beiu, Dragos Pasculescu, Mircea Risteiu <i>MANAGEMENT OF ELECTRICAL EQUIPMENT AND PROTECTIVE DEVICES USED IN ELECTRICAL INSTALLATIONS</i>	263
46	Radu Mares, Mihai Popescu - Stelea, Roland Iosif Moraru, Gabriel Bujor Băbuț, Mariana Nagy <i>EMPLOYEES PROTECTION IN MAINTENANCE ACTIVITIES. A STATISTIC IMAGE</i>	269
46	Anca Elena Antonov, Georgeta Buicaa, Constantin Beiu, Raluca Aurora Stepa <i>MANAGEMENT OF DANGEROUS SUBSTANCES RELEASED BY MACHINERY, CONDITION TO ENSURE SAFETY AND WORKERS' HEALTH AND ENVIRONMENTAL</i>	275
SECTION 2.		
CHALLENGES IN MINING ENGINEERING, SURVEYING AND CIVIL ENGINEERING		
1	Emeric Chiuzan, George Artur Gaman, Cristian Tomescu, Adrian Matei, Razvan Dragoescu <i>ANALYSIS OF THE METHODS OF EXPLOITATION APPLIED TO ROMANIAN SALT MINES</i>	281
2	Marius Simion Morar, Doru Cioclea, Cristian Raul Cioara, Vlad Mihai Pasculescu <i>UNDERGROUND ENVIRONMENT OPTIMIZATION USING SPECIALIZED PROGRAMS</i>	287
3	Bușe Florian, Bușe Gheorghe Florin <i>THE IMPACT OF THE INTEGRATED TECHNICAL SYSTEM ON THE QUALITY OF CONSTRUCTION WORKS</i>	293
4	Florin Rădoi, Ion Gherghe, Emeric Chiuzan, Adrian Matei, Răzvan Drăgoescu <i>EFFICIENCY OF INDUSTRIAL VENTILATION INSTALLATIONS</i>	299
5	Kovacs Attila, Ghicioi Emilian, Laszlo Robert, Dinu Florea, Jitea Ciprian Ilie <i>ANALYSIS OF THE BEHAVIOR OF METALLIC STRUCTURES OF MULTI-LEVEL BUILDINGS WHEN EXPOSED TO DYNAMIC EFFECTS DUE TO EXPLOSIVE DETONATION</i>	303
6	Adrian Matei, Răzvan Drăgoescu, Doru Cioclea, Emeric Chiuzan, Florin Radoi <i>ANALYSIS OF EXPLOSIVE ENVIRONMENTS THAT INTERRACTS WITH INDUSTRIAL VENTILATION SYSTEMS</i>	309

7	Doru Cioclea, Nicolae Ianc, Marius Morar, Adrian Matei, Răzvan Drăgoescu <i>EFFICIENCY OF COMPLEX VENTILATION NETWORKS</i>	315
8	Laszlo Robert, Gheorghiosu Edward, Vasilescu Dragos Gabriel, Kovacs Attila, Jitea Ciprian, Galvitu Mihaela <i>INCREASING THE SAFETY, QUALITY AND EFFICIENCY OF DEMOLITION / DISMANTLING OF METAL STRUCTURES BY USING BLASTING WORKS</i>	321
9	Ion Gherghe, Doru Cioclea, Cristian Tomescu, Florin Rădoi, Corneliu Boantă, Emeric Chiuzan <i>FANS, SPECIFIC OPERATIONAL PARAMETERS OF INDUSTRIAL VENTILATION INSTALLATIONS</i>	327
10	Ianc Nicolae, Cioclea Doru, Gherghe Ion, Radoi Florin, Chiuzan Emeric, Matei Adrian, Dragoescu Razvan <i>THE IMPACT ON THE ENVIRONMENT PRODUCED BY THE METHANE GAS RELEASED IN THE JIU VALLEY COAL MINES</i>	333
11	Karoly Charles Kocsis, Roghanchi Pedram, Teixeira B. Marcelo, Parrish Jacob, Scalise Kyle <i>SENSITIVITY ANALYSIS ON MAJOR HEAT SOURCES AND EVALUATION OF COOLING SYSTEMS TO PROVIDE ADEQUATE WORK CONDITIONS IN UNDERGROUND METAL MINES</i>	339
12	Jozsef Molnar, Ákos Debreczeni, Richárd Tompa. <i>CHALLENGES AND OPPORTUNITIES OF UNDERGROUND COAL MINING IN NORTH-EASTERN HUNGARY</i>	347
13	Gelu Madear, Camelia Madear <i>PROBABILISTIC APPROACHES IN TUNNEL DESIGN</i>	353
14	Gelu Madear, Camelia Madear <i>LOADS ESTIMATION IN BLOCK CAVING MINING</i>	359
15	S.A. Lutsenko, S.A. Zhukov <i>PLANNING THE DEVELOPMENT OF MINING OPERATIONS UNDER THE CHANGING DEMAND FOR IRON ORE PRODUCTS</i>	365
16	Toderas Mihaela, Danciu Ciprian <i>ASSESSMENT METHODOLOGY OF INSTANTANEOUS ELASTIC DEFORMATION OF SEDIMENTARY ROCKS</i>	371
17	Filip Larisa <i>THE DEVEPELOMENT OF MINERAL TIANGULATION NETWORKS USING A SIMPLIFIED CALCULATION PROCESS</i>	377
18	Zhukov S.A., Skachkov A.A., Titov D.A. <i>IMPROVEMENT OF BLASTING OPERATIONS IN OPEN PIT BY DIFFERENTIAL STRAIN AND SYMMETRICAL BLASTING OF THE ROCK</i>	381
19	Danciu Ciprian, Toderas Mihaela, Lorint Csaba, Florea Adrian <i>CHARACTERIZATION AND CLASSIFICATION OF ANDESITES OF CRISCIOR AND ALBINI FROM SOUTHERM APUSENI MOUNTAINS, FOR CAPITALIZATION</i>	387

SECTION 3.

SUSTAINABLE ENVIRONMENTAL ENGINEERING AND PROTECTION

1	Nikolay Savov, Teodora Hristova, Petya Gencheva <i>EXPLORING POSSIBLE ACCIDENTS AND RECOMMENDATIONS FOR BIOLOGICAL WASTE TREATMENT INSTALLATIONS</i>	393
2	Florin Adrian Paun, Mihaela Paraian, Adrian Marius Jurca, Dan Gabor, Niculina Vatavu, Catalin Mihai Popa <i>SELECTION OF PERSONAL PROTECTIVE EQUIPMENT FOR USE IN POTENTIALLY EXPLOSIVE ATMOSPHERES</i>	399
3	Cătălin Mihai Popa, Silviu Marin Nan, Mihaela Părăian, Adrian Marius Jurca, Florin Adrian Păun, Leonard Lupu, Niculina Vătavu, Dan Gabor <i>STUDY OF EXPLOSIVE CHARACTERISTICS OF COMBUSTIBLE POWDERS</i>	403
4	Niculina Vatavu, Emilian Ghicioi, Sorin Vatavu, Mihaela Paraian, Adrian Jurca, Florin Paun, Dan Gabor, Mihai Popa <i>RESEARCH ON THE IDENTIFICATION OF THE DANGERS OF DUST AND WATER ENTERING EQUIPMENT FOR POTENTIALLY EXPLOSIVE ATMOSPHERES</i>	409
5	Alexandru Florin Simion, Angelica Nicoleta Calamar, Lorand Toth, Marius Kovacs, Sorin Simion <i>RESEARCHES ON THE MACROELEMENTS CONTENT FROM JIU VALLEY COAL ASH</i>	415

6	Marius Kovacs, Angelica-Nicoleta Călămar, Lorand Toth, Sorin Simion, Alexandru Simion, Kovacs Izabella <i>OPPORTUNITY OF USING DRONES EQUIPPED WITH SENSORS FOR MEASUREMENT OF COMBUSTION GASES</i>	421
7	Maria Lazar <i>QUALITY OF THE ENVIRONMENT - THE RESULT OF THE INTERACTION BETWEEN TECHNOLOGICAL PROGRESS AND EDUCATION</i>	427
8	Andrei-Cristian Lupu, Marius Gabriel Petrescu <i>EQUIPMENT FOR WATER OZONIZATION IN FISH BREEDING PONDS</i>	433
9	Andrei-Cristian Lupu, Marius Gabriel Petrescu <i>PLANT FOR IMPROVING WATER QUALITY IN JUVENILE FISH PONDS</i>	437
10	Andrei-Cristian Lupu, Marius Gabriel Petrescu <i>MOBILE AUTONOMOUS AERATOR</i>	441
11	Roland Romend, Zoltán Virág, Tamás Magyar <i>MECHANICAL PROCESSING METHODS OF WASTE ELECTRONIC AND ELECTRICAL EQUIPMENT WITH SPECIAL REGARDS TO NIR SEPARATION</i>	445
12	Andreea Adriana Petcov, Camen Dorin, Moatăr Mihaela, Petolescu Cerasela, Turc Alina, Sasu Andraia <i>NITRITE CONTENT IN THE SAMPLES COLLECTED FROM IN LAND SURFACE WATERS IN GRADINARI VILLAGE</i>	449
13	Lucian-Ionel Cioca, Larisa Ivascu, Szilard Szekely <i>CHALLENGES AND OPPORTUNITIES ASSOCIATED WITH WASTE RECYCLING DEVELOPMENT IN ROMANIA</i>	453
14	Ileana-Sorina Rakos, Sorinel Căpușneanu, Dana-Maria (Oprea) Constantin, Dan Ioan Topor, Elena Bogan <i>IMPROVE AIR QUALITY MANAGEMENT BY MONITORING AND ASSESSING HEAVY METAL EMISSIONS. CASE STUDY: HUNEDOARA COUNTY, ROMANIA</i>	459
15	Pavla Hlavatá, Karla Meixnerová, Vladimír Horák, Jiří Kosek <i>INFLUENCE OF THERMAL CONDITIONS IN A QUARRY ON THE LOCAL CLIMATE.</i>	465
16	Faur Florin, Lazăr Maria, Nyari (Apostu) Izabela-Maria <i>SUBSTANTIATING THE DECISION REGARDING THE ECOLOGICAL RECONSTRUCTION OF MINING WASTE DUMPS - CASE STUDY FOR LUPENI DUMP</i>	471
17	Camelia Madear, Gelu Madear <i>CLAY LINER DESIGN OF A LANDFILL IN JIU VALLEY BASED ON DETERMINISTIC & STOCHASTIC RISK ANALYSIS</i>	477
18	Camelia Madear, Gelu Madear <i>RISK-BASED REMEDIAL TARGETS FOR CONTAMINATED LAND</i>	483
19	Camelia Madear, Gelu Madear, Sorin Mihai Radu <i>CONSTRUCTION QUALITY ASSURANCE AND QUALITY CONTROL AT LANDFILLS</i>	489
20	Camelia Madear, Gelu Madear <i>DESIGN OF LEACHATE COLLECTION SYSTEM USING MONTE CARLO SIMULATION</i>	495
21	Corina Dufour, Larisa Ivascu, Adrian Mateescu, Anca Draghici <i>A PROPOSED INVENTORY OF SUSTAINABLE DEVELOPMENT INDICATORS FOR THE MANUFACTURING PROCESS ASSESSMENT</i>	499
22	Buia Grigore, Nimară Ciprian <i>QUALITY ASSESSMENT OF PETROȘANI URBAN LANDSCAPE</i>	505
23	Daniela Ionela Ciolea, Emilia Cornelia Dunca <i>THE UNDERGROUND SPACE, A SOLUTION FOR THE PROTECTION OF THE ENVIRONMENT</i>	509
24	Apostu Izabela Maria, Lazar Maria, Faur Florin <i>VISUAL ANALYSIS OF DEFORMATIONS FROM THE QUARRY AND INNER DUMP STEPS FROM NORTH PESTEANA MINING PERIMETER</i>	515

SECTION 4.		
INNOVATIONAL CHALLENGES IN ELECTRICAL ENGINEERING AND ENERGETICS TECHNOLOGY		
1	Niculescu Titu, Păsculescu Dragos <i>QUALITY IMPROVEMENT OF SWITCHING PARAMETERS AT SWITCHING WITH DC HYBRID BREAKER</i>	519
2	Pană Leon, Pasculescu Dragos, Florentiu Deliu <i>MANAGEMENT OF THE OPTIMAL OPERATING STATES OF ELECTRICAL DISTRIBUTION STATIONS</i>	525
3	Danut Grecea, Sorin Burian, Marius Darie, Tiberiu Csaszar, Cosmin Colda, Adriana Andris, Gabriela Pupazan, Lucian Moldovan <i>ISSUES CONCERNING THE REQUIREMENTS FOR THE ACHIEVEMENT OF A SPARK TEST APPARATUS SIMULATOR FOR LINEAR CIRCUITS</i>	531
4	Lucian Moldovan, Sorin Burian, Mihai Magyari, Dragos Fotau, Marcel Rad, Diana Salasan <i>CONSIDERATIONS REGARDING THE ASYMMETRIC PULSE AND ASYMMETRIC POWER TESTS OF ELECTRONIC BALLASTS FOR FLUORESCENT LUMINAIRES WITH TYPE OF PROTECTION INCREASED SAFETY "E" DESIGNED FOR USE IN EXPLOSIVE ATMOSPHERES</i>	537
5	Marcel Daniel Rad, Sorin Burian, Mihai Magyari, Lucian Moldovan, Dragos Fotau, Diana Salasan <i>STUDY AND EVALUATION OF REQUIREMENTS FOR BREATHING AND DRAINING DEVICES</i>	543
6	Dragos Fotau, Sorin Burian, Mihai Magyari, Lucian Moldovan, Marcel Daniel Rad, Diana Salasan <i>THERMAL ENDURANCE TESTS PERFORMED ON EQUIPMENT USED IN POTENTIALLY EXPLOSIVE AREAS</i>	549
7	Cosmin Colda, Sorin Burian, Marius Darie, Tiberiu Csaszar, Danut Grecea <i>CONSIDERATIONS ABOUT THE ENCAPSULATED EQUIPMENT TESTS</i>	553
8	Mihai Magyari, Sorin Burian, Lucian Moldovan, Dragos Fotau, Marcel Daniel Rad <i>INFLUENCE OF THE VOLUME AND GEOMETRICAL SHAPE OF LARGE ELECTRIC MOTOR ENCLOSURES ON THE EXPLOSION PRESSURES WHEN TESTED IN EXPLOSIVE MIXTURES</i>	557
9	Adriana Andriș, Constantin Sorin Burian, Marius Darie, Tiberiu Atila Csaszar, Iosif Lucian Moldovan, Cosmin Ioan Colda, Dănuț Nicolae Grecea, Gabriela Pupazan <i>ASPECTS ON SMALL COMPONENTS IGNITION TEST USING EXPLOSIVE GAS MIXTURES</i>	563
10	Stochitoiu Maria Daniela, Utu Ilie <i>THE LIMITS OF ELECTRICAL GRID FOR INCREASING THE QUALITY IN THREE PHASES SYSTEMS THROUGH THE POWER FLOW CONTROL</i>	569
11	Stochitoiu Maria Daniela, Marcu Marius Daniel <i>INNOVATIVE AND QUALITY SOLUTIONS WITH HVDC AND FACTS – FACE TO THE NEW CHALLENGES</i>	573
12	Mariana Dumitrescu <i>INFLUENCE OF POWER QUALITY AND EFFICIENCY FOR AN ENERGY DELIVERY SYSTEM REAL STUDY CASE APPLICATION</i>	577
13	Mariana Dumitrescu <i>INTELLIGENT ELECTRICAL MICRO NETWORK APPLICATION WITH DISTRIBUTED ENERGY RESOURCES</i>	581
14	Krasimir Marinov Ivanov, Tsviatko Kolev Varbov, Georgi Tsonev Veleve, Panayot Ivanov Yankov <i>STUDY OF THE ELECTROMAGNETIC COMPATIBILITY PARAMETERS OF LED LIGHTING SOURCES</i>	587
15	Dragos Pasculescu, Leon Pana, Georgeta Buica, Vlad Mihai Pasculescu, Remus Dobra <i>A QUALITY-BASED APPROACH FOR IMPROVING THE LIGHTING DESIGN PROCESS</i>	593
16	Marius-Daniel Marcu, Florin Gabriel Popescu, Titu Niculescu, Razvan-Ioan Slusariuc, Maria Daniela Stochitoiu <i>QUALITY MANAGEMENT ALGORITHM USED IN A PROGRAMMABLE MICROCONTROLLER AS MAXIMUM POWER POINT TRACKER</i>	599

17	Titu Niculescu, Florin Gabriel Popescu, Marius Marcu, Ioan Razvan Slusariuc <i>IMPROVING THE QUALITY OF MEASUREMENTS IN ELECTRICAL PROCESSES USING NI USB DATA ACQUISITION SYSTEMS</i>	605

Abstract

There are two positions describing fire growth in a building - the differential and integral level of the process description. The first approach is based on the study of the equations of continuum mechanics. The system of these equations describes the change in time of density, pressure, temperature and composition of the gaseous medium at individual points of the structure's volume. However, this system is cumbersome and its solution encounters great difficulties. Taken into account this circumstance, as well as the fact that there is no need for such a detailed study of the process to perform the calculations, the concept describing fire growth at a differential level should be considered unacceptable for engineering practice. The integral level of the description of fire growth foresees determination of the state parameters by the averaged volume structure and allows to reveal the general regularities of the process of fire growth. Complex physical processes are considered by integral characteristics obtained experimentally. In the proposed work, based on the study of physical processes occurring during underground exogenous fires, and based on laws on the conservation of mass and energy, the system of differential equations is proposed. It describes fire growth in a specific section of the mine working/tunnel, called as a zone of fire growth; The possibility of determining the temperature beyond the zone of fire growth, through the chain of excavations/tunnels is shown; The necessity of physical modeling of the process of fire growth is justified, the requirements providing similarity of the process in nature and on the model are determined; The formulas for calculating the parameters behind the zone of fire growth are recommended.

Keywords: a zone of exogenous fire growth; constant velocity of fire center movement; time of fire growth; polysulfide sealant and anti-corrosion coatings such as fire load.

1. Introduction

The problem of protection underground structures (capital and preparatory production of mines and deposits, transport tunnels) from exogenous fire, arose at the end of the last century. The statistics of underground fires forced specialists to state a number of scientific problems of an experimental and theoretical nature [Kumar, 1992; Ingason, 1985; Haack, 1992; Mikkola, et al, 1987]. In recent years, as new materials effective in terms of operational characteristics have appeared and a computer technology has progressed, the work in this domain has been developed and a number of recommendations have been offered allowing to reduce the risk of underground fires [Ilias et al, 2017; Lanchava et al, 2017; Moraru et al, 2012, 2017]. Reduction of the risk of fires is also resulted by the prediction of the development of this process and the development of prevention measures.

It has been shown that it is possible to describe underground exogenous fire using a system of differential equations (for the fire growth zone) and some calculated empirical formulas (for beyond the fire growth zone, along the length / chain of the structure) [Abashidze et al, 1986, 2006].

Through the development of this mathematical apparatus, the following works were used [Koshmarov, 1981; Davidkin, 1996]. Below, there is a system of differential equations describing the process in the fire growth zone.

* Corresponding author. Tel.: +40737992546
E-mail address: iliasnic@yahoo.com

$$P_{av} = \rho_{av} R_{av} T_{av} \quad (1)$$

$$V_{fg} d\rho_{av}/d\tau = G_a + \Psi F_{com} - G_g \quad (2)$$

$$\rho_{av} V_{fg} d\bar{C}_{O_2}/d\tau = G_a(\bar{C}_{O_2}^a - \bar{C}_{O_2}) + G_g \bar{C}_{O_2}(1 - n_1) - \Psi F_{com}(\eta L_{O_2} + \bar{C}_{O_2}) \quad (3)$$

$$\rho_{av} V_{fg} d\bar{C}_{CO_2(CO)}/d\tau = \Psi F_{com}(L_{CO_2(CO)} - \bar{C}_{CO_2(CO)}) - G_g \bar{C}_{CO_2(CO)}(n_2 - 1) - G_a \bar{C}_{CO_2(CO)} \quad (4)$$

$$\rho_{av} V_{fg} d\bar{C}_{N_2}/d\tau = G_a(\bar{C}_{N_2}^a - \bar{C}_{N_2}) - \Psi F_{com} \bar{C}_{N_2} \quad (5)$$

$$\frac{V_{fg}}{K-1} dP_{av}/d\tau = Q_{av} \Psi F_{com} \eta + C_p^a G_a T_a + \Psi F_{fg} \mathcal{Y} - Q_{lin} - m c_{(p)av} T_{av} G_g \quad (6)$$

Entry conditions: at $\tau = 0$ $\rho_{av} = \rho_{av}^0$; $T_{av} = T_{av}^0$; $\bar{C}_{O_2} = \bar{C}_{O_2}^0$; $\bar{C}_{CO_2(CO)} = \bar{C}_{CO_2(CO)}^0$; $\bar{C}_{N_2} = \bar{C}_{N_2}^0$

The notations accepted in the equations are: Ψ – burnout rate, $\text{kg}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$; η – completeness of combustion; L_{O_2} – the mass of oxygen required to combust a unit of material mass, $\text{kg}\cdot\text{kg}^{-1}$; $L_{CO_2(CO)}$ – the mass of products formed at combustion of a unit of material mass $\text{kg}\cdot\text{kg}^{-1}$; \mathcal{Y} – enthalpy of a substance formed during the decomposition of the material, $\text{joule}\cdot\text{kg}^{-1}$. The others: P_{av} , ρ_{av} , R_{av} , T_{av} – accordingly average-volumetric pressure, Pa, density, $\text{kg}\cdot\text{m}^{-3}$, gas constant, $\text{joule}\cdot\text{kg}^{-1}\cdot\text{K}^{-1}$, air temperature, K; V_{fg} – volume of fire growth, m^3 ; F_{com} – area of combustion, m^2 ; \bar{C}_{O_2} , $\bar{C}_{CO_2(CO)}$, \bar{C}_{N_2} – accordingly concentration of oxygen, products of combustion and nitrogen; τ – time, sec; G_a and G_g – accordingly quantity (consumption) of air and gas, $\text{kg}\cdot\text{s}^{-1}$; K – adiabatic index; C_p – heat capacity of gas, $\text{joule}\cdot\text{kg}^{-1}\cdot\text{K}^{-1}$; Q_{lin} – heat flow in the lining of the structure, W; $n_1 = \bar{C}_{CO_2(CO)}^g / \bar{C}_{O_2} \leq 1$; $n_2 = \bar{C}_{CO_2(CO)}^g / \bar{C}_{CO_2(CO)} \geq 1$; $m = C_p T_g / (C_p)_{av} T_{av} \geq 1$. The index “a” (lower or upper) concerns the air, entering the construction.

The length of the zone of fire growth is determined by the formula:

$$L_{fg} = 2C_{fg}\tau_{fg}/3 \quad (7)$$

where C_{fg} – constant velocity of fire growth, τ_{fg} – time of fire growth.

Thus, in order to describe the fire growth in its origin zone and beyond this zone, it is required to determine experimentally: η , L_{O_2} , $L_{CO_2(CO)}$, \mathcal{Y} , Ψ , the dependences on heat and mass transfer, constant velocity and fire growth time.

2. Methodology and research materials

Due to the fact that laboratory tests do not provide reliable data on fire growth in the mine working / tunnels, many experts have recognized the need to conduct research on field facilities.

To select the object to carry out a full-scale testing, scientists were guided by the fact that the results obtained in the development of a certain cross-sectional area are easily transferable to another cross-sectional area. The situation is more complicated with carrying out full-scale experiments in tunnels because of their large cross-sectional area. In addition, a mine can be considered as a physical model of the tunnel and thus, under adherence of the similarity conditions to obtain the data on fire growth in tunnels. The structure selected to carry out the full-scale experiments was the 130-meter-long mine with a trapezoid cross section of 2.8 m^2 abandoned by a geological–searching expedition. The mine did not have an inclined part, it was fenced on both sides by iron doors. The ventilation device injecting air into the mine, was equipped with a slide device, allowing smoothly change the velocity of the ventilation flow from 0.5 to $7\text{ m}\cdot\text{s}^{-1}$. At the mouths, the mine had compartments for measuring equipment (Fig). The essential conditions to carry out the tests were adopted: give the testing materials the necessary humidity content, the air - necessary humidity, creation of a seat of fire of calculated capacity. Humidity content of materials was determined by Humidity meter FFM 100 and Humidity & Temperature meter & Wet Bull Temperature Dew point Temperature FHT 100. Air humidity (and other parameters of air condition, see below) was determined by Enviromux-5D*.

For arson of structures and materials, the fires made of 80 kg of firewood and poured with 3 liters of kerosene were used. The given rate of the ventilating flow was monitored by the above-mentioned Enviromux-5D.

While using the mine as a model of the tunnel, its sides and roof were fixed with sheets of non-combustible material. For temperature measurements, mainly, chromel-aluminum thermocouples with recording equipment were used.

The wires of thermocouples were placed in ceramic tubes and were pulled along ditches in the soil at the depth of 0.3 m. Thermocouples were installed in 13 sections of the mine, as shown in Fig. The distances between sections for 40 m of the mine were 5 m. In the remaining section - 15 m.

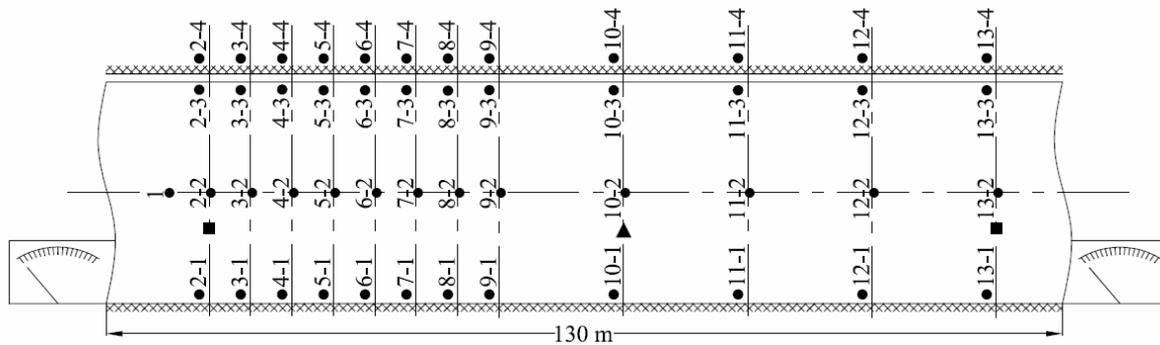

Fig. The layout scheme of thermocouples and aerometer tubes, location of air sampling.

● - thermocouples; ▲ - aerometer tubes; ■ - location of air sampling.

The rock temperatures were also measured by thermocouples at the depth of 0.5 m of the wall of the tunnel model. Enviromux-5D was used to fix the temperature at the end of the mine, as well as to the seat of fire, with fresh air jets.

The length of the combustion zone and the constant velocity of the movement of fire in the mine were determined from the dynamics of fire growth. For this purpose, the graphs of the temperature change of fire gases over the length of the mine in time were designed. The length of the combustion zone was taken where the maximum temperature of fire gases was fixed after certain time. The term "time of fire growth" means the time during of which the temperature increases up to the maximum value in the seat of fire. Enviromux-5D was used to measure the concentration of substances containing in fire gases at the end of the mine. The velocity of movement of fire gases was determined by the high-speed (dynamic) head, for the measurement of which Pitot tubes were used in combination with a micro-manometer. The density of fire gases, taking into account their temperature, was calculated by the formula $\rho_g = 0.455P_a / (273 + t_a)$. The consumption of materials on the model was determined taken into account that it had to be n^2 times less than the material consumption in kind (n is the ratio of the mine and model dimensions). The similar moments of time were calculated from the condition $\tau^{mo} = \tau^{nat} / n$, where the indexes "mo" and "nat" refer to the model and nature.

As a value of the velocity of the ventilation flow, on the basis of the condition of aerodynamic similarity, $0.8-1.2 \text{ m} \cdot \text{s}^{-1}$ was used. As a fire-retardant agent for wood, a compound made of liquid glass, fluorsilicate sodium, nepheline fire-retardant, silicomanganese slag, aluminum silicate filler (clinoptilolite) was used. Epoxy-rocked coal mastic was consisted of a mixture of epoxy resins, rocked coal resin and hardener-polyethylenepolyamine. The fireproof paint corrosion-resistant insulation was a polymer composition with kieselguhr content. The modified polysulphide sealant was consisted of factory-made polysulphide with the addition of micro-powder obtained by grinding of bentonitic clay of alkaline composition on a planetary mill.

The sealant met the exploitation requirements for insulating materials formulated in [Lanchava et al, 2017].

It is impossible to state all performed work in the context of one article. Here, only some basic outcomes are presented obtained through full-scale experiments.

3. Results and discussion

Totally, two experiments were carried out in the mine and on a model of the tunnel. In the mine, the support was installed from non-fireproof and fireproof wood (Experiments 1, 2). On the model, the wall was covered with epoxy-rocked coal mastic and modified sealant (Experiment 3) and fireproof pain hydro-insulation in combination with the above-mentioned sealant (Experiment 4).

Experiment 1. The mine was fixed with a solid wooden support between the 2 and 11 sections (Fig). Frames with the sides and roof tightened with boards 2 cm thick, racks and tops 13-17 cm in diameter were used. The distances between the frames are 1 m. Stacks of dry wood with dimensions $1.2 \times 1.2 \times 0.7 \text{ m}$ (weight 360 kg), covered with 2 liters of kerosene and located 1 m apart were the source of firing. The picture of fire growth is as follows: after the origin of fire, the fire spread only along the ventilation flow. The fire first appeared from the seat of fire on the wall tightening in 9 minutes after firing of the source. After 20 minutes, the fire broke through to the roof. In the beginning, the flame was directed towards the ventilation flow, but later it was bound against the air flow and the support ignited behind the seat of fire. After 24 minutes, the fire spread to approximately 12 m^2 of the mine. Burning fires appeared occurred from the supports dropped on the ground. Throughout the perimeter, the mine ignited after 38 minutes. After 43 minutes, the flame spread through the entire fixed section of the mine and the average temperature reached 1300 K.

The time regime of temperature can be divided into 4 stages: an increase to a maximum value (23 min), a constant maximum temperature (20 min), a temperature drop to the initial value (17 min), a normal temperature regime.

Experiment 2. In this case, the nature of fire growth remains the same as in Experiment 1. But a slow process of fire growth is observed. Fire appeared on the wall gripping in 15 minutes after the fire was set. The fire broke to the roof in about 45 minutes. The spread against the ventilation flow is insignificant. Throughout the perimeter, the mine did not ignite. The flame did not spread to the entire fixed area. The average volume temperature reached 640 K.

Experiment 3. A vigorous fire growth after its beginning was observed, and not only along the ventilation flow, but also against it. The fire first appeared on the walls near the seat of fire in 5 minutes after the fire was set.

In 16 minutes, the fire spread through approximately 25 m² of the model and melted drops of anticorrosive coating and sealant appeared. Throughout the perimeter of the model, the fire occurred after 25 minutes. Fire growth was ended by 29 minutes. The average volume temperature reached 940 K.

Experiment 4. The fire began with difficulty. Within the total experiment, the propagation of fire against the ventilation flow was not observed. There was no intensive dropping from the heating of the coating. The flame covered a surface of the model area of 16 m² in about 32 minutes. The fixed average volume temperature is 465 K.

Temperature of fire gases and wall/lining. The measurement results of the maximum and average volume temperatures under different values of the ventilation flow (v_f) are shown in Table 1.

Table 1.

$C_{vf}, m \cdot s^{-1}$	T_{max}, K	T_{av}, K						
	Experiment 1		Experiment 2		Experiment 3		Experiment 4	
0.5	1023	911	498	408	995	912	492	446
1.0	1259	1172	650	563	1010	916	506	461
1.5	1395	1300	710	640	1015	935	521	472
3.0	1573	1498	835	753	1075	1000	567	516

The empirical formulas correspond to the presented data (their processing was carried out by the method of the least squares):

$$T_{av} = C_{vf}/(a + b)C_{vf} \quad (8) \text{ – for experiments 1, 2}$$

$$T_{av} = a' + b'C_{vf} \quad (9) \text{ – for experiments 3, 4}$$

The values of the coefficients of these equations are given in Table 2.

Table 2.

Coefficient	Experiment			
	1	2	3	4
a	$2.5 \cdot 10^{-4}$	$6.7 \cdot 10^{-4}$	—	—
a'	—	—	423	434
b	$0.6 \cdot 10^{-3}$	$1.11 \cdot 10^{-3}$	—	—
b'	—	—	25.6	27.1

The measurement results of the average volume temperatures and the temperature of fire gases (f_{rg}) on the outgoing flow, recorded at the same time, are shown in Table 3.

Time of fire spread. The experimentally obtained data to determine the time of the complete fire spread (f_s) are presented in Table 5.

Table 5.

Experiment	$\ell_{t,max}, m$	τ_{f_s}, \square
1	45	1.21
2	30	1.08
3	45	1.16
4	35	1.02

Distances $\ell_{t,max}$ in Experiments 3, 4 are determined taken into account the scale of modeling.

The dependences of fire growth time (in hours) on the length of the section at the end of which the maximum temperature is fixed as in the mine, as well as on the model of the tunnel, have got a linear character and can accordingly be expressed by empirical formulas:

$$\tau_{f_s}^w = 0.81 + 0.009\ell_{t,max} \tag{10}$$

$$\tau_{f_s}^t = 0.57 + 0.013\ell_{t,max} \tag{11}$$

Constant velocity of fire growth and the length of a zone of fire growth. The experiments have shown that the accelerated fire growth takes place in the first 2-17 minutes. Further, the velocity takes a constant value.

For its calculation, it is essential to know the distance from the seat of fire to that place, where the maximum temperature of fire gases is fixed and the time for the complete fire growth, excluding the time interval when its accelerated growth takes place.

These time intervals for the experiments 1,2,3,4, accordingly, were 1015, 240, 300 and 120 seconds. Taking this into account, the velocity of fire gases under the conditions of these experiments takes the following values: $1.35 \cdot 10^{-2}$; $8.2 \cdot 10^{-3}$; $1.16 \cdot 10^{-2}$ and $9.9 \cdot 10^{-3} m \cdot s^{-1}$ (at a ventilation flow rate of $1 m \cdot s^{-1}$).

The dependence of a constant rate of fire growth on the velocity of the ventilation flow has been found having the following form for all experiments:

$$C_{fg} = C_{vf} / (a'' + b''C_{vf}) \tag{12}$$

The values of coefficients a'' , b'' , are given in Table 6.

Table 6.

Coefficient	Experiments			
	1	2	3	4
a''	51.1	53.4	66.7	69.8
b''	23.0	68.5	19.5	31.2

Having known the constant velocity and the time of fire growth, according to the formula (7), the length of the fire growth zone was determined, that was 39, 21, 32, 24 m. for the experiments 1, 2, 3, 4, accordingly.

4. Conclusions

As a result of the full-scale tests:

- a) The dependences of the medium-volume temperature of fire gases on the velocity of the ventilation flow were determined. Medium-volume temperatures and wall temperatures (lining) at the same time of fire growth were measured;
- b) The time of the full fire growth was determined – 1.02 – 1.21 hours. Empirical formulas were found for their determination;

- c) The constant velocity and length of the fire growth zone were determined. The dependence of the constant velocity of fire growth on the velocity of the ventilation flow was revealed. The coefficients being in the empirical formula were calculated. The length of the fire growth zone in the carried out experiments was 21 - 39 m.
- d) The velocity of fire gases was determined by the dynamic velocity pressure. It has been established that under various conditions to carry out full-scale experiments, the velocity of fire gases can increase up to 8.8 times.

Abstract

Thanks to modern technologies of construction and operation of transport tunnels, it is assumed in the present work that drainage of water does not occur inside the membrane in the volume of reinforced coating of the tunnel and here takes place a non-stationary process of transfer of hygroscopic mass (moisture) together with a similar process of heat transfer between the ventilation stream and the surrounding mining massif. Thus, we have to deal only with the sorption mass content in the pores of the massif and the water in the explicit form in the tunnels can only be in exceptional cases as local sources and therefore, their influence on the ventilation flow should be considered separately. In addition, based on the principle of Onsager reciprocal relations, this article assumes that the heat flux is affected not only by the direct driving force-the temperature gradient, but also by the gradient of the mass transfer potential that is indirect in relation to this flow. Consequently, in the process of heat transfer is taken into consideration of the effect of Sore. Similarly, the mass (moisture) transfer is taken into consideration of the addition effect Dufour, when the cause of the mass transfer is not only the direct driving force - the gradient of the mass transfer potential, but also the indirect driving force in relation to this flow - the temperature gradient.

Keywords: Non-stationary heat and mass transfer, temperature gradient, mass transfer potential gradient, modeling.

1. Introduction

For the determination of changing of climatic parameters of the ventilation air of tunnels, it is necessary to considerate with naturally magnitudes of temperature and natural mass (moisture) transfer potential of surrounding rock massif. Due to seasonal fluctuations in the temperature and relative humidity of the atmospheric air, heat and mass transfer between the massif and the air is non-stationary. The nonstationary nature of the processes is more abundant by the formation of cooled zone and decreased moisture content zone in the massif around the tunnels. Therefore, the exchange of heat and matter between the massif and the ventilation flow occurs through the marked zones and the rate of marked exchanges decreases steadily over time.

Thus, the ventilation flow due to heat and mass transfer, through tunnel coating and liner, forms perturbed zones in the surrounding mining massif, which leads to a decrease in the natural values of the temperature and the mass transfer potential in these zones. As a result of this, the natural values of the marked physical quantities will be observed only in the depth of the massif. In classic papers non-stationarity considered by means of appropriate ratio when applied the natural temperature of the massif. For example works of (Shcherban et al., 1977), (Oniani, 1973), (Kuzin et al., 1979) and (Kremnev and Zhuravlenko, 1980). But non-stationary of heat and moisture transfer may be considered by means of dimensionless temperature and dimensionless mass transfer potential on the dividing surface of the "tunnel wall - airflow" and of stationary appropriate ratio of transfer. Among similar works it is necessary to note papers (Lanchava and Ilias, 2017; Băbuț et al. 2015), (Moraru et al, 2009; 2012), (Lanchava, 1982; 1985), (Petrelean, 2013) and (Petrelean et al., 2014; 2017). In this approach, the entire complexity of changing physical fields in a massif is, as it were, transferred to the surface of the tunnel and the variable values are the dimensionless temperature and the potential of mass transfer of the walls of the tunnel.

For the circular shape of the tunnel, hypsometrically located below the first waterproof layer, the scheme of the natural temperature fields and the mass transfer potential is shown in Fig. 1. The noted scheme is typical for tunnels located at great depth, in which the width of the cooled and drained zones increases with time. The equations of fields

of the temperature and of the mass transfer potential in surrounding rock massif, respectively, have the form $t = f(R, \tau)$; $\vartheta = F(R, \tau)$ where τ is the time. For an infinite length of the cylindrical coordinate, the values of the temperature and the mass transfer potential take their natural magnitudes. Similar nonstationary heat and mass transfer processes are considered in (Lanchava, 1982; 1985).

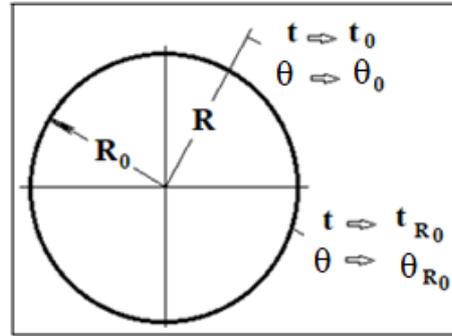

Fig. 1. Distributions of temperature and of mass (moisture) transfer potential on the tunnel surface and the surrounding rock massif on the tunnel axis: R - cylindrical coordinate; R_0 - equivalent radius of tunnel; 0 and R_0 indexes show the temperature and mass transfer potential values in the surrounding isotropic environments and on the dividing surface

As for the tunnels located at low depths, in particular transport tunnels and especially the tunnels of the metro, here the hygroscopic mass exchange behind the membrane in depth of massif does not occur, because the membrane is waterproof. Similar membranes are widely used in modern tunnelling. Thus, inside the membrane, within volume of the reinforced coating takes place moisture-equalizing. The mentioned volume has absorbed moisture from the air or gives moisture to the air depending on the season of the year. The moisture content of this volume is about the maximum hygroscopic index. Consequently, in the tunnels of the metro, non-stationary heat exchange takes place, during which the cooled zone in the massif spreads beyond the boundaries of the membrane. Mass transfer takes place only spread within a volume of reinforced coating.

2. Materials and methods

Non-stationary heat transfer coefficient for tunnels with reinforced coating is determined by formula

$$K_{\tau} = K_1 \bar{t} \quad (1)$$

where K_{τ} - non-stationary heat transfer coefficient, $W/(m^2 \cdot ^\circ C)$; $\bar{t} = t(\tau, R_0)$ - dimensionless surface temperature of the tunnel, in parts of the one, $0 \leq \bar{t} \leq 1$; K_1 - coefficient of heat transfer from the massif to the ventilation flow, with consideration the influence of reinforced coating of the tunnel, which is determined by the formula

$$K_1 = \left(\frac{1}{\alpha} + \frac{\delta_1}{\lambda_1} \right)^{-1} \quad (2)$$

where α - stationary heat transfer coefficient from surface of the tunnel, $W/(m^2 \cdot ^\circ C)$; δ_1, λ_1 - respectively, the thickness of reinforced coating of the tunnel and the coefficient of thermal conductivity of the coating material, m; $W/(m \cdot ^\circ C)$.

Non-stationary mass transfer coefficient for tunnels with reinforced coating is determined by formula

$$K_m = K_2 \bar{\Theta} \quad (3)$$

where K_m - non-stationary mass transfer coefficient, $kg.mol/(J.m^2.s)$; $\bar{\Theta} = \Theta(\tau, R_0)$ - dimensionless mass transfer potential of the tunnel surface, in parts of the one, $0 \leq \bar{\Theta} \leq 1$; K_2 - coefficient of mass transfer from the massif to the ventilation flow, with consideration the influence of reinforced coating of the tunnel, which is determined by the formula

$$K_2 = \left(\frac{1}{\alpha_m} + \frac{\delta_1}{\lambda_{m1}} \right)^{-1} \quad (4)$$

where α_m - stationary mass transfer coefficient from surface of the tunnel, $kg.mol/(J.m^2.s)$; λ_{m1} - the coefficient conductivity of mass transfer potential of the coating material, $kg.mol/(J.m.s)$.

Hygroscopic mass transfer potential can be calculated with the following formula (Tsimermanis, 1971)

$$\Theta = RT \ln \varphi \quad (5)$$

where Θ - hygroscopic mass transfer potential, J/mol; R - universal air constant; J/(mol.K), $R = 8.3144$; T - absolute temperature, K; \ln – symbol of natural logarithm; φ – equilibrium relative humidity of air, balanced with a sorbent, $0 \leq \varphi \leq 1$. In which, apart from explained dimensions Θ - hygroscopic mass transfer potential, J/mol;

In this formula, $\ln \varphi = 0$, when $\varphi = 1$, in the rest of the cases, for hygroscopic area $\varphi < 1$ and value of the potential determined by the formula (5) is of negative sign.

The potential calculated with formula (5) is acceptable in order to evaluate hygroscopic mass transfer in mining massive. As commonly known, increasing temperature causes decrease of van der Waals powers of sorption field, which is resulted in decrease of isothermal specific mass factor (this factor of the capillary-porous body $c_m = 0$ on the critical temperature for water that equals of 647K, because at this temperature water vapor sorption is impossible). In such a case, the power of sorption field and its characteristic size – transfer potential should be necessarily decreased. Formula (9) permits to establish inversely proportional addition between Θ and T as well c_m , T couples, while between Θ , c_m couples it arises directly proportional addition. This not contradicts neither to existing theoretical views nor to experimental results of determining isothermal specific mass factor.

Calculating mass transfer potential for mining massif is also possible with the formula offered below:

$$\Theta = RT \ln \left(\frac{U}{U_{\max}} \right) \quad (6)$$

where U - hygroscopic moisture content of mining massif on the temperature T , kg/kg; U_{\max} – maximum hygroscopic moisture content of mining massif on the same temperature, kg/kg.

3. Results and discussion

3.1. Thermophysical and Mass-physical characteristics of rocks

Thermophysical and mass-physical coefficients of rocks (or soils) (λ , a , c , λ_m , a_m , c_m , δ_θ , γ_0), which are related to each other with a known law (Dzidziguri et al., 1966)

$$\lambda = ac\gamma_0, \quad (7)$$

where λ is the heat conductivity coefficient of the rock, W/(m. K); a - coefficient of thermal diffusivity of the rock, m²/s; c - specific heat, J/(kg. K); γ_0 - the rock density, kg/m³.

Mass-physical characteristics of rocks are related to each other by analogical formulation, thus confirming the analogy of these processes (Lanchava, 1998)

$$\lambda_m = a_m c_m \gamma_0 \quad (8)$$

where λ_m mass conductivity factor of the rock, kg.mol/(J.m.s); a_m – the mass transfer potential diffusivity factor for the rock, m²/s; c_m - the isothermal specific mass factor for the rock, mol/J.

In the case of ventilation of tunnels, thermal exchange in a binary system "mining massif - ventilation flow" is not only under the influence of the temperature gradient but also of the gradient of mass transfer potential. The ultimate thermal flow consists of two elements: one is caused by the temperature gradient and the second by mass transfer potential gradient. Similarly, the mass flow consists of two elements. In this case the direct driving force is a gradient of mass transfer potential, and the temperature gradient is additional driving force. This is reflected in the mathematical expression of the principle of Onsager (1931) reciprocity that express the equality of certain ratios between flows and forces in not equilibrium thermodynamic systems

$$J_i = \sum_{k=1}^n L_{ik} X_{k(i=1,2,\dots,n)} \quad (9)$$

where J_i is thermodynamic driving forces (temperature and mass transfer potential) that generated both flows; $L_{i,k}$ - the physical environment in which energy or substance is transmitted (in our case thermophysical and Mass-physical characteristics of rocks); X_k - potential gradients that originated streams.

For the thermodynamic driving forces, such are a gradient of thermodynamic temperature and a gradient of mass transfer, the principle of Onsager's reciprocity has a form

$$J_1 = L_{11}X_1 + L_{12}X_2 \quad (10)$$

$$J_2 = L_{21}X_1 + L_{22}X_2 \quad (11)$$

where J_1 is a thermal flow density, which is determined by the Fourier law in a private case; J_2 - the mass flow density, which is determined by the Fick's law or Luykov law, in the private case, in according what is the nature of the forces X_2 , the gradient of concentration, or the mass transfer gradient.

3.2. Criteria for the similarity of heat and mass-exchange processes

Equations (10), (11), for the circuit depicted in Fig. 1, in the case of an isotropic and homogeneous mining massif, have the following differential form (Luikov, 1978)

$$\frac{\partial t}{\partial \tau} = a\Delta^2 t + \varepsilon r \frac{c_m}{c} \frac{\partial \Theta}{\partial \tau} \quad (12)$$

$$\frac{\partial \Theta}{\partial \tau} = a_m \Delta^2 \Theta + a_m \delta_\theta \Delta^2 t \quad (13)$$

where ε - criterion for the phase transition of moisture in the mining massif. The rest of the symbols were determined previously.

Initial and boundary conditions have the form

$$\tau = 0, R = R_0: t_{(R_0,0)} = t_0, \Theta_{(R_0,0)} = \Theta_0 \quad (14)$$

$$\tau > 0, R = \infty: t_{(R,\tau)} = t_0, \Theta_{(R,\tau)} = \Theta_0 \quad (15)$$

$$\tau > 0, R = \infty:$$

$$-\lambda \frac{\partial t}{\partial R} + \alpha(t_k - t_h) + \alpha_m r(\Theta_k - \Theta_h) = 0 \quad (16)$$

$$-\lambda_m \frac{\partial \Theta}{\partial R} - \lambda_m \delta_\theta \frac{\partial t}{\partial R} + \alpha_m(\Theta_k - \Theta_h) = 0 \quad (17)$$

where t_k, Θ_k - temperature and mass transfer potential of the walls of tunnel, 0C , j/mol; t_h, Θ_h - the same for ventilation flow. The rest of the symbols were determined previously.

From these equations, initial and boundary conditions follow criteria for the similarity of heat and mass-exchange processes: Bio, Fourier, Kosovich, mass transfer criteria Fourier, Bio and Posnov that respectively have the form

$$Bi = \frac{\alpha R_0}{\lambda}; Fo = \frac{a\tau}{R_0^2}; Ko = \frac{rc_m}{c} \frac{\Delta \Theta}{\Delta t} \quad (18)$$

$$Bi_m = \frac{\alpha R_0}{\lambda}; Fo_m = \frac{a_m \tau}{R_0^2}; Pn_m = \delta_\theta \frac{\Delta t}{\Delta \Theta} \quad (19)$$

where τ time, s; R_0 - equivalent radius of the tunnel, m; Δt , $\Delta \theta$ - temperature and potential increments respectively; δ_θ - thermal gradient factor showing additional mass transmission in the system in the form of Soret effect, J/mol. K);. The rest of the symbols were determined previously.

Equation (16) is an expression of the energy conservation law for the mentioned system. To analyse it, application of a new similarity criterion is needed. According to the π -theorem, in this formula the number of dimensional quantities, primary dimensions and dimensionless quantities (similarity criteria) are 9, 5 and 4, respectively (Kutateladze, 1982). These criteria are the dimensionless temperature, the Bio and Posnov criteria. The definition of a dimensionless temperature is given below. We note that, according to the π -theorem, there must be four criteria, but there are only three of them.

$$\frac{\Delta_\tau t}{\Delta_R t} = t_{(R,\tau)} = \frac{t - t_2}{t_0 - t_2} \quad (20)$$

where t_0 - natural temperature of mining massif, 0C .

After insertion of limited proportional quantities according to L'Hopitale's rule and multiplication by $R/\lambda\Delta_\tau t$, equation (16) will transform as

$$\frac{\Delta_\tau t}{\Delta_R t} = \frac{\alpha R}{\lambda} + \frac{\alpha_m r R}{\lambda} \frac{\Delta_\tau \Theta}{\Delta_\tau t} \quad (21)$$

For the tunnel wall, i. e. when $R = R_0$ after simple transformations equation (21) will get the following form

$$\frac{\Delta_\tau t}{\Delta_{R_0} t} = Bi + La \frac{Bi}{Pn_m} \tag{22}$$

where a new criterion is introduced

$$La = \frac{\delta_\theta \alpha_m r}{\alpha} \tag{23}$$

As it is seen from equation (22), dimensionless temperature of a tunnel wall is combination of the appointed complexes. Thus, criterion expressed by formula (23) is the fourth dimensionless complex that is necessary for the process analysis according to π -theorem.

The new criterion relates thermal resistance $1/\alpha$ with mass transfer analogical resistance $1/\alpha_m$ within the limits of corresponding boundary layers. Thus, estimation of the ventilation air flow by it appears to be possible as both of those values are the current characteristics.

The first impression is that the same result can be obtained by Lewis, Kosovich, or Posnov criteria separately. This is not quite correct as each of them taken separately characterizes just the massif showing only a rate of increase of cooled and dried up layers thicknesses.

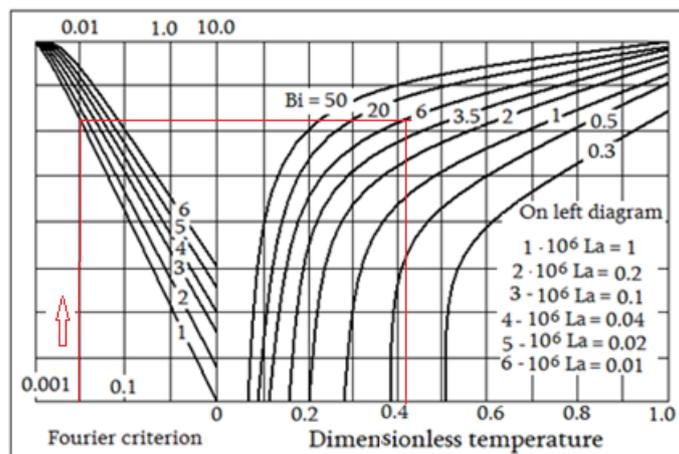

Fig. 2. Changing of dimensionless surface temperature of the tunnel $\bar{t} = f(Fo, Bi, La)$

use the nomogram as follows according to the red lines (beginning on the left diagram): $Fo = 0.01; 10^6 La = 1; Bi = 6$; Dimensionless temperature $\bar{t} = t(\tau, R_0) = 0.42$

In fact, temperature gradient always causes additional mass flow and vice versa – gradient of mass transfer potential causes additional thermal current, but there are cases in practice, when consideration of these additional currents is not necessary for calculation of ventilation flow temperature, mass transfer potential and relative humidity.

The said is corroborated by the critical value of the new criterion $10^6 La = 1$. Consideration of interference of these two processes for solution of multiparametric tasks is needed when this equality fails.

Using formula (1) and the dimensionless temperature from Fig. 2, it is possible to determine the non-stationary heat transfer coefficient with or without additional heat flow and accordingly perform thermal calculation.

4. Conclusions

Thus, heat and mass fluxes in the two-component system "mountain massif-ventilation air" are the result of the influence of two gradients-the temperature potential and the mass transfer potential. The additional threads initiated by the effects of Sore and Dufour tend to amplify the main flows, but in practice, there is a case where there is no need to consider the effect of additional flows. Based on the analysis of processes, the criteria that determine their numerical values show that accounting for additional flows of Sore and Dufour is mandatory. Marked effects can be ignored when $10^6 La = 1$. By means of the presented results can definite of non-stationary heat transfer coefficient for any cases of mentioned processes.

Dynamics of spread of fire-related harmful factors in metro tunnels during a forced stoppage of the metro train

Giorgi Nozadze*

*LEPL G. Tsulukidze Mining Institute, Tbilisi 0186, Georgia

Abstract

The present work deals with emergency situations which develop as a result of 30 MW-magnitude fires that may occur for various reasons within the metro (subway) tunnel infrastructure. The article will produce numerical modelling of the emergency situation within the PyroSim 2016 programme environment. It will offer a base model of the emergency situation for the following tunnel geometry: cross-sectional area of the tunnel – 20 m²; length of the tunnel – 800 m; volumetric efficiency of the tunnel – 0,375; length of the metro train – 80 m; cross-sectional area of the train – 7.5 m². The article will explore the changing dynamics of the harmful factors (temperature, carbon monoxide, carbon dioxide and oxygen concentration levels) which develop in portals along the tunnel as a result of fires. The boundary conditions for various ventilation flows will be examined. We will study the effect of the location of the train and the fire on the dynamics of spread of harmful factors as a result of stoppage of the train inside the metro tunnel. The modelling process will determine the required time parameters for safe self-evacuation in an emergency situation. It can be used for the quick planning and implementation of emergency assistance activities.

Keywords: Metro tunnel; fire, Harmful factors; numerical modelling.

1. Introduction

Underground transport (metro) represents the fastest-growing transport network in global megalopolises. The metro has a history of approximately 150 years. The total length of underground metro networks across the world is 15, 000 km, of which 5,000 km have been constructed during the past 15 years. Existing networks are being expanded and reconstructed, while elsewhere, new subway transport centres are being established. Security of the underground transport system is particularly sensitive with regards to fire safety (Moraru et al, 2013; Moraru et al, 2017). This is primarily due to the shortage of evacuation options during fires in the metro, as well as the difficulty of the evacuation process scenario. Statistics of the main causes of fire in the metro (Long Poon and Richard Lau, 2007; Moraru and Babuț, 2014) is presented in the form of a circle diagram (see Fig. 1).

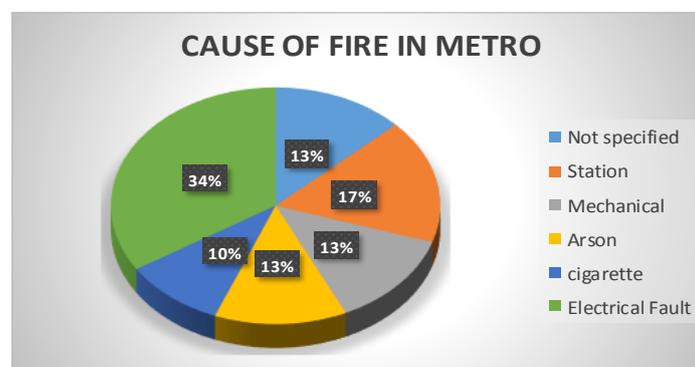

Fig. 1. Statistic data of the causes of fires in the metro

Based on the given statistics, approximately 17% of the metro fires occur at the stations and in areas adjacent to the stations, while the remaining 83% are accounted for by metro tunnels, where fire safety and evacuation activities are more difficult to implement than at the stations.

These instances usually lead to the stoppage of the metro train and the start of the self-evacuation process towards a free portal inside the tunnel.

During the last 30-35 years, there have been several cases of catastrophic fires occurring in the subway and funicular transportation systems. Although these were not particularly powerful fires, they all had disastrous results. For example, the Baku Metro fire in Azerbaijan killed 337 people in 1995, while 155 people died in Kaprun (Austria) in 2000, and 198 people in Daegu (South Korea) in 2003.

The aforementioned cases have all got several common characteristics: The materials involved in the fires were characterised by flammability and high toxicity of the substances released during the fire; The metro train was forced to come to halt inside the tunnel (Baku, Kaprun), or did not leave the station (Daegu);

The majority of the victims were poisoned by toxic gases.

- The complexity of the causes of fire.

- The absolute majority of metro systems use a high-voltage electrical power system. Statistics show Fig. 1. that electrical faults constitute the most common cause of fires today.

Fires in the metro can be subdivided into the following two categories:

- Fires in the metro's power supply infrastructure;
- Fires in the metro's metro train.

In present article we study fire in metro's power supply infrastructure.

2. Task of numerical modelling

2.1 Initial Conditions

In the present study we do numerical modelling of possible fire scenarios in the metro's power supply system, using the tunnels of the Tbilisi metro as an example. The geometric data of the tunnel and the metro train is presented below:

- Length of the tunnel – $L_t=800$ m; cross-sectional area of the tunnel – $S_t=20$ m²; length of the train – $L_{tr}=80$ m; cross-sectional area of the train – $S_{tr}=7.5$ m²; the location of the halted train is measured from the left-hand portal, using the coordinates $X_{tr,1}$ and $X_{tr,2}$, whereby $X_{tr,2}=X_{tr,1}+L_{tr}$; fire location – X_F ; location of the tunnel air shaft – $X_S=400$ m from the left-hand portal; cross-sectional area of the shaft – $S_i=1,4,9$ m²; surface area of the burn – S_F ; general formula for the burn reaction type – $C_xO_yH_zN_r$, the carbon compounds used in the high-molecular electric isolation material are modelled on the simple reaction of burning polyurethane, with the average carbon monoxide share of 0.2 g/g (Sean Thomas McKenna and Terence Richard Hull, 2016).The location of the halted train is measured from the left-hand portal, and the modelled cases are: $X_{tr,1}=202$ m, 302 m, 351 m, 402 m, 502 m, 602 m. The fire source is located at the $X_F=700$ m mark from the left-hand portal. The modelled cases are classified as follows, depending on the position with respect to the air shaft (see Fig.2.):

$$\begin{aligned}
 & - X_{tr,1}, X_{tr,2} < X_S < X_F; & X_{tr,1} = 202 \text{ m}, 302 \text{ m} \\
 & - X_{tr,1} < X_S < X_{tr,2} < X_F; & X_{tr,1} = 351 \text{ m}, \\
 & - X_S < X_{tr,1}, X_{tr,2} < X_F & X_{tr,1} = 402 \text{ m}, 502 \text{ m}, 602 \text{ m}
 \end{aligned}
 \tag{1}$$

2.2 Boundary Conditions

The flow of heat from the fire and the boundary conditions for the ventilation flow are presented in Fig. 2.

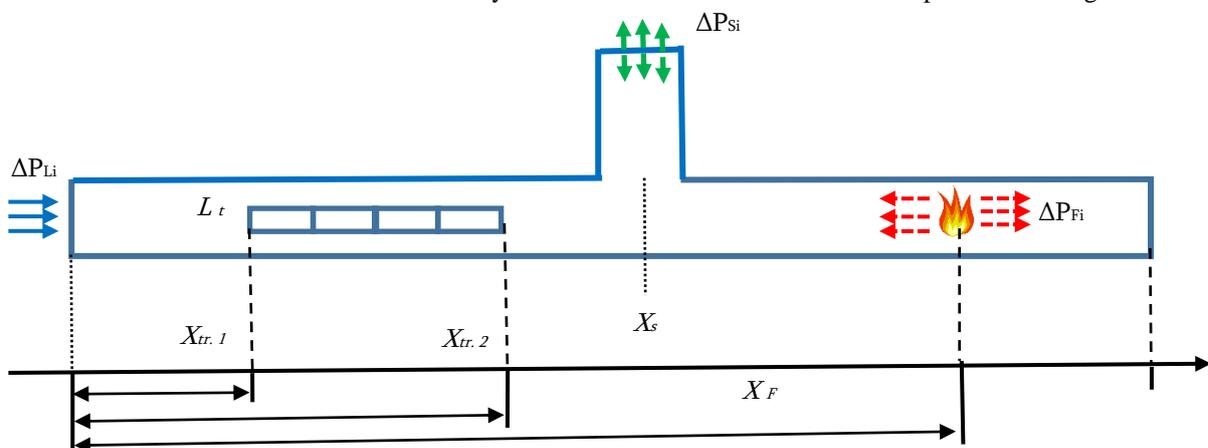

Fig. 2. An emergency situation model of a forced stop of a train during infrastructural fires in a subway tunnel.

The dynamic pressure from the ventilation flow in the left-hand portal is modelled as the difference in pressure between the portals – ΔP_{Li} .

A numerical model was established within the set task. Numerical modelling was used to study the dynamics of spread of harmful factors from heat flow ΔP_{Fi} which stems from the fire. Boundary conditions created by additional dynamic flows at one of the portals and the outer cross-section of the intermediate air shaft inside the metro tunnel have also been examined – $\Delta P_{Li} = \pm 1, \pm 10, \pm 100$ Pa, $\Delta P_{Si} = \pm 1, \pm 10, \pm 100$ Pa. Numerical modelling time – 300 sec, 1200 sec, 2400 sec.

The effect of the location of the halted train on the dynamics of the harmful factors has been studied. In order to obtain quick and optimal results from multiparameter numerical modelling, we have introduced the ‘base model concept,’ (Ilias at all, 2017) which involves forming the worst possible starting and boundary conditions for the given geometric parameters of the tunnel, and obtaining the worst spatial scale and time scale for the harmful factors.

The harmful factors examined in the present study are the increase in carbon monoxide and carbon dioxide concentration levels, decrease in oxygen levels, as well as the dynamics of temperature distribution in the metro tunnel in case of a 30 MW-magnitude fire. For the correct formulation of the problem of the distribution of the temperature harmful factor, it will be necessary to consider the influence of the surrounding tunnel wall. This can be taken into account in the "base model" with the help of the technology proposed in the articles (Lancava, 1982,1985)

Detectors are located along the symmetric interface of the tunnel’s cross section, at a height of $Z=1.5$ m from the tunnel bottom, at 100 m intervals.

Clearly, the worst possible situation applies to fires of the maximum strength required by technical regulations (30 MW), whereby the train is located at a short distance from the fire source (in our case, 602 m from the left-hand portal), and the cross section of the 10 m tall air shaft is minimal (1 m^2 in the case of our model). See Fig. 3

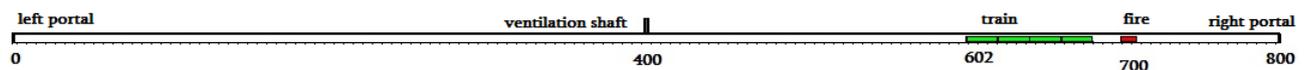

Fig.3. The Geometry data of ‘base model’ of metro tunnel in Pyrosim software.

Results of numerical modelling, displaying the dynamics of each harmful factor in time for the ‘base model,’ are shown below.

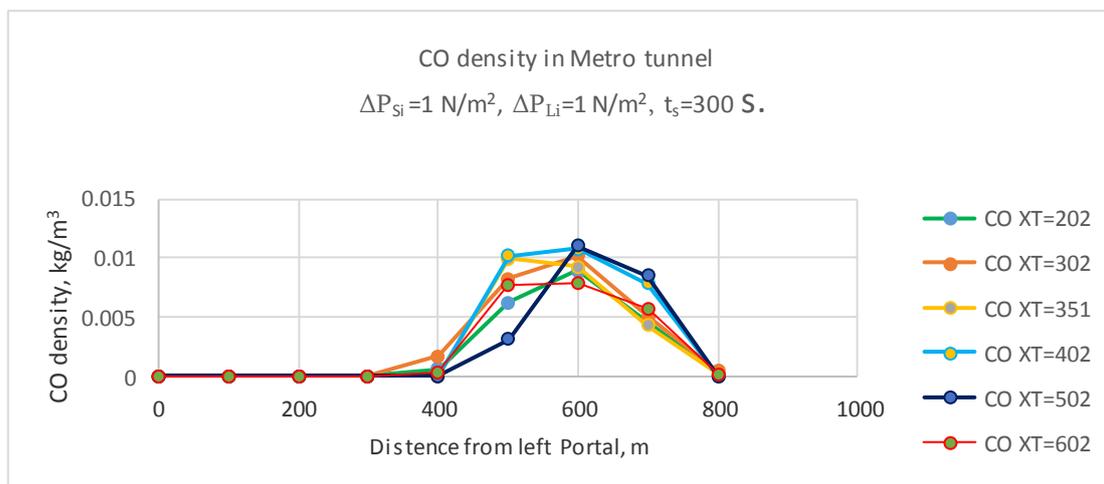

Fig. 4. Dependence of distribution of carbon monoxide concentration in the tunnel of the subway on the forced stop location of train. (HRR 30 MW, height $Z = 1.5$ along the tunnel, simulation time 300 seconds)

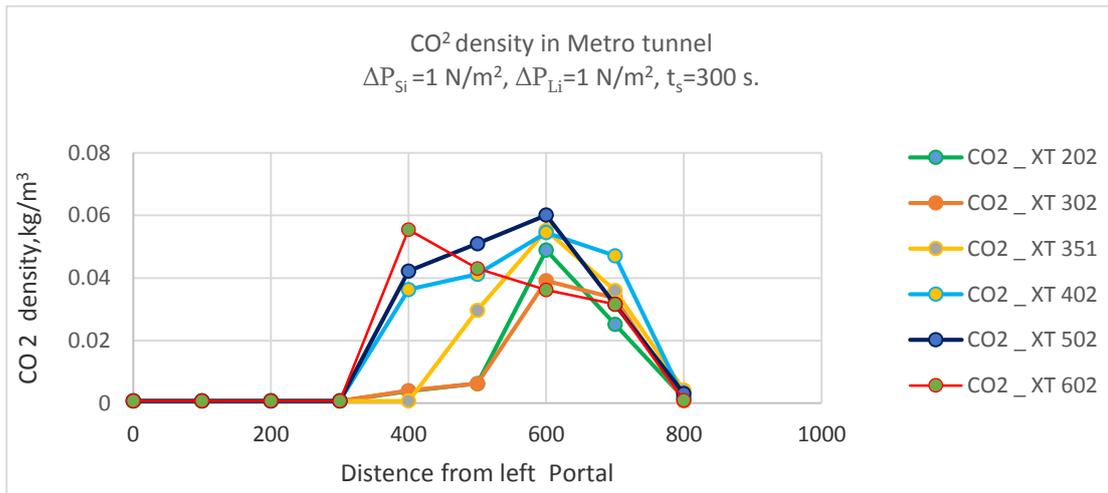

Fig. 5. Depends of distribution of carbon dioxide concentration in the tunnel of the subway on the forced stop location of train. (HRR = 30 MW, height Z = 1.5 along the tunnel, simulation time 300 seconds)

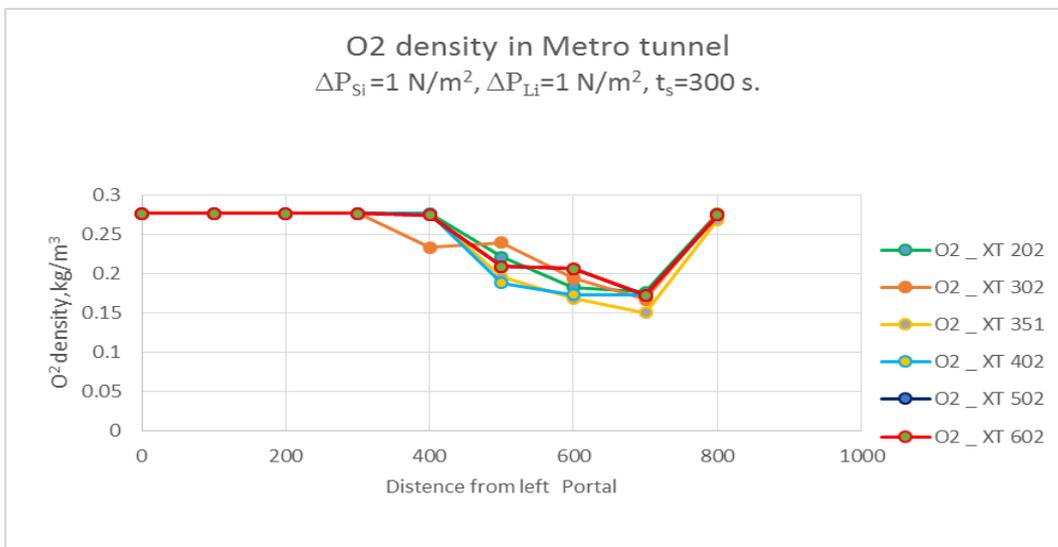

Fig. 6. Depends of distribution of oxygen concentration in the tunnel of the subway on the forced stop location of train. (HRR = 30 MW, height Z = 1.5 along the tunnel, simulation time 300 seconds)

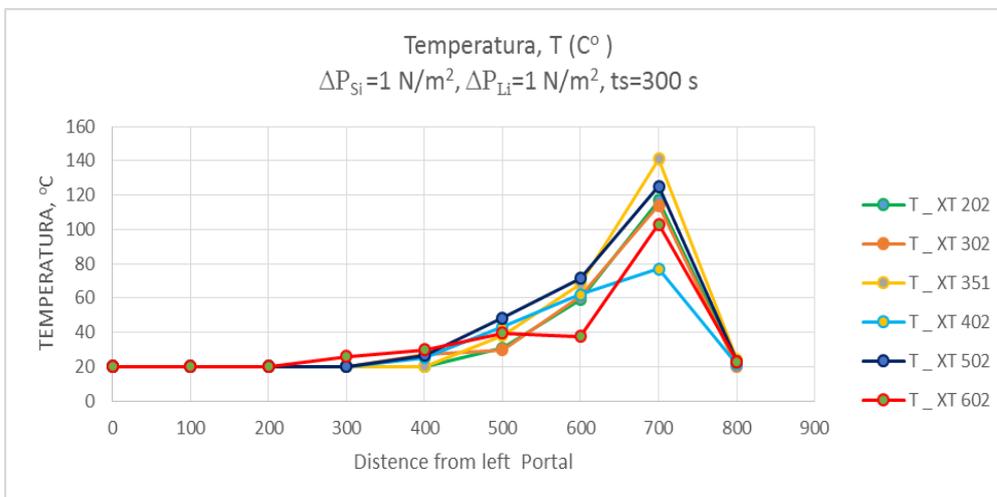

Fig.7. Depends of distribution of Temperature in the tunnel of the subway on the forced stop location of train. (HRR = 30 MW, height Z = 1.5 along the tunnel, simulation time 300 seconds)

We examine a situation where the metro tunnel ventilation system becomes disabled, which is modelled on the boundary conditions for the ‘base model’ – through the total minimal increase of the natural dynamic pressure on one of the portals ($\Delta P_{Li} = \pm 1 \text{ n/m}^2$), and the total dynamic pressure increase on the outer cross section of the air shaft ($\Delta P_{Si} = \pm 1 \text{ n/m}^2$) For the Basic model, the process of changing the spatial scale of the harmful factors along the tunnel was studied. time of modeling $t = 300 \text{ s}, 1200 \text{ s}, 2400 \text{ s}$. The results presented on the Fig. 9-12

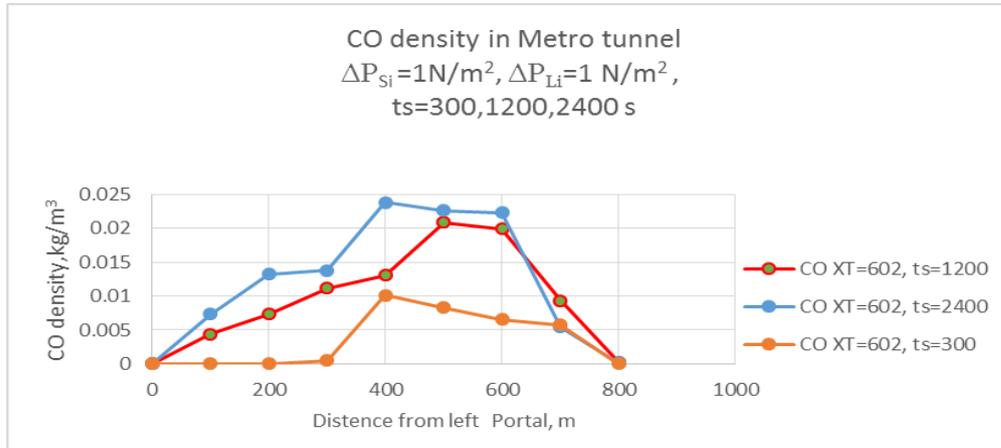

Fig.8. Dynamics of changes the spatial scale of concentration increase of carbon monoxide along the tunnel. The simulation time is $ts = 300 \text{ s}, 1200 \text{ s}, 2400 \text{ sec}$.

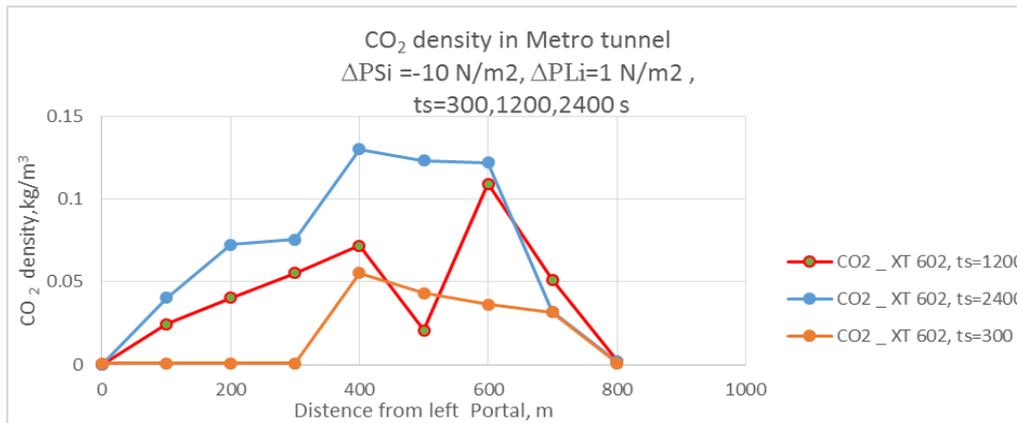

Fig. 9. Dynamics of changes the spatial scale of concentration increase of carbon dioxide along the tunnel. The simulation time is $ts = 300 \text{ s}, 1200 \text{ s}, 2400 \text{ sec}$.

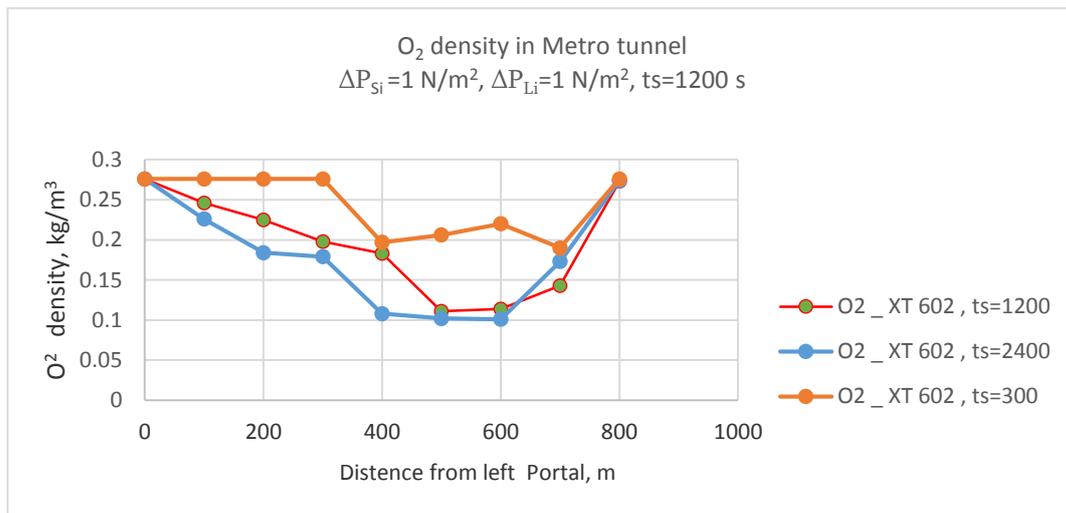

Fig. 10. Dynamics of changes the spatial scale of concentration decrease of Oxygen along the tunnel. The simulation time is $ts = 300 \text{ s}, 1200 \text{ s}, 2400 \text{ sec}$.

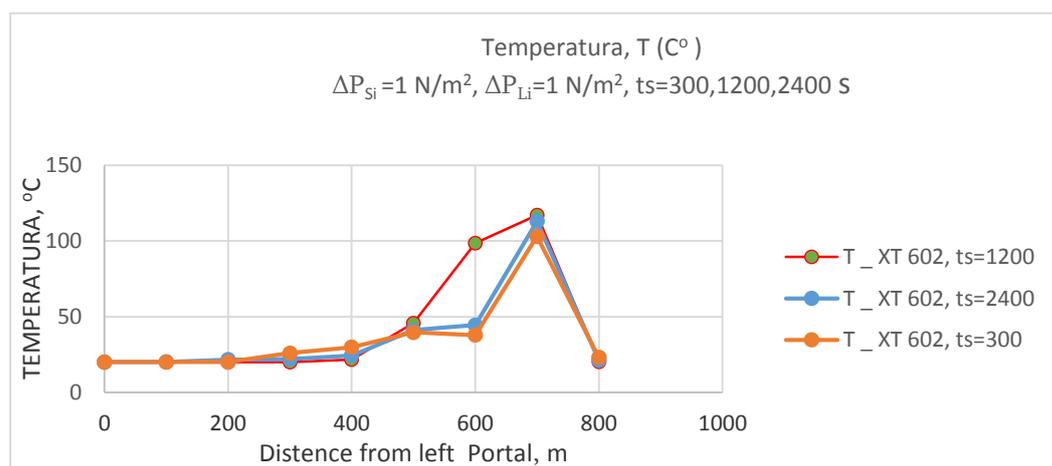

Fig.11. Dynamics of changes the spatial scale of Temperature along the tunnel. The simulation time is $t_s = 300 \text{ s}$, 1200 s , 2400 sec .

Results

Results of the numerical experiments allow us to produce a practical assessment of spatial and time distribution of the harmful factors during the realisation of various boundary conditions. The test quantity of toxic and/or asphyxiants gases is their concentration level in the tunnel space, while the thermal harmful factor is represented by the average gas temperature along the tunnel.

- The modelling of the emergency situation caused by fire inside the metro tunnel is carried out on the basis of the 'base model,' which accounts for the numerical realisation of the worst possible scenario of creation and spread of harmful factors based on the existing tunnel geometry, as well as initial and boundary conditions;
- It is shown that the dynamics of spread of harmful factors are not significantly affected by the location of the halted train, when the volumetric efficiency of the tunnel's cross section is $\alpha=0,375$;
- In case of 30 MW-magnitude fires, the spread of toxic and asphyxiant gases occurs over almost 300 m in 5 minutes, under the boundary and initial conditions that are realized in the base model. The spatial scale of these factors is characterised by a tendency of growth.
- The danger zone of the temperature factor is quickly stabilised. Its spatial boundary is located within a distance of 100-150 m from the fire source, on both sides of the tunnel.

Abstract

Based on the European approach to the "work accident" concept, this paper addresses the occupational injuries in terms of the statistical indicators reflecting this phenomenon as a relevant factor to substantiate the need for prevention and protection of risks related to industrial presses operation. An analysis of the causes of occupational accidents during operational use of industrial presses argues the need to address prevention and protection from a new perspective, taking into account the general principles of prevention as laid down by Law nr.319 / 2006 on safety and health at work.

The aim is to investigate the evolution of occupational accidents occurred in six counties from the North – Western region of Romania, between years 2005-2016 and to obtain a preliminary picture of the magnitude and prevalence of occupational injuries for subjects operating industrial presses. Findings confirm that human errors are the main underlying causes of accidents occurring at work.

Keywords: accident at work; statistic indicator; press operator; human error.

1. Introduction

Determining the sequence of causes and effects leading to the generation of an accident is a basic element in the equation of prevention. Therefore, how work accidents are occurring and statistic developments in the field have been extensively studied by specialists in the field (Guberan and Usel, 1998; Feyer et al, 2001, Fabiano et al., 2004; Cheng et al., 2010; Moraru et al., 2014; Moraru et al., 2013; Moraru et al., 2016).

Considering that an accident of work requires the involvement of objective and subjective causes, whose interaction generates event, over time there have been various attempts to explain accidents, differentiated by approach and the importance given to each of triggers (Moraru, 2012). Law no. 319/2006 on safety and health at work introduces the wider generic term of "event" to describe "*the accident who trained fatality or injury produced during employment or fulfillment of duties, the situation of missing person, route or traffic accident, hazardous incident, and the work-related occupational disease*" (Romanian Parliament, 2006). "Accident at work" is defined in the same law as "*violent injury or occupational acute poisoning that occurs during employment or service duties and causes temporary disability of at least 3 days, invalidity or death*" (Romanian Government, 2006). In this context there are noticeable some significant differences between EUROSTAT definition of accident at work and the legislation in Romania, transposing Directive 89/391 / EEC. Thus, Regulation (EC) No. 349/2011 of the European Commission implementing Regulation (EC) No. 1338/2008 of the European Parliament and of the Council on Community statistics on public health and health and safety at work concerning defines the accident at work as any "*discrete occurrence in the course of a occupational activity, which leads to physical or mental injury*" (CEU, 1986), regardless of consequences and its scale, while in Romania, events that lead to an inability to work less than 3 consecutive days are not included in this category. This is one reason why the legislator felt the need to introduce the term "event". Another term used in the literature is the "*hazardous incident*" that, according to Law nr.319 / 2006 means "*identifiable event, such as explosion, fire, technical*

E-mail address: roland_moraru@yahoo.com.

accidents, emissions of major pollutants, resulting the failure of an activity or a work equipment and / or the inappropriate behavior of the human factor, which did not affect workers, but it would have been possible to have such consequences and / or caused or were likely to cause losses" (Romanian Parliament, 2006). This term came also from the need to expand the scope of situations in which workers must be protected in their physical and / or mental integrity. There are several ways of highlighting, in statistical terms, the situation of occupational accidents. In the literature, are used primary indicators expressed in absolute values and derived indicators expressed as relative values (Babut et al, 2011; European Union, 2010; ILO, 2012; Northwood et al, 2012; Takala et al, 2006; Wiatrowsky, 2014).

2. Evolution of occupational accidents primary indicators between 2006 – 2015 in Maramureş , Cluj , Bihor , Sălaj , Bistrița Năsăud and Satu Mare counties

Primary indicators are obtained in the primary processing of statistical data following a process of centralization of data. They have concrete content and form of expression, being measured in the natural units. For this reason, the primary indicators are also called **absolute indicators** or indicators expressed in absolute values and they represent the basis of information statistical knowledge. For statistical analysis of occupational accidents, the following primary indicators are used:

- *The total number of injured workers* - the number of affected workers for which the consequences of accidents is terminated during the reference period, whether the event occurred during the same period or in previous periods.
- *The total number of victims* - the number of persons injured (dead or with temporary disability), recorded in the reference period.
- *Number of days of temporary disability* resulting from accidents, corresponding with the *total number of injured workers*. Depending on what is intended by the statistical survey, temporary disability days lost are considering the calendar days or working days.

Often statistical studies of this kind are referring to *the average number of employee*. In determining this indicator should be considered all activities of an enterprise and the staff turnover in the reporting period. Primary indicators provide a suggestive image of the extent of the situation, but without allowing a correct curve plotting for the evolution with time of the work accident phenomenon. Indicators expressed in absolute values do not take into account developments in the labour market, the variation in the number of employees or work program, which makes irrelevant a comparison of such indicators, not reflecting the real evolution or involution of the situation. After presenting statistically the average number of employees in north-western counties of Romania in graphical expression (Figure 1), in the same format we highlight the evolution of statistical indicators of accidents at work between 2006-2015 the analyzed region, accidents at work resulting in temporary incapacity for work (Figure 2), fatal accidents (Figure 3) and disabling accidents at work (Figure 4).

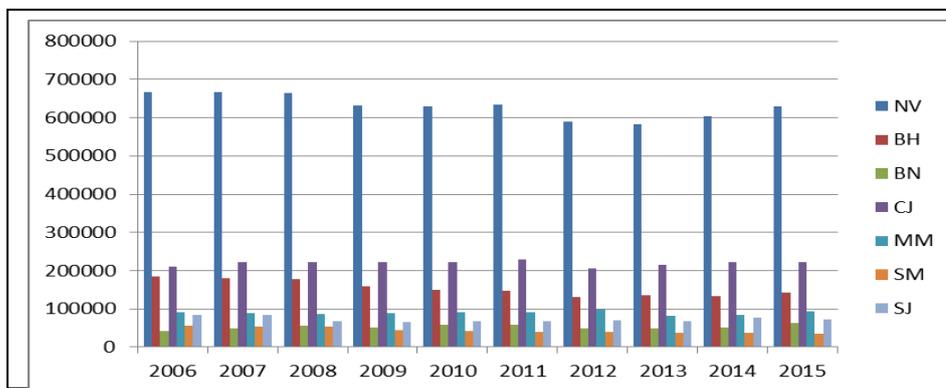

Fig.1. Average number of employees in north-western Romanian counties

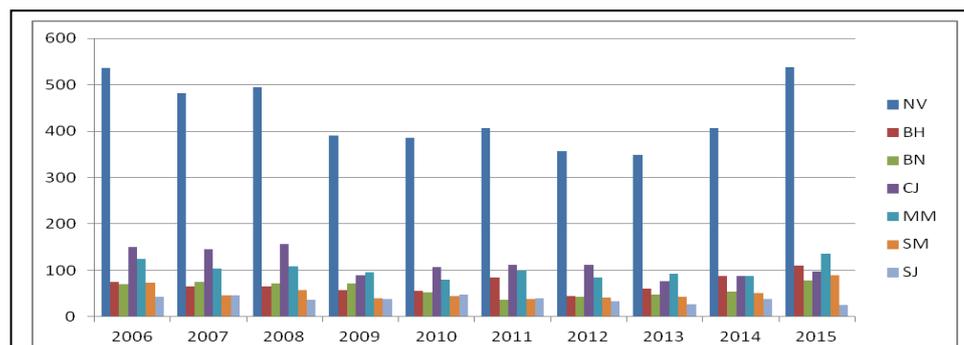

Fig. 2. Evolution of statistical indicators of accidents at work between 2006-2015 in north-western Romanian counties - accidents with temporary work incapacity

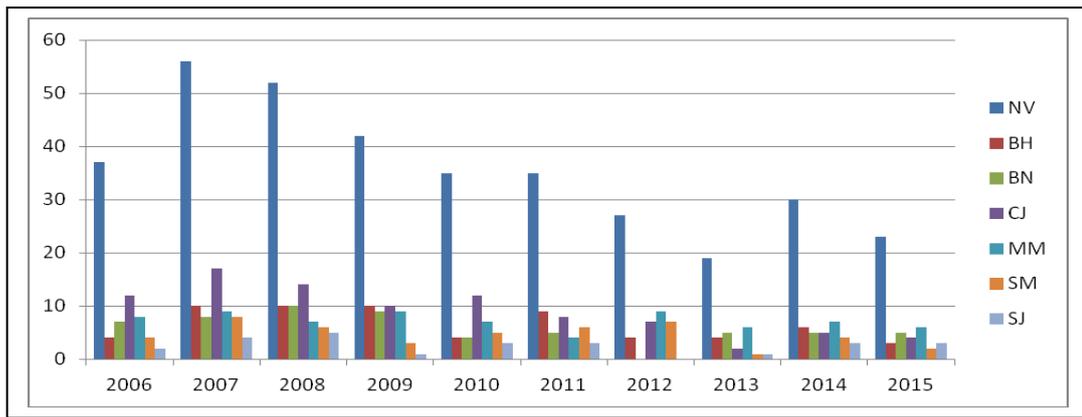

Fig. 3. Evolution of statistical indicators of accidents at work between 2006-2015 in north-western Romanian counties – fatal accidents

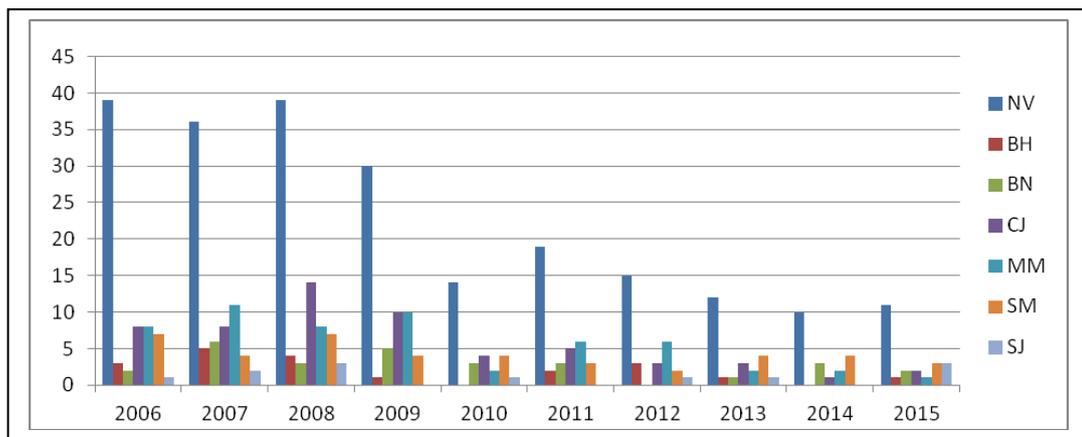

Fig. 4. Evolution of statistical indicators of accidents at work between 2006-2015 in north-western Romanian counties –disabling accidents

3. Evolution of occupational accidents derived indicators between 2006 – 2015 in Maramureş , Cluj , Bihor , Sălaj , Bistriţa Năsăud and Satu Mare counties

The derived indicators are calculated as the ratio between two absolute values so that they are known as *indicators expressed in relative values*. Unlike the primary indicators the analysis of those expressed by relative values are more accurately capturing the time evolution of the occupational injury phenomenon. While reported to 1,000 workers they make the figures comparable regardless of employment market development. For statistical analysis of accidents at work the following derived indicators are used:

- **Average Duration Index (IDM)** expresses the ratio between the total duration of temporary work incapacity (ITM), and the number of injured workers with ITM in the same period, expressed in days. IDM expresses both the accident severity and the effectiveness of the medical recovery system.
- **Gravity Index (IG)** expresses the severity scale of accidents that occurred in the statistically analysed entity. It is determined by the total number of man-days of work incapacity, for 1000 workers.
- **Frequency Index (IF)** expresses the frequency of the injury in the analyzed entity, namely, how many workers per 1000 were injured.

Frequency index is calculated for a reference period. The indices of frequency, gravity and of average duration allowing to perform factorial analysis, analysis of distribution of values, etc., thus making it possible to study the common factors and deviations which may be of practical interest. It should be stressed in this context the difference between the indicators used in Romania and those used in EUROSTAT system, where the number of accidents is related to the average number of hours worked. We believe that this latest version is more suggestive and reflect more accurately the real situation.

Next we present in the same graphic expression the evolution of derived statistical indicators of accidents at work in the period 2006-2015 in counties in north-western Romania, respectively and the gravity index (IG, Figure 5), average duration index (IDM, Figure 6) and the frequency index (Figure 7).

As a significant related value, which can be correlated with these indexes, the figure 8 gives the total number of Temporary Work Incapacity days between 2006-2015 in the investigated north-western Romanian counties.

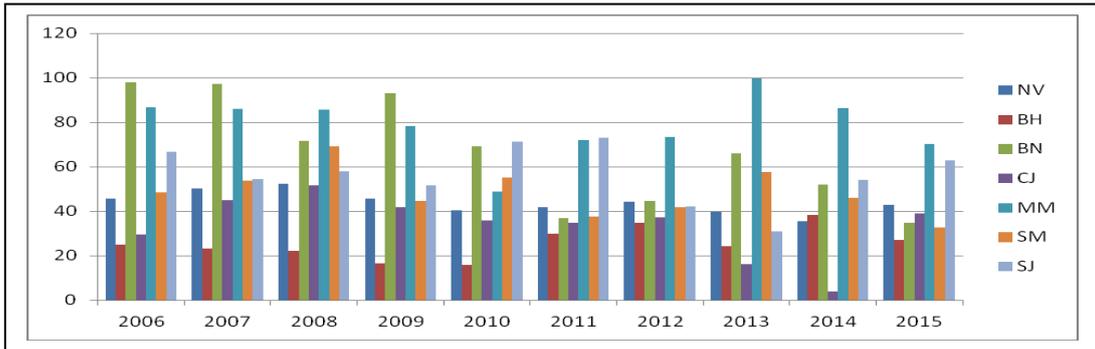

Fig. 5. Evolution of gravity index for accidents at work occurred between 2006-2015 in north-western Romanian counties

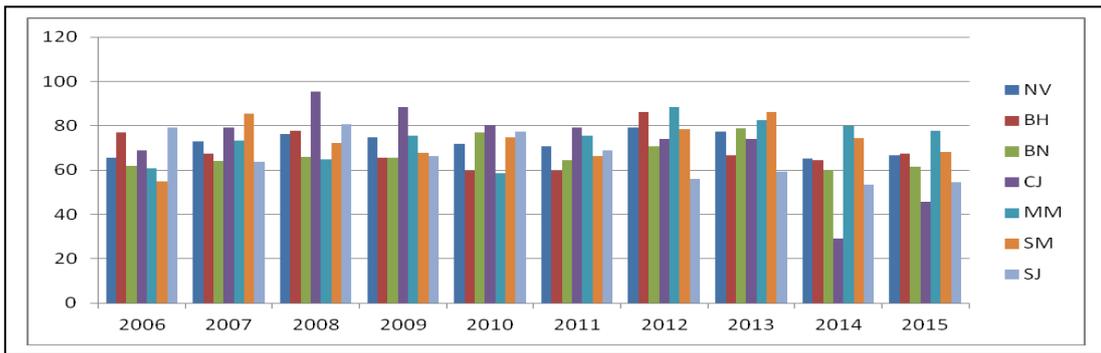

Fig. 6 . Evolution of average duration index for accidents at work occurred between 2006-2015 in north-western Romanian counties

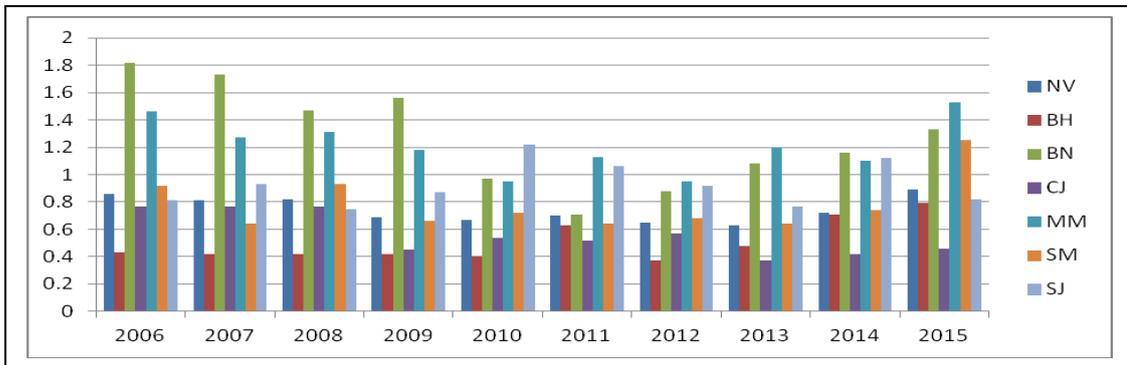

Fig. 7. Evolution of frequency index for accidents at work occurred between 2006-2015 in north-western Romanian counties

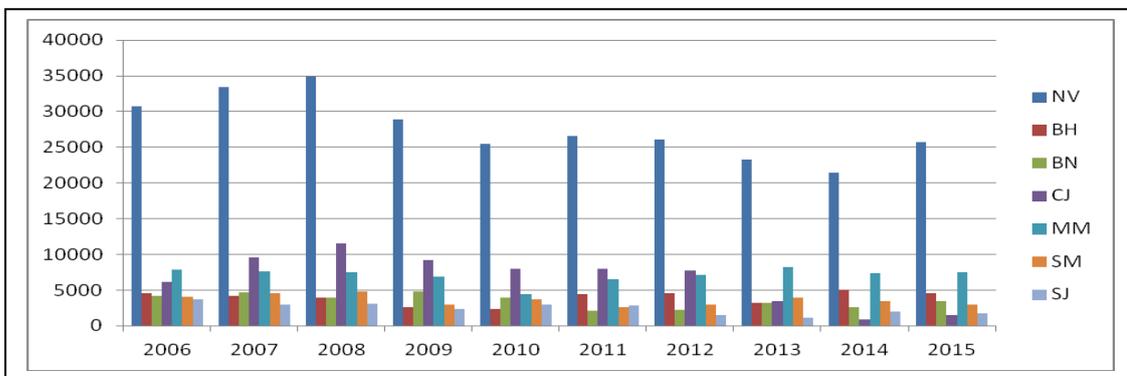

Fig. 8 . Total number of Temporary Work Incapacity days between 2006-2015 in north-western Romanian counties

4. Statistical inventory of accidents at work occurred between 2005 – 2016 in Maramureş county in industrial presses operation

Study of safety and health at work must begin by knowing the general problems, the basic focus being placed on the risk factors of accidents and professional diseases that may occur in work processes and key measures to combat them. After acquiring this knowledge valid for all conditions and jobs will be addressed issues specific to certain industries. Socialization of production has generated a new situation: the beneficiary, leader, organizer and executor of work are distinct. Consequently, the first ones will be an additional source of potential danger either directly or indirectly, becoming largely responsible for exceeding the normal consumption of the labor contractor. Added to this is the ability the means and equipments which are employed in performing the working task, the work environment in which the process takes place and the workers itself, to disrupt the normal course of activity.

Automation (with its related monotony of the work and the pace imposed), the new technologies, the raw materials used, etc. may affect in different ways anatomical and functional integrity of the press operator. Table 1 is highlighting statistics of occupational accidents in the county of Maramureş in activities which are using mainly industrial machinery as presses.

Table 1. Statistics of occupational accidents in Maramureş county in activities which are using industrial presses

Branch	Year											
	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016
Textile, clothing, footwear industry	5	1	4	1	6	1	1	1	1	2	1	3
Wood processing industry	21	21	21	16	18	12	17	18	14	19	22	21
Paper, plastics, ceramics manufacturing	9	7	2	3	1	7	6	7	11	8	9	4
Metalurgy	9	13	9	5	5	4	4	5	3	7	6	7
Steel work	7	9	4	8	8	5	7	7	8	4	10	13
Mining	26	12	3	3	1	0	0	0	0	0	1	1
Agriculture	0	1	1	1	0	2	2	1	1	0	2	1
Forestry and logging	5	3	4	19	5	5	7	4	5	6	7	7

The figures revealed by this analysis are highlighting the need for increased prevention and protection with particular attention to the SME sector. As mentioned above, in analyzing the absolute values of work accidents should be considered the phenomenon of significant decrease in the number of workers in the national economy. Hence, again, the need for indicators that take into account the variation in the number of employees or of the overall hours worked. Out of 1082 accidents in Maramureş County during the years 2005 to 2016, 55 occurred in operating industrial presses of various types.

Figure 9 shows the synthesis of a quasi-exhaustive analysis conducted on accidents at work occurred in the period from 2005 to 2016 at the operational use of machines such as industrial presses in 28 companies / enterprises in Maramureş county.

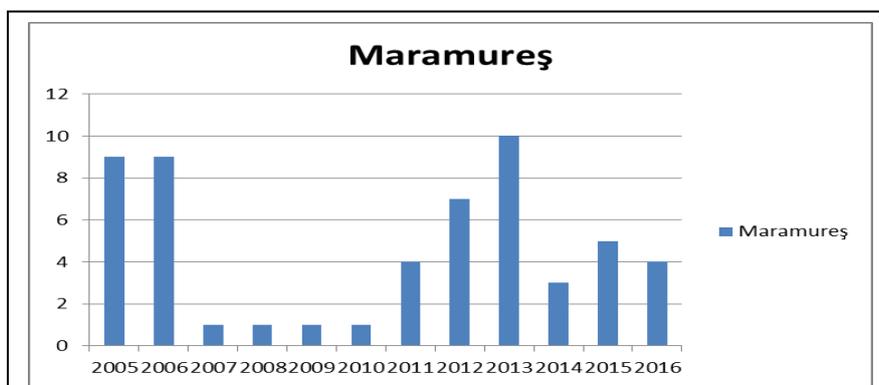

Fig. 9. Accidents at work at industrial presses in Maramureş county between anii 2005-2016

From the statistical study carried out it resulted the fact that root causes were 100% dependent on the human factor involved in the operation of industrial presses.

5. Conclusions

Starting from the new European approach to the concept of "accident at work" this paper has addressed the phenomenon occupational injury and disease from the perspective of the statistical indicators reflecting this phenomenon as a relevant factor to substantiate the need for prevention and protection, including those aimed at eliminating or minimizing the risks associated industrial presses operation. The analysis was based on secondary information from the Labor Territorial Inspectorates information system.

Based on a quasi-exhaustive analysis performed on accidents at work occurred during 2005-2016 in operational use of such machines as industrial presses within 28 companies / enterprises in Maramures county it was emphasized on the one hand the fact that all unwanted events in which the press operators have undergone various types injuries or health issues had as primary cause what is referred to generically in the literature as "human errors" and, on the other hand, the fact that 10 investigated companies have registered 37 from the total of the 55 accidents at work. This share of 67% is another statistical indicator of major importance and significance in highlighting certain accidental behavior patterns arising from malfunctions and latent failures of organizational nature that will determine that further studies and researches to pay a more thorough attention to the reciprocal relationship "human factor - safety management".

Abstract

Fire and explosion risk assessment and consequence modeling for hazardous storage facilities is of great importance, taking into account the potential hazards for the local population and surrounding assets. In this case, consequence modeling aims the estimation of numerical values or the graphical representation which describe the physical outcomes of various accident scenarios involving a LPG filling station located in an urban area, with respect to their impact on people or assets. In case of LPG filling tanks may occur malfunctions, thus generating leakages which may escape into the atmosphere, may burn as jet fire or the tank may even explode and generate the fireball burning of the LPG (boiling liquid expanding vapour explosion - BLEVE). Moreover, the proximity of LPG filling stations to populated areas may magnify the potential damage. Prescriptive regulations in force govern the design, execution and exploitation of LPG filling stations. In this paper, various emergency situations which may occur in case of a LPG filling station are modeled and simulated using specialized software. Also, there are analyzed the safety measures from regulations in force concerning the location of such units in urban areas and the safety distances set in the regulations are compared to the ones generated using software tools, leading to measures proposed for limiting the effects of the studied phenomena.

Keywords: filling station; fire; explosion; LPG; safety distance;

1. Introduction

Leakage of pressure vessels from LPG (Liquefied Petroleum Gas) filling stations may lead to hazardous fire or explosion type events. One of the most hazardous situations is the one involved by the (BLEVE) Boiling Liquid Expanding Vapour Explosion. Once the gas is ignited, it leads to the formation of fireballs (Kamaei et al., 2016).

Taking into account the price of LPG/litre which is less than half the price/litre of regular fuel (petrol and diesel), the number of vehicles using LPG as has increased over the past years. Most LPG filling stations are located in inhabited areas, this involving the potential risk of casualties if any accident takes places. In fact, in several places of the world happened before accidents involving LPG filling stations which have resulted in human and material losses.

Even if the safety measures have been improved in time, it is practically impossible to avoid such accidents completely. Therefore, it is of high importance to assess the possible consequences of the accidents and to better understand the accidental scenarios. In this paper, there has been performed an attempt to analyse the consequences of an LPG release from the tank of a LPG filling station located in an inhabited area. T

he catastrophic failure of the pressure vessel is analysed using state-of-the art computational methods, investigating different scenarios concerning the distances around the LPG filling station which are likely to be hazardous for facilities and persons nearby (Suvar et al., 2012, and Suvar et al., 2014), taking into consideration the huge amount of energy which can be emitted in case of such accidents.

2. Safety distances

Safety distances relate to the distance from a hazardous equipment/process (Irimie et al., 2017) representing the lowest separation which is going to mitigate the effect of an of a likely foreseeable incident and to prevent a minor incident escalating to a larger incident. Also, safety distances have to be established for providing protection from foreseeable external impact or activities outside the control of the operation ((Buica et al., 2017; Micu et al., 2017). Concerning LPG filling stations, Romanian regulations in force establish safety distances in compliance with the destination of the installation, the destination of the adjacent buildings / premises and the capacity / type of the tanks (Table 1). Taking into account the progress in terms of safety measures for decreasing risks to an as low as possible level, recent projects of such regulations tend to provide lower safety distances (Table 2) (ANRE Project, 2015; ANRGN Decision, 2006; MLPTL Normative, 1999; WLPGA Guidelines, 2008).

Table 1 Examples of relevant safety distances between the LPG filling station with over-ground tank ($V \leq 5 \text{cbm}$ water equivalent) and neighbouring constructions according to NP 037/1999.

No.	Type of construction	Distance to the LPG filling station [m] *
1.	Living homes: - apartment houses located in residential districts	40
	- individual houses located in isolated areas	20
2.	Education buildings (kindergarten primary and secondary schools, high-schools and universities)	40
3.	Health buildings (hospitals, clinics, orphanages, retirement homes, rescue stations and other sanitary units)	40
4.	Cultural buildings (exhibitions, libraries, cinemas, theatres etc.)	40
5.	Cult constructions: - places of worship	40
	- monasteries, hermitages, cemeteries	60
6.	Commercial buildings: - general stores, stores for food and non-food trade	40
	- supermarkets, trade fairs, wholesale storages	50
7.	Sports buildings: - sports complexes, stadiums, ice skating rinks, sports competitions buildings	60
	- training buildings, bowling alleys	40
8.	Leisure buildings: children play locations, parks	60
9.	Tourism buildings: - hotels, motels and restaurants and other accommodation buildings with over 50 places capacity	40
	- hotels, motels, villas, chalets, restaurants etc. with under 50 places capacity	20
10.	Highways and international roads	30
11.	National and county roads	15
12.	Local public streets	10

* Distance is measured from the tank vessel and/or from the tank filling point

Table 2 Examples of relevant safety distances between the LPG filling station with over-ground tank ($V \leq 5 \text{cbm}$ water equivalent) and neighboring constructions according to NTGPL 2015 Project

No.	Type of construction	Distance to the LPG filling station [m]	Observations
1.	Individual homes and their annexes. Sports fields. Cemeteries.	15	
2.	Residential blocks, apartment houses	20	
3.	Children play areas, Parks, Leisure areas. Civil constructions: Education, Health, Culture, Cult, Commercial, Tourism, Administrative, Sports (sport halls, sports fields with tribunes etc). Any other civil constructions.	25	Distance is measured from the limit of the building (base of the building, limit of the sports field/play area etc.)
4.	Highways and Express Roads	15	
5.	National and County Roads	9	Distance is measured from the edge of the road
6.	Streets and local access roads, other than the previous	7	

3. Considerations on mathematical modelling of hazardous events

The continuous improvement of mathematical models has led to their wide use for estimating the effects of hazardous events (Niculescu and Pasculescu, 2015, and Vlasin et al. 2016). Mathematical models developed comprise sets of equations describing events and which are able to provide the prediction of issues such as thermal radiation generated by fire type events, maximum pressure generated by explosion type events, distance and direction of thrown pieces or change in gas concentration after releases (Prodan et al., 2016).

For predicting such phenomena (Leba et al., 2014) the first step is to estimate the amount of materials involved in the incident and the rate of emission, achieved by initial condition models. Initial condition models are based on heat transfer and on fluid dynamics, requiring temperature and pressure parameters of materials. These parameters change once with the change of conditions, changing for example once with the heating of the pressure vessel.

Also, for calculating the output flow rate arising from a leak of a pressure vessel, there are required the data concerning the shape and size of the leak information which are unlikely to be available in case of accidents, therefore using simplified assumptions or standard initial conditions (Pasculescu et al., 2015a; Pasculescu et al., 2015b; Pasculescu et al., 2014).

Safety engineers and researchers have developed mathematical models which are able to describe effects of complex phenomena, such as fires, emissions or explosions, models expected to provide accurate results, but which require a wide range of data which is not always available (Babut et al., 2011; Lupu et al., 2017). After the characteristics of an accident are determined, there may be employed damage assessment models for predicting the effects on surrounding people and buildings (Cioclea et al., 2015; Magyari et al., 2015).

For such analyses, mathematical models have been implemented within state-of-the-art software tools which are commercially or open-source made available for experts in the health and safety field.

4. Overview of Phast Software

There are a number of software tools which can be used for modelling consequences of chemical releases, such as Phast, Aloha or Degadis. However, for the analysis performed and presented in this paper there has been opted for using the Phast 8.1 software, taking into account that the validated mathematical models incorporated and the particular use for tank's explosion (Technical Datasheet, 2018). Phast 8.1 is a commercial software for mathematical modelling of various hazardous situations such as dispersions, fires or explosions which can be used for assessing the consequences of these scenarios so that to be able to better understand their behaviour in order to prevent possible material and human losses. Using Phast 8.1 there can be performed the following main computational simulations and modelling:

- Discharge of mixtures of pure substances or components.
- Dispersion The software includes the Uniform Dispersion Model (UDM) of DNV GL, a global scale dispersion model for: Jet, heavy and passive dispersion phases; Buoyancy; Interaction with the substrate; Gaussian pan; Drip formation and rain-out phenomenon;
- The rain-out phenomenon;
- Spreading and vaporization;
- Indoor and outdoor analysis of toxic effects in the wind direction;
- Radiation, explosions and fires: Jet Fire, Pool Fire, Fire Ball, including the Roberts (Health and Safety Executive) and TNO models, Explosions, including TNT, Multi-energy models and Baker Strehlow.

4.1. Phast Multi-Component extension

For improving the modelling capability of the software, there are available several extensions and add-ons. One of the main extensions available is the Multi-Component (MC) extensions, which brings along the following main specifications and possibilities:

- It includes integrated multi-component properties system with built-in chemical database;
- It supports the most commonly used state equations, including Redlich-Kwong, Soave-Redlich-Kwong and Peng-Robinson;
- It can generate graphs of phase composition during dispersion;
- It contains a "Pool" multi-component vaporization mode.

4.2. Phast 3D Explosion extension

The 3D Explosion Extension adds the advanced vapor / gas cloud modeling capability (incorporating the Baker-Strehlow-Tang and Multi-Energy models) taking into account interactions between the flammable cloud profile and the congested regions of process installations in all three dimensions (length, width, height), according to wind conditions, to characterize the explosive potential and the generated loads (eg overpressure, pulse and duration).

- Selection of technical capabilities:
- Advanced Vapor Cloud Explosion Modeling (VCE), allowing for a more detailed and realistic explosion hazard analysis.
- Multi-scenario contouring of hazards.
- Able to provide directional modeling.
- Allows a detailed analysis of a series of dangerous consequences associated with a dangerous event, taking into account various factors that influence its development (eg variation in weather conditions).
- Uses connected models so that complete analysis of an event and its associated consequences can be executed in a single integrated computation execution.

- It incorporates powerful viewing tools that allow application ranges to be applied to location maps, allowing a clearer understanding of impact areas.
- The results of the analysis can be presented in different formats (graphs, tables, comments).

5. Case study - LPG pressure vessel leak

For performing the consequence analysis, there has been used the case of a mono-block LPG filling station, located in an inhabited area, whose technological diagram is presented in Figure 1. In the proximity of the LPG filling station are located several types of buildings and civil facilities, namely: city road (distance from LPG filling station: 8 m); restaurant with a capacity of less than 50 persons (distance from LPG filling station: 30 m); supermarket (distance from LPG filling station: 50 m); gym (distance from LPG filling station: 63 m); highschool (distance from LPG filling station: 60 m); apartment houses (distance from LPG filling station: 101 m), presented on the map in Figure 2.

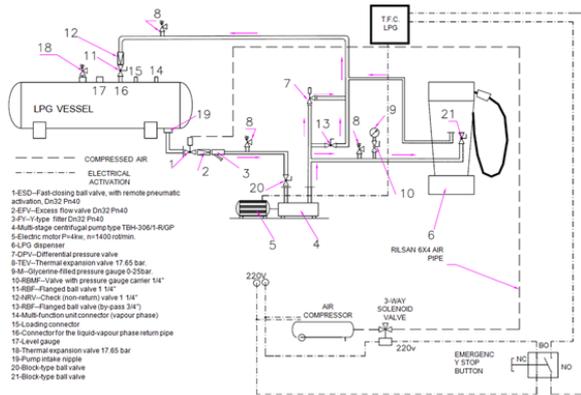

Fig.1. Technological diagram of the mono-block filling station

Fig.2. Layout of the LPG filling station and immediate surroundings

The properties of the pressure vessel and of the LPG contained along with other relevant data for performing the modeling have been set as input data for the consequence analysis. The analysis has been performed for two weather case, the meteorological information being presented in Table. 3

Table 3 Selected meteorological information

Case No.	Temperature [deg C]	Wind speed [m/s]	Wind direction	Pasquil stability
Day	25	2	NE	A very unstable – sunny, light winds
Night	10	1	NE	F stable – night with moderate clouds and light/moderate wind

After running the calculations, the software generates the data for the scenarios modeled and which can be displayed in various forms: data reports, graphs or GIS, depending on the types of interest. In the following are presented selected data concerning flash fire, fireball or explosion, resulting from the modeling of a scenario related to the catastrophic rupture of the pressure vessel and from the scenario involving a line rupture, with release in vapour phase.

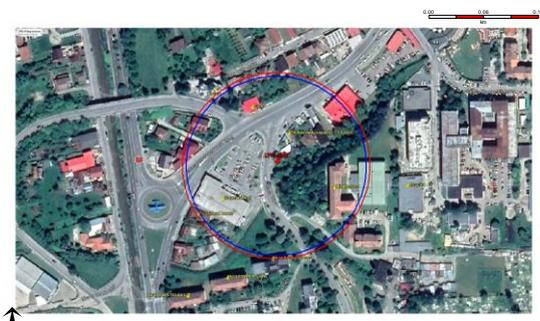

Fig. 3 Flash fire envelope, catastrophic rupture (GIS)

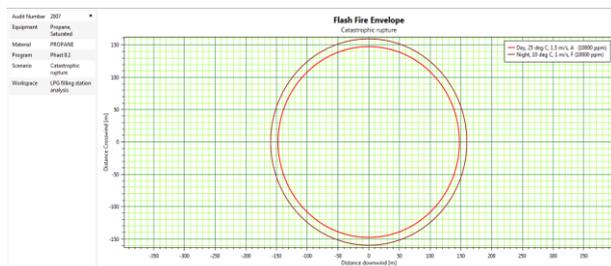

Fig. 4 Flash fire envelope, catastrophic rupture (graph)

Fig. 5. Intensity radii for fireball, 50kW/m2 (BLEVE)

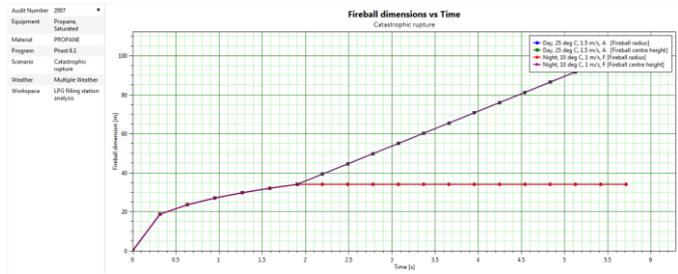

Fig. 6. Fireball dimensions vs. time

Fig. 7. Explosion worst case radii, effect zone only

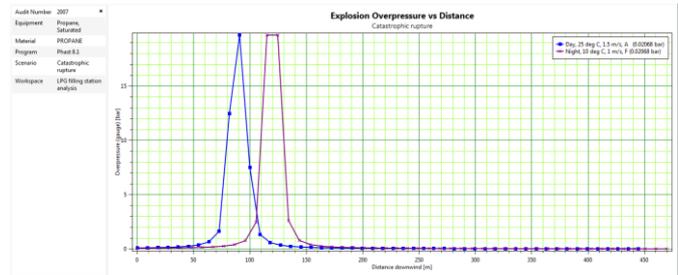

Fig. 8. Explosion overpressure vs. distance

6. Conclusions

Following the modelled scenarios, there can be noted that the safety distances provided in regulations are not suitable for worst case scenarios. However, even if such scenarios are unlikely to occur, it cannot be assumed that they are not possible. Therefore, using combustible materials around LPG filling stations should be limited and there have to be taken measures to that to ensure that vehicle is not going to collide with the pressure vessel and if this happens, the burning vehicle can be removed fast and safely from the area of interest so that not to head up the tank.

For determining the proper safety measures, every possible scenario has to be treated separately so that to be able to respond to each type of emergency. The use of software tools such as the one used in this paper may represent a powerful tool for risk analysis and mitigation. Results of the computational modelling of hazardous scenarios can be used for establishing area evacuation methods, safety measures for intervention teams and the type of intervention.

Since the accidents happen suddenly and are not foreseeable, it is important to maintain a buffer zone around hazardous locations. The results of the modelled scenarios can be used to identify the phenomenon causes and its effects on nearby people and equipment. On this basis, there can be implemented preventive controlling measures and also determined the proper layout and design of LPG filling stations so that to ensure the safety of personnel, civilians and surroundings.

Abstract

Ergonomics is a discipline that studies the working climate, to facilitate the individual's adaptation to the workplace. After 2000's, there has been a trend towards psychologising the work, the technology, the education. New needs of people have been defined, which have changed the workspace. There is a need for a place to relax, to rest at work, the need for socialization and activities outside the program. Thus, organizations, corporations that meet the multiple needs of employees, in order to increase the quality of the services offered, as well as to increase the quality of employees' lives as a motivational factor, appeared. Starting from the vision of the pedagogue Rudolf Steiner, the present paper proposes an inductive research, based on a questionnaire on the ergonomic modelling of the workspace of the engineers, depending on individual sensory sensitivity, in order to increase the state of well-being, the mental health of employees, as well as to improve safety at work. The paper sets out managerial strategies regarding the design, organization and finishing of a building in which engineer's work, as well as the interior design of the workspace and the relaxation space.

Keywords: ergonomics; engineer personality; quality of life; work safety.

1. Introduction

Ergonomics is a discipline that studies the working climate, to facilitate the individual's adaptation to the workplace. Ergonomics deals with the study of man-machine-work relationship (DEX, 2012). Etymologically, the ergonomic word comes from Greek: ergon means work, and nomos means law. Ergonomics, as discipline, is an integrated character, overcoming inter- and multidisciplinary barriers. It combines, in a harmonious unity, like a country, specific notions of engineering, psychology, sociology, economics, anthropometry, design, biology, physiology. The integration of corporate social responsibility into management structures facilitates the development of organizations (Cioca, 2014).

Business processes are becoming increasingly person-oriented, so marketing and linking top management with employees is extremely important (Cioca, 2013). The present work presents the ergonomics of production conception. The ergonomic elements to be researched in relation to the psychology of engineers will be interpreted from the point of view of the Senses Theory of the pedagogue Rudolf Steiner. The orientation of ergonomics only on visual and auditory stimulus appears to be restrictive, bearing in mind that there is research on 12 human senses.

Rudolf Steiner has identified 12 senses that complement those identified by Aristotle: the sense of life; sense of touch; the sense of movement; the sense of balance; visual sense; olfactory sense; sense of taste; the sense of heat; auditory sense; verbal sense; sense of thought; the sense of self.

In the human-work system, sensory organs receive different types of information: written instructions, other people, objects, events, and environmental factors. Following the processing of the information, the decision-makers execute the decision. In this context, it is ideal to ergonomically conceive the information sources of all analysers (of the 12 senses presented above).

Workspaces are part of the IT-specific terminology and represent how to configure the control bar, buttons, and commands (Workspace, 2016). Workspace at the organization level is the configuration of the room so as to increase employee productivity. Productivity can be the direct result of settings made in the workspace, but also the indirect result of the well-being of employees.

The ultimate goal of improving workplace conditions is to increase organizational performance: productivity. To achieve this, it is very difficult to motivate employees because you are not sure that an extrinsic motivator is causing the expected psychological effect. Research has highlighted that it is much easier to increase employee well-being to improve performance within the organization. It seems that money is no longer a defining element in the attraction and retention of personnel, people want to be first and foremost happy (Ghira, 2017). In conclusion, a recipe that creates an ideal psychosocial environment cannot be defined precisely because the variation of temperamental types and group sentiment is very large.

2. Objectives

The study on the psychological and behavioural profile of engineers aims at determining the characteristics of the workspace of engineers, by studying the behavioural profile, following the application of the self-evaluation questionnaire.

The purpose of the study is to optimize the human resources management methods at the organizational level and the ergonomics elements appropriate to the psychological and behavioural profile of the engineers in order to increase the employees' well-being and improve the organization's results (increase productivity).

The working hypothesis emerging from the established objectives is:

- Enhancement of the workspace by the employer increases the intellectual and physical comfort of the employees and increases the productivity of the engineers.

3. Methods

The evaluation of the behavioural profile of the engineers in order to optimize the work space was done by developing a tool that directly targets the characteristics of the environment.

The sociological survey is the most widely used research method. It is a complex method, with the tools and techniques it uses. The survey is a way of knowing scientifically the opinions, attitudes, aspirations of people and being a means of influencing it. It achieves quantifiable results on human behaviours or other psychosocial studies (Cauc, 2007). The survey based on a questionnaire is a method of sociological research (Miftode, 1995).

116 questionnaires were completed by the engineers. All the people employed in a given place, who have manifested both availability and willingness to collaborate, have been chosen.

The present test, "Ergonomic organization of workspace", is non-standardized, does not have standardization samples. It is an objective test, with structured questions with a nominal scale. The measured dimension is sensory sensitivity. It consists of 18 statements, which contain 85 items.

4. Results

The analysis of the workspace of the engineers is based on two main coordinates: the determination of the physical and psychological workspace, as described by the ergonomics of the organization.

Part I of the questionnaire, "Determining the Physical Work Space", follows four categories of stimulus:

1. Sensitivity of engineers to tactile stimulus

The items on tactile sensitivity aim to discover the favourite texture of furniture engineers, objects in the surrounding area, and the favourite material for a service uniform.

2. Engineers' sensitivity to visual stimulus

The visual stimuli analysed relate to the colour of the work room, the colour of the office, the clothing, and the sensitivity to the visual elements in the environment. It aims to be able to generalize a certain style of workspace for engineers.

3. Sensitivity of engineers to space stimuli

The spatial stimuli analysed in the questionnaire are:

- Geometry of the workspace;
 - Perception of others in the workspace;
 - Workspace dimensioning;
 - Choosing relaxation spaces during the break.
- The characteristics of the environmental space that were analysed are:
- Order vs. Not necessarily order (avoiding the use of the word clutter because it has social negative connotations);
 - Predictable vs. unpredictable;
 - Symmetric vs. Asymmetric;
 - Lines, straight shapes vs. Curved lines, round shapes;
 - Fixed furniture vs. Modular furniture.

4. Sensitivity of engineers to auditory stimuli

Testing sensitivity to auditory stimuli tracks the composition of the workspace with / without auditory stimuli. It identifies the preference for listening to music during work and pause, as well as the type of music listened to during leisure.

The music genres predefined in the questionnaire are: rock; classical; popular; pop; another genre.

Another item refers to the preference for changing the gender / permanent post. There are people who get bored quickly, they are always in change, they are not consistent in elections, they show some instability, they are impatient, they are always on the move and their behaviour is to change music permanently.

Part II of the questionnaire studies the physical and emotional interaction of engineers with the physical and social work environment in order to increase the well-being of employees.

Well-being is a concept that refers to the individual's perception of psychological health and quality of life, cognition and affectivity. The cognitive dimension is related to the subjective significance of mental health and life satisfaction, and the affective component includes personal affective, positive or negative affective practice (Tudorel, 2013, Corey, 2013, Warr, 2004, Moen, 2000).

A six-dimensional model of well-psychological state has been built, starting from a person's lifecycle and human developmental theories (Salami, 2011). The six dimensions are:

- self-acceptance - how satisfied individuals are with their own person;
- positive relationships with others - the ability to empathize and show compassion to others;
- autonomy - self-regulation of behaviour and independence in decision-making;
- environmental protection - ability to manage the environment, according to personal needs and purposes;
- the goal in life - the goals and personal goals that create it;
- personal development - continuous development and use of all capacities to reach the maximum potential (Salami, 2011).

According to the above presented model, at organizational level, environmental control and positive relationships with others have a direct impact on employees' well-being (Warr, 2017, Gough, 1998, Diener, 2000, Boehm, 2008). Recent research has explored the relationship between team work and productivity, a relationship based on increasing employee welfare (Maynard, 2013; Dierner, 2017). The other three dimensions of the model indirectly influence employees' well-being through the interaction with the work environment.

1. Analysing the interaction of employees with the working environment. Environmental control.

Employee control over the working environment, related to the improvement of the state of well-being, is analysed in the questionnaire by 7 items. The purpose of the questions is to establish the overall coordinates of the individual's interaction with the environment, to build an attractive workspace that increases the well-being of employees. The 7 questions are:

- I like to have plants in the field of view.
- As I work I like to look out of the window from time to time.
- I like the space I see on the glass to be ...
 - An open state;
 - With natural elements (trees, ponds, mountains, etc.);
 - Urban landscape (streets, buildings);
 - People;
 - It does not matter.
- When I'm on a break, sometimes I feel the need
 - Standing up;
 - Make a move;
 - Exit outside;
 - I like to stay inside.
- I like to work in a space with furniture ...
 - To stimulate my concentration power;
 - With classic lines;
 - Nonconformist.
- I like to work in position ...
 - Vertical;
 - Seated;
 - Laying down;
 - Comfortable and relaxed.
- In my workspace ...
 - I have photos, posters, amulets, memories from places of interest in the field of view;
 - I like to have familiar, personal items (cups, etc.).

2. Analysis of employee interaction with the social environment at work. Positive relationships with others.

Increasing the well-being of employees at work is influenced by positive relationships with other employees as well as with hierarchical superiors. In this regard, the relationships with other people at the workplace were analysed using the following questions:

- I like to socialize with my colleagues on the break.

- In the break I like to dive into my thoughts and think about ...
 - Service related issues;
 - Family;
 - Friends;
 - What I'm about to do when I leave my job;
 - I dream my eyes open;
 - I do not want to think of anything.
- During the work pause I prefer to ...
 - I walk alone;
 - Walk with my colleagues;
 - Stand alone;
 - Being with colleagues;
 - Standing and interacting with others.

5. Discussions and conclusions - Ergonomic organization of the workspace

In conclusion, if 10 engineers work in an office, then:

- Description of the individual features of the 10 engineers:
 - 5 engineers would be women, 5 men.
 - 4 people would wear uniform, 6 conform to the organization's clothing code.
 - One person would be dressed carelessly.
 - 2 are doing sports and wearing synthetic materials.
 - 5 would wear blue cotton, 3 cotton black, 1 blue cloth, and one white cloth.
 - 8 listen to music on headphones while working.
 - When they leave from work, 9 listen to music.
- Dimensioning of the room and location:
 - 10 engineers would work in 2 rooms. The first office includes 4 people, and the second office, 6, of which 2 would have individual spaces.
 - Each room is wide, airy. Space 1 would have 28m² and space 2 would have 42m². The dimensioning is done according to the normative norms that each employee has a working space that varies between 2/3 m² and 15/18 m² (Puiu, 2010). An average value of 7 m² per person was chosen.
 - In each space, 3 employees face the window. In space 2, those working in separate spaces face the door. There are three women and three men seated facing the window.
 - The building perspective, if we consider it included in a circle, would be: 360° mountains, hills, field and 83° perspective on the city.
- Arrangement of the office:
 - The offices are white and the orange hall. At a forest detour, all the walls would be green. It is recommended to try painting the offices in the blue colour.
 - 7 spaces stimulate the power of concentration.
 - 7 offices / workspaces would be made of wood and 3 of modern materials (plastic combination with other structures).
 - The office / workspace would be light, cheerful.
 - 6 workspaces will be predictable, will not change often, and all IT will want to work in them. 4 spaces will be unpredictable, meaning they will often change their arrangement.
 - 6 spaces will be symmetrical, geometric, and 4 will be asymmetric (two of the asymmetric would be occupied by IT).
 - 5 spaces will have lines and straight shapes with a fixed movable. 5 spaces will have curved lines, round shapes and modular, mobile furniture.
 - 8 prefer a relaxed, comfortable position. 6 prefer to sit. 2 prefer nonconformist and comfortable furniture, which is 1 IT engineer. In conclusion, the IT specialist and one other employee are in the cushion chairs. 6 have very comfortable chairs and pillows.
 - There will be symmetrical / asymmetric 6 plants, 3 in each office. Of the 6 plants, 3 would be in the vicinity of the women's workspace.
 - 10 offices are ordered, but on 3 can sometimes see paper that is not put in place.
 - 4 have familiar objects on the desk (cups, personalized pad, personalized pens, etc.), of which at least one woman and one male.
- Their behaviour during the meal break (30 minutes to 8 hours of work):
 - 9 socializes with colleagues on the break, including the two working alone.
 - 8 go out and walk, one of whom walks alone. Four outdoor sports apparatus can be fitted out of metal and plastic, and a wooden circuit and climbing ropes can also be used, also for the women dressed in skirt.
 - 5 stands for stories.
 - 4 engineers would sit in the dining room and watch monitors with:
 - 12 minutes - music, of which 4 minutes pop, then radio;

- 3 minute - news;
- 12 minute - news in the field;
- 3 minute - meditation by wise men.
- o 2 would sit for coffee.
- o 2 would stay in the office (excluding those who are alone).
- o 2 would go to the cigarette.
- In pause, employees are thinking about:
 - o 5 to family (2 males and 3 females);
 - o 6 at what they have to do at home;
 - o 5 to friends.

Increasing the well-being of employees by setting up a workspace according to individual needs:

- Change the attitude of employees towards work, colleagues and tasks;
- Increase employee motivation;
- Make collectivity fun;
- Change employee attitudes - is optimistic;
- Increases the level of energy concentration;
- Increases employee performance;
- Develops positive emotions in relation to work;
- Reduces quitting and staying;
- Decreases tensions and negative emotions.

Limitations of research and future research directions

The only threat to this perfect mechanism of engaging employees in solving tasks is the phenomenon of hedonic adaptation, that is the habit of employees with that state and environment. For this reason, it is recommended to change the working environment to about 2 years.

The questionnaire also raises another problem: the grid is self-evaluation, so it represents people's perception of their own person.

Abstract

The emergence of new types of risks and developments at the international level generate increasingly complex needs in the field of risk management, as well as implications for their management at national or local level. In this context, there is a need to use a common language in the field of risk management and a coherent and unique analysis process so as to be able to identify risks with a major impact at national level with international connotation but also integrated risk management. Critical Infrastructures at ultra high and very high voltage represent the most sensitive and most vulnerable areas of the National Power Grid, and for this purpose, critical infrastructures must be an indisputable priority for both system and power processors and those who seek to attack, destabilize and destroy National Power Grid (terrorist actions). The purpose of the paper is to identify potential risk scenarios for critical infrastructures within National Power Grid for the purpose of assessing risks and improving National Power Grid quality.

Keywords: risks scenarios/assessment; critical infrastructures; national power grid; quality.

1. Critical infrastructure risk assessment methodology and integrating sectorial risk assessments

1.1. Purpose and objectives of the methodology

Purpose: to provide a common framework for analysis of sectorial risk assessments, to provide information about the types of risks present on the territory of Romania. This methodology is applicable to all types of sectorial risks present in Romania (Cioca et al., 2010, and Web-reference, 2016).

Objectives:

- formulating unique definitions of key terms used in national risk assessment;
- developing scenarios by identifying and building them;
- prioritization and selection of scenarios that will later be included in sectorial risk assessments;
- identifying major national risks and assessing intervention capabilities that can influence the risk of scenarios; in the recommendation phase, analyzes are carried out and the resources to be supplemented are identified; cost-benefit analyzes are carried out to determine whether investments will be made to increase intervention capacity or prevent measures.

1.2. Types of risk identified in Romania

Natural hazards:

- dangerous meteorological phenomena (storms, floods, tornadoes, drought, frost); forest fires; avalanches; destructive phenomena of geological origin (landslides, earthquakes).

Technological risks:

* Corresponding author. Tel.: +40-731-063-310.

E-mail address: daniel@electrosecuritate.ro.

- accidents; failure; explosions and fires (industry, transport and storage of dangerous goods, transport, nuclear); water pollution; construction collapses, installations or fittings; the failure of public utilities; falling objects from the atmosphere or from the cosmos; unexploded ammunition.

Biological risks: epidemics; epizootic / zoonoses.

1.3. Probability and impact assessment for selected scenarios

The scenarios are framed on the Probability scale - probability calculation results in identifying the possibility of a disaster within a predefined time horizon (Pasculescu et al., 2017a, and Pasculescu et al., 2017b), considering available information.

Table 1. Probability scale

Probability scale	Time interval
1 – Low	category 1 - events that can occur once every 1000 years or more
2 – Low-Medium	category 2 - events that may occur between 100 and 1000 years
3 – Medium	category 3 - events that may occur between 10 and 100 years
4 – Medium-High	category 4 - events that may occur between 1 and 10 years
5 – High	category 5 - events that may occur several times a year

Assessment of the impact of selected scenarios - at this stage, the impact of those scenarios obtained following the application of the prioritization criteria is assessed. Impact types are defined specifically by Impact Criteria (C).

Table 2. Impact types, criteria and impact indicators

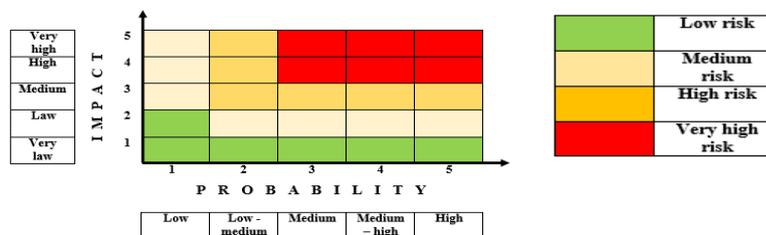

TYPE OF IMPACT	IMPACT CRITERION	IMPACT INDICATORS
T1. Impact on the population	C1.1. Deaths	Number of people
	C1.2. Wounded (injureds)	Number of medical records
	C1.3. Evacuate	Number of persons x number of days T1
	C1.4. People without access to basic services	Number of individual entries in shelters x number of days
T2. Economic and Environmental Impact	C2.1. Material and financial losses	Amount in euro and percentage of GDP (gross domestic product)
	C2.2. Environmental impact	IM (units) = affected area km ² (scaled in % by reference to the protected area) x number of species x number restoration years
T3. Social and psychological impact	C3.1. Interruption of everyday life	Units (number people without access x number services to which they have no access x number of days without access)
	C3.2. Psychological impact at the society level	Index of psychological impact on society (IP)

1.4. Risk calculation

For the risk assessment proposed in this methodology (Pasculescu et al., 2015), the risk is mathematically expressed according to the following formula:

$$Risk = Impact \times The\ probability\ of\ occurrence\ of\ the\ event$$

Table 3. Scenario placement on the risk matrix

2. Identification of risk scenarios on critical infrastructures from the national power grid

2.1. The real functioning of the Romanian National Power Grid

In Romania, the responsibility for the safety and security of the National Power Grid operation lies with the Company TRANSELECTRICA (Web-reference, 2016), being subordinated to the Ministry of Economy, which is subordinated to the Government of Romania.

The National Power Grid (Valciu et al., 2009) is interconnected to ENTSO-E, which is the European transport and system of the European Union (Hungary, Bulgaria, North Ukraine) and the power grid of Serbia, the Republic of Moldova and South Ukraine.

TRANSELECTRICA responsibilities:

- power carrier:
 - operation of the power transmission network;
 - maintenance of transmission network infrastructure;
 - development of transmission network infrastructure.
- ✓ on: 81 power substations and 8834,5 km. overhead lines;
- ✓ through 8 power transmission branches and 5 subsidiaries (Opcom, Smart, Formenerg, Teletrans, Icemenerg).
- system operator:
 - operational management of National Power Grid;
- ✓ with: EMS / SCADA dispatching infrastructure;
- ✓ by: 1 national dispatcher - ND and 5 territorial dispatchers - TD.
- operator on the electricity market:
 - electricity exchanges between Romania and the European Union;
 - electricity exchanges between Romania, Serbia, Ukraine and the Republic of Moldova.

Conexion to ENTSO-E or other neighboring power system
Injection of electrical energy from power stations
Vulnerabilities (lack interconexion, non-closing ring 400 kV)

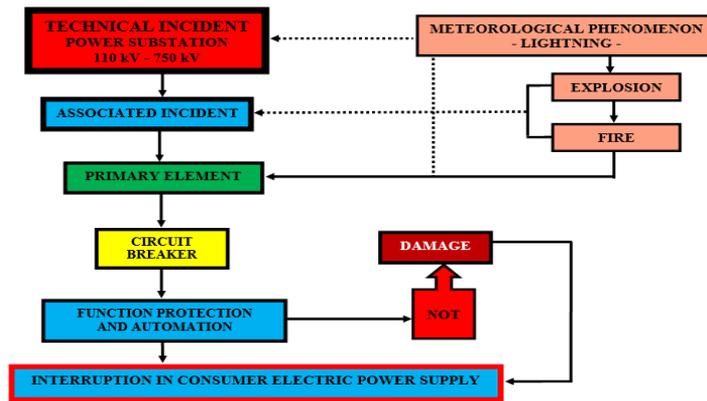

2.3. Identification of possible risk scenarios with effects of instability of National Power Grid

Technical Incident - 110 kV - 750 kV power substation

Timing of phenomena and events in case of a Technical Incident - 110 kV - 750 kV power substations

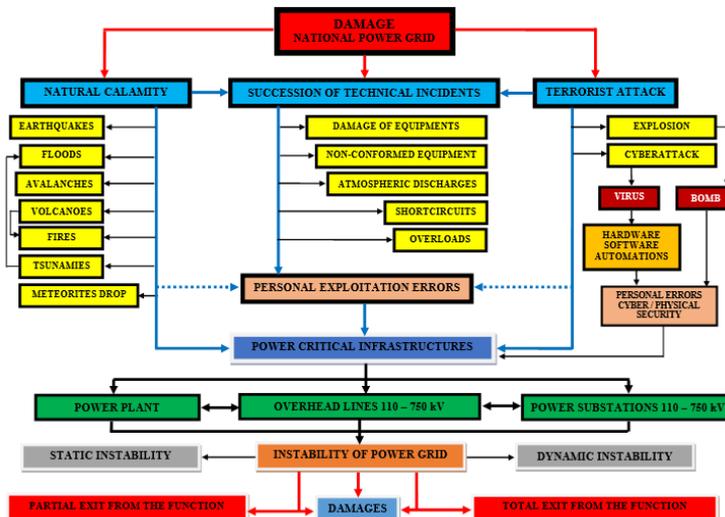

Risk scenario 1: Technical Incident: Lightning → Explosion → Fire → Interruption in Electricity Consumption of Consumers

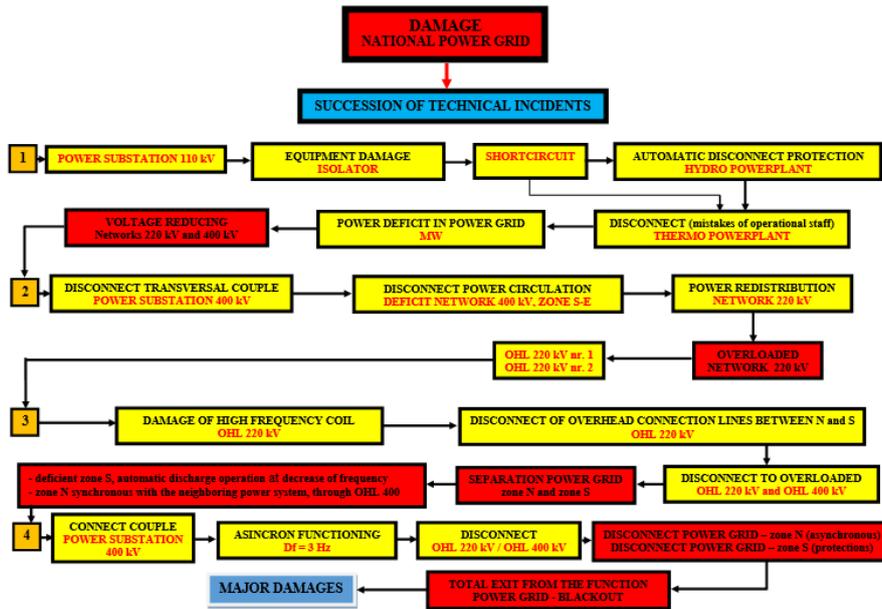

Damage – National Power Grid

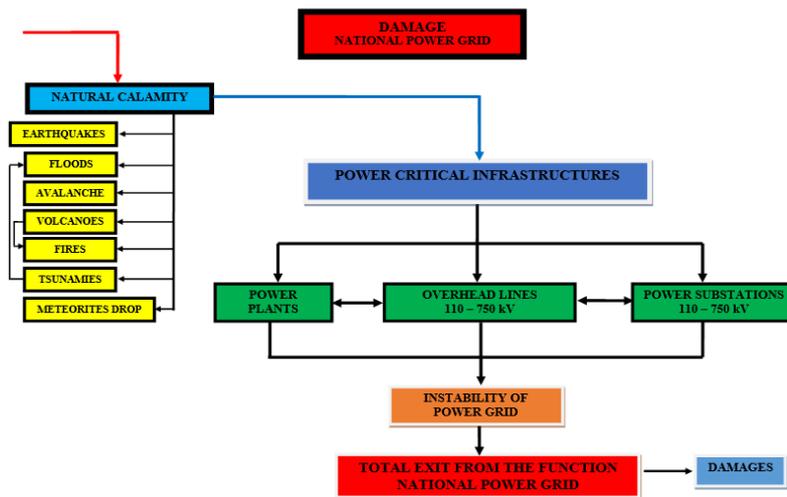

Timing of phenomena and events in case of damage – National Power Grid

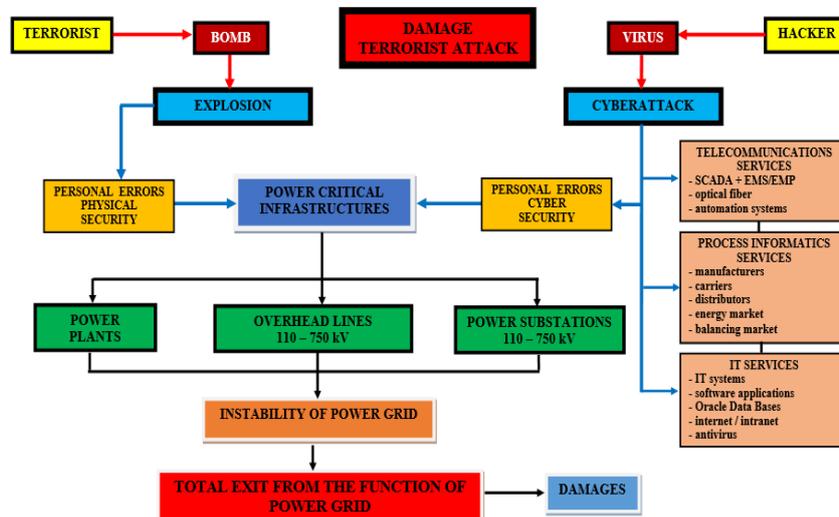

Risk scenario 2: Damage: Technical Incident Sequence - Full Output of the National Power Grid (black-out)

Risk scenario 3: Damage: Natural Calamity - Total Output of the National Power Grid (black-out)

Risk scenario 4: Damage: Terrorist Attack - Total Output of the National Power Grid (black-out)

3. Conclusions

The following risk scenarios for the critical infrastructures of ultra high and very high voltage from National Power Grid have been identified:

Technical Incident - 110 kV - 750 kV power substation:

- Risk scenario 1 - Technical Incident: Lightning → Explosion → Fire → Interruption in Electricity Consumption of Consumers.

Damages – National Power Grid:

- Risk scenario 2 - Damage: Technical Incident Sequence - Full Output of the National Power Grid (black-out);
- Risk scenario 3 - Damage: Natural Calamity - Total Output of the National Power Grid (black-out);
- Risk scenario 4 - Damage: Terrorist Attack - Total Output of the National Power Grid (black-out).

Once the risk scenarios have been identified, the risks associated with each scenario can be assessed.

Abstract

Worldwide, fires are always a topical issue, being events with a high probability of production, followed by significant material and sometimes, human losses. Statistics show a slightly decreasing trend in the number of fires reported in recent years, respectively by victims, reflecting a growing focus on fire safety, through national regulations and legislations.

Sprinkler fire extinguishing systems fall under the category of protection and fire active control systems. They are fire extinguishers that use dispersed water in the form of droplets as extinguishing agent, dispersion made with specific armatures called sprinklers. These systems can limit or stop the development of the fire, especially in the initial phase, by inhibiting the pyrolysis of combustible materials and slowing down the process of heat transfer. In addition, sprinklers can play an important role in reducing the temperature of gaseous effluents and in changing the parameters that characterize the smoke layer (height, stability of the stratified smoke layer, etc.), thus influencing the safe evacuation capacity of the occupants.

Through the computer simulations performed in the Pyrosim application, using the FDS model, the paper aims to analyze the interaction of fire sprinkler systems, both with fire and the layer of hot gases and smoke.

Keywords: fire simulation, sprinkler systems, FDS, safety evacuation

1. Introduction

Water has favorable physical properties for fire suppression. Its high heat capacity and high latent heat of vaporization can absorb a significant quantity of heat from flames and fuels. Its property to expand considerably when it evaporates to steam conducts to the dilution of the surrounding oxygen and fuel vapors. The effectiveness of water in fire suppression is increased even more with the formation of fine droplets, due to the significant increase in the surface area of water what is available for heat absorption and evaporation (Friedman, 1997).

The fixed fire extinguishing systems use water for sprinklers and water mist equipment. The differences between the two methods mainly consist in the flow rate, the size of water droplets and the droplet size distribution.

The provision of a fire suppression system such as a sprinkler system in a building can considerably improve the life safety and property protection performance of the building. Fire sprinkler systems have revolutionized fire safety by automatically putting out fires in the room of origin and preventing fires from spreading or re-igniting. The amount of time this process requires depends on the type of fire sprinkler system. The design, installation and maintenance of fire suppression systems are regulated nationally and globally, through a series of codes of good practice, standards and regulations. These standards are based on requirements formulated by reputable organizations such as: International Code Council, the National Fire Protection Agency (NFPA), U.S. Fire Administration (USFA), etc.

Fire extinguishing systems are especially used in buildings with large areas to protect: warehouses, shopping centers, office spaces, hotels and hospitals, etc.

The system is automatically switched on when a temperature threshold (typically ranging from 57 to 74° C) is exceeded, when the sprinkler vial breaks and the water starts to spill. Only those sprinkler heads open at which the temperature has exceeded the trigger threshold and their operation reduces the damages caused by the fire.

Overall, the sprinkler fire extinguishing system (Fig. 1) is a heat-activated automatic system. When the thermal fuse (set at about 30° C above the normal ambient temperature) reaches the activation temperature, the sprinkler head opens automatically, causing the pressure in the distribution and supply pipes to drop, then opening of the activation valve and commissioning of the sprinkler from the fire extinguishing system. After the sprinkler is opened, the water is discharged as drops. Only those sprinkler heads that are above or near the source of the fire are opened, namely those whose operation is required for the fire-fighting operation.

Fig. 1. Fire extinguishing system with sprinklers

Because fire sprinkler systems protect a variety of buildings and property, many different types have been developed over the years. These include wet, dry, deluge, pre-action and foam. Each has its own unique set of characteristics that protect the specific building and property for which it was installed.

The water-water sprinkler (wet sprinkler) system is the simplest and most used sprinkler system, especially in commercial-purpose buildings. The distribution network is filled with pressurized water, up to the sprinkler heads. When a sprinkler head is activated, the pressure inside the pipes is instantly released, providing a shorter response time than any other type of extinguishing system. This system can generally be installed in any place that is not exposed to the risk of frost.

In the case of water-air (dry) sprinkler systems, the distribution network is filled with compressed air or nitrogen. When the extinguishing head is activated, a valve releases the compressed air through the sprinkler head. After removing the air in the pipes, the pressure inside them changes, activating the ACS control and signaling station (mounted in a heated area) to pump water into the network. This mode of operation leads to a higher reaction time (delay of up to 1 minute). The accelerator guarantees fast evacuation of pressurized air or nitrogen and rapid replacement of them with water. This type of system is installed in spaces where the temperature can fall below the freezing point: loading ramps, warehouses without heating systems, etc.

Pre-action suppression systems are extinguishing systems where the sprinkler network is dry and where the control valve is connected to a fire detection system. At the time of the fire alarm, the water fills the distribution network but is not sprayed by the extinguishing heads, unless the temperature exceeds the vial break limit. These extinguishing systems can be either single interlock or double interlock; in case of the second category, the water penetration into the pipeline is subject to multiple factors: fire alarm from a smoke or temperature detector, as well as the automatic action of a sprinkler head. These systems have the advantage of ensuring a high level of protection against accidental spills, in rooms where water can cause serious damage: bookstores, archives, etc.

2. Sprinkler system simulation in FDS

2.1. Water spray dynamics

Water droplets, like fuel droplets, flow tracers and other objects that cannot be described through the numerical mesh, are treated in FDS as Lagrangian particles. These particles can be initialized to a part of the computational domain at the beginning of a calculation, or they can be introduced to the flow field from vent surfaces.

A discharge nozzle or a sprinkler is treated in FDS as a point device, namely a device located at a single point inside the computational domain, having a set of properties. For a sprinkler or a discharge nozzle, this point is the virtual origin of all particle trajectories. In practice, droplets are introduced into the flow field at a spherical surface surrounding the point device and having user-defined radius (Vaari et al., 2012).

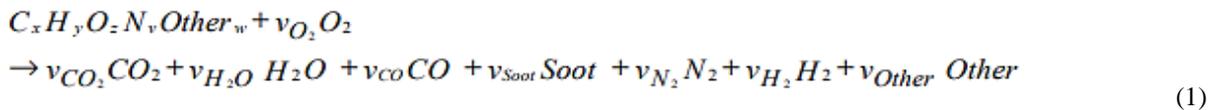

When setting up a simulation, the user must specify the properties of the sprinkler or discharge nozzle point device, such the water spray dynamics is correctly reproduced. The sprinkler properties that must be specified are:

- Sprinkler name;
- Spray model: defines the particle type (water, fuel or custom type), the flow rate and the jet stream shape;

- Dry Pipe (for a dry pipe sprinkler system). The dry pipe may be created and edited at this point;
- Activator: By default, the sprinkler is activated by a temperature link, with a response time index. These properties can be selected from the menu between the already defined types (Commercial, Industrial, Residential or Storage Link, or can be edited in terms of activation temperature and response time index.
- Location of the sprinkler, as geometric coordinates;
- Orientation, meaning the components of the direction vector;
- Rotation, in the case when we need to rotate the spray pattern circumferentially.

Nozzles are very much like sprinklers, only they do not activate based on the standard response time index model. The nozzles are activated using custom control logic (McGrattan et al., 2018).

FDS models use a mixture fraction model to simulate the combustion of fuel. Simplified, the mixture fraction model assumes a reaction of the following form:

When the mixture fraction is between the lower and upper fuel specific flammability limit, the combustion will take place regardless of if an ignition source is present or not. This will increase the generated heat from the combustion and, as a result, also increasing the temperatures.

After the activation of the first sprinkler head, the water will discharge, cooling the smoke layer and cause turbulence in the enclosure. In the same time, the discharged water will control the fire growth to some extent.

FDS simulations use a number of source terms, necessary to define the problem. A user defined heat release rate (HRR) is one important source term. The extinguishing coefficient is another user defined term, defining the value with which the HRR can be reduced under the effect of the sprinkler water discharge. This coefficient must be determined empirically.

The fire can be specified as a solid fuel that does not burn at a user specified rate, where the physical properties of the burning object defines the mass burning and hence the output HRR. In this case, the sprinkler water discharge model in FDS would be able to extinguish the fire by completely halting the pyrolysis mechanism. Regardless of which burning method the user decides to choose, the sprinkler discharge simulation in FDS will cool the smoke layer by heat transfer from the hot gases to the water droplets (Carlsson, 2013).

3. Results and discussions

As mentioned above, the purpose of the study was to assess the capacity of the FDS to simulate the influence and the quality of a water suppression system, in the case of a virtual fire scenario. In this respect, the following aspects were followed:

- the water jet's ability to lower the temperature in the studied room, to below the critical threshold, so that the process of evacuating the potential victims to be carried out safely;
- the interaction between the discharged water droplets and the smoke and gaseous effluents layer, produced by the combustion of flammable materials;
- the system capacity to suppress the fire or to limit its evolution, for the studied scenario.

In order to analyse the efficiency of methods for optimizing the calculation time using FDS specific techniques, there have been performed several computer simulations of a fire occurring in an extremely common confined space, namely an office room (Šuvar et al., 2015).

The office compartment which is subject to this study is of rectangular shape 5x4x3m (L x W x h), according to Fig. 2. On one side there is located a door (1 m width and 2 m height), and on the opposite side a window. The furniture in the room consists of a closet with horizontal shelves, located near an office desk on which is located a portable computer. On the shelves of the closet are located several boxes with paper, specific for the work environment in the office. On the wall opposite to the closet is located another closet with doors. Office furniture (office desk, chair, closets) is made of wood (agglomerated wood - PAL). In the simulated scenario, the window is considered closed and the door is open, in order to observe the migration of hot gases and smoke on the corridor and the influence of fresh air on the combustion mechanism.

The ignition source is represented by a power supply socket, located on the wall, behind the shelves, at a 0.3 m height. The source initiates the burning of the first paper box from nearby, in a time frame which represents the sum of the pyrolysis time of the solid and the time of gaseous phase induction. From this phase, the fire increases in intensity due to the step by step combustion of flammable materials from the analysed space. In this phase, the temperature acceleration is typical.

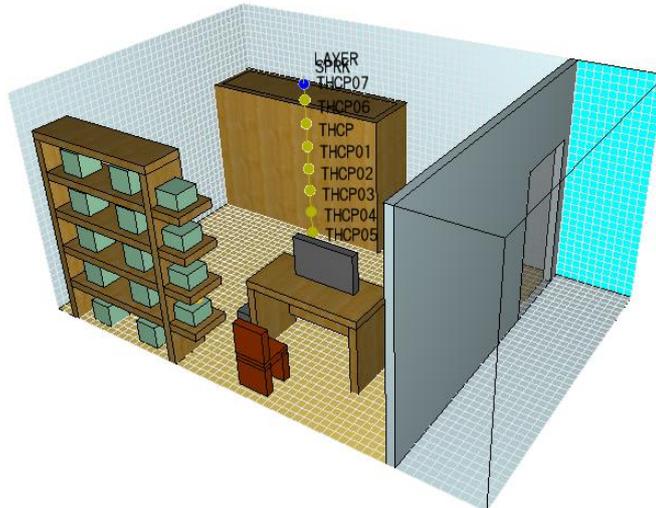

Fig. 2. Office room geometry used for FDS simulation

The flammable materials from the analyzed model are: wood (agglomerated wood, in furniture composition), PVC (computer and display composition), cardboard and paper (boxes containing office paper, located near the ignition source); these materials explain both the extremely fast fire propagation and the release of a significant amount of smoke and toxic gases. The grids used in computations would have a major impact on the simulation results. In order to select an appropriate cell size, three grids (20 cm, 10 cm and 5 cm) were tried in the computations. The results from 20 cm cell size have the largest deviations in these computations. At the fire plume area, the results from 10 cm cells and 5 cm cells are close to each other. Using a cell size of 5 cm, the computational time was highly increased, so the 10cm cells were used in this paper.

The same cell size was also chosen by Novozhilov in the simulation of sprinkler interaction with a fire ceiling jet (O’Grady and Novozhilov, 2009) and by Zhang and Chow (Zhang and Chow, 2013).

In order to study the time distribution of the temperature inside the analyzed space, there have been used a number of 8 virtual devices (thermocouples), placed in the central point of the room, on a vertical axe, evenly distributed between 0.6 and 2.7m high.

FDS permits to study the smoke layer characteristics, by using a layer zone device. Layer height is an approximation that is more used in two-zone models than CFD models. Layer height offers an approximation for where the hot and cold gas layers interact. In real fires, this region is not a distinct line, but estimations for a distinct elevation can be calculated, also the lower and upper temperatures for the smoke layer.

The temperature distribution, the air masses movement and the smoke visibility were also being monitored, by using planar slices, located at 2.5m on the X-axis and at 0.7m on the Y-axis. The wall temperature was registered as boundary quantity parameter.

For the studied case, there were simulated three different situations: room fire without any sprinkler system, fire with one sprinkler head placed in the middle of the room, under the ceiling level, and fire with the same sprinkler head, but placed 1 m closer to the fire source location. The sprinkler characteristics are specific for the residential type of sprinklers: generic residential spray model, with conical distribution, water flow rate: 49.05L/min, jet stream velocity: 5.0 m/s and a spray angle of 75°. The sprinkler head activation temperature was set to 68.33°C, with a response time index of 50.0 $m^{1/2}s^{1/2}$, falling in the class of fast response sprinklers (according to NFPA).

The fire source is presented in Fig. 3. Typical results of fire development and temperature distributions are shown in Fig. 4. Fig. 5 presents the evolution in time for the total Heat Release Rate for the three cases analyzed.

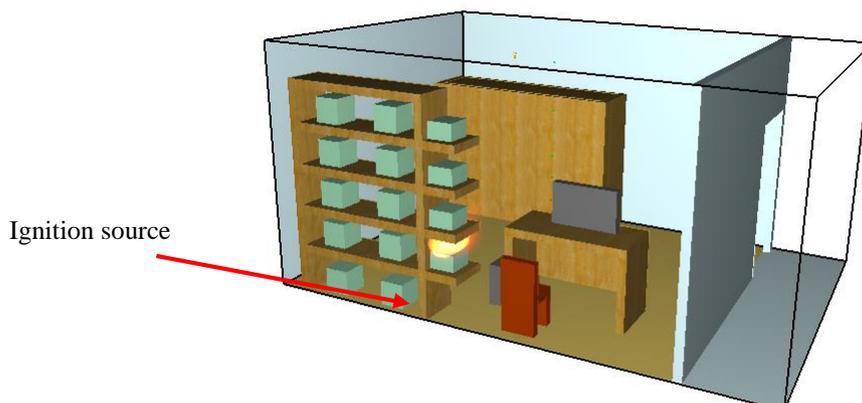

Fig. 3. Ignition source location

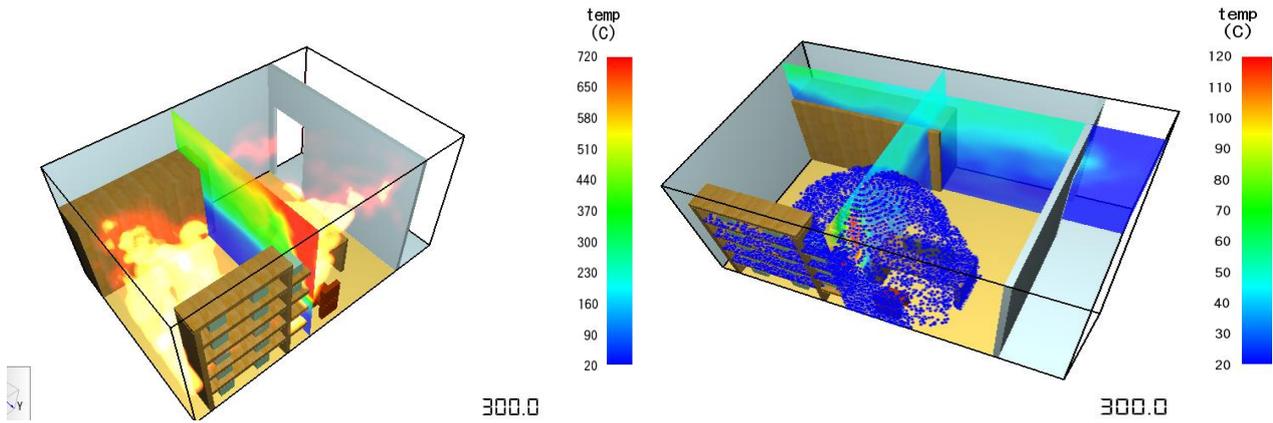

Fig. 4. Fire spreading and temperatures slices for the 1st case (no sprinkler), respectively for the 3rd case (sprinkler closer to the ignition source location)

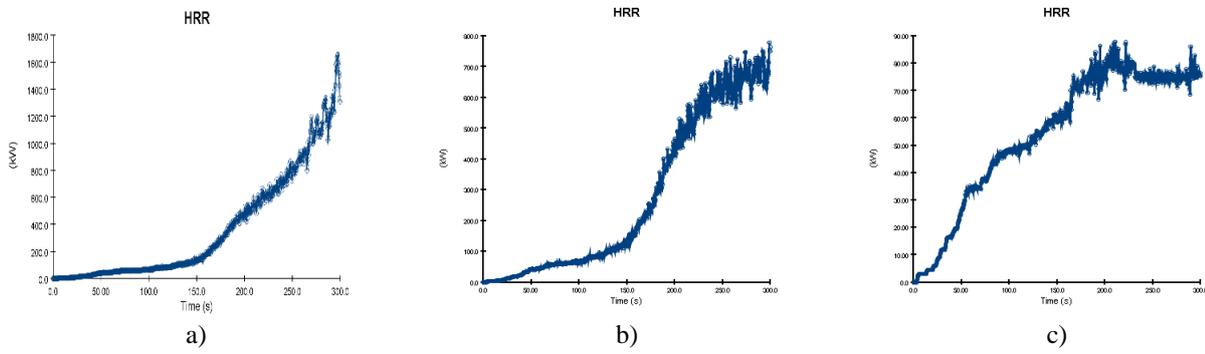

Fig. 5. Heat Release Rate for the three cases analyzed.

From the three cases studied, there could be observe that the presence of the sprinkler head in the office room plays a crucial role in cooling down the room temperature, and also limiting the heat released in fire. In FDS, if the governing burning reaction is well defined, or if the extinguishing coefficient for every material that participate to the fire is specified, water droplets can not only limit the flame spreading, but also suppress the fire.

The smoke layer temperatures present an almost linear decrease to the sprinkler working pressure.

At about 150 s after the fire ignition, a steady smoke layer was formed and the hot smoke flowed out across the upper part of the door (Fig. 6a). There was a clear smoke-air interface at about 1.2-1.5 m above the floor. From the ceiling to smoke-air interface, the temperature declined smoothly. The situation changed when the sprinkler was activated. Due to the cooling effect and the drag force on the smoke, the temperature would decrease apparently. The smoke would not keep on the ceiling and move downward (Fig. 6b). The soot visibility and temperatures in the door direction were favorable when the sprinkler were used, permitting the evacuation in good conditions for the potential occupants (Ghicioi et al., 2018).

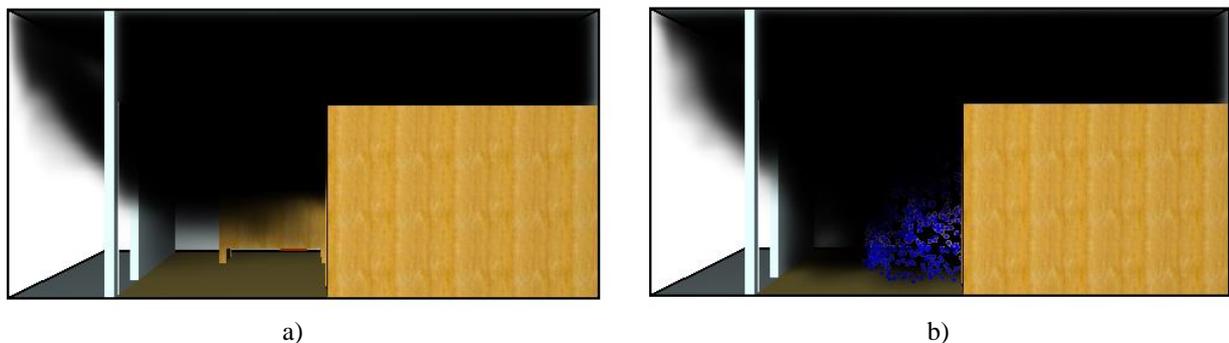

Fig. 6. The smoke layer in different conditions. a) before sprinkler activation; b) after sprinkler activation.

4. Conclusions

The interaction of fire smoke and the water spray was studied in this paper. Fire Dynamics Simulator version 6.6.0 (FDS), software developed by NIST, was used for the numerical simulation. A number of 3 cases, room fire without water suppression and using sprinkler located in different positions were analyzed. The following observations are made:

- after sprinkler activation, the temperature inside the room would decrease under the cooling effect of the water droplets;
- the sprinkler capability to extinguish the fire depends on the sprinkler head position relative to the zone affected by fire;
- comparing with the condition before sprinkler activation, the smoke temperature after sprinkler activation at the same height was significantly lower.
- due to the drag force of water spray, once the sprinkler was activated, the smoke would descend. The smoke-air interface surface would not be kept horizontal. The descend depth depends on the fire heat release rate and the working pressure of the water extinguishing system with sprinkler.

Improving the quality for classification of pyrotechnic articles on the basis of pyrotechnic composition content

Ilie Ciprian Jitea^{*}, Gabriel Vasilescu, Robert Laszlo, Cristian Raul Cioara, Claudia Miron

National Institute for Research and Development in Mine Safety and Protection to Explosion-INSEMEX Petrosani, 32-34G-ral. Vasile Milea Street, 332047 Petrosani, Romania

Abstract

The applicable legislative framework for pyrotechnic articles as regards the placing on the market and use of these products safely is regulated both at national level (Law 319/2006 on Safety and Health at Work with subsequent amendments; Law 126/1995 on the regime of explosive materials and Technical implementation rule, with subsequent amendments), and at European level (through Directive 2013/29 / EU) which states the principles to be applied for insurance the legality for performing operations with explosive materials, the sale, handling and use of pyrotechnic articles, as well as the registration and authorization to carry out the operations with them, in order to avoid personal injury, damage to property or damage to the environment. Thus, according to the regulations in force pyrotechnic articles are classified into different categories depending on the level of risk, taking into account their place of use and destination (in accordance with Article 5 of the Technical Implementation Rule 126/1995 on the regime of explosive materials). Also, pyrotechnic articles are products that present a specific risk to the supplier due to the mode of operation and the quantity / content of the pyrotechnic composition involved, and the possession, marketing and use of such products whose security quality is not legally guaranteed are the object of unlawful actions or the source of risk factors that may affect the security of individuals, material assets and the environment. Also, a number of technical information and data related to security parameters (NEC, safety distances) must be taken into account on the basis of pyrotechnic articles which must be scientifically determined using high-performance equipment to get verosimiles results.

Keywords: pyrotechnic composition, pyrotechnic articles, categories

1. Introduction

According to the literature, pyrotechnics is the science, technique and art of creating, maintaining and controlling fire. Studying, designing and developing pyrotechnic compositions or devices requires in all situations thorough studies theoretical and experimental. The use of pyrotechnic compositions for the generation of heat, light, sound or projectiles, or rockets was possible after "black powder" discovery. The use of pyrotechnic articles has become more and more frequent in recent years throughout the world for the celebration of significant cultural and religious events, the most famous and common being the fireworks. Pyrotechnics can also be used for special effects at concerts, theater performances, film and sporting events, and even rocket launches (CORE Programm PN 16 43 03 04; Jitea I., C., Vasilescu G., Kovacs A., et.al. 2016; Cioara C., R., Şuvar M, C., Morar M., S., Jitea C., 2018).

2. Theoretical and practical considerations regarding the determination of the content of pyrotechnic articles

Established methodology from a technical - scientific point of view which has been regulated on the basis of the applicable harmonized referenced and transposed in an accredited work procedure, aims at assessing the net mass of pyrotechnic mixture of pyrotechnic articles by separating the pyrotechnic mixture and weighing it with a suitable technical balance in order to obtain precise results with superior veracity on the result indicators. First of all, the separation of the pyrotechnic mixture takes place which occurs as a result of the sectioning operation, splitting the pyrotechnic article by facilitating the removal of packaging and related ballast. Second, to determine the nature of the load and appreciation for considering it as being or not pyrotechnic mixture, is taken from the quantity resulting from 1

^{*} Corresponding author. +4-0731-390-812; fax: +40-254-545-277.
E-mail address: ciprian.jitea@insemex.ro.

÷ 2 g of the material considered to be pyrotechnic, after which it is introduced into a crucible and the test is followed by the direct contact with the flame open if there is a reaction after this contact is then considered to be a pyrotechnic composition and in the opposite sense it is appreciated as if lest. In order to ensure an adequate health and safety climate, these tests are carried out on the basis of a technical work procedure accredited by trained personnel and with the appropriate technical expertise only in specially designed spaces. Exceptionally, if the pyrotechnic article subjected to the technical expertise of the sectioning operation can not be safely performed, then the determination of the net mass by difference, obtained by subtracting from the total (initial) mass of the pyrotechnic article determined by weighing it before consumption of pyrotechnic substance by the test of operation and the resulting mass of the pyrotechnic product after the pyrotechnic article has been subjected to the operational test (the packaging and the inert material remaining after the test). In order to carry out the test according to the principles of quality and rigor of the operations required by the recognition of accreditation attributed to the field of competence of the specialized laboratory, sampling and sample preparation shall be carried out in the explosive handling room and the tests shall be carried out individually on each individual product in the form were delivered by the manufacturer. Also for separating the net mass of the pyrotechnic composition from the package, the packaging is cut into the area where is the most readily accessible the cargo is and the pyrotechnic composition content is drained without being polluted by the material lest. However, is done the tare of the balance and of the vessel in which the pyrotechnic composition is emptied, and the pyrotechnic composition content is then weighed, after which are noted the results obtained in the primary data register. The result indicators obtained from the testing of the content of the pyrotechnic articles may be used for framing the pyrotechnic articles in categories according to the provisions of Art.5 (1) of the Technical Norms to Law 126/1995, as subsequently amended and supplemented, Art. 7. of Decision no. 1102/2014, SR EN 15947 - 2: 2016, SR EN 15947 - 4: 2016 respectively SR EN 15947 - 5: 2016, (Cioara C., R., Kovacs A., Morar M. S., Jitea C. I., Rădeanu C., 2018; Directive 2013/29/EU, 2013; Jitea I.C., Kovacs A., Vasilescu G., et.al., 2017)

3. Results of determination of the contents of pyrotechnic articles OBJECT TESTED (description and identification):

In order to determine the content of pyrotechnic articles, two types of articles have been technically examined, namely:

- Roman candle (Description: tube containing alternate propellant charges, pyrotechnic units and transmitting fuses.), shown in Figure 1
- battery (Description: Battery: assembly which includes elements such as shot tubes of the same type and size that are in category F2, which has a parallelepipedal shape (150/122/125 mm), 1 initial fuse, 16 shot tubes tubes) and 9 shot tubes (inner tubes), material: cardboard, paper, ballast material) shown in Figure 2.

Fig.1- Roman Candles F2 – 5 skuds romerlys

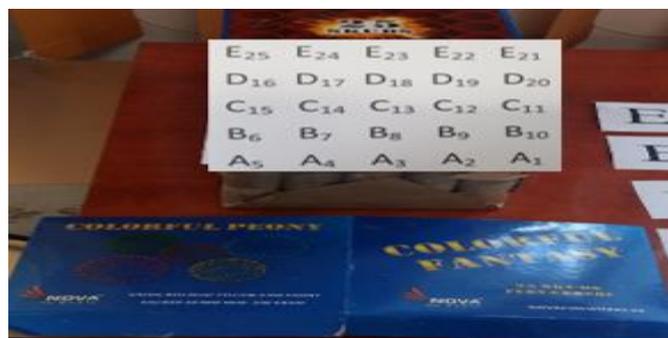

Fig.2- Battery F2 - Colourfull Peony

The results determined from the tests performed are summarized in table no. 1 for Roman candles and in table number 2 for battery.

4. Interpretation of results

From the analysis of the results of the performed tests, the following assessments can be made: (1) three pyrotechnic articles were tested for both types of pirotechnic articles, roman candles as well as for the battery for which 3 kinds of pirotechnic composition were determined (lift charge, burst charge, pyrotechnic effects), obtaining a total value of 37.5 g, 37.41 g and 37.76 g of pyrotechnic composition / article for roman candles (Figure 3) and 192, 31 g, 197.24 g and 199.05 g for battery (figure 4); (2) in accordance with the applicable legislation and taking into account the values obtained in the determination of pyrotechnic articles content, these pyrotechnic articles may be classified in the F2 category, as confirmed by the technical documents certifying the products.

Fig.3- Roman Candles F2 –composition

Fig.4- Battery F2 – composition

5. Conclusions

The implementation of harmonized standards SR EN 15947 in full compliance with the harmonization of applicable legislation by promoting Decision No. 1102/2014 on the application of the requirements of the European Directive 2013/29 / EU as well as Law 126/95 and the Technical Implementation Norms with amendments and further additions to the testing laboratory in the field of civilian explosives and pyrotechnic articles LMEAP within the GLI - INSEMEX laboratory, accredited RENAR, allowed to provide the technical and administrative framework for the technical tests, assessments and expertise in the field of pyrotechnic articles in accordance with the applicable security requirements.

The tests for determination of pyrotechnic articles content (NEC) were made on two types of pyrotechnic articles of Danish origin, respectively the roman candles and battery using the high-performance technical infrastructure within the INSEMEX polygon, in order to obtain accurate results with high verosimilitude.

Analyzing the data and the results obtained from the tests carried out, it results that these products comply with the requirements of the applicable standard and the technical product documentation.

National Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX, 32-34 G-ral Vasile Milea street, Petroşani, 332047, Romania

Abstract

Qualitative and/or semi-quantitative risks analysis measures are not able to model and assess the effects of two or more simultaneous faults or the benefits which redundancy may bring to the safety system. One of their shortcomings is the incapacity of being used efficiently for low frequency modelling and predication of events with severe consequences. By approaching the scientific study upon human reliability along with technical and performance data are ensured the premises for developing an innovative tool for dynamic modelling the safety of a complex socio-technical system.

Keywords: Bayesian network, industrial risk, monitoring system.

1. Introduction

Qualitative and/or semi-quantitative risks analysis measures are not able to model and assess the effects of two or more simultaneous faults or the benefits which redundancy may bring to the safety system. One of their shortcomings is the incapacity of being used efficiently for low frequency modelling and predication of events with severe consequences. Examples of quantitative risk analysis models include: Fault Tree Analysis (FTA), Event Tree Analysis (ETA), Level of Protection Analysis (LOPA), First Order Reliability Method (FORM), Monte Carlo simulation, as well as other mathematical models (Covello and Merkhofer, 1993; Lee et al., 2012; Vasilescu, 2010)). Quantitative assessments exceed the shortcomings and are adapted for situations in which are available proper data for the design, exploitation, maintenance or for the modification of a technical or work system. Also, results of quantitative analysis may be used for cost-benefit studies and for demonstrating the fact that risks for workers, industry, society and environment are as low as reasonably practicable (ALARP), especially when the assessment refers to the risks with catastrophic consequences which may be defensively prevented only by quantitative analysis. Therefore, research has to focus on analysing the reliability and opportunity of using quantitative risk analysis methods in the industry. Using performance data will objectively support the assessment and comparison of complex technological systems, testing and assessment of the adaptation capacity in design, exploitation and maintenance. This approach is proper for identifying the vulnerabilities of the system and the mitigation strategies intended for reducing risk exposure, so that by efficient and correct modelling, the changes can be simulated before being put into practice. By approaching the scientific study upon human reliability along with technical and performance data are ensured the premises for developing an innovative tool for dynamic modelling the safety (Vasilescu et al., 2013b; Vasilescu and Mija 2013) of a complex socio-technical system.

2. Occupational risk assessment methodology

Probability graphic models and graphs in which the junctions represent random variables and the arches (respectively their lack) represent conditioned independence assumptions (Vasilescu et al., 2012). Therefore, they provide a compact representation of cumulated probabilistic distributions. Risk assessment by using Bayesian networks consists in building

* Corresponding author. +4-072-434-3017; fax: +40-254-545-277.
E-mail address: dragos.vasilescu@insemex.ro.

up the Bayesian model by taking into account the observations regarding the identified risk factors (work equipment, work environment, work load and performer), based on which are highlighted the formal results of such risks perception depending on the hazardous event’s occurrence probability and the maximum predicted severity (Pasculescu et al., 2012). In this regard, there is proposed for example an occupational risk assessment sheet which has been designed by taking into account 4 probability classes and 4 severity classes (as shown in Figure 1 and Table 1 and Table 2):

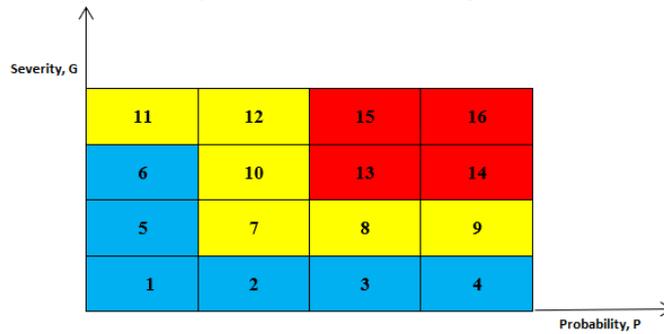

Fig. 1. Occupational risk level assessment grid

where:

Table 1 Risk parameter classes

Severity class		Probability class	
1	Negligible	1	Low
2	Average	2	Average
3	Severe	3	High
4	Very severe	4	Very high

Table 2 Risk level estimation and appreciation

Fuzzy variable x_m	Degree of damage $G(x_m)=\exp[-k_{med} \cdot (1-x_m)]$	Risk level N_R
[0.00 , 0.33]	[0.035 , 0.105]	1÷6
[0.33 , 0.66]	[0.105 , 0.320]	7÷12
[0.66 , 1.00]	[0.320 , 1.000]	13÷16

The method consists of several steps: **(P1)** Identification of causal factors generated by work equipment, work environment, work load and performer; **(P2)** Development of the influence diagram which establishes the causality connections between causal factors; **(P3)** Actual development of the influence Bayesian network, determining the causal factors and the causality connections in which they may be involved, establishing the distribution tables; **(P4)** Assessing the risk level by applying the inference.

For achieving the logic of a safety level monitoring system is proposed a model based on bayesian networks which ahs the following shape (Figure 2):

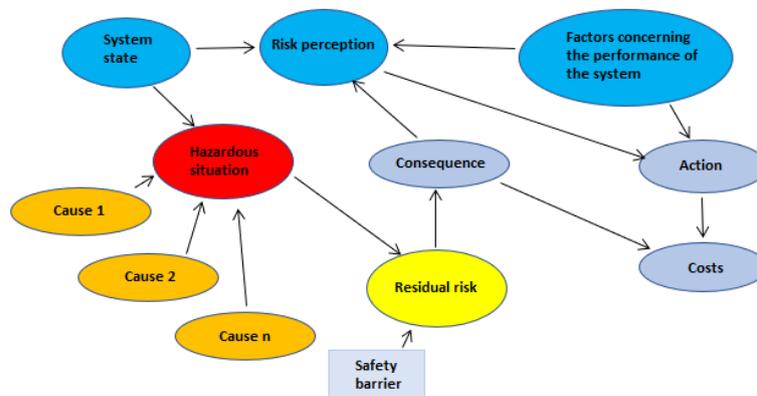

Fig. 2. Risk monitoring model based on Bayesian networks

By implementing this model may be achieved an assessment of a hazard state depending on several observations, being extended up to costs level. Several triggering causes and the state at a given moment of the system may lead to its crossing into a hazardous state. The hazardous state may occur because from the design phase it could not be removed and as a

consequence it is the cause of a residual risk occurrence. The residual risk’s behaviour is determined by the hazardous state of the monitoring system and may be weighted or removed by existing safety barriers with consequences upon the human factor, by affecting his integrity and the costs generated by material, production or other losses. Depending on the perception of the risk may be initiated an action which implicitly positively or negatively affects the costs (Vasilescu et al., 2015; Vasilescu et al., 2014; Vasilescu et al., 2013a).

3. Monitoring system architecture

For performing the monitoring system are required the following equipment: *Server* – PC connected to the local area network and to the internet, through an incorporated network card, on which the software server application is running; *Video camera* – a video camera connected to the server by USB; *Webcam Server* – video camera connected to a specialized software type Webcam server for online live streaming; *Process computer (Client)* – PC connected to the local area network on which the client software is running; *Data acquisition board* – disposing of 8 analogic input channels, which analogic/digital conversion, of 16 bit resolution, connected by USB to the server or to the process computer which runs the client data acquisition software; *Sensors for measuring: temperature, humidity, carbon monoxide or methane concentration* – connected to the data acquisitions board and *Noise Measurement Equipment* – also connected to the data acquisition board (Pasculescu et al., 2014, and Pasculescu et al., 2015). The software for monitoring hazardous workplaces is intended for processing acquired data and real time assessment by applying the probability model based on the bayesian theory. Data are processed and analysed by using the monitoring software designed for controlling and real time assessing the occurrence of a hazardous situation (Cioclea et al., 2015; Leba et al., 2014) (Figure 3).

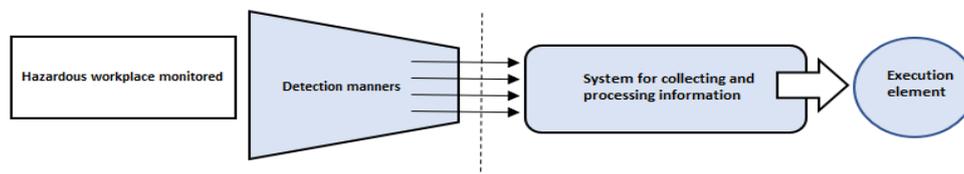

Fig. 3. General structure of a system for monitoring hazardous workplaces

3.1. Hazardous work environment monitoring

a) Operation principle

The monitoring subsystem starts from the idea that the essential factors of the work environment (temperature, humidity, noise, gas concentration – CO or CH₄) may directly or indirectly determine the occurrence of accidents or of occupational disease (Conte et al., 2011, Kotus and Kostek, 2008), in case their values exceed the maximum admitted limits by regulations in force. It contains:

- **Temperature** junction has the following states: *Under/Over MAL* and *Optimal*. If the value collected by the sensor ranges between 18 °C and 24 °C, then it is set and observed the *Optimal* state of temperature, otherwise there is set and observed the *Under/Over MAL* state;

- **Humidity** junction has the following states: *Under/Over MAL* and *Optimal*. If the value read by the sensor concerning the relative Humidity is below 10 %, then it is set as observation the *Optimal* state of humidity, otherwise being set the *Over MAL* state;

- **Noise** junction has the following states: *Under/Over MAL* and *Optimal*. In case the value of the Noise level acquired by the software is below 87 dB(A), then it is set as observation the state of *Optimal* for the noise level, otherwise there is set as observation the *Over MAL* state;

- **Discomfort** junction has the following states: *Yes* and *No*. Depending on the observations concerning temperature, humidity and noise, it sets on the base of the distribution table, the corresponding proofs, as follows (Table 3):

Table 3

Parent junctions for "Discomfort"				
Noise	Temperature	Humidity	Discomfort	
			YES	NO
Optimal	Optimal	Optimal	0.0	1.0
		Over MAL	0.3	0.7
Over MAL	Under/Over MAL	Optimal	0.7	0.3
		Over MAL	1.0	0.0

- **Technical equipment** junction has the following states: *On* and *Off*. Depending on the equipment state at a certain moment, the application sets the proofs corresponding to the state in which the monitoring equipment is found;

- **Gas Concentration** junction has the following states: *Under MAL* and *Over MAL*. In case the value recorded by the sensor for carbon monoxide concentration is lower than 100 ppm, then it is set as observation the *Under MAL* state for gas concentration, otherwise being set as observation the *Over MAL* state;

- **Temperature, Humidity, Noise, Technical equipment, Gas Concentration** junctions are defined as causal independent not having a related distribution table attached;
- **Hazardous event** junction has two states: *Takes place* and *Does not take place*. Establishing the probability for each state of the *Hazardous event* junction is performed based on the following distribution table (Table 4):

Table 4

Work system	Discomfort	Parent junctions for „Hazardous event”			Hazardous event	
		Gas concentration	Work equipment	Takes place	Does not take place	
Affected	YES	Under MAL	On	0.7	0.3	
			Off	0.4	0.6	
		Over MAL	On	1.0	0.0	
			Off	0.7	0.3	
Not affected	NO	Under MAL	On	0.3	0.7	
			Off	0.0	1.0	
Affected		Over MAL	On	0.7	0.3	
			Off	0.4	0.6	

The bayesian model proposed for establishing the probability for an unwanted event to occur by meeting the proper conditions for the occurrence of a hazardous situation is presented in Figure 4:

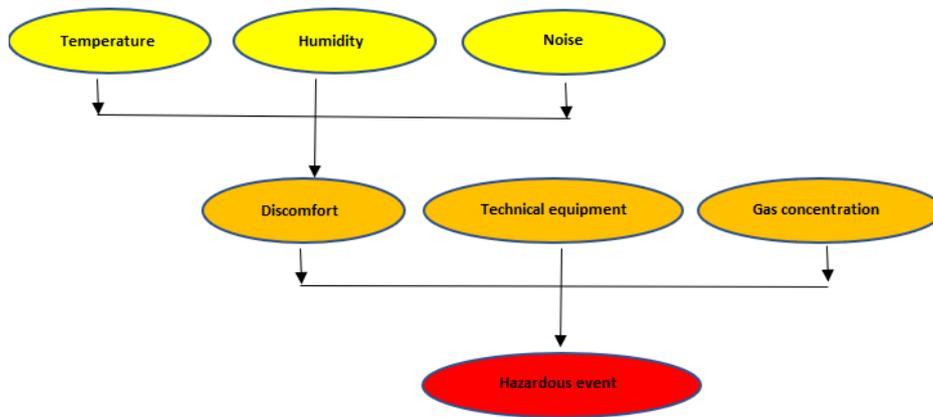

Fig. 4. Model for analysing and assessing the occurrence probability of a hazardous situation which may favour the occurrence of a hazardous event

b) Communication protocol

This work environment monitoring subsystem uses client technology. The server comprises the video monitoring system and it is the one to which the values of environmental factors will be transmitted and where alarm signals will be generated. The client is responsible for local acquisition of values through acquisition equipment, the conversion into the correct format, application of the diagnosis model based on bayesian probability and for sending the data to the server.

4. Results obtained

Following the analysis and assessment of a work system from industrial spaces with potentially explosive and/or toxic atmospheres there have been identified a number of 43 occupational risk factors (independent or derived) which have been assigned depending on the corresponding work system component and on their manner of manifestation as follows: Work equipment (EM)-19 factors ($F_{EMi, i=1,19}$); work environment (Me)-11 factors ($F_{Meij, i=1, j=1,2}$; $F_{Mei, i=2,6}$; $F_{Meij, i=7, j=1,2}$); work load (SM)-5 factors ($F_{SMij, i=1, j=1,2}$; $F_{SMi, i=2,4}$) and executant (E)-8 factors.

The integrated table comprising the results on the monitoring of hazardous conditions (Tables 5, 6 and 7) and the general conceptual model for the assessment of risks from the analysed work system is presented in Figure 5.

Table 5

Parent junctions for “Work system”	Work system impairment	
	Takes place	Does not take place
Work equipment	0.19	0.81
Work environment	0.10	0.90
Work load	0.07	0.93
Executant	0.09	0.91
Work system	0.11	0.89

Table 6

Parent junctions for "Discomfort"				
Noise	Temperature	Humidity	Discomfort	
			YES	NO
Optimal	Optimal	Optimal	0.0	1.0
		Over MAL	0.3	0.7
Over MAL	Under/Over MAL	Optimal	0.7	0.3
		Over MAL	1.0	0.0

Table 7

5. Conclusions

Early identification of hazardous situations during technical faults or emergencies with possible impact upon the health and safety of workers which carry out their activity in hazardous workplaces represents a priority for the OHS field.

The assessment of the OHS level and implicitly of the occupational risk level laid ground for ensuring an efficient risk management system (Babut et al., 2002; Darabont et al., 2002) by the advantages brought along by a computational management system, leading to maximization of the monitoring period and implicitly to the controlled management of risks which may lead to work accidents and/or occupational diseases, as well as to reducing the decisional time and to increasing the rate of revisions for improvement.

By approaching the scientific study upon human reliability along with technical and performance data are ensured the premises for developing an innovative tool for dynamic modelling the safety of a complex socio-technical system.

Research on psychological indicators involved in rescue activities

Izabella Kovacs*, Daniel Pupăzan, Cristian Nicolescu, Alin Irimia, Andrei Gireadă, Cosmin Ilie

¹National Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX Petroșani, 32-34 G-ral Vasile Milea Street, Postcode: 332047, Petroșani, Hunedoara County, Romania

Abstract

The organizational environment has always been receptive to what psychologists call individual differences, such as asymmetries that underlie differences between two or more people. Employers are interested in professional qualities and psychic attributes of their employees. In recent years, the emphasis on staff employment has focused on the personality traits of applicants, on intellectual and behavioural qualities they generate. Differences between individuals in attributes such as intelligence, personality and knowledge are important to explain a broad range of outcomes, including academic achievements, managerial, professional, communication with others, etc.

Only the objective knowledge of all individual features and professional requirements and the achievement of an agreement between them can lead to avoiding negative consequences for the individual (such as adaptation disorders, work accidents, burns, etc.). The need to establish this agreement between the individual and work is imperative, especially in the case of activities with increased responsibilities and risks such as intervention and rescue activities.

The paper seeks to identify the psychological indicators that need to be considered in terms of intervention and rescue, both to achieve occupational selection and to plan effective psychological interventions to reduce the effects of occupational stress.

Keywords: psychological indicator, rescuer, occupational selection, psychological evaluation

1. Introduction

As in any other field of activity, psychological examination also represents a precondition for proper management of the work process when it comes to intervention and rescue activities, in order to increase its effectiveness. Psychological assessment of personnel should focus on both individual psychological diagnosis and individual prognosis. Psychological examination reveals the qualities or the presence / absence of professional contraindications and, based on results obtained, the person concerned can be assigned to a particular job.

Only the objective knowledge of all individual features and professional requirements and the achievement of an agreement between them can lead to avoiding negative consequences for the individual (such as adaptation disorders, work accidents, burns, etc.). The necessity of establishing this agreement between the individual and the working activity is imperative, especially in the case of activities with increased responsibilities and risks such as intervention and rescue (situation stipulated by the Romanian legislation in force).

2. Particularities of the intervention and rescue activity in toxic/ explosive/ flammable environments

A complete definition of intervention and rescue activity in toxic / explosive / flammable environments may be: a specialized response to an emergency situation that puts lives, material assets and the unit's continuous operation at risk.

* Corresponding author. Phone: +40 254 541 621; Fax: +40 254 546277
E-mail address: izabella.eisler@insemex.ro

Rescuer's job falls into the "hard work" category, because the effort implies numerous high amplitude oscillations, as far as effort is concerned. The higher their duration, the harder the work is. In addition, the rescue activity is occasional, not permanent, assuming change of the daily skills from the basic profession. Rescuers must undergo training in conditions similar to those in the damaged area, enabling them to act efficiently and safely.

Main tasks in intervention and rescue activity (Kovacs et al., 2017; Pupázan et al., 2017):

- Respond to alarms of incidents and other requests (industrial accidents, etc.).
- Drive and use machines and equipment necessary for intervention and rescue.
- Identify incident sources by using their knowledge on fire types, construction, building materials, etc.
- Restricting the affected area to prevent unauthorized access.
- Creates openings / breaches in various structures to provide ventilation and access, using axes, blades, saws, ropes, etc.
- Search the area to locate potential victims.
- Rescue victims of the incidents.
- Provide first aid and take measures to resuscitate injured persons.
- Act to identify / find (flammable) chemicals that could cause explosions and fire extensions.
- Inspect and check the location of the incident to ensure there is no danger.
- Performs physical training and simulations to maintain a proper level of training.
- Participate in exercises and demonstrations on intervention and rescue techniques.
- Participate in seminars, conferences and study literature to learn new intervention and rescue techniques.
- Clean and maintenance intervention and rescue equipment.

Also, intervention and rescue personnel in toxic / explosive / flammable environments must have the following skills:

- Exploration of the affected area skills, mapping certain areas, determining the proportion of the damage;
- Execution of various works for isolating the damaged area (construction of interim and / or permanent dams, removal of cave-ins, water pumping and installation of interim claims etc.);
- Operating under special visibility, temperature, workspace and communication conditions;
- Effort under stress and observance of safety and protection rules as well as performing operations such as: construction of buildings for insulation, injured evacuation, and passing through narrow spaces;
- Correct use of protective breathing apparatus;
- Correct handling of machinery, tools and intervention devices skills acquired in the production process;
- Cooperation skills with team members to achieve assigned tasks;
- Ensuring individual and collective security during rescue interventions.

3. Psychological particularities of intervention and rescue in toxic/ explosive/ flammable environments

About the psychology of intervention and rescue activity, information can be obtained from various sources, documents and reports, analyzes, scientific papers, etc. In general, there is an acceptable convergence of information obtained from these relatively different sources, in terms of aptitudes and personality profile required by this activity, with different accents on certain groups of psychic attributes, or on how to develop them in the process of preparation and occupational training.

At present, recruitment, expertise, selection and psychological training of personnel is based on the establishment of a minimum of skills, abilities and psychic features (the optimal profile of personality), subjected to an initial and periodic assessment.

In order to identify those psychological indicators that have the greatest relevance in the intervention and rescue activity, a number of 25 people familiar with this activity (i.e. holders of the job concerned, labor analysts, people familiar with the job, trainers and instructors in the field) were questioned. Thus, they were asked to indicate, on a scale of 1 to 7, where 1 is a very small intensity and 7 a very high intensity, the level of intensity involved in the activity of intervention and rescue of a number of 35 abilities. The processing of responses has shown that the most important psychological indicators for the activity under consideration are:

Table 1 Psychological indicators of intervention and rescue personnel (Kovacs et al., 2016)

	Average	Rating
Location of sound	7.19	1
Night vision	7	2
Hearing, physical strength, static force	6.8	3
Recognition of speech, peripheral vision, trunk force, explosive force	6.7	4

Body balance	6.6	5
Hearing sensitivity, depth perception, dynamic strength	6.5	6
Remote visual acuity, dynamic flexibility, reaction time	6.4	7
Vision in brilliant light, close visual acuity	6.3	8
Movement Assignment Coordination, Extension Flexibility	6.2	9
Chromatic vision	6.1	10
Selective attention, spatial orientation	6	11
Distributive attention	5.7	12
Peripheral vision	5.6	13
Self-control, the speed of information structuring	5.5	14
Speed of perception, memory capacity	5.3	15
Flexibility of structure, ordering of information	5.2	16
Categorical flexibility, deductive reasoning, inductive reasoning	5	17
Fluency of ideas	4.9	18

Other sources that refer to the necessary skills for carrying out intervention and rescue activities, such as a series of interviews with people with experience in this field, bring to the forefront the following psychological indicators (most of them representing social / interpersonal groups and emotional abilities) (Boboc, 2017):

Table 2 Psychological indicators of rescuers

	Average	Rating
Seriousness, responsibility, discipline	3.25	1
Courage, spirit of sacrifice	2.8	2
Intelligence, reason, cleverness	2.25	3
Empathy, cooperation, openness, team spirit	1.6	4

The profile of cognitive skills of firefighters, occupation with a high degree of resemblance to the intervention and rescue occupation, developed by “Cognitrom”, is shown in Table 3 (http://www.cjraetm.ro/images/meserii/pompier_specialist.pdf).

Table 3 Profile of cognitive skills - firefighter

Skill	Level of development	Average	Average superior	Maximum
Overall learning ability			X	
Verbal aptitude		X		
Numerical aptitude		X		
Perception of form			X	
Functional skills		X		
Rapidity in reactions				X
Decision-making capacity			X	

Also, for good performance in this occupation, it is also necessary for the following skills to be present, developed at a minimum level: manual dexterity, digital dexterity, eye-hand coordination, instrument control, chromatic discrimination, spatial perception, near and distant visual acuity, strength, flexibility and body extension, static muscle strength.

As far as social / interpersonal skills are concerned, the same “Cognitrom” profile points out that the exercise of this occupation can be achieved by people who are inclined towards things outside their own person, attention oriented to the physical and social environment, action-oriented, ease of communication, sociability. They are conscientious, correct, serious, aimed at clearly defined purposes, manifesting exigency, meticulousness and rigor in carrying out tasks through awareness of rules. They have the ability to maintain their emotional balance in stressful situations without showing extreme manifestations inconsistent with the situation.

Profile organizations, such as the RTDCS (Rescue Team for Disaster and Community Safety), a volunteer organization that was designed to build a society that is aware of all possible disaster that mankind might be subject to, emphasizes that ideally, the rescuer will have the following qualities (<http://www.rescuers.org/about-rescue-personal-traits.html>):

- Interest - a real interest in rescue work.
- Training - the desire to continue training to maintain a high professional standard.
- The ability to ensure self-reliance - the lives of victims and team members rely on it.
- Initiative - the nature of rescue operations means that it is often impossible to closely supervise each member of the team. Everyone needs to be able to see what they have to do, set priorities and perform tasks at hand.
- Versatility - every situation is unique. A person must be able to apply a wide range of skills and knowledge in new situations.
- Co-operation - rescue work is usually a team effort, cooperation with others is vital.
- Physical capacity - rescue work of any kind is physically difficult and often continues for long periods of time.
- Driving qualities - driving qualities are required for all rescuers at different times and to varying degrees.
- Control over fears (phobias) - rescuers need to know what they can and cannot do.
- Clothing and wearing - the look must inspire trust in others.

However, if we refer to characteristics necessary for success of rescue activity, evaluated by practitioners themselves, then, according to the results of a study carried out within INCD INSEMEX Petroșani, the situation is shown in Table 4, which presents the positions obtained by each quality, as they were hierarchized by research subjects (grouped in three series A1, A2, A3). The questionnaire stated that 1 is the most important quality and 10 is the least important quality (Pupăzan et al., 2015).

Table 4 Characteristics required to successfully perform rescue activities

Characteristic	High qualification	Experience	Health	Emotional balance	The ability to detect hazards	Occupational interest	Social cooperation	Responsibility	A receptive attitude towards the tasks received	Courage
A1	9	6	1	4	7	10	8	2	3	5
A2	9	7	1	3	6	8	10	2	4	5
A3	9	7	2	6	4	8	10	1	4	3

Therefore, from the analysis of data presented in Table 4 we can state the following (Pupăzan et al., 2015):

- health is considered to be the most important attribute for a rescuer;
- responsibility is the following quality (having the rank of 1-2 depending on the training series);
- social cooperation, high qualification and professional interest were the least important qualities in the perception of subjects;

- there are three qualities (emotional balance, the ability to detect dangers and courage) that have been rated quite differently depending on the three types of training.

Thus, physical health and long-term experience (translated by the high degree of skill development) are the most important characteristics that are self-assessed as necessary in the intervention and rescue activity in toxic / explosive / flammable environments. These are followed by a series of psychological features such as: professional interests, the ability to detect dangers, emotional stability. Of great importance is also high qualification, namely the possession of solid and multiple knowledge regarding the intervention and rescue activity in toxic / explosive / flammable environments.

The conclusions of the study mentioned above are that for the practice of the mine rescue occupation, the individual must have cognitive skills necessary to understand and acquire all the above mentioned knowledge (concentric and distributive attention, memory, analytical reasoning, spatial skills, etc.), physical and mental characteristics which allows him to cope with the great effort he is subjected to, both during training and during interventions (special ability to adapt the body to demands, self-control of stressful situations and full control of behavior) as well as personality characteristics (emotional balance, team spirit, responsibility, devotion, courage, and sometimes even the spirit of sacrifice).

4. Conclusions

The demand on the human body, beyond the limits of an optimal activation, has negative, unfavorable effects because it leads to phenomena such as: fatigue, monotony, saturation, etc. In the case of occupational adaptation difficulties, the human body reacts negatively by developing various pathogenic mechanisms.

Rescuer's job falls into the "hard work" category, because the effort implies numerous high amplitude oscillations, as far as effort is concerned.

In general, there is an acceptable convergence of information obtained from these relatively different sources, in terms of aptitudes and personality profile required by this activity, with different accents on certain groups of psychic attributes, or on how to develop them in the process of preparation and occupational training.

By synthesizing the information obtained from the analyzed sources, we can state that the psychological indicators to be considered in terms of intervention and rescue can be grouped into: cognitive, emotional, social and relational skills. So, summarizing the information obtained from the above-mentioned sources, we can say that the psychological indicators [6] that we must follow in terms of intervention and rescue activities are:

- cognitive abilities (clarity of thinking, concentration, lucidity, attention, linguistic ability, decision, memory, visual-space ability, flexibility in thinking, mental agility, mathematical ability)
- emotional abilities (empathy, emotional stability, adaptation to stress, emotional comfort, impulse control, emotivity);
- social and relational skills (assertiveness, group spirit, respect for others, sociability, tolerance of opposing opinions, conformism, interrelation trust);
- other abilities and skills (vitality, vigilance, ambition, dynamism, courage, altruism, responsibility, perseverance, patience, realism, strength of character, generosity, prudence, sincerity, temperance, self-control, mental calm).

Considerations on low current circuits proficiency tests with explosive gas mixtures

Marius Darie^a *, Sorin Burian^a, Tiberiu Csaszar^a, Cosmin Colda^a, Dănuț Grecea^a

^aNational Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX Petroșani, 32-34 G-ral Vasile Milea Street, Petroșani 332047, Hunedoara County, Romania

Abstract

The article is based on the data emerged from a conducted research related to investigations on stochastic behavior of results of tests using spark test apparatus with explosive gas test mixtures. For the purpose of this demarche it was employed a mathematical model for characterization the distance between any two pair set of tests results.

In the first part of the paper was mentioned the spark test apparatus used for the experimentation and were presented the results of the experimental data obtained during the tests.

In the second part was proposed and presented the theoretical model based on Hellinger distance applied to exponential probabilistic distributions of results.

In the third part was exposed results of the used theoretical model. On this occasion was found that proposed distance is adequate for assess the proficiency tests results with explosive gas mixtures.

Keywords: proficiency tests; pseudo metrics; probability distributions; explosion probability

1. Introduction

Usually in the field of power plants but not just here, the industrial activities have a certain degree of exposing to explosion risks.

Due to increased complexity of such technological systems and also due to necessity to operate them safe but also in an efficient manner, those are supervised by a special kind of automatic system. This automatic system of the technological installations are low current systems which comprises sensors, computing parts and executive parts.

Usually, these systems are interfering also with the special spaces endangered by the presence of flammable substances called zones.

Consequently, these systems obey to explosion protection rules especially but not exclusive represented by the intrinsic safety type of protection.

The process of certification of such intrinsically safe systems involve also tests done in presence of explosive gas mixtures.

Next, the paper is focusing on the possibility to assess of such proficiency tests.

Previous results (Darie, 2012), (Johansmeyer, 1994) underlined that the results of such tests have stochastic behavior characterized by an exponential probability density distribution.

For the purpose of experimenting the new proposed theoretical model for proficiency testing assessment was used the data resulted from a previous research. The aim of that research was the investigation of moisture influence over the ignition sensitivity of explosive gas mixtures prepared with methane and air.

Also, that results were found as being adequate for assessing the explosion risk in coal mines.

In that mines, characterized mainly by one-dimensional development (galleries) the propagation of explosion is characterized by the occurrence of pre-compression phenomena and the increase of the speed of propagation in the

* Corresponding author. Tel.: +4 0729 499 084
E-mail address: Marius.Darie@insemex.ro.

explosion wave front. Those particular aspects lead to casualties and material losses. But also, explosions, in the underground, damage the ventilation system. Consequently, the capacity of exhausting the methane emissions together with the capacity of providing the required fresh air to the workers caught in the associated underground mine works could be severely affected (Cioclea, 2015).

The variations in the ignition probability due to the moisture of air used for preparation of the explosive test gas mixture will be used in this paperwork as perturbations which generate independent set of tests assigned, for the scope of this paper, to different participating laboratory in the proficiency test program.

2. Presentation of experimental data

A spark test apparatus (IEC Standard 60079-11, 2012) was employed together with a relative humidity transducer for the inlet air.

According to a specific standard an 8,3% air-methane test mixture was used during the tests, having the air relative humidity values at the air inlet between 11 ÷ 38% RH.

Also, the parameters of the electric circuit in which the spark test apparatus has been connected were $U_0=24V_{cc}$, $L=121mH$, $I_0=110\div 111mA$.

During the tests the inlet air moisture changed according due to weather and the values are shown in the diagram in Figure 1. In the same diagram the value of the number of rotations of tungsten wires holder at which the ignition occurred is also shown. It was performed tests in rainy days (increased moisture) and also in sunny days (lower values of moisture).

In the process of testing, due to the time constant of the humidity sensor, were assigned stabilized red value of relative humidity for every 15 tests done.

Before all tests, conditioning of the cadmium disk of the test rig were performed, according to specific standard.

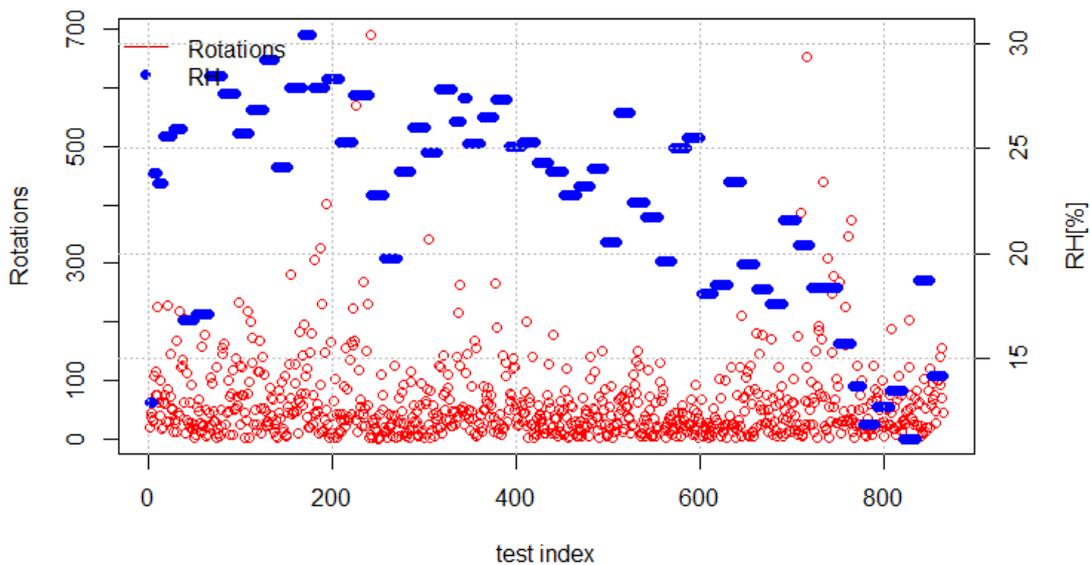

Fig. 1. Inlet air moisture values and the rotations number at which the ignition had occurred

3. Proposed theoretical model

In order to quantize the ignition sensitivity for each participating laboratory is proposed using the ignition probability computed according to equation (1).

$$p = \frac{1}{4 \cdot \text{mean}(R)} \tag{1}$$

where p is the ignition probability and the vector R is the set of rotations number at which ignition occurred for each laboratory.

For the purpose of investigation of the similarity of the probability values obtained from each lab, has been proposed a new theoretical model based on Hellinger distance (Wikipedia, 2018) applicable to density probability distributions as it is shown in equation (2).

This equation also takes in account the exponential probability distribution of test results values.

$$Hellinger(m_1, m_2) = \frac{1}{2} \sqrt{\int_{-\infty}^{\infty} \left(\frac{e^{-\frac{x}{2 \cdot m_1}}}{\sqrt{m_1}} - \frac{e^{-\frac{x}{2 \cdot m_2}}}{\sqrt{m_2}} \right)^2 dx} = \frac{\sqrt{2} |\sqrt{m_1} - \sqrt{m_2}|}{\sqrt{m_1 + m_2}} \tag{2}$$

where m_1 and m_2 are the mean of test results values for each laboratory.

Consequently, if we consider $k=m_1/m_2$ then the equation (2) became the equation (3)

$$Hellinger(m_1, m_2) = Hellinger(1, k) = \frac{\sqrt{2} |1 - \sqrt{k}|}{2 \sqrt{1+k}} \tag{3}$$

Also, the equation (2) and (3) underline the commutativity property.

In order to obtain the expected value “c” was considered the equation (4) which is an optimum problem.

$$\sum_{i=1}^n Hellinger(R_i, c)^2 \rightarrow min \tag{4}$$

Having in view Hellinger distance was proposed data transform presented in the equation (5).

$$T_{Hellinger}(x) = sign(x - c) \cdot Hellinger(x, c) \tag{5}$$

where: sign is the signum function which return the sign of a number;

The raw data was processed by selecting all test results having exactly each 15 identical values for relative humidity. Then was computed ignition probability and assigned all 36 values obtained to a virtual laboratory. Obtained ignition probability values is shown in the Figure 2.

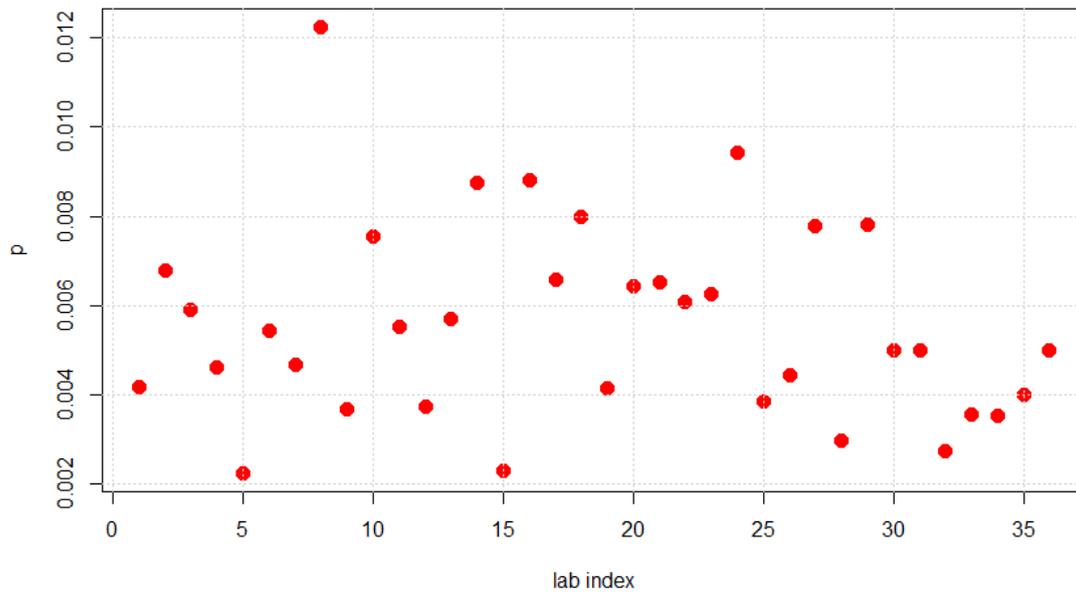

Fig. 2. Ignition probability assigned to each virtual laboratory

The distribution of ignition probability values assigned to each virtual laboratory is presented in Figure 3.

The Figure 3 shows that the skewness is moderate even the data comes from exponential distribution because of central tendency of averaging process implied to obtain the ignition probability.

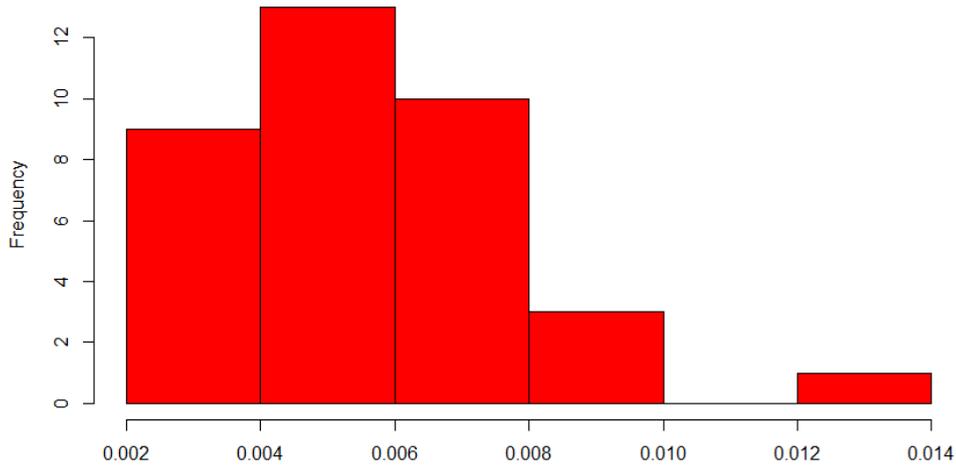

Fig. 3. Histogram of ignition probability values assigned to each virtual laboratory

4. Results and discussions

After using the theoretical model on the experimental data were obtained the results presented in the form of dendrogram in Figure 4.

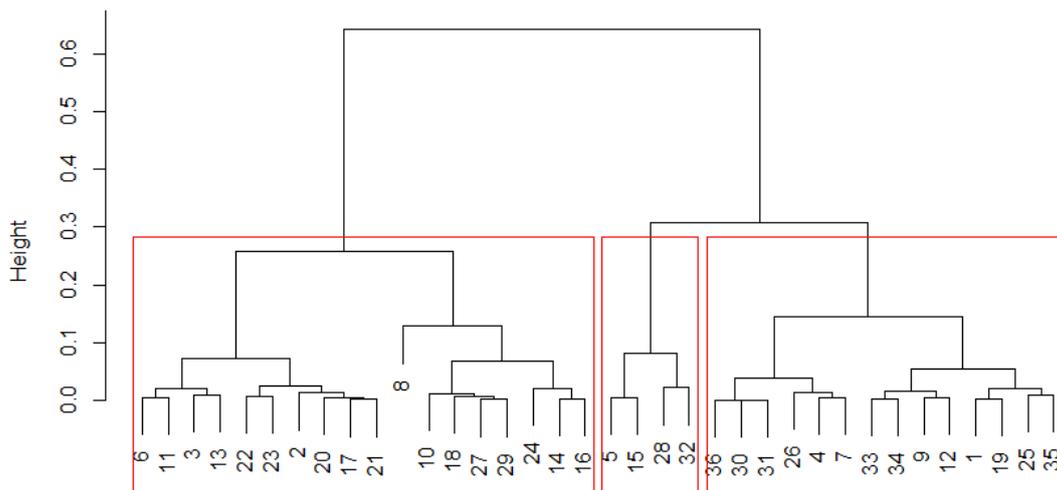

Fig. 4. Dendrogram of clustered results using Hellinger distance and ward D2 algorithm

The red rectangles are automatically chosen in order to obtain 3 clusters.

Having in view the Hellinger distances between clusters shown by the dendrogram in Figure 4 the experimental data could be easy split in two or three clusters.

Additional, analysis done underlined a very interesting aspect emerged by simulation, that the using of the Hellinger distance makes the results being uninfluenced in process of this cluster classification even at the input was applied the transformed data by using decimal logarithm. Also, this distance preserves the relative separation of the clusters. The logarithm transform is already used for exponentially or heavy positively skewed distributed data.

The diagram in Figure 5 show that the cluster number 1 collected the central values.

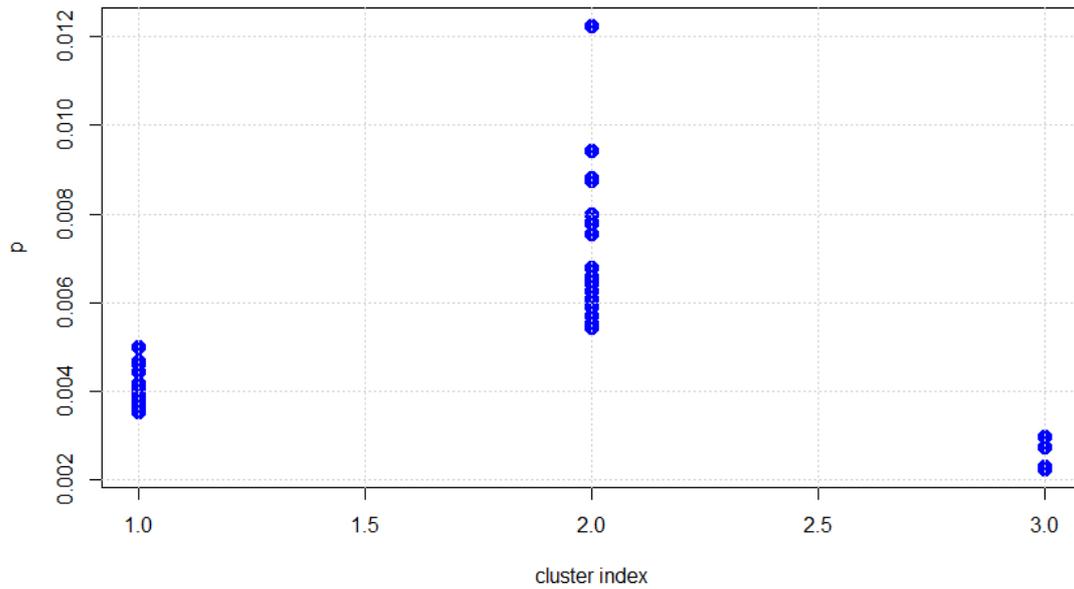

Fig. 5. Distribution of clustered results using Hellinger distance and ward.D2 algorithm

In the table 1 is presented the synthesis of results. Analysis of border between the ranges of clusters could indicate empiric limits of favorable results.

Table 1 Synthesis clustering process

Cluster / Parameter	1	2	3
Mean	0.004245286	0.007314909	0.002566244
Range	0.003521954÷0.005010020	0.005442671÷0.012244898	0.002244837÷0.002989835
Size	14	18	4

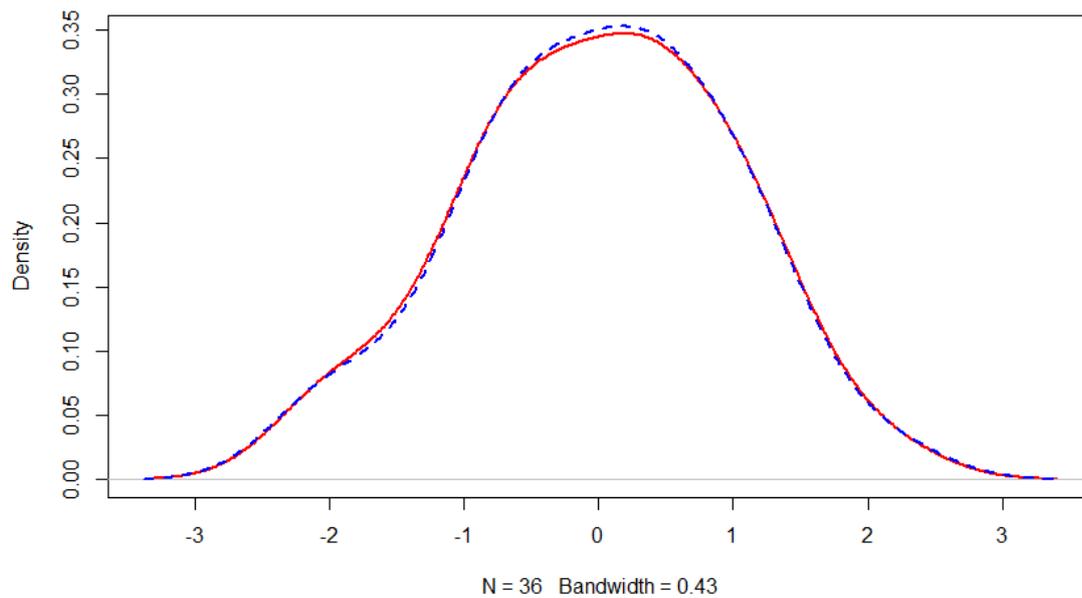

Fig 6. Density distributions of z transform of Hellinger transformed points (red) and log10 transformed points (blue).

Using the proposed transform based on Hellinger distance (5) together with z transform were obtained a new set of data. Additionally, the data was transformed using decimal logarithm and followed by z transform and were obtained a second set of transformed data.

Figure 6 contains the density distributions of Hellinger transform and decimal logarithm transform. It shows an equivalence of those transforms.

Conclusions

Ignition probability variations induced by the presence of moisture was a good process for generating new experimental data population.

Clustering process based on Hellinger distance ensure the stability of results.

For exponentially distributed values, based on Hellinger distance was proposed a new transform which is equivalent with logarithm transform.

The proposed Hellinger transform open new way for comparisons even for data sets which do not obey to a specific density distribution.

Acknowledgements

This paper contains a summary of the researches regarding the determination of the humidity influence of the air used in the test mixtures of 8.3% air + methane on the sensitivity to ignition. Tests and preliminary statistical analysis were performed inside the national project "Study of the test mixture humidity influence over the sensitivity of the spark test apparatus" National Research Program no.45N / 31.01.2007-2015. This paper was developed within a Research Program - Nucleu Program 2018, project PN 18 17 02 01 – "Researches for developing the assessment and testing of technical equipment designed for use in areas with hazard of explosion and of personal protective equipment".

For performing the calculus and diagrams were used the R language and R Studio environment (R Development Core Team R, 2008), (R Core Team R, 2015).

Determination of danger, risk and fire vulnerability parameters. Numerical simulation in fire extinction

Cristian Tomescu¹, Doru Cioclea¹, Ion Gherghe^{*}, Emeric Chiuзан¹, Marius Morar

¹National Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX,
32-34 G-ral Vasile Milea Street, Petroșani, Hunedoara, Romania

Abstract

The specialized literature deals with the phenomenology of fires in the industrial and civilian area, as well as with protection against fire, as a very complex problem in order to give a specialized response to such an emergency situation.

INCD-INSEMEX Petroșani, in his fire and explosion portfolio, owns numerous research expertise based on the causes that generated such events, in which it succeeded to elucidate these causes by analysing the situations, states and circumstances and reporting them to the mechanism of the phenomenon initiation, development and propagation.

The numerical analysis software using the ANSYS-based CFD solution - a finite element analysis software package widely used in industry and research, is the tool that renders the image of a fire or explosion event. But in most cases, this computerized program was used to identify causes and not to prevent fires.

Thus, the present paper proposes an analysis of the fire risk parameters and the numerical simulation of a selection of fire-extinguishing systems.

Keywords: fire, danger, risk, vulnerability, simulation.

1. Introduction

Fire prevention activities are a set of technical and organizational measures, as well as specific actions planned and executed according to the legislation, in order to prevent, reduce or eliminate the risks of fires and their consequences, the protection of persons, material goods and the environment through specific means and measures.

Fire risk is the performance criterion that represents the overall probability of a fire outbreak determined by the interaction of the properties of specific materials and combustible substances with potential ignition sources under certain circumstances at the same time and space. It cannot be analysed and treated in the study of combustion without elements vulnerable to fire: humans, buildings and the environment.

2. The parameters for harmful risk assessment

In industrial facilities, institutions, residential buildings, technological installations and times where materials and combustibles are stored, handled and used, there is a fire hazard. This is due to the fact that the materials and substances have stored a certain caloric potential (thermal load). If a source of ignition is in the same space or surroundings, the danger of fire is imminent. It occurs when there is a correlation in time and space of specific conditions. (Balulescu, P., Macris, V., 1979)

In practice, it is necessary to appreciate as accurately as possible the fire hazard in order to take the most effective preventive measures, which have as main purpose:

- keeping the probability of a fire out to a low level;
- stopping the fast propagation of a possible fire or limiting it to minimal damage.

The force of destruction of a fire acts in two directions: on the building and on its contents. The building ruins consist of the destruction of the building elements. The degree of destruction is determined by two factors acting in the opposite direction: the intensity and duration of the fire on the one hand and the resistance of the construction on the other.

^{*} Corresponding author: Cristian Tomescu
E-mail: cristian.tomescu@insemex.ro; Phone: + 40 254541621; Fax: +40 254546277

For determining the potential fire risk, the following factors will be taken into account:

- thermal load;
- visibility conditions and the possibility of increased damage due to smoke releases;
- the size of fire compartments according to the possibility of evacuation of the building and ventilation of the rooms;
- the height of the room or building;
- the possibility of increased damage due to the release of corrosive combustion gases;
- agglomeration of values (materials) per unit area.

Fire risk factors for buildings and people, as well as the amount of damage caused by fire, smoke, corrosive combustion gases, etc. must be determined by using risk factors.

The calculation of the fire hazards must take into account two main factors:

- thermal load calculated in a certain manner;
- fire resistance of buildings, assessed and interpreted with all the implications.

Thermal load S_Q is the first and most important parameter of fire risk. It represents the amount of heat that can be released by the complete combustion of all the combustible, fixed and mobile materials present in the space affected by the fire. There are several calculation formulas according to the standard used and updated. The general formula for calculating the heat load is given by:

$$S_Q = \sum Q_i \times M_i \quad [\text{MJ}] \quad (1)$$

M - the mass of combustible materials of the same kind in the space considered in Kg;

Q - lower calorific value for an MJ / kg or MJ / m³ gas.

The thermal load density is determined by the ratio of the thermal load to the surface of the fire-affected space (the surface of the fire compartment) according to the following equation:

$$q = \frac{S_Q}{A} \quad (2)$$

S_Q - total thermal load in MJ

A - The area of the room, the fire compartment in m²

The amount of heat that is thought to act upon the building elements (S_A) is determined by the relationship:

$$S_A = c \cdot p \cdot \sum_{i=1}^n m Q_i M_i' \quad [\text{MJ}] \quad (3)$$

in which:

c - Coefficient which takes into account the size of the geometric dimensions of the space considered;

p - Coefficient which takes into account the number of levels and the conditions of ventilation and dissipation of heat;

m - coefficient to account for the combustion capacity of the materials under fire conditions;

Q_i - lower calorific power (defined above);

M - the amount of combustible materials of the same type in MJ;

The values of the coefficients c , p and m are found in the default tables.

Fire resistance of building elements is a precise and measurable notion, but calculations are obtained due to research and experimental results in the field, based on analytical and alternative methods for verifying the fire resistance of incandescent structures. The minimum fire resistance of the main building elements in the structure of the building is specified in specific technical regulations.

The assessment of the fire hazard of combustible substances and materials is likely to be performed only if a number of parameters are known, such as:

- *Fuel group* - the property that some bodies have to burn in the presence of oxygen or air;
- *Fuel index* - dimensional size, expressing the ratio between the amount of heat released by the burning material and the amount of thermal energy of the ignition source;
- *Ignition temperature* - the minimum temperature at which the vapours of a combustible liquid form with the air above it a mixture of a certain concentration that ignites it in contact with a source of ignition (flame, incandescent, sparks, mechanical sparks etc.);
- *Ignition temperature* - the lowest temperature at which a substance in the presence of air or oxygen is to be heated to ignite and continue to burn on its own without further heating;
- *Self-ignition temperature* - the minimum temperature to which it is necessary to heat a combustible substance to produce ignition of the vapor-air mixture without coming in direct contact with a source of ignition;
- *Self-ignition tendency* - a phenomenon found in a number of combustible substances and materials that are first subjected to self-heating as a result of chemical or biological processes in the mass of organic substances themselves;
- *Explosion limits (minimum and maximum)* - combustion vapours and gases may form explosive mixtures with air which ignite only if they have a certain concentration;

- *Vapour ignition limits* - minimum magnitude of the energy of an electrical or mechanical spark sufficient to ignite a gas-air, vapour-air or air-to-light mixture at a certain concentration (the one that ignites more easily);
- *Minimum fire-extinguishing concentration* - the minimum oxygen concentration in the air mixture, where a diluent is introduced under which it is not possible to inflate their mixtures with gases, vapours, or combustible dusts, and thus the propagation of combustion in the whole volume;
- *Minimum oxygen content for the explosion* - the oxygen content of the environment in which a combustible material continues to burn without being subjected to the action of the ignition source;
- *Burning rate* - the amount of fuel consumed by combustion in the unit of time;
- *Liquid heating rate* - determined by the rate of increase of the thickness of the liquid layer, if it burns on a free surface, the temperature of which is equal to the boiling temperature of the liquid;
- *The maximum explosion pressure* - the maximum explosion pressure that would occur if there was no heat exchange between the combustion products and the walls of the plant can be calculated by knowing the concentration, composition of the respective substances, the initial state of the system, and the quality of volatile substances (dusts);
- *Most suitable extinguishing agent* - for each material and fuel substance, the most effective extinguishing agent should be established.

3. Numerical simulation of fire extinguishing

Three main categories are known as fire protection elements:

- passive fire protection, specialized building elements and materials for the protection against fire;
- active protection, automatic signalling and fire-extinguishing systems;
- passive-active protection, manually operated intervention means.

3.1. Fire extinguishing systems

The system of active fire protection or active fire control is also provided by equipping buildings, technological installations and fire extinguishing installations: external and internal hydrants, sprinkler systems, drenched installations as well as sprinkler systems, foam, powders and inert gases. The most widespread fire-extinguishing systems are those with water. The paper is dealing with sprinkler systems.

Sprinkler systems are automatic fire detection, signalling and fire-extinguishing systems, automatically operating when the ambient temperature due to fire exceeds the set limits. The system uses dispersed water as a spraying agent in the form of droplets made with sprinklers. It automatically switches to heat when the thermal fuse (set to approximately 30 ° C above the normal ambient temperature) reaches the activation temperature, the sprinkler head opens, the water drops in the form of drops. Only those sprinkler heads that are above or near the source of the fire are opened, those whose operation is required for the fire-fighting operation. Types of sprinkler extinguishing systems: in water-water system, in water-air system and in mixed system.

3.2. Considerations on Computational Fluid Dynamics (CFD).

CFD - Computational Fluid Dynamics is a model of fluorescence dynamics in the ANSYS program, more focused on the virtualization of fluid flow in fire-affected environments, based on Navier-Stokes equations suitable for low speed, thermal fluxes, focusing on transport of heat and smoke. Partial derivatives of mass, torque and energy conservation equations are approximated as finite differences, and the solution is continuously updated over a three-dimensional network. Thermal radiation is calculated by finite volume technique on the same fluid flow network. To simulate smoke movement, spraying water or fuel injection, Lagrange particles are used.

3.3. Geometry creation

To perform the simulation, a spray head model for water fog extinguishing installations was used, mounted vertically with the deflector down. This cutting head was drawn in the ANSYS program using the actual dimensions (Fig.1). (Dumitru, L., Serban, M., et al. 2015)

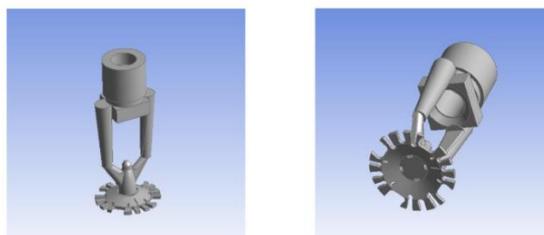

Fig. 1 – Geometry of the chosen sprinkler model

3.4. Dividing into finite elements (MESH)

Taking into account that a computer can only perform simple mathematical operations, it must be brought into an algebraic form appropriate for programming. This transformation is known as the discretization of equations. The stability of the numerical calculation of the meshing equations cannot be predicted analytically, it is demonstrated in practice. This stability is being tested, especially in the area of discontinuities. Both Euler's equations and the Navier-Stokes equations admit discontinuities. (Lupu C., Vlasin N., et al.2015)

Once the shape of the field of analysis has been determined, it must be meshed (Figure 2). The sprinkler meshing was 0.1 mm, 1 cm outboard, and 1 dm room walls.

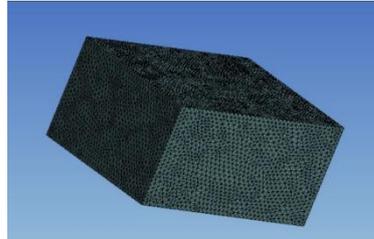

Fig. 2 – Dividing into finite elements

Number of finite elements that make up the entire domain analysed is presented in Table 1:

Table no. 1.

Units	Fields	Elements
Default Domain	862734	3378320

3.5. Boundary conditions (SETUP)

The boundary conditions in the simulation are as follows:

- Type of analysis - 180 s simulation run time is selected;
- the scope includes the entire assembly of components, in this option the air and water particles (particles forming the fluid jet) are defined, the particles used are small particles with a diameter of 400 microns, average particles with a diameter of 600 microns and particles large diameters of 900 microns;
- inlet - subsonic flow at 2.6 m / s, 3 types of particles having equal velocity and a temperature of 25⁰ C;
- outbreak - is an area of 1 m², to which a temperature of 400⁰ C with a radiation of 8,000 W is applied;
- walls (without friction, the particles are perpendicular to the floor);
- the floor having a temperature of 25 ° C;
- the height of the sprinklers is 2.2 m;
- sprinkler - all parts of the spray head are defined.

3.6. Solving equations (Solutions)

At this stage, the program performs the calculations without user intervention based on the boundary conditions imposed in the previous step. It is the only step that runs without user intervention.

Figure no.3 illustrates the graph of solutions imposed by the boundary conditions.

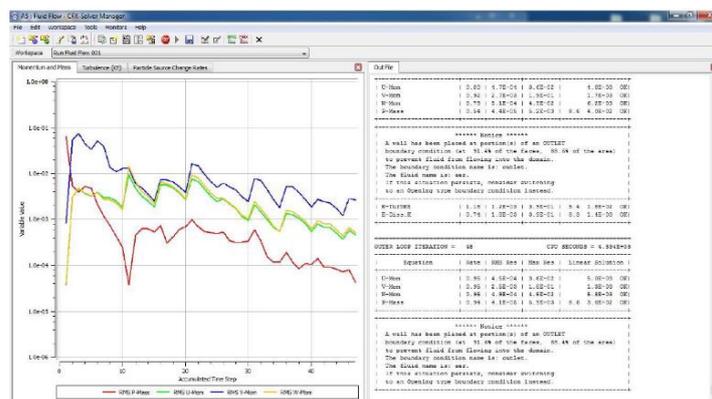

Fig. 3 – Solving equations in the ANSYS software

3.7. Results

The results are displayed following the mathematical calculations presented in the previous stage. This step is very important because it helps to interpret the results according to the chosen parameter. It has been chosen to plan a vertical plane through the focal axis of the furnace.

In Figure no. 4 a) a high temperature is observed in almost all of this room being around the furnace of about 400⁰ C. In figure no. 4 b), c), it is noticed that the room temperature started to drop, the temperature in the furnace decreased by approx. 100⁰ C. In figure no. 5 - a), b), c), the fire involution is observed within 60 seconds and after, until extinguished. After the fire was cleared, the temperature in the fired area reached almost the same value as the ambient temperature except the furnace.

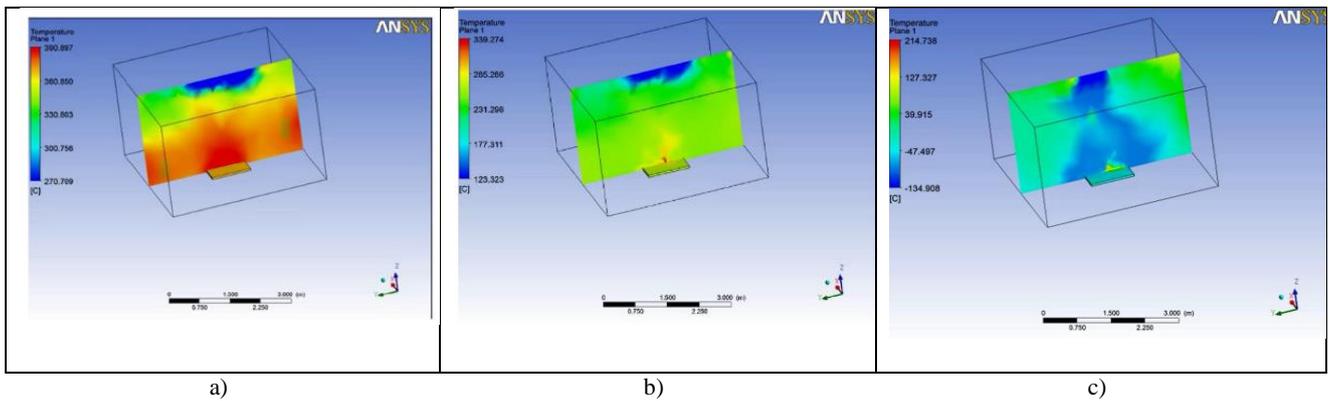

Fig. 4. a) - Section with a vertical plane after 5 seconds from the sprinkler triggering;
 b) - Section with a vertical plane in the area of the furnace after 15 seconds from the sprinkler triggering;
 c) - Section with a vertical plane after 25 seconds from sprinkler triggering.

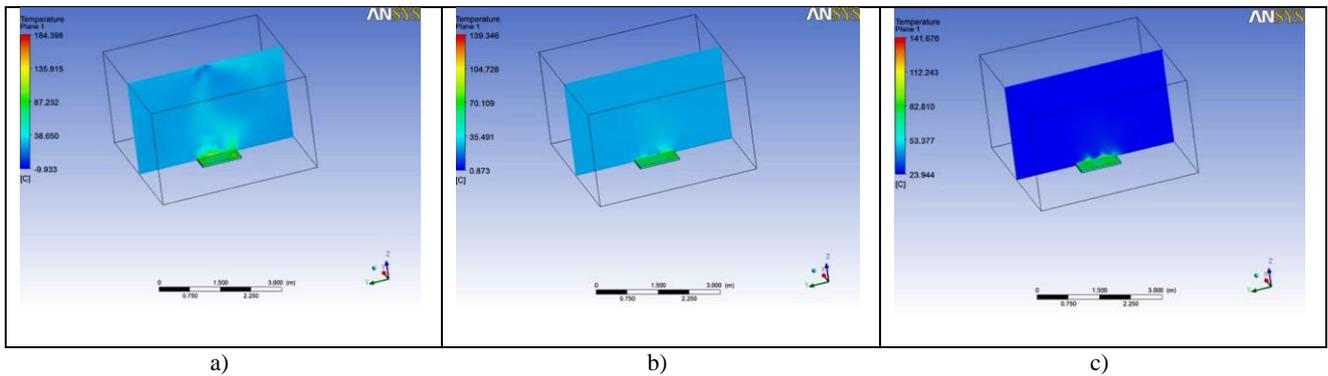

Fig. 5. a) - Section with a vertical plane after 40 seconds from the sprinkler triggering
 b) - A section with a vertical plane after 50 seconds from the sprinkler triggering
 c) extinguished fire

Figure no. 6 shows the variation of the internal temperature at a height above the furnace over a period of 0 to 180 s. The air temperature in the room after 30 s is approximately 240⁰ C and at the top of the room it is much slower. It can be noticed that at t = 60 s there is a sudden increase in the temperature at the ceiling due to the fact that the contact of the water particles with the furnace takes place a sudden evaporation of them by transporting some of the heat of the furnace to the ceiling. The simulation shows that it is sufficient to operate the sprinkler for 300 seconds to complete the fire extinguishing.

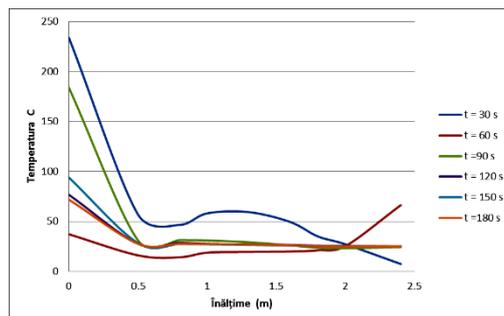

Fig. 6 – Temperature variation over the furnace

4. Conclusions

1. For the assessment of fire risk in fire prevention, it is necessary to analyse a matrix of parameters that characterize a fire and the results of this analysis lead to the low probability of a fire outbreak, as well as to the stop of the rapid propagation of a possible fire or to minimal damage.
2. In practice, it is important to choose, depending on the types of protected material, but also the likely types of fire detection, fire extinguishing systems, fire detection, signalling and fire extinguishing, automatically entering into operation when the ambient temperature due to fire exceeds the established limits.
3. The sprinkler extinguishing system uses water as a water scavenger, dispersed as fine water drops, which performs a heat exchange with the energy produced in the combustion zone, preventing the temperature from rising. This energy exchange is proportional to the surface covered by water droplets, not their volume. At an equal volume, the smaller the droplets, the higher the area on which the energy exchange takes place. The secondary effect is the decrease in oxygen concentration.
4. ANSYS computational simulation software for phenomena occurring in spaces where fires can occur, includes information about the network that defines the geometry, environment, solid body geometry, material properties, combustion kinetics, and desired output data. The numerical network consists of several cells of uniformity, with which all the geometric features of the bodies in the scenario must comply.
5. By numerical simulation of the Sprinkler fire extinguishing system, with the CFD model, a fire extinction was obtained during 5 minutes in a room whose ignited materials developed a temperature of 240⁰ C.
6. Fire risk assessment and the use of computational simulations is a proper tool for designers and economic and non-economic agents in establishing the fire risk scenario as well as for reaching and increased safety factor for humans, materials and for environmental safety.

Abstract

Fatigue is a body defensive measure, limiting the intensity and volume of effort. The intensity and volume of effort can be maintained at a high level only if the body's adaptability allows it.

Measurement of fatigue is performed by measuring pulse and respiratory rate.

The decisive factor in ensuring the success of an intervention and rescue operation in toxically or chemically aggressive environments resides in the optimal and efficient design of a training process for intervention personnel, correlated, amongst other things, with the evolution of pulse and oxygen saturation, which need to be monitored through an integrated system.

Pulse is a physiological parameter commonly used in telemonitoring as it allows assessment of the rescuer's general condition, heart rhythm disturbances being recorded promptly and variations being easily differentiated between abnormal / normal. The parameter provides indications of cardiovascular function. Pulse sampling is performed automatically using devices that frequently use photometric plethysmography at the level of peripheral arteries as a measuring method.

Blood oxygen saturation (SpO₂) is a global indicator of blood oxygenation (the amount of oxygen bound to haemoglobin in arterial blood), being used in cardiovascular and respiratory monitoring.

Within the paper, change in heart rate and blood oxygen saturation will be monitored, so as to determine the physical exertion of rescuers, using closed-circuit breathing apparatuses, as well as open-circuit breathing apparatuses, in confined spaces, ergometers, treadmill and ladders on different degrees of temperature and humidity.

Keywords: rescuer, pulse, blood oxygen saturation, training facility, monitoring, breathing apparatus

1. Introduction

Effort is the result of multiple demands (muscular, cardiorespiratory, psychic, etc.) to which the human body, (Drager, 2010) is subjected while performing different activities, (Gireadă et al, 2017).

From a biological point of view, physical effort is an appropriate biological stimulus (excitant) that forces the body to respond by electrical, mechanical, thermal manifestations. This stimulus, when properly dosed and administered to individual's particularities, leads to quantitative and qualitative accumulations aimed at achieving maximum performance, (Rotariu, 2010).

The activity of body's organs, apparatuses and systems takes place concurrently with the intensification of the body's vegetative functions, (Pupăzan et al, 2012). The greatest demands during effort are supported by systems involved in the increased supply, transport and consumption of oxygen by active tissues, (Pupăzan et al, 2015).

Increased need for oxygen and energy means within physical effort is achieved by alterations in cardiovascular parameters, that can be: immediate (acute) alterations are installed for all types of exercise, (Pupăzan et al, 2012) and during recovery and late (training) alterations, which are the result of the systematic practice of physical education and sports, for a longer period of time, (Mesina, 2013).

During effort, body adaptation is assured on one hand by nervous regulation and on the other by neuro-hormonal regulation, (Ilie et al, 2015). During exercise, a series of changes in body apparatus and systems occur, as an expression

* Corresponding author. Tel.: +40 254 541 621; fax: +40 254 546277.
E-mail address: andrei.gireada@insemex.ro.

of the functional adaptation tendency, changes most apparent in the cardio-vascular system activity, (Mesina, 2013). The most obvious adaptation of this apparatus is the acceleration of heart rate, increased heart rate, which reflects the heart rhythm. Heart rhythm may reach 60 to 70 beats per minute, 120 to 150 or even 200 beats per minute in extraordinary cases at very great effort, (Pupăzan et al, 2015).

Heart rate adaptation begins immediately after initiation of effort, first with an increase over need and then a stabilization at a constant level if the effort is also constant, (Gireadă et al, 2017). After the effort ends, return to normal is made in two stages: first by a sudden drop in the beginning, then by a slow and progressive sometimes wavy decline, (Rotariu, 2010).

Another manifestation of circulatory changes during exercise is the increase in blood pressure, which is proportional to effort intensity, in this situation, both the maximum and the minimum being of interest, (Ilie et al, 2015). After the training ends, pressure returns to normal, a rebound depending on effort intensity and fitness of the trainee. In the first few minutes, pressure values fall below the resting value, then rise to normal, (Ilie et al, 2016). In the event of inappropriate adaptation of the cardio-vascular apparatus, the maximum pressure decreases abruptly before the end of the effort test, so the heart is at the limit of its resources, (Pupăzan et al, 2012).

2. Types of breathing apparatuses

Respiratory protection devices are divided into:

- closed circuit respiratory devices type MEDI 17128 and DRAGER BG4, compressed oxygen-based devices, which have an autonomy of up to 4 hours depending on type and size of the filter cartridge which also has the role of regenerating breathing air. These two types of apparatus are most often used in underground industry due to their high operating time, (Ilie et al, 2015);
- open circuit respiratory devices type DRAGER PA 90, DRAGER PSS 7000, PROSALV 2000, PROSALV FIRE PLUS and PROSALV ARIAC D "DIABLO" compressed air-based devices, without regeneration of exhaled air. These devices have an autonomy of up to 60 minutes at medium effort and a cylinder load at nominal pressure. These types of apparatus are most often used in surface industry because of their low operating time, (Ilie et al, 2016).

3. Optimizing physical effort of rescuers according to the activity performed and type of respiratory protection equipment

In the practical training process, intervention and rescue personnel were divided into two groups: personnel operating in the underground mining industry using closed circuit breathing equipment and surface rescue personnel using open circuit respiratory protection equipment. Two teams of 3 rescuers were selected, the first team with a surface profile and the second team with underground profile.

Rescue teams performed several types of exercises with varying degrees of difficulty, workload pertain to physical being calculated for each of them.

3.1. Route no. 1 - surface

Within the training facility, a team of three surface rescuers performed several types of exercises with varying degrees of difficulty using open circuit breathing equipment:

- three narrow-space circuits;
- three series of 80 ergometer pull-ups;
- five minutes of walking on the ergometer treadmill;
- ascending and descending on the metallic scale for 50 times;
- climbing and descending the shaft ladder;
- two turns of the modular circuit.

Fig. 1. Surface rescuers

For each type of exercise, workload was calculated as follows:

I. The amount of work performed for passing thru a narrow section of the gallery, with the length of 12 meters and the section of 0.54 m², in crawling position, repeating the activity three times:

$$A_1 = 0,5 \cdot 100 \cdot 12 \cdot 3 = 1800 \text{ Kgm}$$

II. The amount of work performed for passing thru a narrow section of the gallery, with the length of 12 meters and the section of 0.9 m², on all fours, repeating the activity three times:

$$A_2 = 0,25 \cdot 100 \cdot 12 \cdot 3 = 900 \text{ Kgm}$$

III. The amount of work performed for passing thru a narrow section of the gallery, with the length of 12 meters and the section of 1.5 m², in bent position, repeating the activity three times:

$$A_3 = 0,125 \cdot 100 \cdot 12 \cdot 3 = 450 \text{ Kgm}$$

IV. The amount of work performed for passing thru a labyrinth type section, with the length of 40 meters, repeating the activity 3 times:

$$A_4 = 0,055 \cdot 100 \cdot 40 \cdot 3 = 660 \text{ Kgm}$$

V. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 3 meters and the section of 0.9 m², on all fours, repeating the activity 3 times:

$$A_5 = 0,25 \cdot 100 \cdot 3 \cdot 3 = 225 \text{ Kgm}$$

VI. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 3 meters and the section of 0.54 m², in crawling position, repeating the activity 3 times:

$$A_6 = 0,5 \cdot 100 \cdot 3 \cdot 3 = 450 \text{ Kgm}$$

VII. The amount of work performed for climbing and descending a 3 meters high ladder at an angle of 90⁰, repeating the activity 2 times:

$$A_7 = 0,25 \cdot 100 \cdot 6 \cdot 3 = 450 \text{ Kgm}$$

VIII. The amount of work performed for lifting a weight of 20 kg at the ergometer, at a height of 1.2 m, two series of 30 repetitions each:

$$A_8 = 20 \cdot 1,2 \cdot 30 \cdot 2 = 1440 \text{ Kgm}$$

IX. The amount of work performed for climbing and descending a 9 meters high ladder at an angle of 90⁰, repeating the activity 2 times:

$$A_9 = 0,35 \cdot 100 \cdot 18 \cdot 2 = 1260 \text{ Kgm}$$

X. The amount of work performed for passing thru a normal (horizontal) profile working, on the ergometric treadmill at a speed of 5 km/h for 5 minutes:

$$A_{10} = 0,055 \cdot 100 \cdot 400 = 2200 \text{ Kgm}$$

XI. The amount of work performed for passing thru a working, by climbing and descending a 5 steps ladder, at an angle of 45⁰, repeating the activity 40 times:

$$A_{11} = 0,25 \cdot 100 \cdot 80 = 2000 \text{ Kgm}$$

XII. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 6 meters and the section of 0.6 m², in crawling position, repeating the activity 2 times:

$$A_{12} = 0,5 \cdot 100 \cdot 6 \cdot 2 = 600 \text{ Kgm}$$

XIII. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 41 meters and the section of 0.9 m², on all fours, repeating the activity 2 times:

$$A_{13} = 0,25 \cdot 100 \cdot 41 \cdot 2 = 2050 \text{ Kgm}$$

XIV. The amount of work performed for passing thru a labyrinth type section, with the length of 36 meters, repeating the activity 3 times:

$$A_{14} = 0,055 \cdot 100 \cdot 36 \cdot 3 = 594 \text{ Kgm}$$

XV. The amount of work performed for climbing and descending two 3 meters high ladders at an angle of 90⁰, repeating the activity 2 times:

$$A_{15} = 0,35 \cdot 100 \cdot 6 \cdot 2 = 420 \text{ Kgm}$$

Total amount of work performed is:

$$A = \sum A_1 \div A_{15} = 1800 + 900 + 450 + 660 + 225 + 450 + 450 + 1440 + 1260 + 2200 + 2000 + 600 + 2050 + 594 + 420 = 15.499 \text{ Kgm}$$

The total amount of work performed by a surface rescuer in training for passing thru the first training route was 15,499 Kgm.

Measurements of blood oxygen saturation and pulse of each rescuer were also performed, repeating the measurements after the end of each activity.

For this route, oxygen blood saturation and pulse are shown in table no. 1 and graphically in figure 2.

Table 1 – route no. 1 - surface

No.	GROUP 1 INSTRUCTION	Subject 1		Subject 2		Subject 3

3.2. Route no. 2 – underground

Within the training facility, a team of three underground rescuers performed several types of exercises with varying degrees of difficulty using closed circuit breathing equipment:

- two narrow-space circuits;
- three series of 80 ergometer pull-ups;
- seven minutes of walking on the ergometer treadmill;
- ascending and descending on the metallic scale for 30 times;
- climbing and descending the shaft ladder;
- two turns of the modular circuit.

Fig. 3. Underground rescuers

For each type of exercise, workload was calculated as follows:

I. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 11 meters and the section of 0.54 m², on all fours, repeating the activity 2 times:

$$A_1 = 0,5 \cdot 100 \cdot 11 \cdot 2 = 1100 \text{ Kgm}$$

II. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 12 meters and the section of 0.9 m², in crawling position, repeating the activity 3 times:

$$A_2 = 0,25 \cdot 100 \cdot 12 \cdot 3 = 900 \text{ Kgm}$$

III. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 12 meters and the section of 1.5 m², in bent position, repeating the activity 3 times:

$$A_3 = 0,125 \cdot 100 \cdot 12 \cdot 3 = 450 \text{ Kgm}$$

IV. The amount of work performed for passing thru a labyrinth type section, with the length of 40 meters, repeating the activity 3 times:

$$A_4 = 0,055 \cdot 100 \cdot 40 \cdot 3 = 660 \text{ Kgm}$$

V. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 3 meters and the section of 0.9 m², on all fours, repeating the activity 3 times:

$$A_2 = 0,25 \cdot 100 \cdot 3 \cdot 3 = 225 \text{ Kgm}$$

VI. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 3 meters and the section of 0.54 m², in crawling position, repeating the activity 3 times:

$$A_1 = 0,5 \cdot 100 \cdot 3 \cdot 3 = 450 \text{ Kgm}$$

VII. The amount of work performed for climbing and descending a 3 meters high ladder at an angle of 90⁰, repeating the activity 3 times:

$$A_7 = 0,25 \cdot 100 \cdot 6 \cdot 3 = 450 \text{ Kgm}$$

VIII. The amount of work performed for lifting a weight of 20 kg at the ergometer, at a height of 1.2 m, two series of 30 repetitions each:

$$A_8 = 20 \cdot 1,2 \cdot 30 \cdot 2 = 1440 \text{ Kgm}$$

IX. The amount of work performed for climbing and descending a 1.5 meters high ladder at an angle of 90⁰, repeating the activity 2 times:

$$A_9 = 0,35 \cdot 100 \cdot 23 \cdot 2 = 1610 \text{ Kgm}$$

X. The amount of work performed for passing thru a normal (horizontal) profile working, on the ergometric treadmill at a speed of 5 km/h for 5 minutes:

$$A_{10} = 0,055 \cdot 100 \cdot 436 = 2401 \text{ Kgm}$$

XI. The amount of work performed for passing thru a working, by climbing and descending a 5 steps ladder, at an angle of 45⁰, repeating the activity 500 times:

$$A_{11} = 0,25 \cdot 100 \cdot 112 = 2800 \text{ Kgm}$$

XII. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 9 meters and the section of 0.6 m², in crawling position, repeating the activity 2 times:

$$A_{12} = 0,5 \cdot 100 \cdot 9 \cdot 2 = 900 \text{ Kgm}$$

XIII. The amount of work performed for passing thru a reduced profile section of gallery, with the length of 38 meters and the section of 0.9 m², on all fours, repeating the activity 2 times:

$$A_{13} = 0,25 \cdot 100 \cdot 38 \cdot 2 = 1900 \text{ Kgm}$$

XIV. The amount of work performed for passing thru a labyrinth type section, with the length of 36 meters, repeating the activity 3 times:

$$A_{14} = 0,055 \cdot 100 \cdot 36 \cdot 3 = 594 \text{ Kgm}$$

XV. The amount of work performed for climbing and descending two 3 meters high ladders at an angle of 90⁰, repeating the activity 2 times:

$$A_{15} = 0,35 \cdot 100 \cdot 4,5 \cdot 2 = 320 \text{ Kgm}$$

Total amount of work performed is:

$$A = \sum A_1 \div A_{13} = 1100 + 900 + 450 + 660 + 225 + 450 + 450 + 1440 + 1610 + 2401 + 2800 + 900 + 1900 + 594 + 320 = 16.200 \text{ Kgm}$$

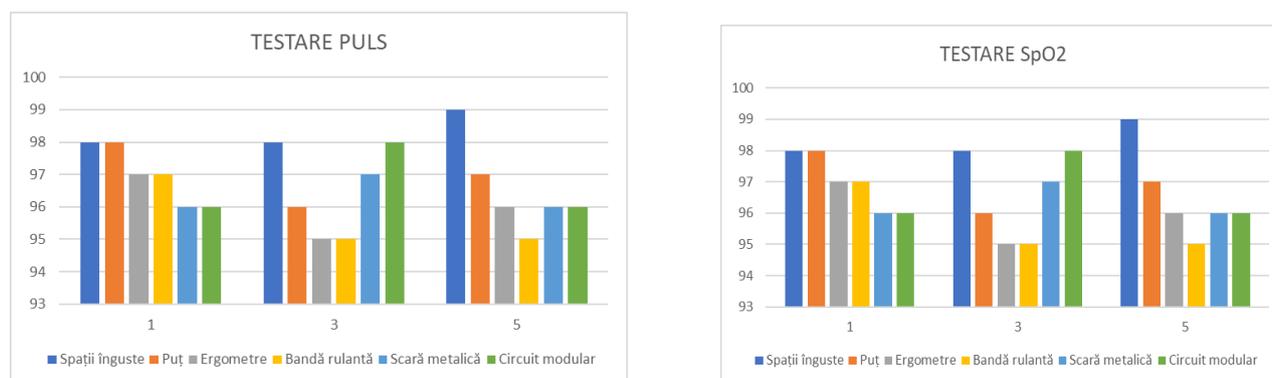

The total amount of work performed by an underground rescuer in training for passing thru the second training route was 16,200 Kgm.

Measurements of blood oxygen saturation and pulse of each rescuer were also performed, repeating the measurements after the end of each activity.

For this route, oxygen blood saturation and pulse are shown in table no. 2 and graphically in figure 4.

4. Conclusions

Training of rescuers in the narrow spaces training facility leads to an increase in the level of safety and health at work, by increasing the capacity for safe intervention in case of accidents, disasters, etc.

Rescue activities in toxic/ explosive/ flammable environments, either in response to incidents, simulated emergency situations or training activities, are confronted with dangerous situations. These hazards are an integral part.

When properly recognized and managed, hazards can be reduced to an acceptable level of risk. Obviously, the acceptability of a risk depends on the importance of operation's outcome, involving that risk. If people's lives are in danger, more dangerous operations are allowed, ensuring that risks are recognized and measured. This is a practical use of hazard identification and control activity.

Intervention activity under such special conditions may only be carried out by personnel trained and certified to do so, personnel using individual breathing equipment.

Abstract

Compressed air breathing apparatuses have the widest range within industrial activities and are subject to intense demands from the work environment. During interventions, the apparatus may be subjected to flames or high temperatures. To meet these demands, insulating appliances are inspected, during test stage, for high temperature exposure with the use of a test stall. The components of the stall are the dummy carrier of the test apparatus, its transport carriage, the preheating furnace and the burner battery. Testing an insulating apparatus at high temperatures involves checking the integrity of the device after exposure to flames and checking functional parameters with a breathing machine after the exposure flame has ended. The insulating device is exposed to flames of a burner battery for 15 seconds, after which the breathing apparatus is subject to a free fall. The materials of the apparatus must not allow the persistence of flames nor damage after exposure to flames.

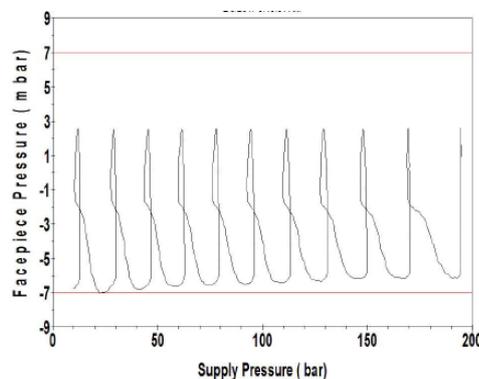

The paper presents the approach to carrying out the stall for high temperature testing of compressed air insulating devices.

Keywords: temperature proof, insulating apparatus, stall, flame, furnace

1. Introduction

Compressed-air self-contained breathing apparatuses should be capable of functioning without disturbance when exposed to temperatures between -30°C and 60°C . Temperature proof of appliances involves the use of materials that don't allow the persistence of flames for more than 5 seconds after the flame has been removed from the exposed surface. Hoses used in insulating appliances as well as materials from which valves are made must not allow flame propagation. From a mechanical point of view, the apparatuses subjected to the high temperature test must remain sealed, the air supply must operate even if there are deformations of the components. (Ilie et al, 2015)

Prior to exposing the device to high temperature, a functional parameter check of the insulator is performed by means of the breathing machine. The breathing machine is set at 25 cycles / minute with a volume of circulating air of 2 liters / cycle. During the test, a mask pressure graph and an outline of the minimum and maximum pressure values in the mask are obtained. A print screen of a test performed with the use of a breathing machine is shown in figure 1.

E-mail address: alin.irimia@insemex.ro

Fig. 1. Print screen of testing the breathing resistance of an insulating device

The breathing machine also tests the tightness of the high-pressure circuit, opening of the safety valve, accurate display of the cylinder pressure on the pressure gauge and the mask tightness, values highlighted in the print screen shown in figure 2 (Ilie et al, 2017).

Pressure Gauge Test :		Pass	
70 bar :	100 bar :	150 bar :	
Pass 74.7	Pass 105.4	Pass	154.
Alarm Accuracy :	Pass	55.	bar
Static Facepiece Pressure :		Pass	0.0 mbar
Bypass Test :		Pass	6 L/min
High Pressure Leakage :		Pass	0.8 bar
Safety Valve Opening Pr.		Pass	12. bar

Fig. 2. Print screen of testing the essential parameters of insulating devices with the breathing machine

2. The test bench

Before being tested, the insulator with both the cylinder and mask is conditioned at 60° C and a relative humidity of 50% for 4 hours. During conditioning, the filling pressure of the cylinder will be 100 bar and in the case of cylinders made of composite materials, the conditioning time will be 12 hours. After conditioning, the insulator, along with the mask and cylinder, will be fitted on a dummy. The dummy will be equipped with a flame proof jacket, to be used for up to three flame exposures. The dummy is made of hardwood, of several mechanically joined elements, their dimensions being shown in figure 3.

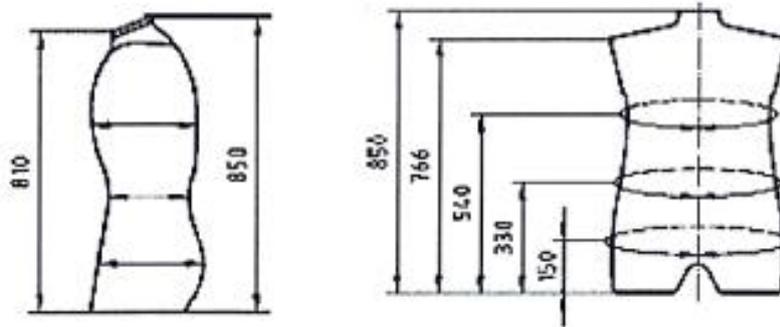

Fig. 3. Dummy dimensions

On the centre pivot, the dummy will be provided with a channel to connect the Sheffield fake head to the breathing machine. Both the dummy and the breathing machine will be placed on the transport carrier, which will be effected by overlapping two platforms, the lower one will provide the space needed for the breathing machine, while the dummy will be fitted on the upper platform. The upper platform shall be equipped with a mechanism allowing the dummy to free fall on a distance of 150 mm. As the upper part of the carrier will be exposed to high temperatures and the breathing machine will be placed on the lower part, between the two floors there must be a bridging made of flame proof heat insulating material. The transport carrier shall be equipped with four wheels positioned on two axes to allow movement along the tread to the preheating furnace and e burner bank (SR EN 137_2008)

The preheating furnace has the purpose of providing a homogeneous temperature of 90°C around the dummy. The heating is done through air circulation, the heat source power must be chosen so as to allow the return to test temperature within 60 seconds from the moment that the dummy was put in.

Figure 4 shows the positioning of the dummy in the preheating furnace and the isolation of the carrier's lower level from the inside of the furnace.

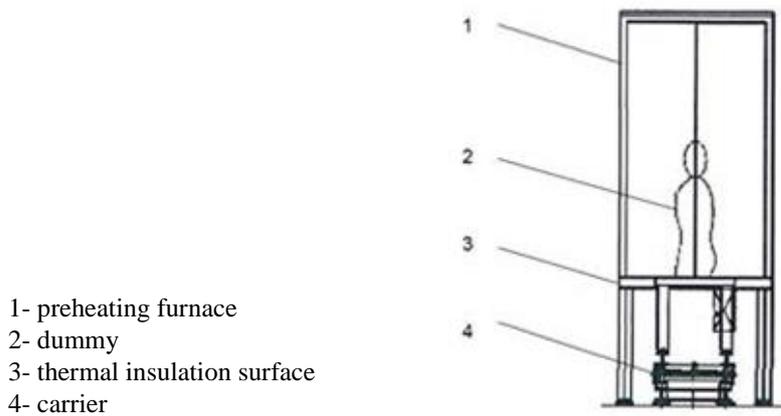

Fig. 4. Dummy's carrier inserted into the furnace

After 15 minutes of exposure to 90° C in the furnace, the dummy is transported with the carrier to the centre of the burner. This is made in the form of two burner batteries composed of four lines of linear burners spaced at 190 mm from each other, in front of and behind the dummy, each having 900 mm in length. The fuel used is propane of at least 99.5% vol. injected along with air. In order to reach a temperature of 90-100°C measured at 250 mm of the burner, an optimal air and gas mixture must be achieved in dynamic mode, propane being injected at a pressure of 1.5 bar through a nozzle of 4.5 mm and the compressed air at 5 bar through a 6 mm nozzle. The ignition system must ensure simultaneous ignition of the burner batteries and insertion of the dummy in between the burners must occur no more than 30 seconds after leaving the furnace. Details on making the burner battery are shown in figure 5.

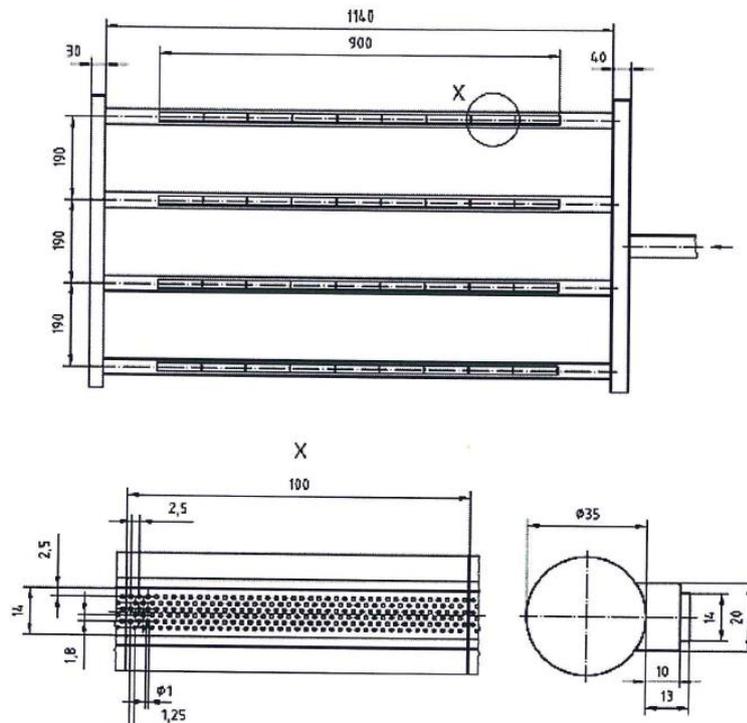

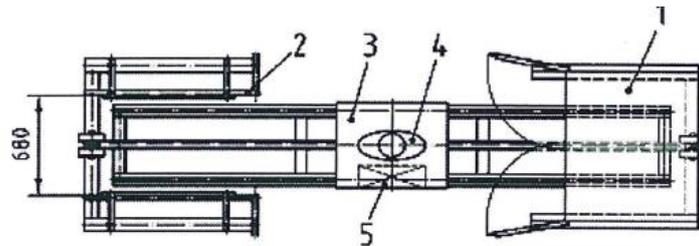

Fig. 5. Details on making the burner battery

After a 10-second exposure to flame, the possible persistence of fire on the device components is monitored to establish if the appliance meets the flame proof conditions. The apparatus is then subjected to a mechanical shock by releasing the locking mechanism of the upper platform on which the dummy is fitted and by free fall thereof at a height of 150 mm. Figure 6 shows a top view of the test bench elements

- 1 preheating furnace
- 2 burner
- 3 carrier with mechanical shock test mechanism
- 4 dummy
- 5 breathing machine

Fig 6 top view of the test bench

Throughout the entire test, the breathing apparatus is connected to the breathing machine which has been set at a rate of 25 cycles of breath / minute with 2 liters of air / cycle and respiratory resistance is monitored (Ilie et al, 2017). When analysing the breathing resistance graph the first three respiratory cycles after the free fall will be excluded.

Conclusions

The use of self-contained breathing apparatus, based on compressed air, requires, prior to placing on the market, their certification.

One of the certification requirements is high temperature testing by exposing the device to a temperature of 900°C for 10 seconds.

High temperature testing involves placing the self-contained breathing apparatus in the heated oven at 90°C for 15 minutes, flame exposure with propane-air mixture for 10 s, and the shock resistance test by free fall at a height of 150 mm.

In order for the apparatus to be tested at high temperature to pass the test, it is necessary that its components do not allow flame persistence for more than 5 s after the burner is switched off and that the breathing resistance monitored by the breathing machine does not change beyond the maximum permissible value.

Abstract

Exposure to physicochemical pollutants in the work environment leads to occupational illnesses. Workers working in the fields of production of raw materials, energy, material goods, etc. are exposed to these noxious substances over a long period of time. Long-term exposure to many pollutants may have a cumulative effect on the worker. In order to quantify the occupational exposure generated by cumulative exposure to noxious substances, it is necessary to determine the exposure level for each harmful substance. In this respect, the current paper presents a case study, where workers carry out their activity under difficult working conditions in an environment where physicochemical pollutant concentrations exceed limits allowed by national / international legislation. Also, the paper presents the monitoring of physicochemical pollutants in order to be able to quantify the exposure of workers and their health status. Physical and chemical monitored pollutants (omnipresent in industry) are: noise, vibrations, particulate matter and chemicals used in / generated by the workplace atmosphere (CO, CO₂, NO_x, etc.). Disabilities resulting from the exercise of a job or profession, caused by physical and / or chemical damaging factors characteristic of work places, are difficult to diagnose in the absence of systematic monitoring of health, as causality between factors that generated occupational illness must be assessed, these being usually determined by a combination of determinants (main factors) and biasing (secondary) factors. The effects of exposure to physicochemical pollutants on health of workers are presented both quantitatively by measuring the level of exposure and from the situation of occupational illnesses point of view.

Keywords: hazardous conditions; occupational pollutant; occupational illness; exposure; risk

1. Generalization

Occupational diseases can be defined as: „those disorders that result from the exercise of a profession or occupation caused by physical, chemical or biological factors, features of the workplace and the overworking of various organs or systems of the body in the work process“. (Toma, 1985)

In order to be considered "occupational disease" or "occupational disease", the condition in question must meet certain characteristics such as:

- The onset of illness is the result of the exercise of a profession or profession;
- Physical, chemical or biological harmful factors are characteristics of the workplace;
- Overworking of different organs or systems is characteristic of the work process.

The most important feature of the causal relationship between exposure to pollution and occupational disease is the complex nature of the factors that generate them, most often the diseases are not caused by a single generator, but by a set of factors.

Within the generating factors (etiological) it is noticeable:

- a major or determinant etiological factor;
- a set of favorable or secondary etiological factors.

E-mail address: sorin.simion@insemex.ro.

In professional pathology, the determinants (main) or the favored (secondary) factors belong to the working conditions, being generated by the existence of professional harm / noxae.

Working conditions consist of all the factors existing at the workplace, namely:

- physiological factors such as the intensity of physical work (predominantly muscular) or predominantly neuropsychic and sensory, duration of work, rhythm of work, monotonous work, etc.
- factors of the working environment, such as: physical factors of the working environment (temperature, humidity, speed of air currents, presence of noise and vibrations, electromagnetic radiation, etc.), chemical factors (toxic chemicals in the work environment) physicochemical factors (professional powders), biological factors (microbes, parasites, etc.)
- Ergonomic factors are determined by the human-machine relationship being a resultant between a series of elements with physiological characteristics (static effort, dynamic, working position, etc.) and features of the working environment (noise, vibrations, etc.) for example, the driver and vehicle relationship that determines a static work position with high neurophysical demand but also exposure to noise, vibration, chemical poisoning from internal combustion engines, etc.
- psychosocial factors such as teamwork, motivation of work, positive / negative appreciation, subordinate relationship, etc.

When one or more factors defining working conditions have a negative effect on health and / or work capacity, and thus become factors generating occupational illness, they are defined as occupational harm / noxae. (Toma, 1985)

2. Case study on occupational exposure to physicochemical pollutants

The investigations carried out in this paper have been carried out on a steelwork the subject of activity of the company is the production of ferrous metals in primary and ferroalloy forms - CAEN code 2410.

The technological flow is of modern design based on the production of steel in furnaces.

The electric steel factory has a stream of in-line production, so it exists:

- - storage area on assortments of scrap iron;
- - berthing area of scrap iron;
- - the furnace loading area with the old iron in the bonnet;
- - the steel making area in the electric furnace;
- - the area of the steel treatment in the pot;
- - the area of the steel depot.

Description of the activities carried out by the factory staff:

- loading the oven with a scrap iron;
- handling and transportation of raw materials and materials (lime, ferro-alloys, slag foaming material, furnace maintenance materials, etc.)
- melting scrap iron in the oven;
- dosing and administration of the addition materials in the oven and pot;
- injecting oxygen and slag foaming materials into the oven;
- kiln sampling, primary chemical analysis, slag analysis, temperature;
- assuring the furnace with casting pots for the purpose of download;
- assuring the oven with slag pots;
- emptying the slag pots and evacuating the slag from the hall;
- evacuating the liquid steel from the furnace to the casting pot;
- transporting the liquid steel pot to the LF plant;
- treatment of steel in the pot at the LF plant (steel alloy - through corrections necessary for final chemical analysis);
- sampling for final chemical analysis;
- slag cleaners, steel blasts, flue gas extraction systems, smoke channels, etc.
- changing the electrode columns from the furnace and LF installation;
- servicing the electric furnace (EBT) and the steel treatment plant (LF) by means of cranes;
- transporting the casting chamber filled with liquid steel in order to be taken over by the crane from the continuous casting machine;
- placing the casting pot on the rotary tower of the MTC;
- providing the necessary materials for the continuous casting process (protection tubes, casting powders, etc.);
- casting of steel into profiles (round tags);
- installing / removing the drawer to open the pot;
- cutting, hot marking, cooling and evacuation of tags;
- rewriting tags, marking by dyeing, tagging and tagging;
- maintenance of electrical, mechanical, hydro-thermal, etc., of all the machinery from the steelworks and of the continuous casting machine

In order to monitor exposure to professional pollutants, INCD INSEMEX Petroșani has made determinations for the main occupational noxious substances in the work environment.

The manufacture of steel products mainly generates exposure to the following professional noises, noise, vibration, dust, carbon monoxide and carbon dioxide.

The method of determining the method of determination of these occupational harm / noxae is the direct method of measuring devices with numerical display.

The results of the determination of the occupational harm / noxae in accordance with the regulations in force are presented in Table 1. (GD 493/2006, GD 1876/2005, GD 359/20015)

Table no. 1.

Work place	Noise Exposure limit (87dB(A) GD 493/2006	Global vibrations Exposure limit (1,15 m/s ²) GD 1876/2005	Breathable breathing particles from the suspension Exposure limit (5 mg/m ³) GD 359/2015	CO ₂ Exposure limit (9000 mg/m ³) GD 359/2015	CO Exposure limit (30 mg/m ³) GD 359/2015
Electric Furnace (EBT)	105.5	1.82	1.15	534	3.21
Steel treatment plant (LF)	91.6	1.01	0.16	320	1.23
Pouring potting sector	90.4	1.62	7.52	620	1,65
The steel vacuuming plant	91.6	1.25	2.4	320	1.25
Continuous casting workshop	90.2	1.59	1.25	420	1.22
Flue gas capture and treatment plant	87.5	1.55	8.71	250	1.02
Crystallizing hall	90.8	1.02	6.12	620	1.23
Crane bridge cabine	84.2	1.25	25.15	836	2.47
Masonry formation	95.6	2.98	13.17	906	1.23

Exceeding the level of exposure to these noxes generated by the individual and / or cumulative effect of a series of occupational or profession related illnesses over a 5-year monitoring period are presented in table .2.

Table no. 2.

Disease related to the profession	Causal professional factors	2017	2016	2015	2014	2013
Cardiac disorders (HTA CICD) (pers.)	Noise, vibration, temperature, high caloric radiation, increased neurophysiological stress	114	106	113	128	100
Respiratory disorders (pers.)	Dusts, irritating gases, organic solvents	31	31	31	18	6
Hearing disorders (pers.)	Noise, chemical harm / noxae	4	12	12	6	8
Osteo-muscular joint disorders (TIW days)	Unfavorable microclimate, vibration, increased effort, inconvenient posture, mechanical traumatic effect	457	401	349	264	420

In conclusion, there is a decrease in the number of occupational diseases as a result of the implementation of the plans for measures regarding the reduction of the occupational exposure to physicochemical risk factors and the awareness of the employees regarding the use of PPE and observance of the working instructions. Also, the result of medical assessments demonstrates that in these jobs activities are carried out in the presence of physicochemical noxes, which indicates a risk control, without being eliminated due to the characteristics of the activities carried out (Băbuș, 2011).

3. Conclusions

Following the determination of the noxiousness in the workplaces in order to assess their impact on the health status of the personnel involved in the steelworks, the following conclusions were drawn:

- Periodic measurements of professional pollutants are widely used to confirm or deny their existence in their work environment. Occupational exposure monitoring is mainly performed to verify the exposure level, respectively to comply with the limit values set by applicable legislation and to establish a plan of measures to reduce occupational harm / noxae.
- The permanent medical surveillance carried out by the labor medicine cabinets within the compulsory medical control quantifies the number of occupational illnesses and occupational harm / noxae susceptible to its occurrence.
- Quantification of occupational exposure and their characteristics helps the employer determine the best methods to reduce exposure to them.

- There is a decrease in the number of occupational illnesses as a result of the implementation of the action plans on the reduction of occupational exposure to physicochemical risk factors and employee awareness of the use of PPE and the observance of the working instructions
- Conclusively, the steelworks presented above should continue to modernize and optimize the production process by implementing new technologies that provide increased protection for workers. Due to the specific nature of the activity carried out, it is not possible for the production process to take place automatically without the direct participation of the worker. This requires the adoption of a system that integrates several variables, namely: competitiveness, economic development, health and safety at work, through differentiated approaches, short, medium and long term.

Abstract

Personal protective equipments used by firefighters, builders or climbers includes so called carabiners made of carbon steels. In use, those connecting components - carabiners - are subject to corrosion, so the corrosion protection is requiring, such as anticorrosion phosphating. This study aims to elaborate a proper phosphating technology which two types of additives, a series of metal cations, on one hand, and surface active agents, on the other hand, with multiple roles in the nucleation processes, allowing to obtain compact layers, homogen and adherent to substrate. It also highlight the presence, form and structure of the phosphate layer.

Keywords: Personal Protective Equipment, Carabiner, Surface Structure, SEM-EDX, Thin Layer, Zinc Phosphate

1. Introduction

Any type of equipment used by workers to keep them safe from dangers can be considered personal protective equipment (Babut et al., 2011; Bejinariu et al., 2017a; Ivascu and Cioca, 2014).

Depending of the area it protects, the personal protective equipment is classified in head protection (hard hats), foot protection (boots), hearing protection (earplugs), hand and arm protection (gloves), eye and face protection (goggles), respiratory masks and body protection (harnesses).

If workers are operating in areas where risk of falling is present and technical measures do not provide adequate protection, workers must use harnesses or safety belts, including necessary accessories, such as safety ropes, hooks, etc. (Babut and Moraru, 2018; Bejinariu et al, 2017b; Darabont et al., 2017a; Moraru et al., 2013).

Full body harness contains: a waist belt, generally made of polyamide straps that are sewn and connected by metal buckles, positioning rope, descender, rope grabs and lanyard assembly (Blair et al., 2005; Bright, 2014).

There are two types of connectors used at fall arrest equipments: carabiners and hooks.

The carabiner is a small metallic shackle with an inward opening gate used as a link between climbing equipment and anchoring point.

Due to their importance for personal safety, these are used in various fields such as: caving, arboriculture, industrial rope work, sports mountaineering, canoeing, fire fighting, etc.

In order to be used in safe condition, the carabiner must be compact, easy to handle and possess good chemical resistance and mechanical properties (Darabont et al., 2017b; Mihai-Adrian et al., 2017).

In this paper we aim to improve the anti-corrosion properties of the material used at carabiner's body, the components of a carabiner are shown in Fig. 1.

* Constantin Baciu. Tel.: +4-072-996-9619
E-mail address: constantin_baciu@yahoo.com

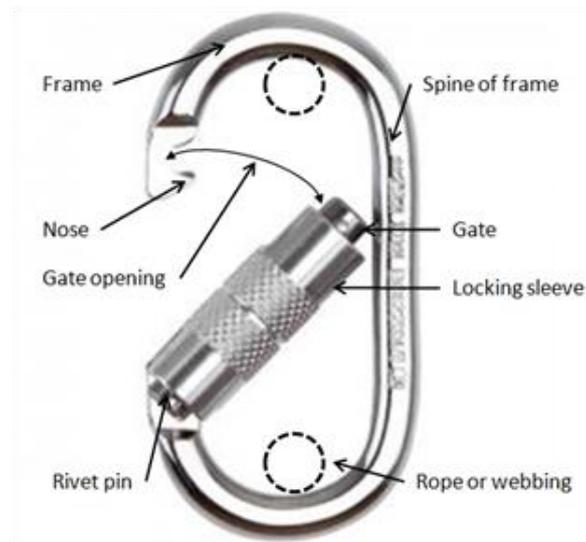

Fig. 1. Carabinier components

The most commonly used materials for carabiners manufacturing are aluminum alloys and different types of steels (Blackford, 2003).

Aluminum carabiners are used especially by rock climbers because, in this situation, the carabiner weight is the most important factor. Instead, steel carabiners are used usually by firefighters, where the refractory properties and mechanical strength comes first (Evans and Truebe, 2015; Scott, 2008).

The characteristics that a carabiner must possess are specified in the following standards: EN 362 Personal protective equipment against falls from a height. Connectors, EN 12275, Mountaineering equipment - Connectors - Safety requirements and test methods, UIAA 121, Mountaineering and Climbing Equipment - Connectors, Union (EN 362, 2004; EN 12275, 1998; UIAA 121, 2004).

EN 362: 2004 is the only standard that includes specifications about corrosion resistance properties of the carabiner, according to this the presence of corrosion on base material is not accepted, but the presence of some oxides stains is acceptable (EN 362, 2004).

In order to improve corrosion resistance, this study aims to elaborate a proper phosphating technology which two types of additives, a series of metal cations, on one hand, and surface active agents, on the other hand, with multiple roles in the nucleation processes, allowing to obtain compact layers, homogen and adherent to substrate. (Lazar et al., 2017; Sandu et al., 2010) The presence, form and structure of the phosphate layer is also highlighted.

2. Phosphating process

Among metal surface corrosion protection general techniques, phosphating has an important place (Buzea et al., 2009; Nica et al., 2012; Sandu et al., 2012). The phosphating process consists in forming of a protective film of insoluble phosphates on the metal surface. This process is cheap and simple because it doesn't involve expensive raw materials, complex machinery and highly qualified personnel (Bejinariu et al., 2010; Earar et al., 2015).

Depending on the environment and process conditions, the phosphate coatings are of two kinds, namely crystalline and amorphous. The crystalline coating present greater interes for industrial application, this having ferrous substrates such as carbon steel, low alloy steel and cast iron (Burduhos Nergis et al., 2018; Nedeff, et al., 2013; Sandu et al., 2013).

For carabiners manufacturing, specialized plants like Concezione Articoli Montagna Premana (CAMP) frequently use the 1045 steel, according to the SAE J1397-1992 standard, with the chemical composition shown in Table 1 (SAE J1397, 1992).

This study was made on steel samples equivalent to 1045 steel, namely C45 steel, which chemical composition according to the standard SR EN 10083-2 is presented in Table 2 (SR EN 10083-2, 2006), and samples chemical composition obtained by EDAX means is shown in Table 3.

Table 1. Chemical composition of 1045 (SAE J1397, 1992)

The phosphating process of C45 samples consist in multiple main and secondary stages, which are presented in Fig. 2.

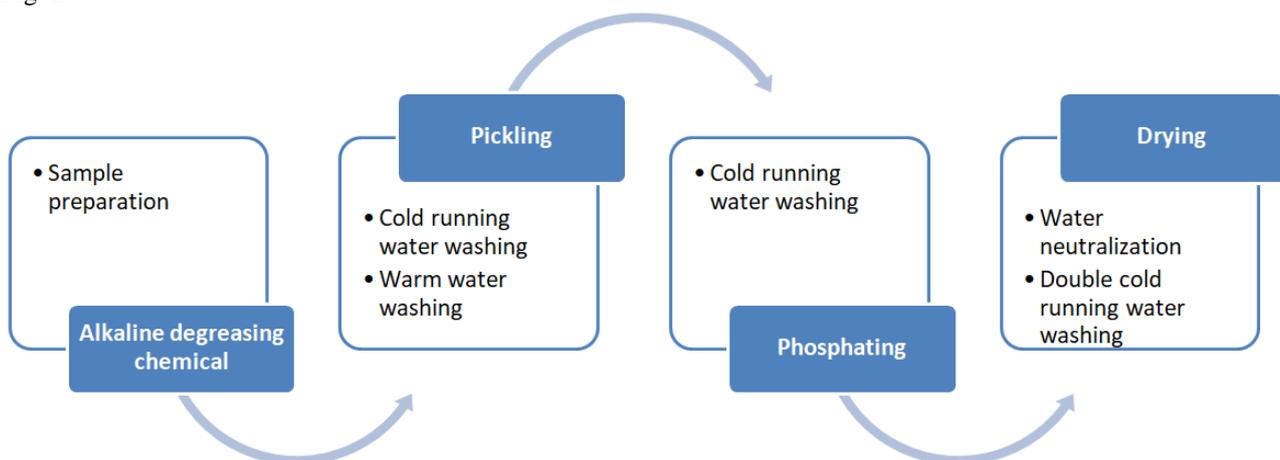

Fig. 2. Phosphating process staages of C45 samples

After crystalline phosphating, a layer of zinc phosphate tetrahydrate $Zn_3(PO_4)_2 \cdot 4H_2O$ is formed on the C45 steel samples surface, metallic bonded to the base material. The general surface of the simple and phosphated C45 steel samples is shown in Fig. 3.

Fig. 3. General surface of studied sample (a) Initial sample; (b) Phosphated sample

For the alkaline degreasing bath, the following components were used: sodium hydroxide (NaOH), sodium carbonate (Na₂CO₃), trisodium phosphate (Na₃PO₄·10H₂O), sodium silicate (Na₂SiO₃·9H₂O) and surfactant detergent. In the first main stage the samples were kept for 10 minutes in the degreasing solution heated to 85 °C.

The solution used for pickling of C45 steel samples consists of: hydrochloric acid (HCl), hexamethylenetetramine (C₆H₁₂N₄) and sodium sulphate (Na₂SO₄·10H₂O). The pickling time was 20 minutes at ambient temperature.

Crystalline chemical phosphating of C45 steel samples solution, was obtained from the following components: phosphoric acid (H₃PO₄), nitric acid (HNO₃), zinc (Zn), sodium hydroxide (NaOH), sodium nitrite (NaNO₂) and sodium tripolyphosphate (Na₂P₃O₁₀). Samples were immersed for 30 minutes in the solution at 90 °C temperature.

The phosphating installation used in this study is shown in Fig. 4.

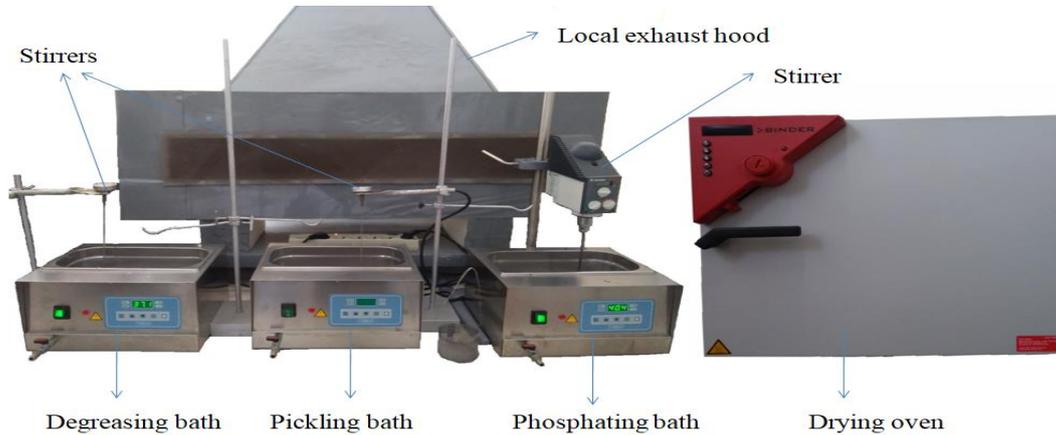

Fig. 4. General view of phosphating installation

Warming up of degreasing and phosphating solutions was done in DIGIBATH-2 Raypa digital thermostats. The agitation of the degreasing and pickling baths is carried out by means of two SIEMES 1AF 2210 0A stirrers with 220V electric motors, and the phosphating solution agitation was carried out using a R2120 Heidolph stirrer at a speed of 500 rpm. Samples drying after crystalline chemical phosphating was carried out using a APT.line™ ED (E2) model oven set at a temperature of 150 °C.

The zinc phosphate layer obtained on the C45 steel samples surface is shown in Fig. 5.

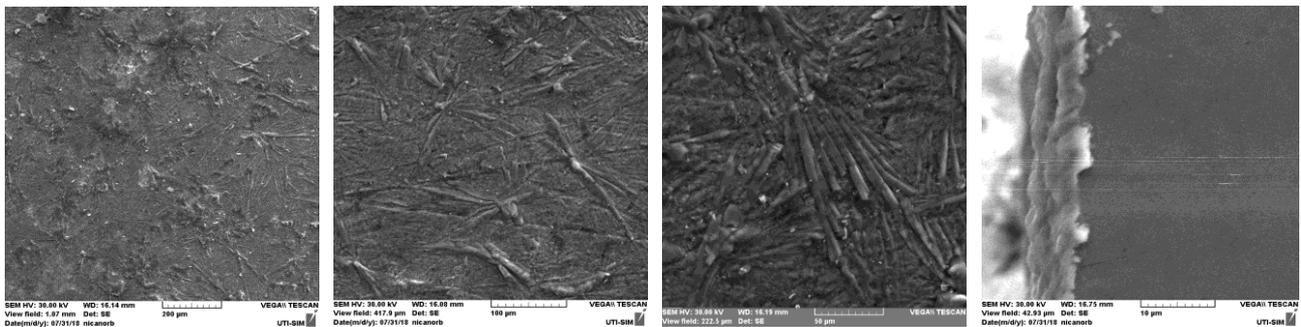

Fig. 5. Microstructure of the Zn phosphate layer obtained by means of scanning electron microscope, a) SEM microstructure, 200 μm; b) SEM microstructure, 100 μm; c) SEM microstructure, 50 μm; d) SEM microstructure, 10 μm.

3. Conclusions

Phosphating has been established as an intelligent solution to improve the corrosion resistance of carbon steel carabiners used in corrosive environments such as caving, navigation, construction and rescue operations.

The fine, uniform and homogeneous crystalline structure of the phosphate layer has also been achieved thanks to the high degree of surface cleaning by preliminary degreasing and pickling which also has the role of surface activation for zinc phosphate film formation by conversion.

The microstructure of the phosphate layer presents high and low areas, with intergrowth dendrites, the crystallinity of the phosphate layer being provided by sodium nitrite (NaNO₂) from the phosphating solution.

Abstract

It is well known the fact thus specialized type of shackles - carabiners – used at personal protective equipment work in harsh environment conditions such as high thermal variation environments for firefighters and mountain climbers, high corrosion environments for builders and seafarers. Therefore, a high corrosion resistant material must be used or a material corrosion protected, in present study, by phosphating. The aim of this study is to highlight the chemically deposited phosphate layer on connecting components surface – carabiners – made of carbon steel, by analyzing corrosion resistance of phosphate layer has also been analyzed.

Keywords: Personal Protective Equipments, Carabiner, Corrosion Test, SEM-EDX, Zinc Phosphate

1. Introduction

Fall protection equipment is required when workers perform their workload at heights and when the risk of falling is present (Babut et al., 2011). The lack of proper equipment, use of inappropriate or outworn equipment or the gear misuse can lead to high working accidents (Bejinariu et al., 2017a; Darabont et al., 2017a; Moraru et al., 2013). "Personal protection against falls from heights" means all the elements and components mounted in a certain order, with the purpose to prevent falls from heights (Darabont et al., 2017b; Earar et al., 2015).

The heights fall protection systems components are: anchor devices (this equipment is designed to provide an anchorage point from which a safety rope or a retractable stop can be mounted), positioning belts (these components are part of safety belts used for worker positioning during job activities and should support the person while using both hands), complex belts (keep under control the person movement by positioning and suspending the worker during activities), fall arrest block (it is a device that can be mounted on flexible anchor supports or rigid elements located above the work area) and connectors like hooks or carabiners (Babut and Moraru, 2018; Bejinariu et al., 2017b; Mihai-Adrian et al., 2017).

The carabiners are small metallic links with an inward opening spring gate used as a connector between climbing gear (harness) and anchor points during climbing. From the locking mechanism point of view the carabiners can be divided in: non-locking gate (with solid gate or wire gate) and locking gate (magnetic gate, twist-lock, double gate, screw gate, etc.) (Blair et al., 2005; Buzea et al., 2009; Evans and Truebe, 2015).

Due to their wide and various using areas, such as firefighting, canoeing, caving or construction, carabiners come into contact with different corrosive environments (salt water, lye used by firefighters). In these areas, the main material used in making carabiners is steel, as it has good mechanical and refractory properties. The most used steels for carabiners are and stainless steels. The main advanced of stainless steel are corrosion properties, but carbon steels possess better wear resistance (Blackford, 2003; Bright, 2014; Nedeff et al., 2013).

According to SR EN 12275 standard, a carabiner includes the following components: frame, nose, gate, locking sleeve and pins, as can be seen in Fig. 1.

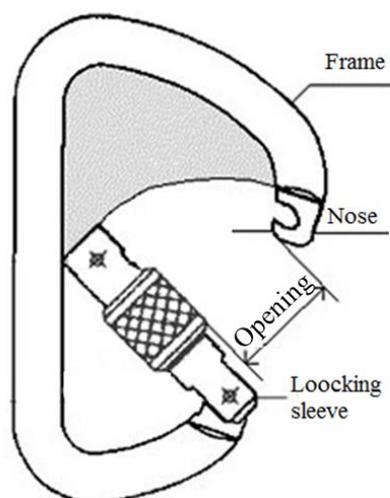

Fig. 1. Schematic presentation of a carabiner components (SR EN 12275, 1998)

The aim of this paper is to highlight the chemically deposited phosphate layer on connecting components surface - carabiners - made of carbon steel, this analysis being made by determining the corrosion resistance of phosphate layer.

2. Phosphated layer analysis

Phosphating is a chemical process which consists in the reaction between a metallic part surface and an acidic solution. By immersing the parts in acidic solutions, a solid phosphate surface bonded to metal is formed by chemical reaction with the base material. This layer is finely crystalline and difficult to dissolve (Bejinariu et al., 2010; Sandu et al., 2010, Sandu et al., 2012).

The phosphating process comes as a solution to improve the corrosion resistance of steel carabiners. The samples analyzed in this paper are made of C45 steel, a similar material from the chemical composition and properties point of view with the most used steels used in carabiners manufacturing (SR EN 10083-2, 2006). Fig. 2 shows the initial samples and the phosphated samples.

Fig. 2. (a) initial samples; (b) phosphated samples

Corrosion resistance analysis

Corrosion is the physico-chemical, spontaneous and irreversible destruction of metals or alloys under the chemical, electrochemical or biological action of the environment. Corrosion processes depend on type of metal and corrosive environment, pressure and temperature conditions and static or dynamic conditions of the corrosive environment (Lazar et al., 2017; Sandu et al., 2013; Scott, 2008).

Depending to the environments, there are several factors that can influence the corrosion resistance of the carabiners material. The firefighters use steel carabiners especially due to their refractory properties. In this case, the most important corrosive factor is the used extinguishing solution (Burduhos Nergis et al., 2018; Nica et al., 2012).

In this work we studied the instant corrosion of C45 steel and C45 phosphated steel samples in a fire-extinguishing solution. A VoltaLab 40 potentiostat (PGZ301) and a three-electrode cell were used to perform the test.

The corrosion potential of corrosion current zero, $E(I = 0)$, Tafel slopes (b_a and b_c), polarization resistance (R_p), corrosion current density (J_{cor}) as well as overlap of Tafel curves were evaluated by means of VoltaMaster 4 software.

An example of assessing the instantaneous corrosion parameters for uncoupled alloys is illustrated in Fig. 3. Since the alloy elements which dissolves are the iron and aluminum, the data used to calculate (equation 1) the corrosion rate were: for iron ($A = 55.85 \text{ g/mol}$, $z = 2$ and $p = 7.8 \text{ g/cm}^3$) and for aluminum ($A = 26.98 \text{ g/mol}$, $z = 3$ and $p = 2.7 \text{ g/cm}^3$).

In Fig. 3, the analyzed area was ± 80 mV from E_{cor} and the linear segment was 25 mV on each side of the polarization curve (cathodic Tafel region and anodic Tafel region).

$$v_p = 3,27 \cdot \left(\frac{A}{z}\right) \cdot \frac{J_{cor}}{\rho} \tag{1}$$

where: v_p is penetration rate;
 A/z – the electrochemical equivalent of the corroded metal (g/val);
 ρ – metal density (g/cm³).

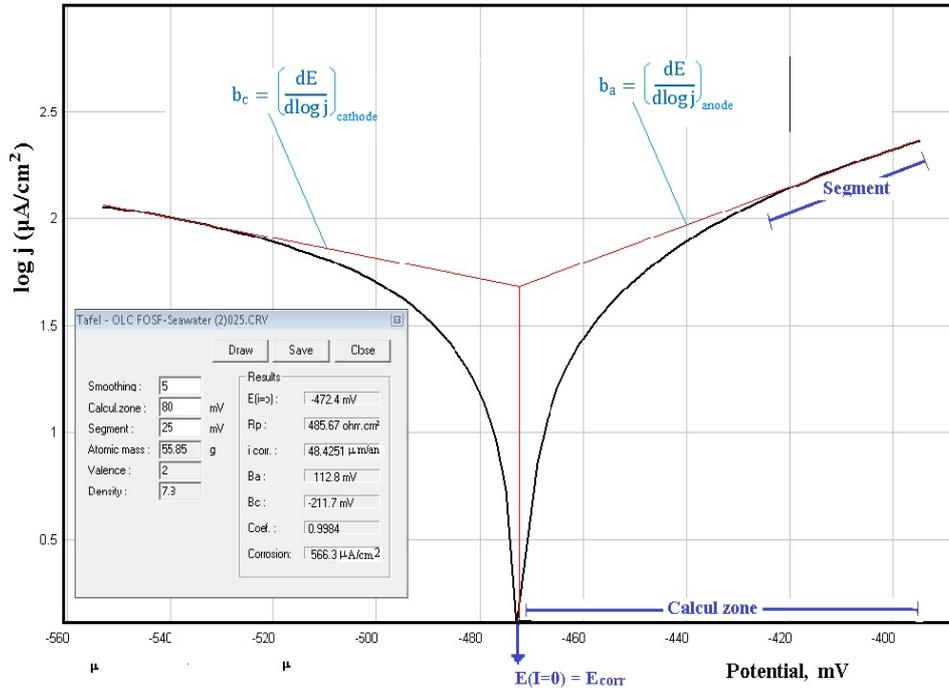

Fig. 3. Evans diagram and explanation

In this study the analyzed area was ± 120 mV from E_{cor} and the linear segment was 20 mV.

Linear polarization curves in fire-extinguishing solution and sea water for two types of steels and aluminum samples were recorded and processed in Evans diagram in order to evaluate the parameters of the instantaneous corrosion process: the corrosion potential ($E_{cor} = E(I=0)$), polarization resistance (R_p), corrosion current density (j_{cor}), Tafel slopes (b_a and b_c) and corrosion rate (v_{cor}). The results are shown in Table 1 and Table 2.

Table 1. Instantaneous corrosion process parameters of analyzed samples in fire-extinguishing solution

Corrosion environment	Fire-extinguishing solution		
	C45	Phosphated C45	Duralumin
Alloy	C45	Phosphated C45	Duralumin
$E(I=0)$, mV	-622	-472	-576
R_p , Ohm.cm ²	172,7	485,7	199,9
j_{cor} , mA/cm ²	0,144	0,079	0,136
v_{cor} , mm/year	1,684	0,924	1,595
b_a , mV/decade	53	161	44
b_c , mV/decade	1147	-440	-10360

Table 2. Instantaneous corrosion process parameters of analyzed samples in Black Sea water

Corrosion environment	Black Sea water			
	Alloy	C45	Phosphated C45	Duralumin
E(I=0), mV	-622	-472	-472	-584
R _p , Ohm.cm ²	172,7	485,7	485,7	222,1
j _{cor} , mA/cm ²	0,144	0,079	0,079	0,125
v _{cor} , mm/year	1,684	0,924	0,924	1,462
b _a , mV/decade	53	161	161	67
b _c , mV/decade	1147	-440	-440	1754

As shown in Equations 2 and 3, the corrosion current density and corrosion rate are inversely proportional to the polarization resistance.

$$J_{cor} = \frac{b_a \cdot b_c}{2.303(b_a + b_c) \cdot R_p'} \quad (2)$$

$$v_{cor} = \frac{A}{zF \cdot \rho} j_{cor} \quad (3)$$

where: A/z is the electrochemical equivalent of the corroded metal in (g/val);
 ρ – metal density (g/cm³);
 F = 96487 C/val.

Under these parameters, the corrosion resistance differences can be analyzed based on corrosion rate values. As can be seen, the phosphated C45 steel sample present higher corrosion resistance in both corrosive environments.

According to table 2 Black Sea water is much more aggressive to C45 nonphosphate and duralumin samples than to C45 phosphate samples, but the corrosion rate differences are not significant. Also, the cathodic Tafel region slopes are larger than those for the anodic Tafel region for all samples, probably due to the complexity of the cathodic process or to speed limitations caused by diffusion processes. However, in case of duralumin sample in corrosive environments, fire-extinguishing solution and seawater (especially), the anode slopes are much larger (in absolute value) than the cathode slopes, so the polarization curves present a non-Tafelian behavior in the Evans diagram, as can be seen in Fig. 4.

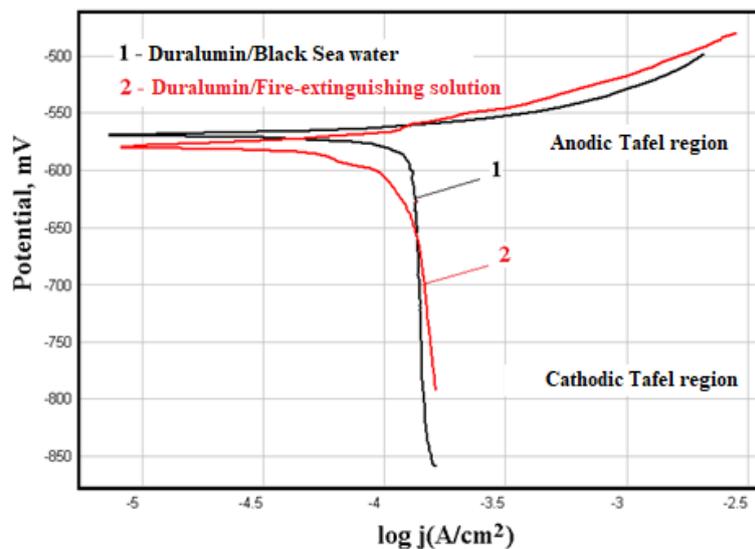

Fig. 4. The polarization curves for duralumin shows non-Tafelian behavior

This behavior is probably due to the existence of an aluminum oxides thin layer formed on the alloy surface, even in air, which restrain the diffusion reaction. In this case, in order to obtain the right corrosion parameters, both the calculation area and the linearity segment have been modified. In the case of C45 unphosphated samples the cathodic slope is much higher than the anode slope when tested fire-extinguishing solution. Another cause of these differences

can be explained by the simultaneous reduction of anode hydrogen and oxygen ions, processes favored by the lye alkalinity.

3. Conclusions

The environment characteristics and any solutions that come into contact with the carabiner can affect its corrosion resistance. Fire-extinguishing solutions used by firefighters can affect the mechanical properties of carbon steel carabiner. Treating the carbon steel surface by phosphating processes significantly improves the corrosion resistance of thus parts.

The phosphated film, zinc phosphate obtained, has anticorrosive protection as main application but can also be used as an anti-seize solution for friction surfaces and as a substrate for dyeing.

Increase in the security quality in use of professional pyrotechnic articles falling in category F4

Cristian Radeanu*, Attila Kovacs, Daniela Rus, Ilie Ciprian Jitea, Gabriel Dragos Vasilescu

National Institute for Research and Development in Mine Safety and Protection to Explosion-INSEMEX Petrosani, 32-34G-ral. Vasile Milea Street, 332047 Petrosani, Romania

Abstract

The importance of the specific risk assessment of the Category 4 pyrotechnic articles is based on the following considerations: (1) in relation to the F1, F2 and F3 category pyrotechnic articles, these products present a significantly higher level of risk due to the mode of operation and the potency of the explosive substance involved, requiring authorized personnel as a pyrotechnician; (2) the national regulations do not have explicit provisions for this type of high-risk product, and the implementation of the European Standards Harmonized with the 2013/29 / EU Directive offers the possibility of testing, evaluation or technical expertise appropriate to the level of current scientific knowledge. The tests were carried out on F4 category professional pyrotechnic products, using the updated test procedure, corroborated with the variation of the principle scheme for measuring and determining the main parameters.

Keywords: quality management security, pyrotechnic article for professional use, functional testing

1. Introduction

The importance of the specific risk assessment of the Category 4 pyrotechnic articles is based on the following considerations:

- in relation to the F1, F2 and F3 category pyrotechnic articles, these products present a significantly higher level of risk due to the mode of operation and the potency of the explosive substance involved, requiring authorized personnel as a pyrotechnician (Kovacs A., 2007);
- the national regulations do not have explicit provisions for this type of high-risk product, and the implementation of the European Standards Harmonized with the 2013/29/EU Directive offers the possibility of testing, evaluation or technical expertise appropriate to the level of current scientific knowledge (Covello V.T., Merkhofer M.W., 1993; Conte, Rubio, Garcia, 2011; Directiva 2013/29/UE, 2013).

Tests have been performed on category F4 pyrotechnical articles, using the updated testing procedure in conjunction with the principle schematic diagram for the measurement and determination of the impulse, of the ascension height (Leba et al., 2014), customized for the case where the angle of deviation in the $\beta_{1,2}$ horizontally plane is different from 0 and the video cameras are located at the same level as the launch point, thus determining a safe distance which corresponds to the condition of recording a maximum noise level (impulse) of 120 dB (A) at its upper limit (Cioara C., R. et.al., 2018; Kotus J, Kostek B, 2008). Equipment used for the determinations performed within INSEMEX testing facility, which have to reproduce the real conditions of use, have a measurement accuracy and a range of action with respect to the coverage range of the parameter range required to be determined, superior to those provided for the lower categories (PN 16 43 02 20, 2016-2017).

2. Considerations on the methodology for carrying out tests specific to pyrotechnic articles for professional use (category F4)

Tests for pyrotechnic articles for professional use (category F4) were performed on the basis of the PI-98 procedure entitled "Verification of the operation of pyrotechnic articles", by applying the methodology developed in accordance to the provisions of standard SR EN 16261-3: 2013, (Rus D., Vasilescu G, Kovacs A., et.al., 2017; Rădeanu Cristian, et. al., 2018).

* Corresponding author. +4-072-720-0773; fax: +40-254-545-277.
E-mail address: cristian.radeanu@insemex.ro.

The main tests/testing requirements for the sections covered by the applicable standard method focused on the following technical aspects (Pasculescu et al., 2014, and Pasculescu et al., 2015): construction and stability (external dimension of the article, caliber determination, gross mass determination); design-verification; angle of ascension and height of explosion (Pasculescu et al., 2012); measurement of the sound pressure level; extinction of flames; visual and sound inspections; mechanical conditioning; thermal conditioning; operating test (see the schematic diagram of Figure 1).

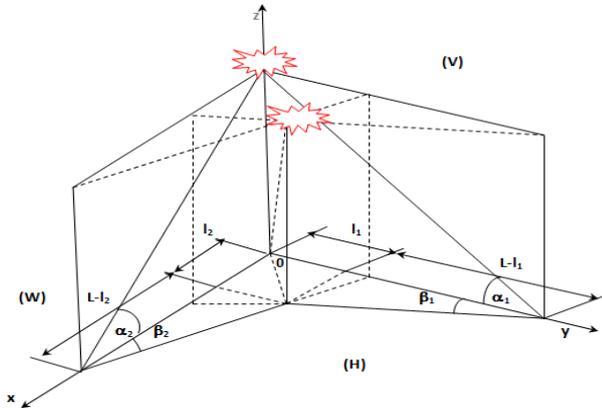

Fig.1- Principle diagram for the testing of pyrotechnic articles for professional use (category F4)

Having as hypothesis data: $L[m]$, $L_{A_{max}}[dB(A)]$; $\alpha_1=\alpha_2[^\circ]$; $(H)\perp(V)\perp(W)$, where (H),(V),(W) represent the three planes (horizontally, vertically and laterally), and the following mathematical calculus relationships provided in the applicable method standard: $h_1 = L \operatorname{tg}\alpha_1[(\cos\beta_2-\sin\beta_2)/\cos(\beta_1+\beta_2)]$, m; $h_2 = L \operatorname{tg}\alpha_2[(\cos\beta_1-\sin\beta_1)/\cos(\beta_1+\beta_2)]$, m; $H = (h_1+h_2)/2$, m; $r_S \geq 10^{\lg L - (L_{A_{max}} - LAI)/20}$, m.

Test have been performed on pyrotechnic articles in category F4 type MINORI BCS 3 "SHELL (figure 2) of Turkish origin, using the state-of-the-art test infrastructure within INCD-INSEMEX Petroşani testing facility, consisting of: video surveillance and results processing system consisting of 2 cameras mounted on a tripod type HDR-PJ530E which provides accurate precision for setting the ascension height, the extent of the burst effect and possible angular deviations from the optimal trajectory; DELL Inspiron 3537 laptop for information processing; stopwatch; anemometer; analytical balance; climatic room / oven; class 0 integrator sound level meter used for noise measurement, a tool which ensures precise determination of peak sound pressure values; shock apparatus; device for measuring effect, ascending, breaking and falling from a height; goniometer etc. Also, the data recording and processing system is well calibrated, being tested in an inter-laboratory testing program with similar European bodies, resulting in proper results, the deviation from the test mean being below 2%, (PN 16 43 03 20, 2016-2017).

Fig. 2- Professional pyrotechnic article (category F4) type MINORI BCS 3 "SHELL

3. Results obtained from tests performed on pyrotechnic articles for professional use (category F4)

The results of the measurements performed on samples of pyrotechnic articles for professional use (samples of products tested in the original form - E_{FI} , samples of products tested after E_M mechanical conditioning and samples of products tested after thermal E_T -conditioning), which were obtained with 2 video recording cameras (Camera 1 and Camera 2) are summarized in Table 1, (Rădeanu Cristian, et. al., 2018; Jitea I.C., Vasilescu G, Kovacs A., et.al., 2016; Jitea I.C., Kovacs A., Vasilescu G, et.al., 2017).

6.8.	Mechanical conditioning (g)	A	Weighing items before and after mechanical conditioning: 1: 208,28 – 208,25; 2: 199,2 – 199,16; 3: 206,87 – 206,83.
6.9.	Termical conditioning	A	Conditioned at 750 °C for 48 hours, no signs of ignition or chemical reaction.
6.10.	Functional testing	A	All products are functional.
6.10.3	Monitor the effect, the height of the ascent / explosion and the fall (m).	A	Height of effect: 88,73(E _{SI} -Purple); 104,785(E _{SI} -Blue); 108,9(E _{SI} -Green); 133,97(E _M -Purple); 102,84(E _M -Red); 90,94(E _M -Yellow); 109,815(E _T -Green); 97,705(E _T -White); 93,025(E _T -Blue). Effect Width: 56,28(E _{SI} -Purple); 61,95(E _{SI} -Blue); 54,24(E _{SI} -Green); 86,195(E _M -Purple); 57,23(E _M -Red); 49,215(E _M -Yellow); 68,44(E _T -Green); 52,19(E _T -Whit); 65,105(E _T -Blue). The height of the fall: 34,7(E _{SI} -Purple); 40,165(E _{SI} -Blue); 55,71(E _{SI} -Green); 49,69(E _M -Purple); 44,28(E _M -Red); 38,845(E _M -Yellow); 44,115(E _T -Green); 48,27(E _T -Whit); 25,45(E _T -Blue).

Note: E_{SI}-The initial form, E_M-The mechanical conditionig, E_T- The termical conditionig; The wind speed during the test was less than 5 m/s.

4. Discussion on the results from the testing of pyrotechnic articles for professional use (category F4)

The results obtained from the functional test for the MINORI BCS 3 "SHELL professional pyrotechnic articles aimed to determine the following parameters by means of the measurements (Camera 1 and Camera 2): A-breaking height (m), B-effect height (m), C-effect width (m), D-drop height (m), divergence angle (vertical). Figures 3 and 4 show the screen snaps of cameras 1 and 2 that capture the image sequences used to determine the previously specified parameters, (Cioara C., R., Kovacs Attila, Rădeanu Cristian, et. al., 2018).

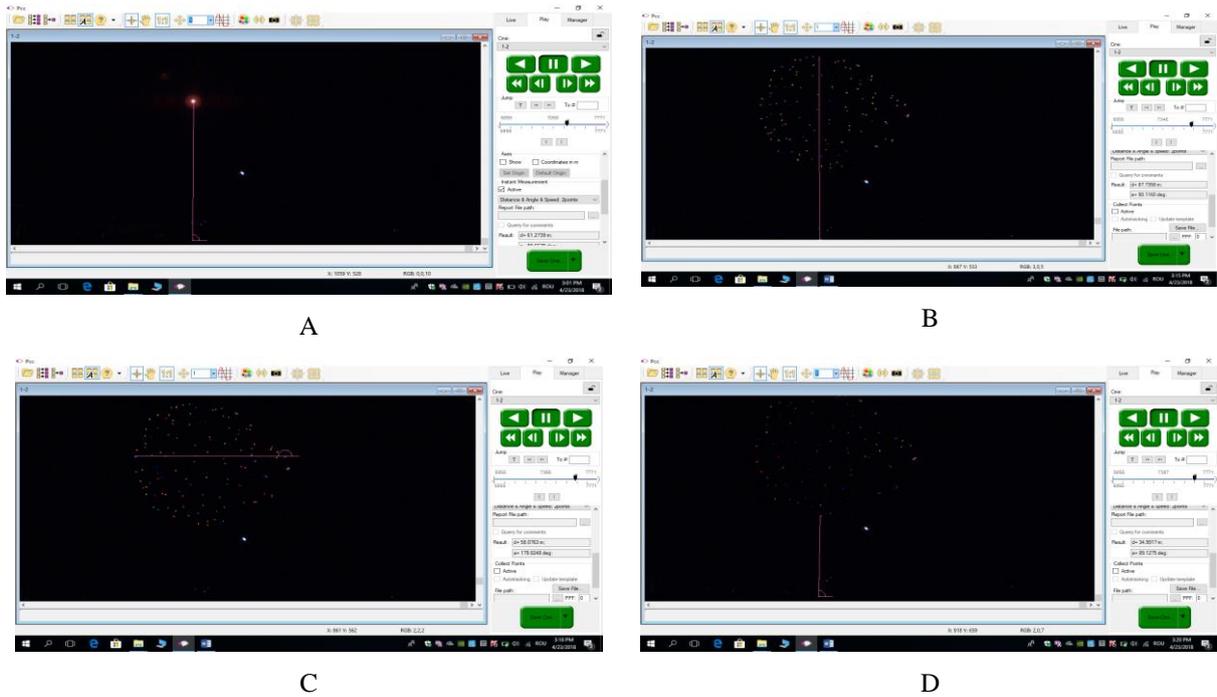

Fig.3- Camera images no.1 for the parameters of F4 category pyrotechnic articles (A-Breaking height, B-Height of effect, C-Effect Width, D-The height of the fall)

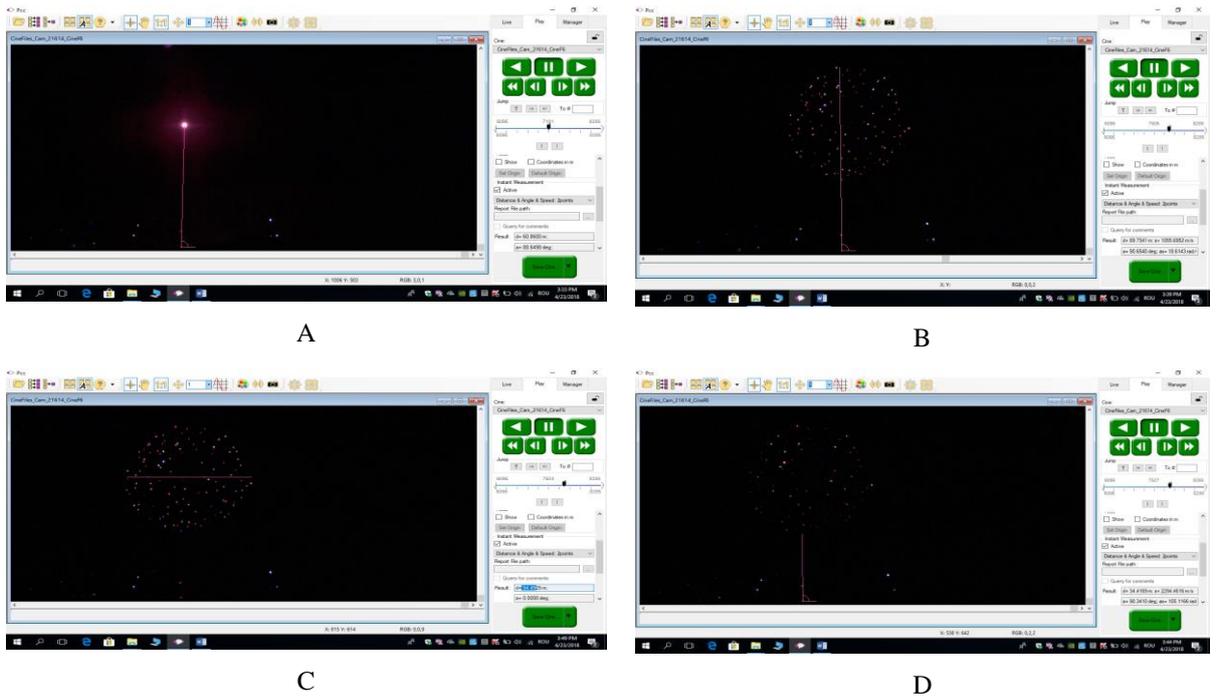

Fig.4- Camera images no.2 for the parameters of F4 category pyrotechnic articles (A-Breaking height, B-Height of effect, C-Effect Width, D-The height of the fall)

5. Conclusions

The implementation of the European standards family harmonized with the 2013/29/EU Directive within the framework of the testing laboratory for explosives for civil use and pyrotechnic articles LMEAP, part of the the RENAR accredited GLI-INSEMEX Group of Testing Laboratories provided the possibility of testing, evaluation / technically appropriate degree of compliance with the safety requirements for pyrotechnic articles for professional use (category F4).

Tests have been carried out on pyrotechnic articles of the MINORI BCS 3 "SHELL category of Turkish origin, using the state-of-the-art technical test infrastructure within the INCD-INSEMEX Petroşani testing facility, in order to obtain results with high confidence concerning the parameters tested.

From the analysis of the results obtained from the tests performed on the F4 type MINORI BCS 3 "SHELL pyrotechnic articles, it is highlighted that these products comply with the requirements of the applicable standard and the technical documentation of the product, which are constructive and operational.

Abstract

The decisive factor in the process of inspection of the pressure networks is determined by the correct choice of the method of carrying out the checks in order to observe with great attention the possible defects due to the physical damage resulting from the long use.

Emphasis is placed on the safety conditions of pressure equipment, which include minimum technical mandatory requirements for the periodic checking of pressurized, liquefied or dissolved gas networks.

Spectroscopy is a branch of physics that deals with the study of methods of obtaining spectra as well as measuring and interpreting them. The spectrum of electromagnetic radiation opposes its decomposition into a spectral apparatus (spectrometer) and consists of a sequence of images of the input slot formed by the different monochromatic radiation of the incident light.

Laser razors Z analyse all types of alloys: steel, stainless steel, aluminium, copper, nickel, titanium, cobalt. Wave Z spectroscopy has the best laser technology, it delivers high energy (5-6 mJ / pulse, 50 Hz) in one billionth of a second to generate gigawatt power densities - the key to a good plasma even and on the most refractory types of alloys.

The paper presents the optimal method of inspection and verification of compressed, liquefied or dissolved pressure networks, represented by the use of spectroscopy technology, in accordance with international principles and practices.

Keywords: Pressure network, spectroscopy technology, safety conditions, compressed gases, technical checks.

1. Introduction

Under pressure networks (fig. 1) are represented by the following categories of installations and equipment:

- Pipelines for gas, liquefied gases, pressurized gases, vapours and liquids whose vaporizing pressure at the maximum allowable temperature is at least 0.5 bar above atmospheric pressure. The pipes are tubular elements for transport of fluids when assembled in a pressurized system. These include pipes, pipe systems, piping, fittings, expansion joints and other pressure components.
- Cylinder containers, represented by any transportable recipient, in which a pressure greater than 0.5 bar can be achieved or developed in a fluid (under pressure compressed, liquefied or dissolved gases).
- Stable under pressure metal containers, installed / fitted on foundations or other stationary stands, containers installed on moving platforms or on their own mobile systems.

Fig. 1 Pressure networks

The cylinder container is an assembly consisting of:

- the under-pressure recipient having a capacity of 0.5 - 40 liters and serving for the transport and storage of compressed, liquefied or dissolved gases exposed to ambient temperature;
- the associated valves, which may be: filling and discharge devices, pressure relief devices, safety devices, measuring devices, pipe joints, fasteners fitted on container, fastenings and protective devices and protection to heat devices.

Stable under pressure metal containers are recipients having maximum permissible working pressures greater than 0.5 bar, as follows:

- containers containing 1st group gases (hazardous fluids: fluids defined as explosive, extremely flammable, highly flammable, flammable, where the maximum permissible temperature is higher than the ignition point, very toxic, toxic and oxidizing);
- containers containing 2nd group gases (steam);
- containers containing 1st group liquids;
- containers containing 2nd group liquids.

2. Technical control of pressure networks

Categories of cylinder containers to be periodically checked, Technical Prescription PT C 5, 2003:

- cylinder containers for pressurized, liquefied or pressure-sensitive gases made of seamless steel, welded non-alloy steel, non-alloy aluminium and aluminium alloys with a capacity of 0.5 - 40 liters inclusive;
- set cylinders for pressurized, liquefied or dissolved gases;
- fire extinguishers;
- cylinder containers for liquefied petroleum gases (LPG), made of steel, welded, part of the liquefied petroleum gas supply systems for motor vehicles.

Cylinder containers for compressed, liquefied or dissolved pressurized gases will be subject to technical control: periodically (at the due date indicated on the container), after a repair of the container, or whenever a fault is found that could endanger safety, Technical Prescription PT C 4, 2010.

The steps to be taken in the technical control of under pressure networks are as follows: checking the general condition of the cylinders, external control, internal control, mass and capacity control, hydraulic pressure testing, leakage testing and pressure gauge testing using the ultrasonic defectoscope, Technical Prescription PT C 6, 2010.

3. Hydraulic pressure test

Under pressure networks that passed outside, internal, mass and capacity control shall be subjected to hydraulic pressure test, Technical Prescription PT C 10, 2010.

Hydraulic pressure (P_v) testing of under pressure networks is carried out at pressures higher than the loading pressure (P_i), as follows (1):

$$P_v = 1.5 \times P_i \text{ (bar)} \quad (1)$$

The pressure test (fig. 2) will be carried out for each piece of equipment in specially designed spaces to provide protection for the other workplaces. Liquids used for the test shall not have a harmful effect on staff health or corrosive action on the material of the container and shall not pass from liquid phase to gaseous phase during testing, Ilie et al., 2014.

The pressure in the cylinder will have to increase gradually, continuously and without shocks (the pressure increase speed will not exceed 5 bar / minute). Seamless bottles will be kept at test pressure for 2 minutes and welded bottles for 5 minutes.

The testing facility shall be provided with two manometer connections. These will be fitted on three-way valves. The control gauge should be fitted to a fillet. The manometers used must be at least of the 2.5 precision class.

After the test pressure time has passed, carefully examine each cylinder.

The test shall be considered to be successful if no leakage, laceration or post-test are found and there are no deformations.

After the test, the pressure in the cylinders will gradually decrease without shocks, then the bottles will be completely emptied.

Cylinders with leakages, tears or deformations will be scrapped in such a way that they can no longer be put into circulation.

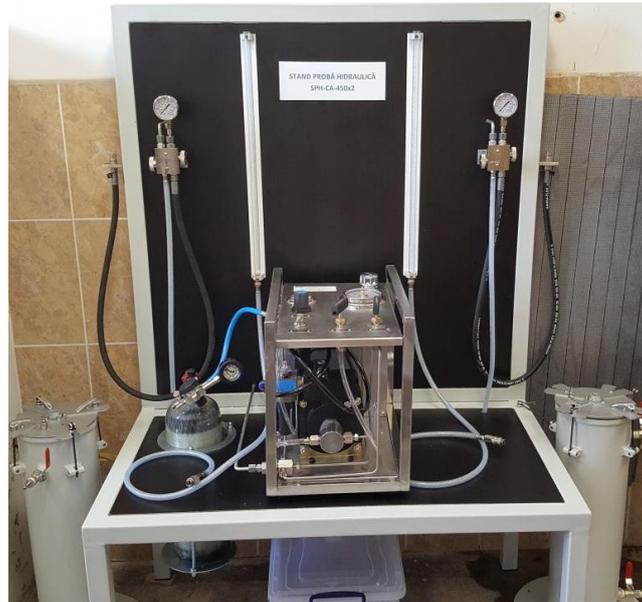

Fig. 2 Hydraulic pressure testing device

4. Laser wave spectroscopy

Spectroscopy is a branch of physics that deals with the study of methods for obtaining spectra as well as measuring and interpreting them. The spectrum of an electromagnetic radiation is obtained by its decomposition into a spectral apparatus (spectrometer) and consists of a sequence of images of the input slot, formed by the different monochromatic radiation of incident light.

Spectroscopy uses spectral, photographic and photoelectric methods to study spectra. Depending on the spectral range of electromagnetic waves and equipment used, spectroscopy may be:

- optical spectroscopy (for visible, ultraviolet and infrared domains).
- X-ray spectroscopy, gamma-ray spectroscopy, Hertzian spectroscopy (for hertz and millimetric waves).
- alpha spectroscopy and beta spectroscopy deal with the study of energy spectra of alpha and beta radiation.

laser-induced decomposition spectroscopy is an optical emission technique that uses a laser to generate plasma. Spectroscopy provides a precise chemical composition and low detection limits (0.01 - 0.1%) because of argon purging. The precision and detection limits are improved by 10 times or more by purging with argon.

Laser waves Z analyse all types of alloys: steel, stainless steel, aluminium, copper, nickel, titanium, cobalt. Z waves spectroscopy boasts the best laser technology, it delivers high energy (5-6 mJ / pulse, 50 Hz) in one billionth of a second to generate gigawatt power densities - the key to a good plasma even and on the most refractory types of alloys.

The Z spectrometer is a portable analyser that uses LIBS spectroscopy (laser-induced breakdown spectroscopy), a type of atomic optical emission spectroscopy (OES). Since the beginning of the 19th century, scientists have known that the elements emit specific light colours. This colour combination represents a unique signature for each element. The wavelength (colour) of the specific lines reveals the present elements, and light intensity at a given wavelength is related to the concentration of each element.

The traditional OES technique used sparks and flames to generate plasma. Recent inventions and developments of laser technology, in turn, allow the use of lasers. This provides more precise control over plasma formation. Unlike sparks and flames, laser can generate plasma on the surface of non-conducting, unprepared samples such as soils, stones or liquids.

The portable LIBS spectrometer Z family ensures rapid and accurate identification and analysis of elements from hydrogen to uranium, depending on the selected model.

The three stages of the portable analysis using LIBS spectroscopy of samples are (fig. 3):

- generating plasma;
- light emission;
- light collection.

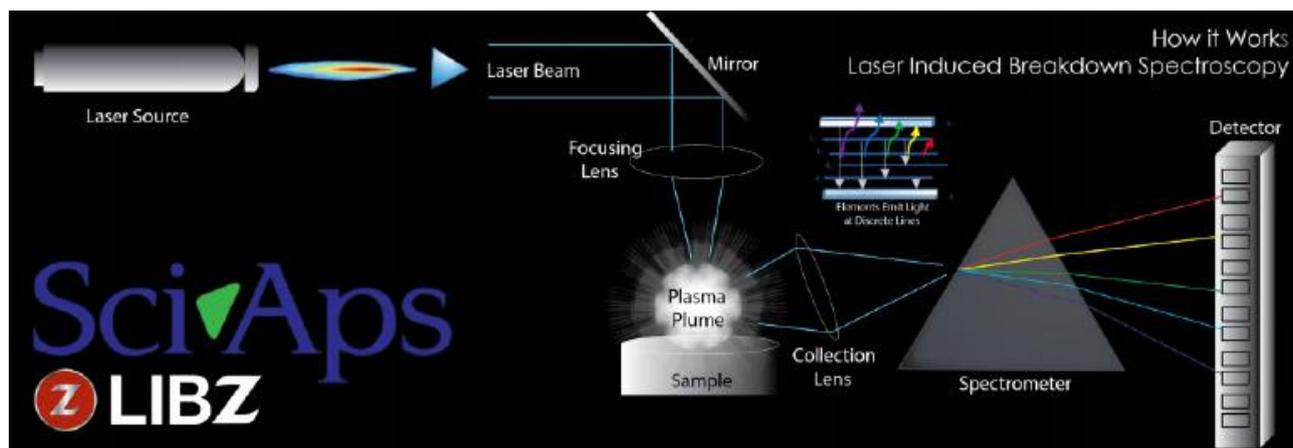

Fig. 3 stages of the portable analysis using LIBS spectroscopy of samples

The Z-300 Spectrometer (fig. 4) is the state-of-the-art LIBS portable analyser. Its advanced technology includes argon purge to provide quantitative results; the laser breaks the cleaned surface to the minimum grinding level or the prepared surface and performs the laser sweep for improved precision, reducing problems related to sample homogeneity.

Fig. 4 Z300 Spectrometer

Sample analysis using the Z laser wave portable spectrometer (fig. 5):

- A high-energy pulsed laser focuses on the sample. The high temperature of the laser on the sample leads to the removal of a small amount of material (about 0.002 inches: the thickness of a banknote) into the plasma wire. Plasma contains activated atoms and ions of the sample.
- As the plasma begins to cool, the electrons of activated atoms and ions return to their normal state. As they return to their normal state, the light of specific wavelength is emitted from the plasma and collected by the spectrometer.
- The spectrometer separates all light emitted by a high-resolution optic, detected by the charge coupled device.
- Elements detected in the sample can be viewed in a graph or in a spectrum. The graph represents the intensity of light emitted as a function of the wavelength.
- An embedded processor compares the height of specific peaks with a calibre. Calibres are built by testing a series of standards with known chemical composition. It provides quantitative chemical results.

Fig. 5 Sample analysis using the portable laser wave spectrometer Z

For most samples, their preparation is not necessary and they can be analysed as such. The Z-Spectrometer uses cleaning impulses to burn dust, surface dirt or other impurities. However, it is important to note that the LIBS technique is a surface measurement, and a layer of dirt or grease can influence the results, as surface elements will be analysed. If a sample is visibly dirty, the surface must be cleaned. If the surface is corroded or covered, the sample may be sanded to remove the corrosive or coating material.

Z Laser waves eliminate surface effects of the sample affecting other portable LIBS instruments. With Z, rarely a sample should be ground before analysis. The laser method of the Z analyser is triggered at 50 Hz (50 pulses / second) at a single location to burn sample contamination and dirt, over a period of 0.2 s, then collects spectral data for chemical analysis for 0.3 s. The laser is then automatically adjusted to repeat this process for multiple locations. The result is precise chemistry, repeatable after 1-2 seconds of testing. The sample cleaning and passivating patented combination of Z analyser eliminates variability from dirt or surface contamination.

To perform a test, the sample must be held in front of the analysis window in a straight (plane) position. The camera image can be used to ensure that the sample is straight with the front of the device and completely fills the laser slot. Once the sample is positioned correctly, press the Start button or the releaser. There will be a noise during the test and the plasma blinking in the device image will be visible. During the test, the screen will display chemical data. At the end of the test, the results screen will automatically open (fig. 6).

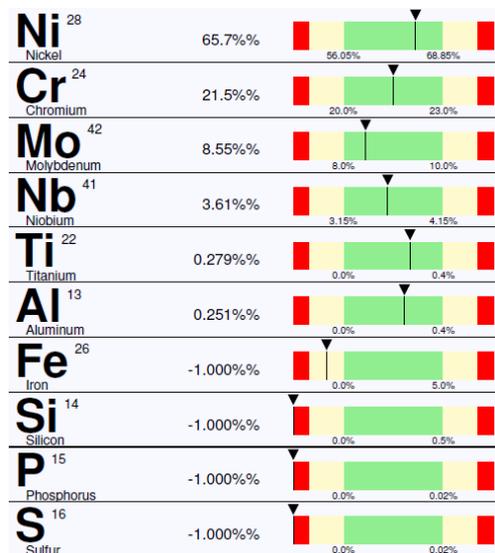

Fig. 6 Results testing using the laser wave spectrometer

5. Conclusions

Under pressure networks are represented by the following categories of installations and equipment: pipelines for gas, liquefied gases, pressurized gases, vapours and liquids, cylinder containers for under pressure compressed, liquefied or dissolved gases and stable under pressure metal containers, installed / fitted on foundations or other stationary stands or on moving platforms.

The steps to be taken in the technical control of under pressure networks are as follows: checking the general condition of the cylinders, external control, internal control, mass and capacity control, hydraulic pressure testing, leakage testing and pressure gauge testing using the laser portable spectrometer for metal analysis.

Spectroscopy is a branch of physics that deals with the study of methods for obtaining spectra as well as measuring and interpreting them. The spectrum of an electromagnetic radiation is obtained by its decomposition into a spectral apparatus (spectrometer) and consists of a sequence of images of the input slot, formed by the different monochromatic radiation of incident light.

The three stages of the portable analysis using LIBS spectroscopy of samples are: generating plasma, light emission, light collection.

Advantages of using laser-wave spectroscopy in the process of technical verification of pressure networks:

- simple and quick preparation of the test sample;
- quick and non-destructive multi-element analysis;
- the ability to provide an overview of unknown samples in a wide array of matrices.

This paper was developed within the Nucleu-Programme, carried out with the support of MCI, project no. PN 18 17 02 02 (Research on improving health and safety in hazardous environments with explosive, flammable and toxic atmospheres).

Assessing the quality safety performance of the deflagration - detonating transient behavior specific to Class 1 hazardous materials, according to Orange Book

Daniela Carmen Rus*, Emilian Ghicioi, Robert Laszlo, Cristian Radeanu, Attila Kovacs, Gabriel Vasilescu

National Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX, 32-34 G-ral Vasile Milea street, Petroșani, 332047, Romania

Abstract

Classification of products in different classes of the Orange Book is based on tests that are grouped into validated procedures and methods through series of tests that lead to the exact Class, Division, and Compatibility Group evaluation. "United Nations Recommendations" is an important global document on the transfer and movement of goods with different risks such as explosion, toxicity, radioactive contamination, chemical contamination, biological contamination, etc. Test kits designed to classify / verify the belonging of a substance as Class 1 (according to the United Nations Recommendations), i.e. explosive, provide clear evidence of classification, and their performance requires tests on significant quantities of materials to which they can find evidence of belonging to "Class 1 - Explosive".

Keywords: dangerous goods, transient behaviour, deflagrant-detonating

1. Introduction

Certain solid substances may have a specific behaviour with explosive stimuli of a detonating nature with restrictions on their transport and storage and the risk of explosion is one of the main industrial hazards in the economy, being present in all units producing, using, handling, storing and transporting solid substances with high level of danger. A chemical analysis in many situations can't provide a correct and complete assessment of the risks that may result from environmentally safe handling / transport / use / disposal, as the quantity of matter subject to expertise is determined in the sense of which the behaviour to external stimuli (of a thermal or mechanical shock) differs significantly depending on the diameter of the presumably explosive charge, the actual initiation capacity of the initiation means, the environmental factors, etc. Carrying out scale tests close to where solids accidents/disasters can occur in terms of detonation, stimulus behaviour and deflagration is essential in diagnosing/confirming risk class 1 classification under the United Nations Recommendations and which is useful for national authorities or other Member States to handle management of the transport and storage of these substances (Low no.126, 1995; Covello, V.T., et.al., 1993; ADR - European Agreement concerning the International Carriage of Dangerous Goods by Road, 2015; Cruz, M, 2004;).

2. Experimental research on the study of the transition phenomenon from deflagration to detonation to various dangerous substances classified in Class 1 according to Orange Book

a) Test on ammonium nitrate

Ammonium Nitrate is classified either in Class 1 explosive materials with multiple UN numbers assigned or class 5.1. oxidising substances and in unusual class 9, as follows: (1) in class 1 is found at no. UN 0222 as ammonium nitrate containing more than 0,2% of combustible substances, including any organic material calculated on carbon, excluding any other additive; (2) in class 5.1. is found at no. UN 1942 as ammonium nitrate containing less than 0.2% combustible matter, including any organic material calculated in carbon, excluding any other additive. At no. UN 3375 can contain emulsions, gel or suspensions of ammonium nitrate in liquid or solid form (intermediate product for brighten explosives). As fertilizer based on ammonium nitrate we find products with no. UN 2067 Class 5.1. liquid ammonium nitrate in high concentrations (over 80% not more than 93%); (3) there are fertilizers containing ammonium nitrate in admixture with phosphates or potassium salts with an ammonium nitrate content up to 45% UN 2071 in Class 9 as recommended by the United Nations (DIRECTIVE 2014/28 / EU, 2014; ADR, 2015).

The United Nations Recommendations on the Transport of Dangerous Goods are based on a risk classification, with ammonium nitrate being classified in both Class 1 (Explosive) and Class 5 (Oxidising) and Class 9 respectively. Ammonium nitrate with high nitrogen content is found in Class 1 or Class 5.1 of danger according to its intended use, the manufacturing specification, the packing and storage mode with certain specified protective measures (figure 1).

Fig.1. Mounting for the test of porous ammonium nitrate

Porous ammonium nitrate was loaded into the trough (about 2100 g in the left side) in contact with the VUFL powder initiation portion (100 g portion right) initiation by firing flame open flame Bickford (figure 2).

Fig.2. The partial melting effect in the contact area between powder and ammonium nitrate tested

Burning of the powder used as an open fire source led to partial melting in the contact area between the powder and the experimental material (porous ammonium nitrate), without burning being maintained, the flame spontaneously extinguishing without a tendency for deflagration or detonation

b) Test performed on an ANFO explosive

The ANFO explosive is a mixture composed of porous ammonia granular porous with fuel oil / diesel fuel or other similar fuel, in compliance with Romanian legislation according to the Law 126/1995 on the regime of explosive materials with subsequent modifications and completions, as simplex mixtures classified in the class 1.5. ANFO is not itself flammable, but it can help combustion, even in the absence of air. When heated, it melts, and further heating may cause decomposition by releasing toxic vapours containing nitrogen oxides and ammonia vapours (figure 3), (DIRECTIVE 2014/28 / EU, 2014; ADR, 2015).

Fig.3 Test assembly for the ANFO type explosive

The ANFO explosive is packed in a bag and loaded into a primed gutter VUFL-type powder classified in class 1.3C (figure 4).

Fig.4 Flame with a tendency to maintain that led to burning a significant part of ANFO

In this case, the sample under test was more strongly affected by the source of initiation in the sense that the flame tended to maintain it, burning a significant portion of the sample to be tested and forming a crumb of molten and partially decomposed material in the flame contact area. Finally, the flame was extinguished by itself, a part of the load not visibly affected by the thermal effect of the fire. In this situation there is no question of analysing the phenomenon of transition from slow burning to violent deflagration or detonation.

c) Test on explosive gel

In order to perform this test, a hydrogel-type explosive for civil uses, supplied as 430 g cartridges, diameter 29 mm and length 550 mm, packed in plastic foil (figure 5), (DIRECTIVE 2014/28 / EU, 2014; ADR, 2015).

Fig.5 Explosion gel test assembly

The test explosive burnt fire with a slow propagation trend with total decomposition over time, without the phenomenon of passage from firing to violent deflagration or detonation.

3. Interpretation of results on the tendency of a substance to undergo the transition from deflagration to detonation, according to Orange Book

For Interpretation of results on the tendency of a substance to submit According to the Orange Book for Class 1 - Explosive, the test series 1-8 are applied depending on the nature of the substance, the presumed sensitivity to the different pulses that can initiate the product, de-flagrant or detonating. For Class 1 Explosives, the test series 1-8 are applied depending on the nature of the substance, the presumed sensitivity to the different impulses that can initiate the product, the deflagration or the detonating reaction. The test set out in Part 1 of the "Test Manual and Criteria" involves making assemblies in which a quantity of matter to be determined is placed and an external pulse, e.g. thermal shock or mechanical shock is applied. The attempt to determine the tendency of a substance to undergo the transition from deflagration to detonation is one of the primary attempts to accurately classify products of explosive nature for their classification in Division 1.5. Depending on the nature of the effects that can be obtained from the pilot tests, it can be concluded that their results are relevant, leading to the application of the whole mechanism involving additional tests provided by the Orange Book for accurate classification based on all criteria of the said document in classes / divisions and compatibility groups.

The results of the tests revealed the following:

- Test performed on an ANFO type explosive (figures 6, 7 and 8)

Fig.6 Complete assembly for performing the transition test from deflagration to detonation

Fig.7 The result of the test to deflate the test substance (ANFO)

Fig.8 The detonation effect of the detonating wound on the plate control (ANFO)

The result of this test to determine the trend of the ANFO substance to undergo the transition from deflagration to detonation was assessed, both in terms of examination of the blank plate surface, as a result of impregnation of the detonating wick on its surface as well as by the destruction of the detonating wick, agreeing that the tested ANFO substance tends to shift from deflagration to detonation.

-Testing on a METANIT explosive type (explosive anti-grit), (figures 9 and 10)

Fig.9 Location of the test assembly on the steel plate in the hopper

Fig. 10 Test result consisting of the detonation of the test substance highlighted by the destruction of the steel pipe

Testing of the explosive type Methanit (explosive classified as low power) highlighted the destruction of the steel pipe in the assembly and the confirmation of the detonating character of the tested material.

4. Conclusions

The pilot tests highlighted in the paper concerned the behaviour of the manifestation of known / unknown fuel substances and the finding of their correct classification in class 1, division 1.5 according to the United National Recommendations; In this respect, the results of these tests highlighted the following: a) The test performed on an ANFO type explosive has demonstrated compliance with the United Nations Recommendations and validation of the correct pilot test. b) Testing of the explosive type Methanit (explosive classified as low power), intended for blasting under the risk of potentially explosive atmospheres, revealed the destruction of the steel pipe in the assembly and the unequivocal confirmation of the profoundly detonating nature of the tested material.

"The test for determining the tendency of a substance to undergo the transition from deflagration to detonation" is a very relevant way in determining the classification as "explosive product" in division 1.5, but insufficient for: a complete description of the mode of manifestation the risk of explosion, the probability of occurrence of the risky situation and the establishment of the technical measures that are necessary for their avoidance.

Implementation of the assembly "To undergo the transition from deflagration to detonation" is a development of the INCD INSEMEX Petroșani infrastructure for the application of the method of determining the sensitivity of solids, which is assumed to be a certain reactivity to external stimuli. Thus, the test itself is relevant to any solid matter, irrespective of granulometry or density, and is performed under the conditions specified in the United Nations Recommendations - Orange Book.

Checking the quality of the electric igniter - pyrotechnic article of category P1, by laboratory methods applied to determine the sensitivity to electrostatic discharge

Edward Gheorghiosu^{a*}, Emilian Ghicioi^a, Robert Laszlo^a, Attila Kovacs^a, Cristian Rădeanu^a, Dan Gabor^a

^aNational Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX Petrosani, 32-34 G-ral. Vasile Milea Street, 332047 Petrosani, Romania

Abstract

Pyrotechnic article are means of any article containing explosive substances or an explosive mixture of substances designed to produce heat, light, sound, gas or smoke or a combination of such effects through self-sustained exothermic chemical reactions.

In this generic term "Pyrotechnic articles", includes fireworks, means a pyrotechnic article intended for entertainment purposes (F 1, 2, 3, 4), theatrical pyrotechnic articles, means pyrotechnic articles designed for indoor or outdoor stage use, including movies and television productions or similar use (categories T1 / T2) and pyrotechnic articles (categories P1 / P2) used for technical purposes or as means of initiating fireworks.

In the category of pyrotechnic articles are classified "Electric Igniter", used as means of ignition of pyrotechnic articles of entertainment, theatrical or technical application.

Electric current is used to heat a resistive element (bridge wire) of this product. The sensitive pyrotechnic composition in contact with the bridge wire is ignited by heat transfer generating a fire with transferable energy.

Burning of the pyrotechnic composition of electric igniter, initiating the fireworks, theatrical pyrotechnic articles or technical pyrotechnic articles.

In order to be used for the purpose for which it was designed, the electric igniter must meet certain operating and safety requirements.

One main security parameter to be checked at the electric igniter is the sensitivity to electrostatic discharges.

This paper presents the results and conclusions obtained in the laboratory tests applying a test method to different configurations to determine this security and the level of this quality parameter.

Keywords: pyrotechnic articles, electric igniters, electrostatic discharge, method for testing, quality assurance;

1. Introduction

The electric igniters are pyrotechnic articles for the electrical initiation (ignition) of other pyrotechnic articles (theatrical pyrotechnic articles of category TI or T2 or fireworks of category FI, F2, F3 or F4), (Fig.1), Gheorghiosu et al, 2012.

The electric igniters have a pyrotechnic composition crossed by a nickel filament which has the role of an incandescent electrical resistance.

Fig. 1. Electric igniter;

The filament is powered by voltage through two copper insulated conductors with lengths of 2 m.

* Corresponding author. Tel.: +4 0731 320757; fax: +4 / 0254 541561.

E-mail address: edward.gheorghiosu@insemex.ro

The pyrotechnic-filament composition can be protected with a plastic sleeve that has the role of protection against mechanical actions but also to direct forward the flame produced by the burner. (Fig.2.)

Fig. 2. Electric igniter with plastic sleeve;

The protective sleeve can be removed when necessary but only before use and taking into account that the inflammatory pyrotechnic is very sensitive to mechanical action, friction and static electricity (especially when it is already connected to the firing line). (Fig.3).

Fig. 3. Electric igniter with plastic sleeve;

1.1. Technical characteristics of electric igniters:

- Fire current: 0,5A.
- Safety current: 0,25A 5s/ 0,18A 5s.
- Resistance: $2 \pm 0,2 \Omega$.
- Leg wires of copper with length 2000 mm, PVC.
- Initiation time: 20÷70 ms;

1.2. Description of method for determination resistance to electrostatic discharge (ESD), SR EN 16265:2015

This test aims at determining whether electric igniters can withstand an electrostatic discharge (ESD) without initiating. (Directive 2013/29/EU) This test should not be undertaken on magnetically-coupled igniters.

For electric igniters with a sole central pin and a casing which acts as second pin, only the “pin-to-pin” configuration shall be taken into consideration, Ghicioi et al, 2012.

For electric igniters where the sensitive element is only protected by a varnish or by a non-metallic protection (Fig.2), the “pin-to-case” configuration corresponds to the application of ESD between the two short-circuited leading wires and a conductive electrode through the protection. (Fig.4)

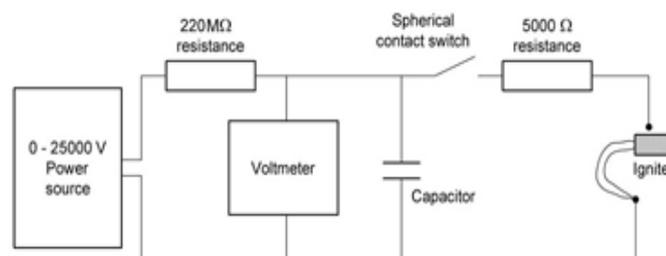

Fig. 4. Schematic of assembly the ESD test circuit;

Apparatus, ESD generator Electrostatic discharge generator with capacitance ranging from 500 pF to 3500 pF and sufficient voltage to give the required impulse.

Preparation of the test:

The samples must be having the same design and construction of the fusehead and the leading wires, in the case of leading wires, they shall have the same length ($\pm 0,05$ m);

Then ensure that the leading wires and all measuring equipment are kept in the same position as they were when adjusting the ESD generator;

The ESD impulse to be applied to the igniter shall be in accordance with the requirements, if no-fire current (I_{NF}) is $0,15 \leq I_{NF} < 0,25$, the minimum ESD impulse must be $0,2 \text{ mJ}/\Omega$ for the "pin-to-pin" configuration and $0,2 \text{ mJ}/\Omega$ for the "pin-to-case" configuration.

The test carry out at $(20 \pm 5,0) \text{ }^\circ\text{C}$ and at a relative humidity not greater than 60 %;

The leading wires and cables (if any) are kept at a distance of at least 100 mm from the ground and from any conductive objects that might cause leakage paths to earth;

For "pin-to-pin" configuration, must be apply the ESD between the two separate ends of the leading wires or between the two pins.

Must be repeat the operation 5 times successively for each igniter, allowing at least 10 s between each pulse;

For pin-to-case configuration twist together the ends of the two leading wires and apply the ESD between the twisted ends of the leading wires or between one of the two pins and the casing of the igniter.

Must be repeat the operation 5 times successively for each igniter, allowing at least 10 s between each pulse.

2. Results and comments

Table 1. Results of tests "pin-to-pin" configuration (I-initiation, N-no initiation)

Test conditions	No. test													
	1	2	3	4	5	6	7	8	9	10	11	12	13	14
Temperature: 19°C	N	N	N	N	N	N	N	N	N	N	N	N	N	N
Relative umidity: 46%	N	N	N	N	N	N	N	N	N	N	N	N	N	N

By applying the configuration, it was obtained the ensemble from figure 5.

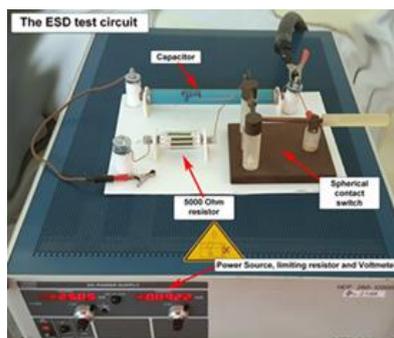

Fig. 5. Stand for testing;

It have been performed 28 tests on electrical igniters in two "pin-to-case" configuration.

The first configuration, a 5 mm wide circular electrode was positioned in the middle of the plastic guard. (Fig.6)

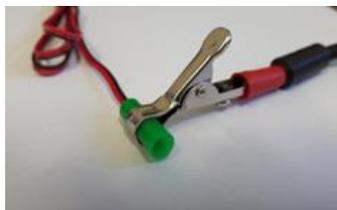

Fig. 6. The electrode positioned in the middle of the plastic guard

Table 2. Results of tests "pin-to-case" configuration (I-initiation, N-no initiation)

Test conditions	No. test													
	1	2	3	4	5	6	7	8	9	10	11	12	13	14
Temperature: 19°C	N	N	N	N	N	N	N	N	N	N	N	N	N	N
Relative umidity: 46%	N	N	N	N	N	N	N	N	N	N	N	N	N	N

The second configuration, a 5 mm wide circular electrode was positioned at the end of the plastic guard. (Fig.7)

Fig. 7. (a) The electrode positioned at the end of the plastic guard; (b) Initiation electrical igniter

Table 3. Results of tests "pin-to-case" configuration (I-initiation, N-no initiation)

Test conditions	No. test													
	1	2	3	4	5	6	7	8	9	10	11	12	13	14
Temperature: 19°C	I	I	I	I	I	I	I	I	I	I	I	I	I	I
Relative umidity: 46%	I	I	I	I	I	I	I	I	I	I	I	I	I	I

3. Conclusions:

The electrostatic discharge test (ESD) is a safety parameter of this type of pyrotechnic article.

To perform the tests, an important technical detail is the method of fixing the electrodes to the electrical igniters.

The most severe test condition must be identified to verify the compliance of the initiators with the safety requirements.

If this principle is not applied the electrical igniters that do not have security in use can be used which can lead to major accidents.

INSEMEX Petrosani has implemented this test method thus developing the expertise / test capacity to check these types of products in the process of certification and technical expertise.

Abstract

Most of the time, in assessing a situation where a leakage of combustible gas is involved, the volume of the room where the release occurs and the volume of the released gas is taking in account, thus resulting in an average concentration of the fuel gas applied to the entire volume of the room. This paper explores the release of methane gas inside a closed space and the initiation of the mixture at different concentrations reached at the spark location. The experiments are virtually performed through CFD techniques. As a result of virtual tests, differences were observed between the simulation results and the calculation currently used for the determination of methane concentrations in enclosed spaces in case of accidental leakages of combustible gases.

Keywords: leakage; methane explosion; CFD; computational simulation; methane ignition.

1. Introduction

A leak or a break in a pipeline is a result of failure of a defect in the pipe wall. Failure of an existing defect may occur as a result of change in load level, dynamic events, defect growth (for example, fatigue, corrosion), or diminishing material toughness (for example, temperature drop, aging) (Cioca, L.I et al., 2012; Pasculescu D. et al., 2012).

Most often, investigating an explosion due to a leakage of fuel gas takes into account the volume of hazardous gas relative to the volume of the space where the leakage occurred, considering the uniformity of gas concentrations in volume (Beveridge A. 2011). But the problem is much more complex.

Firstly, the transport of the fuel gas is based on the pressure gradients generated by the gas pressure in the pipe. Then there is an expansion of the gas, a shift from a higher density to a lower one. When the gas passes through the leakage hole, its temperature decreases, and then, when released into the room volume, a heat transfer takes place between the gas and the inner atmosphere. Also, a larger hole in the pipe provides a greater area over which the pressure can act (Maria P. et al., 2016). The hazard radius is defined as the largest horizontal extent of the hazardous area generated by a leak when situated in an open area (Cleaver R.P et al., 2011).

Even if all of these calculations were made with the utmost precision, locating the cloud of fuel gas and spreading it in to space would remain unknown. Existence of airflow in the room and walls temperatures are other factors to be considered.

The location of the ignition source versus the leakage location has a great importance. Immediate ignition can be considered as the situation where the flammable gases are ignited immediately after leakage accidents by auto-ignition or accident ignition source. Delayed ignition is the result that the release and diffusing flammable gas cloud is ignited by other ignition sources apart from the release point (Changlong Z. et al., 2012).

Therefore, using CFD tools makes a considerable contribution to this domain. With some approximation, these techniques can predict the behavior of the fuel cloud, the way in which initiation of the formed explosive atmosphere

* Corresponding author. Tel.: +40 799 211 677
E-mail address: daniel.florea@insemex.ro

and the development of the explosion takes place. These approximations can be of real use in the explosion risk assessment and decision-making process regarding the necessary safety measures.

2. Setting the computational domain

All the virtual activities, including geometry construction, meshing, setting the boundary conditions, solving and post-processing were performed in ANSYS Multiphysics package. ANSYS Fluent was used to define the domain properties and calculate the results. The Fluent application is based on finite volume method and can perform 2D and 3D simulations of various types of problems including multi-component and multi-phase flows, compressible flows, flows with heat transfer, cavitation and other phenomena.

2.1. Geometry and meshing

The virtual geometry consists of a rectangular tube of dimensions 500 x 50 x 50 mm (Fig. 1.). One of the ends of the tube is closed and the other end has a 10 x 10 mm hole in the center, to release the explosion pressure. The inlet of the gas in the tube is located on the lower surface of the tube at a horizontal distance of 100 mm from the closed end, on a central-longitudinal line of that surface. The inlet is circular and has a diameter of 5 mm. The spark location is in the middle of the closed end of the tube.

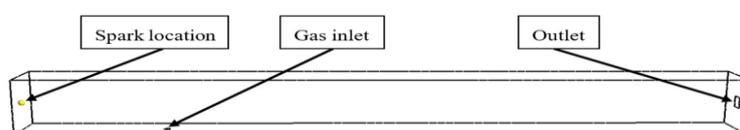

Fig. 1. Rectangle tube with locations of the spark, inlet and outlet

The meshing process used the Proximity and Curvature Size Function, with Fine option for Relevance Center and a maximum Face Size of 3 mm. This resulted in a number of 407884 tetrahedrons and 74610 nodes. Fig. 2. shows the finite volumes, in a 3D representation, which compose the mesh of the tube sectioned by a vertical plane.

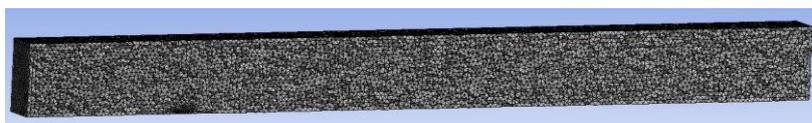

Fig. 2. Discretized geometry

The refined mesh in the proximity of the gas inlet can be seen on the lower surface of the tube. This refining is needed to improve the realism of releasing methane gas into the analyzed space. Fluent application is sensible to the mesh quality. One of the rules of thumb is that the skewness must be below the value of 0.98. Also, the orthogonal quality is a very important factor. When in Fluent, it is necessary to check and report the quality of the mesh.

2.2. Domain setup

Considering the target objectives: transport and ignition of the air-methane mixture at different concentrations obtained at the spark location, the problem was defined as a transient case, density-based, with gravitational acceleration activated. $k-\epsilon$ turbulence model was used with Viscous Heating, Buoyancy Effects and Curvature Correction options checked.

The gas inlet was set as a pressure inlet, inducing a pressure of 103325 Pa, 2000 Pa above the rest of the domain and a temperature of 293 K. Through this surface, the methane enters into domain at unity mole fraction.

The outlet – the hole to release explosion pressure – was set as pressure outlet with an atmospheric pressure on its surface (101325 Pa), and oxygen of 0.2091 mole fraction at a temperature of 293 K.

The other sides of the rectangular tube were defined as walls with the same temperature as the outlet and inlet.

Species Transport was selected for the species model. The air-methane mixture was set as compressible gas (ideal-gas in Fluent application). During the simulation, for compressible ideal gas, ANSYS Fluent calculates the static temperature on the inlet surface based on the enthalpy, which is determined by the total temperature declared as the boundary condition.

The reaction mechanism consists of the stoichiometric reaction of the methane oxidation, from the materials database of application.

The entire domain was set at a temperature of 293 K, a pressure of 101325 Pa and a clean atmosphere (0.2091 oxygen mole fraction).

3. Computational simulations

In order to initiate the explosive atmosphere created inside the tube, a first simulation monitored the increase in methane concentration at the spark location and the average methane concentration on a vertical plane that centrally divides the tube. Thus, at the level of the spark location it was possible to determine the times at which the methane concentrations were in the explosive area, between 5 and 15% vol. CH₄ (Fig. 3.).

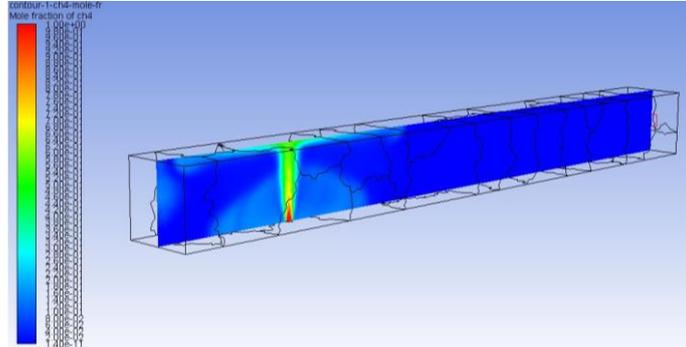

Fig. 3. Monitoring of the molar fractions at the spark location and on the vertical plane

The increase in methane concentrations is shown in Fig. 4. The volumetric methane concentration (%vol. CH₄) is 100 times the mole fraction.

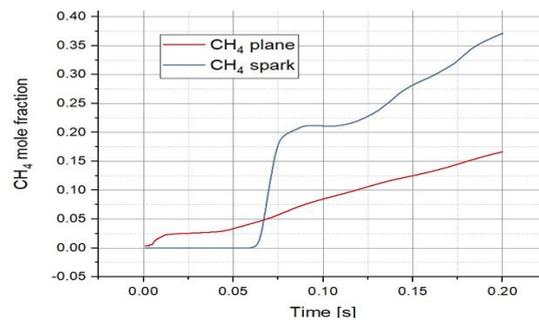

Fig. 4. Mole fractions at the spark location and on the vertical plane

Hence, the relevant data of the passage of methane concentration through the explosive area was obtained for the sparking location, data included in Table 1.

Table 1. CH₄ mole fraction at spark location

Case No.	Timestep No.	Time [s]	CH ₄ mole fraction
1	67	0.067	0.048913
2	68	0.068	0.067778
3	69	0.069	0.086641
4	70	0.070	0.104969
5	71	0.071	0.122878
6	72	0.072	0.140154
7	73	0.073	0.155635

The time step used for this first simulation was of 0.001 s. In order for the simulation to be resumed from each concentration of CH₄ contained in Table 1, the associated data files were written at each timestep. This was done because the simulations of the gas explosions require a smaller timestep.

For the 7 computational simulations related to the 7 timesteps in Table 1, the activation moments were set for the spark located in the center of the closed end of the tube. For each simulation, the spark activation time was set to 0.0005 s from the start of the simulation and the timestep was set to 0.0001 s.

At the spark location, concentrations of methane, oxygen and reaction products (carbon dioxide and water), as well as temperature, were monitored. The ignition of the air-methane mixture occurred in each case, even when the methane concentration exceeded the explosive concentration at the spark location.

Fig.5. shows a series of images of the methane released inside the tube, ignition and performing of the simulated explosion.

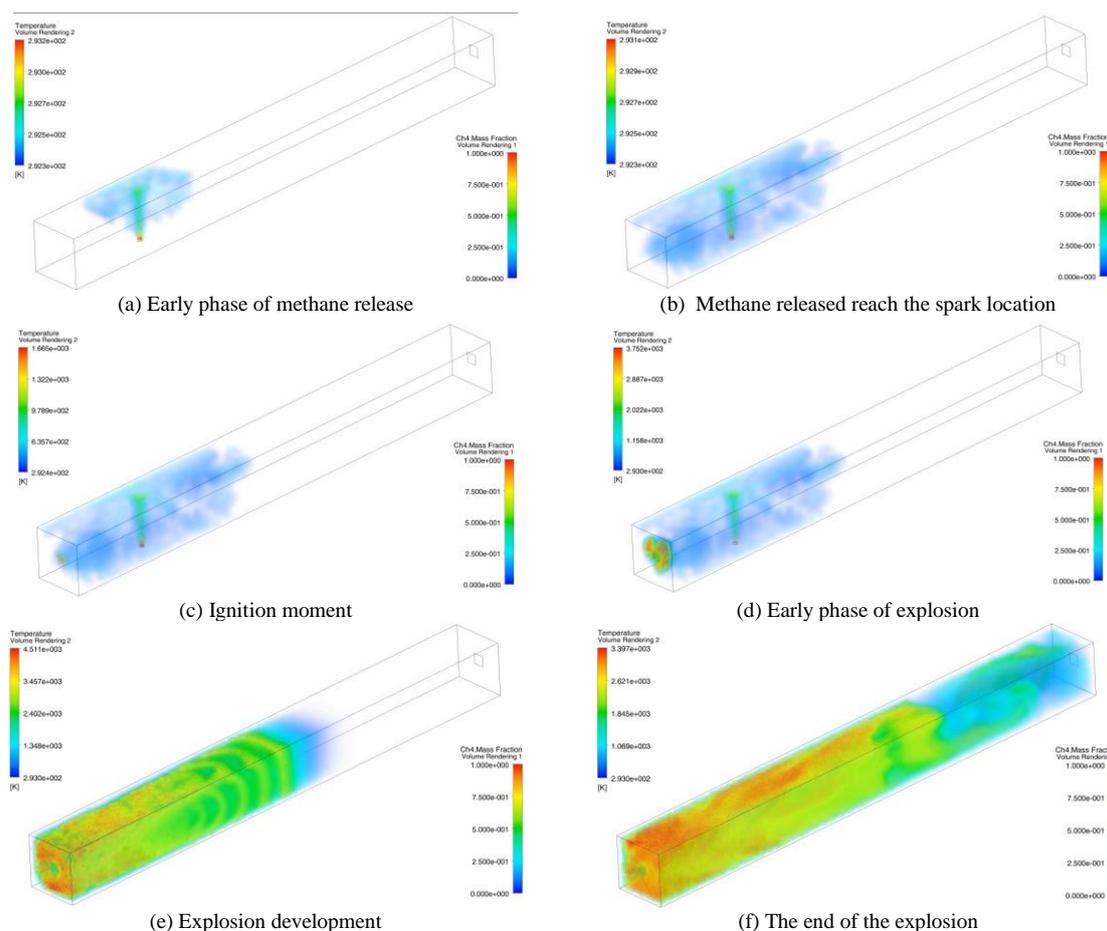

Fig. 5. Series of images of released methane, ignition and simulated explosion

4. Results

In each of the seven simulations, the explosion of the air-methane mixture inside the rectangular tube occurred.

The spark was activated at 0.0005 s from the start time of the simulation for each case, so the exact methane concentrations at the spark location were known only after the simulations run. The times and methane concentrations at which the spark has been activated for the seven cases are listed in Table 2.

Considering the piston effect, the methane in front of the flame was pushed beyond the expansion limit of the release phase so that the flame front advanced, in all cases, close to the explosion pressure outlet.

An interesting case is the last one, where the concentration of methane at the spark location exceeds the limit of explosivity, however the ignition takes place. The case deserves attention, which is why it is discussed below.

Table 2. CH₄ mole fraction at the moment of spark activation, for each case

Case No.	Spark time [s]	CH ₄ mole fraction at the moment of spark activation
1	0.0675	0.054938
2	0.0685	0.074143
3	0.0695	0.092692
4	0.0705	0.110656
5	0.0715	0.128261
6	0.0725	0.144991
7	0.0735	0.159692

The decrease, by burning, of methane mole fraction at the spark location and after the spark activation, for the seven cases, is shown in Fig. 6.

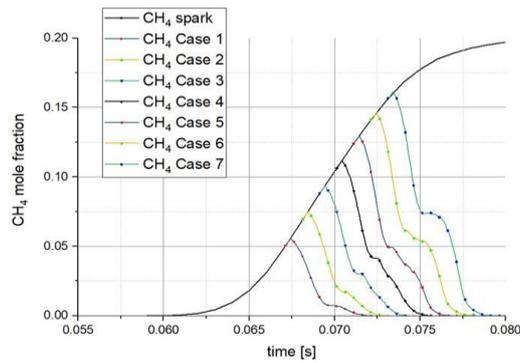

Fig. 6. Mole fractions at the spark location and on the vertical plane

5. Discussion

The most interesting case is the last one, where the ignition takes place at a methane concentration that exceeds the upper limit of explosivity at the spark location. This is why the case has been analyzed in detail, noting what is happening in the proximity of this location.

To analyze the situation, the charts of reactants and reaction products evolution during the process, as well as of the temperature at the location of the spark and the maximum temperature over entire volume were built (Fig.7.).

As can be seen from the figure, the temperatures at the spark location and the maximum recorded inside the volume increase at the same time up to a point where the methane concentration is already in the explosive area. After this moment, the maximum temperature inside the volume shows a higher growth rate.

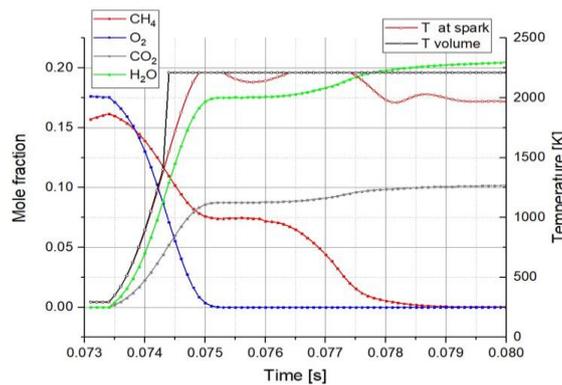

Fig. 7. Case 7. The evolution of the reactants, reaction products and temperatures at spark location and inside the volume

This can be interpreted as a movement of the reaction from the spark location, also motivated by the low oxygen concentration in that place at that moment. In order to have a comparison term, a graph was created with the values recorded in case 3 (Fig. 8.).

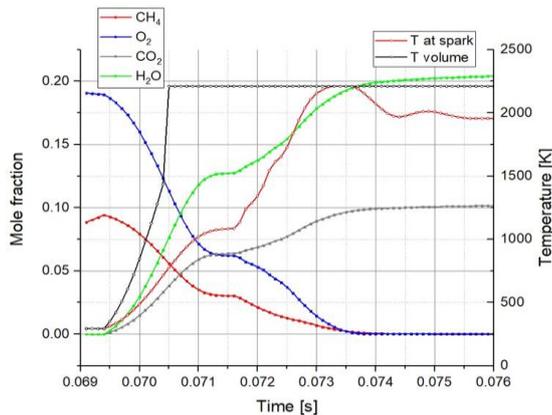

Fig. 8. Case 3. The evolution of the reactants, reaction products and temperatures at spark location and inside the volume

By comparison between the two cases, a totally different behavior of the evolution of the reactants, the reaction products and the temperatures can be observed. For the temperatures in Fig. 8, the curves are separated immediately after the moment of spark activation, which indicates a faster movement of the flame from the spark location.

For Case 7, the moment of separation of the two temperature curves (spark location temperature and the maximum temperature over the volume of the tube) is shown in Fig. 9. At this moment, the flame is out of spark location.

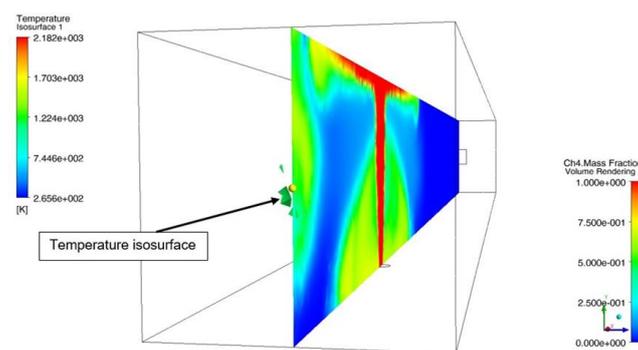

Fig. 9. The moment of separation of the two temperature curves for Case 7

6. Conclusions

Analyzing Fig. 4, it can be seen that at a concentration of approx. 15% vol. CH₄ at the spark location corresponds to a methane concentration of more than 30% vol. at plan level, which would produce an erroneous analysis by the usual calculations.

When a volume of methane is released in a larger volume of air, a non-homogeneous air-methane mixture forms. In this case the initiation of the mixture may occur even if at the spark location the methane concentration exceeds the explosive area, by a local burning of methane and a contribution of oxygen from areas with clean air. However, this possibility of initiation requires further research, by conducting physical experiments and obtaining edifying records.

Abstract

The study of the characteristics of fires or explosions, as well as factors influencing their production and development, leads to the increase of the fire / explosion expertise capacity, the expansion of the knowledge field related to these phenomena, also increasing the health and safety at work. Because of the random evolution, there cannot be two fires the same. A number of factors are involved in the development of a fire: the nature and positioning of combustible materials, the shape and dimensions of the room, the thermal load, the openings to the outside, the location and mode of initiation of fires, etc. Following the similarity of these numerous factors, fire experiments on a natural scale produce very varied results. For the study and experimental determination of the flammability parameters of the different materials and the assessment of the fire behaviour, the following were made: the stand for vertical and horizontal burning determination according to SR EN 60695-11-10, the stand for determination of the ingress efficiency SR 652: 2009. Experimental determinations were performed with these stands.

Also, the evolution of the concentration of the most significant gaseous effluents over time has been studied: carbon dioxide, hydrogen cyanide, nitrogen oxides, etc. Different polymeric materials such as polymethylmethacrylate, rubber, melamine was taken in consideration to study the nature and concentration of gaseous effluents.

As a result of the combustion of the polymeric materials, high concentrations of gases with high toxicity, namely: carbon dioxide, hydrogen cyanide, nitrogen oxides, and the distribution of these concentrations were determined during the tests. The nature of the resulting gas is dependent on the composition of the burning material, such as for example burning melamine, resulting in significant amounts of hydrogen cyanide.

Keywords: fire, toxic gaseous, flammability

1. Introduction

Combustion processes are oxidation reactions of some substances, resulting in different amounts of heat. For the complete oxidation of combustible elements, a minimum amount of oxygen is contained in a minimum amount of air. Combustion carried out in the presence of the minimum required air is called stoichiometric burning or theoretical combustion. Incomplete combustion processes result in significant amounts of carbon dioxide. Calamar et al. 2017.

The main gases of toxic, asphyxiating, irritant, flammable nature, etc., that can be generated from fires / explosions are:

CO₂-carbon dioxide and CO-carbon monoxide are common combustion product and significant amounts of

HCl - hydrochloric acid, is generated by the combustion of polyvinylchloride and chlorine-protected synthetic materials (chlorinated polyesters);

HCN - hydrogen cyanide is released from polyamides, polyacrylonitrile, polyurethane, polybutadiene, polystyrene and nitrate polymers, for example, polyurethane releases the highest amount of HCN at temperatures of about 1000 ° C, HF - hydrofluoric acid is released in the case of polytetrafluoroethylene. Strec A.A. et al., 2008.

NO_x (N₂O, NO, NO₂) is released by burning polyacrylonitrile, polyamide and cellulose, styrene

* Corresponding author: tel +40740242975
E-mail address: andrei.szollosi@insemex.ro

NH₃ - ammonia, is an irritant gas; in the case polyamide combustion has a maximum permissible concentration of 50 ppm, incomplete combustion products such as tar, aliphatic or aromatic hydrocarbons in the form of very fine particles / aerosols, which can cause bronchial / pulmonary damage. Gann et. al. (2010)

Smoke combustion products are fatal to a large extent because in their presence people become disoriented, suffer respiratory disturbances, lose their knowledge and physical mobility. After a period of hyperventilation of the body, as a result of inhalation of irritant gases, the main causes leading to death are the inhalation of carbon monoxide (CO) and hot gases. Abdulrhmann, 2015.

The most significant toxic effluents from common fires are: carbon monoxide (CO), hydrogen cyanide (HCN), carbon dioxide (CO₂), hydrochloric acid (HCl) and nitrogen dioxide (NO₂). Carbon monoxide is considered the most dangerous toxic gas because it can be found in large quantities at all fires. The importance of each toxic gas for a specific fire must reflect both its toxicity and the concentration in which it forms. Exposure time is also important for determining the effects of toxic gases. Carloganu, 1986.

Risks / hazards may increase / may become greater when the listed substances react with each other or react with other substances.

2. Determination of flame propagation testing methods and results

Determination of the flame propagation in the vertical plane for cables can be made by optical cables according to the European standard IEC 60332-1 (3), thus the method of testing the burning rate of the plastic materials from which the cable sheath is made. Fire hazard tests (SR EN 60695-11-10) Part 11-10: Test flames.

Horizontal and vertical flame test methods Horizontal and vertical flame test methods of 50W flame are based on the fixation of the test specimen horizontally and vertically, determining the vertical and horizontal firing rates. The test or preconditioning test leads for 8 hours at 70 ° C. Test specimens have a size of 125mm ± 5mm. Diameters used for testing: 8mm and 4mm. Or conditioning two sets of test materials at 23 ° C, they were marked at a distance of 25mm from the longitudinal axis. The flame burner is applied for 10 seconds or removed if the flame front exceeds the 25mm mark.

Smoke combustion products are fatal to a large extent because in their presence people become disoriented, suffer respiratory disturbances, lose their knowledge and physical mobility. After a period of hyperventilation of the body, as a result of inhalation of irritant gases, the main causes leading to death are the inhalation of carbon monoxide (CO) and hot gases. 3. Method of determining flame-resistance and results

Determination of flame-retardant efficiency: SR 652: 2009 Wood, plywood, chipboard, wood fibre boards. Considering the parameters described in the standard, a test stand was carried out by a method of laboratory determination of the effectiveness of flame retardant products applied on wood, plywood, chipboard. The test consists in determining the mass loss of flameproof specimens subjected to combustion. After the burner gas supply is interrupted, determine the duration of residual flame or residual incandescence. The test method is based on determining the mass loss of flame retardant specimens subjected to combustion.

Fig.2 Testing of flame resistance

Table 4 Determination of flame retardant efficiency

Type of tested material	Loss of the specimen [%]	Thickness of specimens [mm]	Application time of flame [min]
Woods chips plates	24,88	10	15
Pal plates	13,24	15	15
Pal laminated plates	14,71	16	15
Plywood non-fire resisting	66,19	0,5	15
Slim plywood	73,99	0,3	15

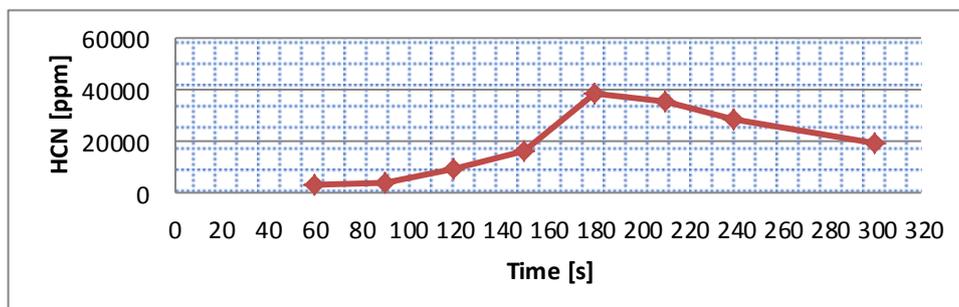

Fig. 3 Variation of concentration of hydrogen cyanide in time in the burning of melamine

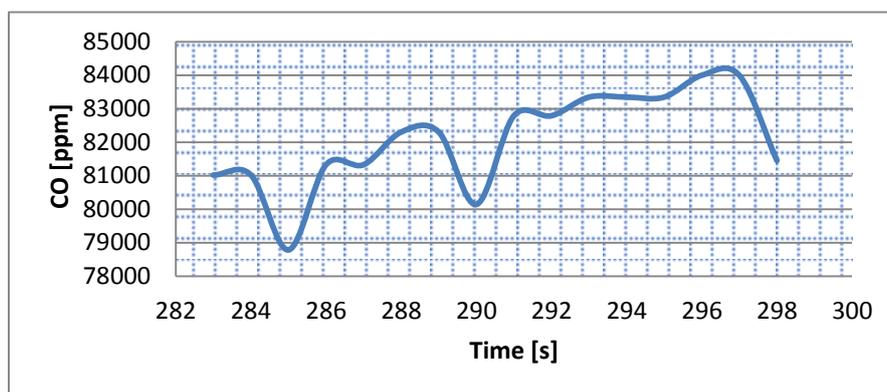

Fig.4 Variation of concentration of concentration of carbon monoxide

The concentration of carbon monoxide and hydrogen cyanide increasing during the firing tests, and these gases are particularly very dangerous for human health.

4. Conclusions

The stand for determining the vertical burning rate was made and determinations were made using electrical cables of 4 and 8 mm diameter for which the vertical burning rate of the test specimens was determined. Smaller cable samples (0.4 mm in diameter) showed a higher average firing rate compared to a larger diameter (0.8 mm diameter). The stand was made for determining the horizontal burning rate and determinations were made for two types of 4mm and 8mm cables. After making the determinations, it can be concluded that the average burning speed for the specimens is inferior to the larger diameter cable.

Toxic products formed in the fire are depending on the chemical reactions and combinations of the resulting products, leading to antagonistic, synergistic effects and other additional interactions. Their nature is directly related to the products involved in the fire and the thermal degradation conditions of the materials and substances. The most significant toxic effluents from common fires are: carbon monoxide (CO), hydrogen cyanide (HCN), carbon dioxide (CO₂), hydrochloric acid (HCl) and nitrogen dioxide (NO₂). CO is considered the most dangerous toxic gas because it forms in large quantities at all fires. The test is designed to reproduce real fire conditions and it is essential to make appropriate observations to ensure that conditions are met.

Experimental determinations were made on smoke, nature and concentration of combustion gases by means of instrumental methods existing in the laboratory, respectively determination methods by electrochemical sensors, spectrophotometry, IR sensors, etc. The behaviour of different combustion materials was studied as follows: polymethyl methacrylate, melamine and rubber.

Abstract

Because in most cases, fires and explosions cause damage with significant economic and social effects, appropriate measures must be taken to prevent these hazards. These measures aim at preventing explosive atmospheres, followed by preventing the occurrence of ignition sources and then limiting the effects of explosions. One source of ignition of the potentially explosive dust / air atmosphere is static electricity. Static electricity discharges vary greatly as type and degree of initiation. Assessing the occurrence and the possibility of initiating discharges in all kinds of real situations is the most important and most difficult step in analyzing the dangers created by electrostatic charges. Knowing the intensity of the discharge (the amount of energy released) and the sensitivity of the existing explosive atmosphere, as characterized by the minimum ignition energy, it can be determined whether ignition occurs or not. The minimum ignition energy of the flammable dust / air mixture is an essential parameter for assessing the risk of ignition of the potentially explosive dust / air explosive atmosphere by electrostatic discharges. For the most common flammable dusts, it is given in the literature or in databases, but new types of flammable substances are always present, for which this parameter defining the sensitivity of the mixture to ignition by electrostatic discharges must be determined. The methods for determining the minimum ignition energy are multiple, but for a unitary evaluation in the context of the assessment in the field covered by the ATEX Directives (Directive 2014/34 / EU, transposed into GD 245/2016 and Directive 1999/92 / EC, transposed into legislation by GD 1058/2006), they must be standardized at European level. The purpose of this paper is the study of methods for assessment of the ignition risk of dust/air explosive atmospheres by electrostatic discharge.

Keywords: dust/air explosive atmospheres, minimum ignition energy, static electricity, electrostatic discharge.

1. Introduction

In many industrial sectors, flammable substances in the form of dusts are processed, transported or stored. If they are ignited, they can endanger the health and safety of people and can cause material damage. These substances include sugar, coal, wood, grains, certain metals and many organic or synthetic chemicals.

Combustible dusts present fire hazard and may be explosive, mixed with air, in certain concentrations and in the presence of a source of ignition. The existence of this real danger has been confirmed by the events that took place in various economic units, for example: in forage factories, textile industry, steel industry, wood industry, mills, etc.

As regards the occurrence of an explosion, it can only occur if the following conditions are met simultaneously:

- presence of fuel (gases, vapors, dust, combustible mist);
- presence of the oxidant (oxygen, oxidizing substances);
- source of efficient initiation to ensure the activation of the molecules in order to initiate and propagate the rapid combustion reaction.

* Corresponding author. Tel.: +40 254 541 621; fax: +40 254 546 277.
E-mail address: dan.gabor@insemex.ro.

Since in most cases fires and explosions cause damage with significant economic and social effects, appropriate measures must be taken to prevent such a hazard. These measures aim at preventing the formation of explosive atmospheres, preventing ignition sources and then limiting the effects of explosions. A source of ignition of the potentially explosive dust / air atmosphere may be static electricity.

The critical factor in assessing the electrostatic charge hazards is the probability that a potentially explosive atmosphere and a dangerous electrostatic charge occur at the same time and place. This probability is very high when manipulating a particular product as it can lead to both dangerous loading and the formation of a potentially explosive atmosphere. In particular, this may occur during the handling of bulk non-conductive solids. In particular, this may occur during the handling of bulk non-conductive solids, but even conductive substances can accumulate large dangerous charges if processed in non-conductive equipment. Large electrostatic charges may also occur in non-conductive or non-earthed conductive installations.

2. Methods for assessing the risk of initiation of flammable explosive air / dust mixtures by electrostatic discharge.

2.1. Formation, accumulation and discharge of electrostatic charges.

Static electricity is one of the most common phenomena in the industry and in the practical activities of everyday life. Accumulation and discharging of electrostatic charges can give rise to hazards and problems in a wide range of industries or work environments. Accumulation and discharging may result in ignition and explosion, especially in the chemical, pharmaceutical, petroleum and food processing industries.

The formation and accumulation of electrostatic charges occurs as a result of charging mechanisms. A charging mechanism that lead to the formation of electrostatic charge is the contact charging. Electrostatic charges are usually generated when any two materials make and then break contact, with one becoming negative and the other positive. Also, another component of the charging mechanism is induction charging, in which case the conductive products may be charged with electrostatic charges from another loaded object in the vicinity. Products can also receive charges by transferring either directly from other objects or through influence through an ion stream.

After separation during the electrostatic charging process, the loads can be recombined very quickly, either directly through contact or through the earth. Charges on a non-conductor are retained due to the strength of the material itself. But in order for a conductor to remain charged, he must be isolated from other conductors and earth.

Under normal conditions, pure gases are non-conductive and charged particles suspended in clouds of dust, mist or spray material can often stay for long periods of time, regardless of conductivity particles themselves.

In all cases, loads leak with a value determined by non-conductor resistances in the system, the process is known as relaxation. The levels of resistance, resistivity, or conductivity that can lead to hazardous situations depend largely on industrial processes.

In many processes there is continuous generation of loads that accumulate on isolated conductors. For example, when a stream of charged liquid or powder flows into an insulated metal container, the potential of the insulated conductor is the result of the balance between the load formation rate and the leakage rate.

The equivalent electric circuit is shown in Figure 1 and the potential of the conductor is given by the equation:

$$V = I \cdot R \left\{ 1 - \exp\left(-\frac{t}{RC}\right) \right\} \quad (1)$$

where:

V is the potential of the conductor in volts;

C is the capacitance in farads;

R is the leakage resistance to earth in ohms;

I is the electrostatic charging current in amperes; t is the time from the commencement of charging in seconds.

The maximum potential is reached when t is high and is therefore:

$$V_{\max} = I \cdot R \quad (2)$$

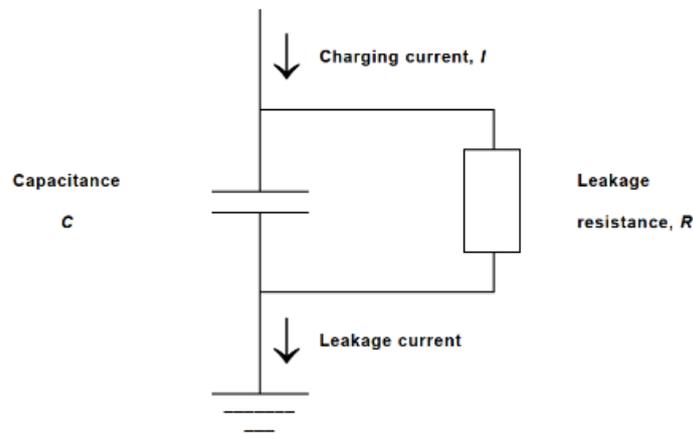

Figure 1 - Equivalent electrical circuit for an electrostatically charged conductor.

The leakage resistance and the capacity of an insulated conductor can usually be measured, by measuring them to determine if dangerous load levels can accumulate. However, this assessment can't be made for suspensions of dust and mist in the air.

Static electricity discharges vary greatly as a type and degree of initiation. The literature relates to the following types of electrostatic discharges:

- Sparks (discharges between two solid or liquid conductors);
- Discharging "Corona" (discharging takes place in sharp areas or at the edges of the conductors, e.g. surfaces with a small radius of curvature). The "Corona" discharge can occur when such a conductor is grounded and moved in the direction of a strong charged object or if the potential of the conductor is greatly increased);
- Brush-type discharges (These discharges can occur when rounded (opposite to the sharp) conductors connected to the grounding network are shifted to load-bearing objects, poorly conductive, for example, between a person's finger and a plastic surface);
- Propagation brush discharges (For this type of discharge it is necessary to have a sheet of high resistivity material and a high dielectric strength with the two surfaces heavily charged with loads but opposite polarity);
- Lightning discharges (In principle, these discharges occur within dust clouds or from dust clouds to earth when the field strength is high due to the charge particles. Such lightning discharges could be observed in the clouds ash during the volcanic eruption);
- Cone discharges (When large silos or containers are filled with a highly charged, weakly dusty dust, a high load density area is generated inside the dust pile).

The incendency of electrostatic discharge varies greatly depending on the type of discharge and environmental sensitivity, characterized by minimal ignition energy.

Assessing the occurrence and the possibility of initiating discharges in all kinds of real situations is the most important and most difficult step in analyzing the dangers created by electrostatic charges. For this reason, table 1 gives the synthesis of the initiation capacity (incendency) of the different types of discharges taking place in practice.

Table 1. Incendency of the different types of discharges.

Type of discharge	Incendency		Dust
	Gases, Vapors		
	MIE < 0.025mJ	MIE > 0.025mJ	
Spark discharge	+	+	+
Corona discharge	+	-	-
Brush discharge	+	+	-
Propagating brush discharge	+	+	+
Cone discharge	+	+	++
Lightning discharges	+	+	+

Thus, an explosion risk assessment must consider the likelihood of electrostatic charges and unloading both equipment and products/material (Figure 2).

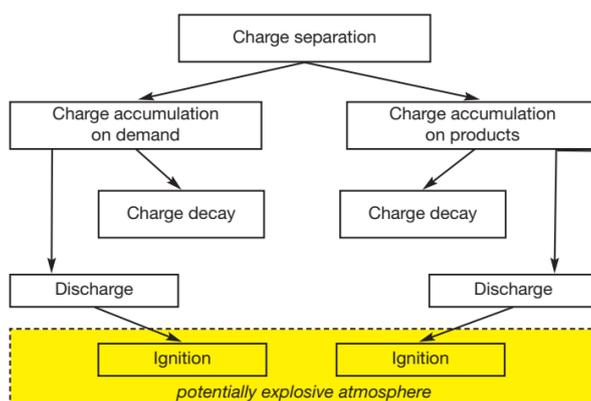

Figure 2 Schematic presentation of the steps leading to the initiation of a potentially explosive atmosphere in the case of electrostatic charges and discharges.

The data required for a reliable analysis are the precise knowledge of the potentially explosive mixture properties that may be present, the resistances or conductivity of the substances, apparatus, packaging, materials and personal equipment used, the volumes and geometric arrangement of the installations and technical devices and the precise knowledge of the conditions existing earthing and potential balancing conditions.

1.2 Static electricity for bulk materials.

According to the practical experience, the bulk material ignition capacity with fine particle size and up to granules or chip sizes increases with decreasing particle size and decreasing minimum ignition energy (MIE). The ignition risk assessment must always be based on the minimum ignition energy of the smallest particle that may be present. This class of particles is usually obtained by sifting a sample through a sieve with meshes of 63 μm .

If the relevant minimum ignition energy is greater than 1 J and no flammable gases and vapors are present, special measures to avoid the risk of ignition due to static electricity are usually not required. A possible exception to this is when it is possible to brush propagation discharge.

Bulk materials are classified into three groups according to their resistivity in volume:

- Low resistivity powders with volume resistivity up to 1 M Ω ;
- Medium-resistivity powders with volume resistivity from 1 M Ω to 10 G Ωm ;
- High resistivity powders with resistivity of 10 G Ωm and above.

In practice, dusts with low resistivity are rare. Even metallic powders do not remain conductive for a long time because oxide films are formed on the surface to increase their resistivity. An exception, however, is carbon black.

Bulk material from silos and other containers for bulk materials must be handled and processed in such a way as to avoid the accumulation of dangerous electrostatic charges. Dangerous charges can accumulate on both the bulk material and the walls of the silo or container.

To prevent the risk of explosion, a risk analysis should be made to determine whether the bulk material can be electrostatically charged at a dangerous value during loading into the silo or container. If necessary, measures must be taken to prevent cone discharge, lightning or sparks. The analysis should be based on the resistivity of the bulk material.

For example, for materials with $\rho > 10 \text{ G}\Omega\text{m}$, a complete analysis is given in figure 3.

As an alternative to measuring the field strength above the deposit / pile of dust, this field strength should be estimated by modeling the electric field inside the silo taking into account the relaxation of charges during the filling procedure. Such modeling calculations should be based on the mass ratio, bulk density and dust fill rate, permittiveness and relative resistivity of bulk dust, as well as on the silo geometry.

If the radially directed electric field remains below 3 MV/m, the bulk dust field criterion is met. The difference between 0.5 MV/m and the limit of 3 MV/m is based on the distribution of the field inside the silo while the maximum field is always radially directed against the silo wall measured at the silo wall and not axially guided over the storage/pile of dust.

During discharges from silos and containers in the absence of flammable gases and vapors, bulk material is generally not expected to accumulate. Moreover, all downloads and transfer devices need to be analyzed separately. However, it should be borne in mind that most of the unloading operations are a filling operation for the next silo or container. From the analysis presented, it is observed that if the incendivity of the discharge (the amount of released energy) and the sensitivity of the existing explosive atmosphere, as characterized by the minimum ignition energy, is known, it can be clearly established whether the ignition occurs or not.

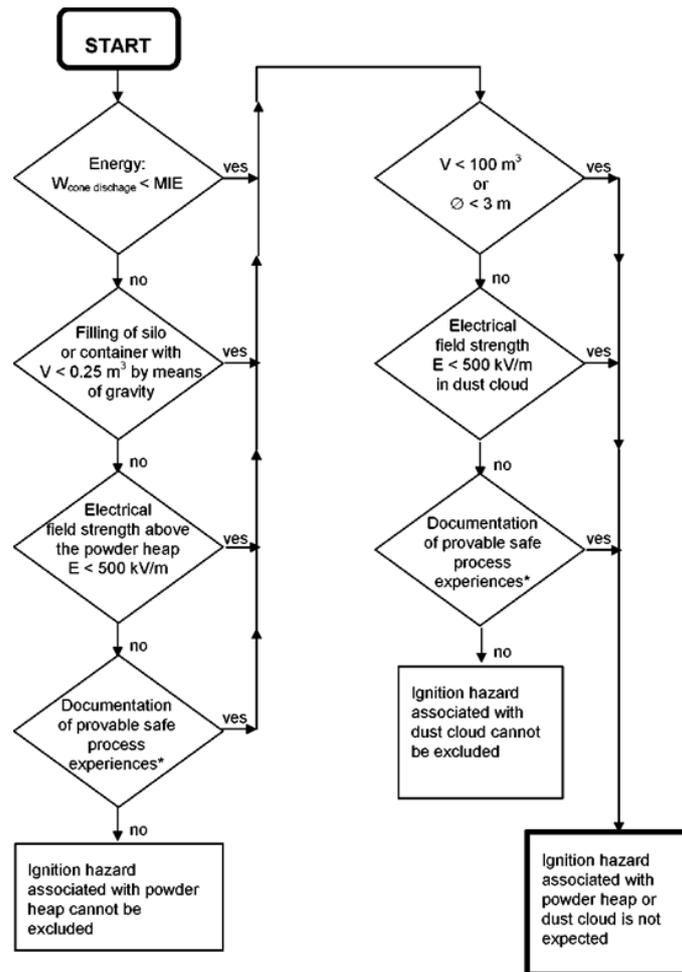

Figure 3: Assessment of bulk material with $\rho > 10 \text{ G}\Omega\text{m}$.

The minimum ignition energy of the flammable dust / air mixture is an essential parameter for assessing the risk of ignition of the potentially explosive dust / air explosive atmosphere by electrostatic discharges. For the most common flammable dusts, it is given in the literature or in databases, but new types of flammable substances are always present, for which this parameter defining the sensitivity of the mixture to ignition by electrostatic discharges must be determined. For information on MIE for dust, see BIA-Report 12/97 "Combustion and explosion characteristics of dusts".

3. Minimum Ignition Energy Methods (MIE).

Minimum ignition energy determination methods may be estimation methods or quantitative methods so they are standardized in IEC 61241-2-3, ASTM E2019 and EN 80079-20-2 / EN 13821.

The MIE for dusts varies depending on particular parameters such as particle size distribution, moisture content/solvents and the test method/appliance, respectively. By tests performed in the INCD INSEMEX laboratories with the KSEP test chamber, an estimated ignition envelope can be determined.

Most of the times, however, for the evaluation, a more accurate value of the minimum ignition energy must be known. That is why, in the research program PN PN 18 17 02 01, in Stage II with a final deadline of 2018, a test stand according to the standardized method.

4. Conclusions

In order to ensure the safety and health of workers and goods in the industrial sectors processing, storing or transporting substances in the form of flammable dusts, an explosion risk analysis should be carried out to establish protective measures to prevent ignition of potentially explosive atmospheres with different sources of ignition, including static electrification.

The necessary data for a reliable analysis is the exact knowledge of the properties of the potentially explosive mixture that may be present, respectively of its ignition capacity, and the resistances or conductivity of the substances, appliances, packaging, materials and personal equipment used, the volume and geometric arrangement of the

installations and technical devices, as well as precise knowledge of the existing grounding conditions and the conditions of balancing the potential.

According to the practical experience, the bulk material ignition capacity with fine particle size and up to granules or chip sizes increases with decreasing particle size and decreasing minimum ignition energy (MIE). The ignition risk assessment must always be based on the minimum ignition energy of the smallest particle that may be present.

Explosion protection requirements fall within the scope of the European directives ATEX: Directive 2014/34 / EU (HG 245/2016) and Directive 1999/92 / EC (HG 1058/2006). Therefore, minimal ignition energy must be determined by methods / equipment complying with European standards to ensure the repeatability and reproducibility of the test.

In the testing laboratory of INSEMEX at present, only the estimated minimum ignition energy can be determined, with the development of the infrastructure of the testing laboratories with the necessary equipment for the determination of the minimum ignition energy according to the standardized method - within the NUCLEU project PN PN 18 17 02 01 - Researches for developing the assessment and testing of technical equipment designed for use in areas with hazard of explosion and of personal protective equipment.

National Institute for Research and Development in Mine Safety and Protection to Explosion INSEMEX Petroșani, 32-34 Gen. V. Milea Str., Petroșani, 332047, Romania

Abstract

The combustion potentiality of a substance or explosive mixture can be identified by ascertaining the structure of their chemical compounds using several methods, including infrared spectroscopy (FTIR).

The objective of this paper is to identify certain hazardous substances that have generated explosion or fire type events, by using modern techniques that consist in physical-chemical characterization of substances or their compounds.

Infrared absorption spectra were assessed by using the attenuated total reflection analysis technique (ATR) and their evaluation was performed by using libraries within the device's software.

The use of this technique is safe, being a convenient method in terms of sample preparation and quantity of sample used, the main advantage being the certainty of results.

Keywords: ATR analysis, combustion, explosive mixture, hazardous substance, infrared spectroscopy

1. Introduction

Fourier Transform Infrared Spectrometry has become one of the main techniques used when analyzing samples of particular specificity that require a non-destructive analysis. (Radu et al., 2012).

In this study some experimental results are presented, which, through the arguments brought, justify the importance of using this technique in elucidating aspects of the structural characteristics of certain types of evidence.

The research was carried out on samples taken from material evidences, used and experimented in the elaboration of reports for technical expertise of explosion or fire type events.

The results of the spectrograms allow the identification of certain types of substances, specific to the event location. In the case of identification of the IR spectrum waveform numbers, specific for burning accelerators (e.g.: gasoline, diesel, oil, etc.), the team of researchers involved in the elaboration of the technical expertise report for the investigated event could correlate the FTIR data obtained with all other relevant elements, in order to determine the causes that led to the occurrence of the event (Ghicioi et al., 2018).

2. Determination method

Fourier Transform Infrared Spectrometry (FT-IR) is a non-destructive technique that involves low analytical costs and fast responses. These features make FT-IR spectrometry one of the most widely used analysis techniques in physico-chemical analysis laboratories. The advantages of this technique have brought to specialists' attention and the problem addressed is very broad: the characterization of some substances in order to identify certain combustion accelerators. (Merticaru and Petroviciu, 2005).

Spectrometry is used both as a qualitative method for identifying the presence of a substance in a solution, as well as a quantitative method for identifying the concentration of a substance in a solution. The method can also be used to determine the equilibrium constant of a solution (Berthomieu and Hienerwadel, 2009).

E-mail address: sonia.suvar@insemex.ro.

The IR range of the electromagnetic wave spectrum contains radiation with wavelengths ranging from $0.8 \mu\text{m} \leq \lambda \leq 1000 \mu\text{m}$. This range can be divided into three sub-domains: near-infrared ($0.8 \mu\text{m} \leq \lambda \leq 2.5 \mu\text{m}$), mid and long wavelength infrared (between $2.5 \mu\text{m} \leq \lambda \leq 25 \mu\text{m}$) and far infrared (over $\lambda = 25 \mu\text{m}$).

In most laboratories, Fourier Transform Infrared Molecular Absorption Spectrometry and Fourier Transform Raman Spectrometry are used as complementary techniques, since each of them exhibits certain aspects for a given sample (Varma et al., 1989; Birzescu et al., 2009).

3. Apparatus

For the identification of combustion accelerators, the samples taken at the event site were analyzed by infrared spectrometry method with a FT-IR type equipment, Nicolet IS 50, made by ThermoScientific, with integrated ATR module with diamond crystal, with the range of $4000 - 400 \text{ cm}^{-1}$ (Figure 1).

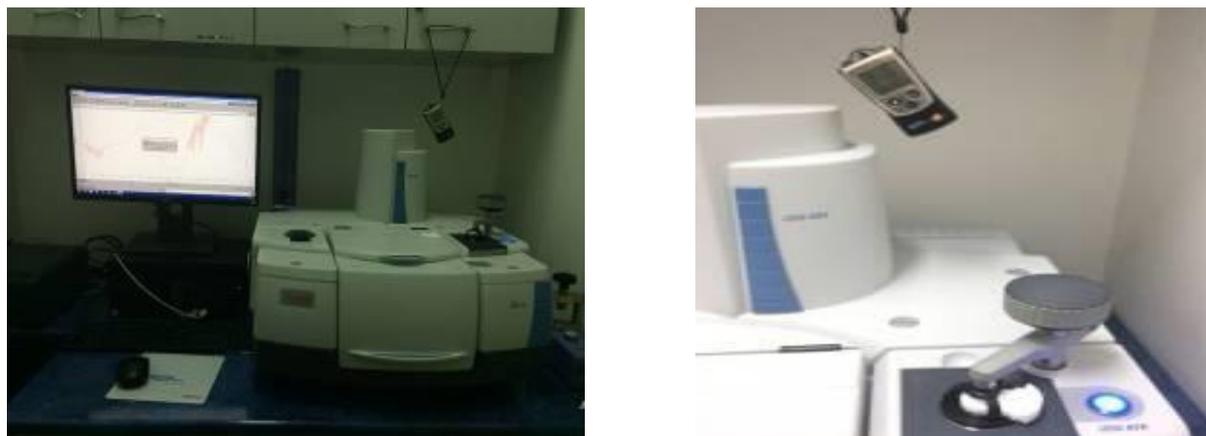

Fig. 1. (a) Nicolet IS50 Infrared Spectrometer equipment; (b) ATR module with diamond crystal and device for analyze of volatile substances.

Infrared absorption spectra were recorded at a resolution of 4 cm^{-1} , using ATR (attenuation of total reflection) analysis technique, as follows:

- Attenuation of total reflection, performed directly on the combustion residue samples - non-destructive analysis;
- Attenuation of total reflection, performed on n-hexane extract, with background read on solvent.

In order to identify the contaminants or compounds found in very low concentrations, the sample was subjected to an extraction operation using solvent (n-hexane), at room temperature.

The experimental data obtained was evaluated using the OMNIC software (Thermo Nicolet Corporation), as well as the dedicated libraries containing more than 40000 IR spectrograms (ThermoScientific, 2013).

4. Results and Discussions

For the identification of certain combustion accelerators in fire events, two cases were analyzed:

- a) A case where no combustion accelerators have been identified;
- b) A case where combustion accelerators have been identified.

For each sample, a spectral analysis was performed directly on the residue, as well as an analysis of the n-hexane extract from the residue.

a) For the first case, 2 samples were taken from the site where the fire event took place and being analyzed in the Laboratory for Physico-Chemical Analysis, the samples representing the residues of textile materials and carbonized residues (Fig. 2).

Fig. 2. Scraps of textile materials – 1st case.

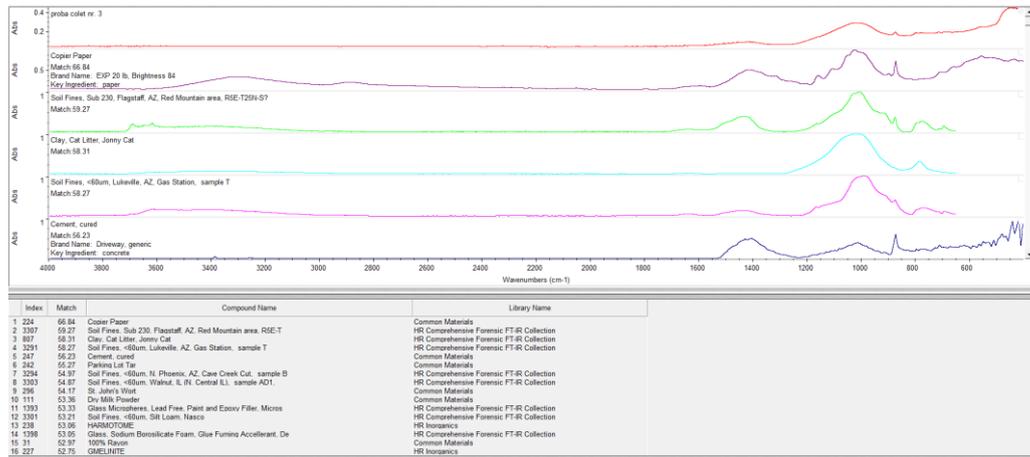

Fig. 3. IR spectrum of the textile material sample, untreated with n-hexane

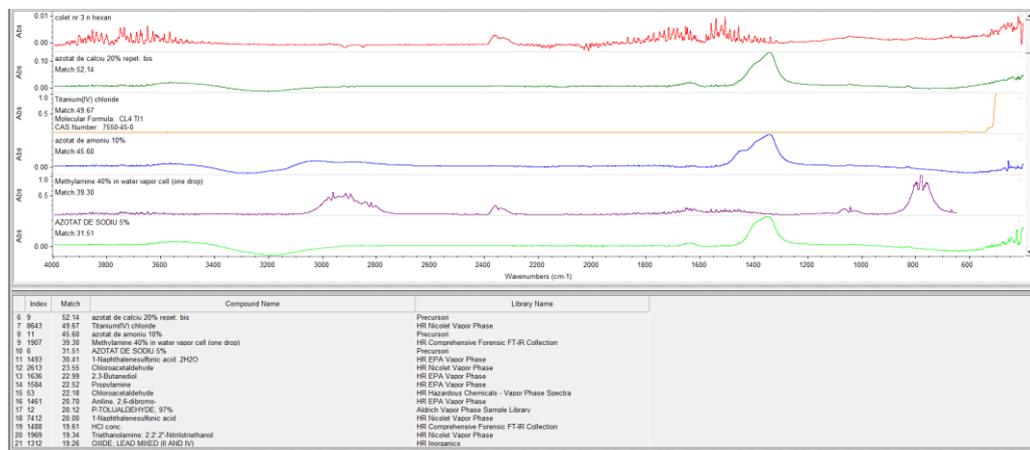

Fig. 4. IR spectrum of the textile material sample, treated with n-hexane

Figure 5 presents a sample consisting in carbonized residues, other than textiles.

Fig. 5. Sample consisting in carbonized residues, other than textile materials.

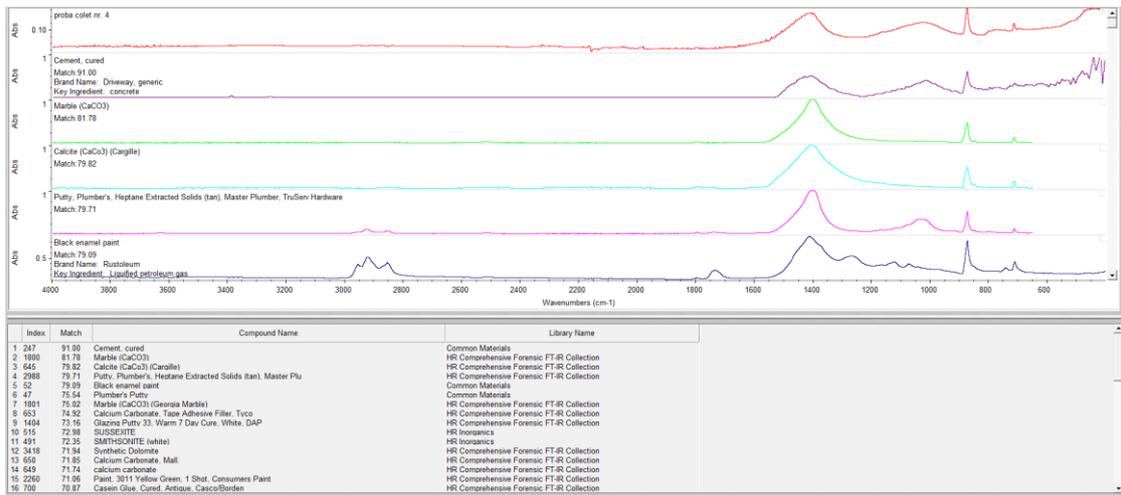

Fig. 6. IR spectrum of carbonized residues, other than textile materials, untreated with n-hexane

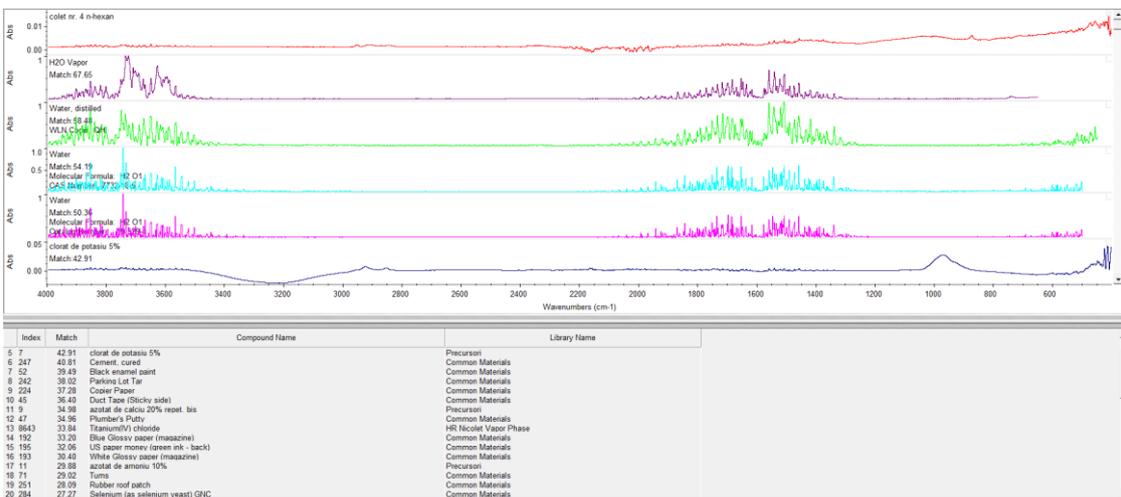

Fig. 7. IR spectrum of carbonized residues, other than textile materials, treated with n-hexane

In the two analyzed samples, no elements were identified that would lead to the existence of specific firing accelerators specific to the Arson type effects.

b) For the second case, 3 samples that were taken from the event site were analyzed in the Physical-Chemical Analysis Laboratory. The samples contained combustion residues (Fig. 8).

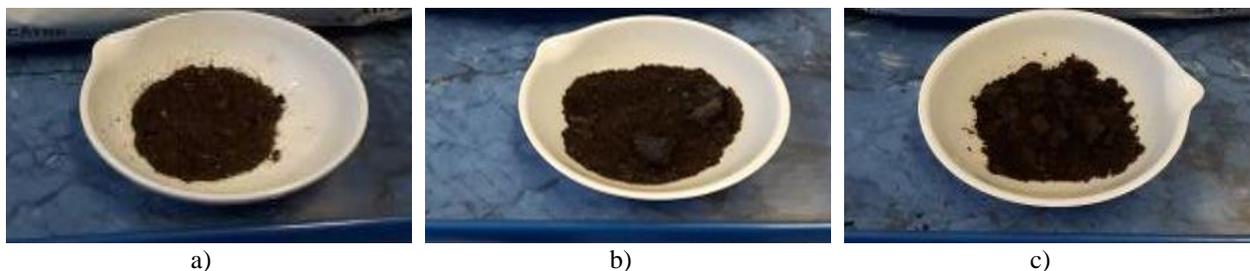

Fig. 8. The three samples consisting in combustion residues.

For exemplification purpose, Figures 9 and 10 show the IR spectra of sample c), both before and after the treatment with n-hexane.

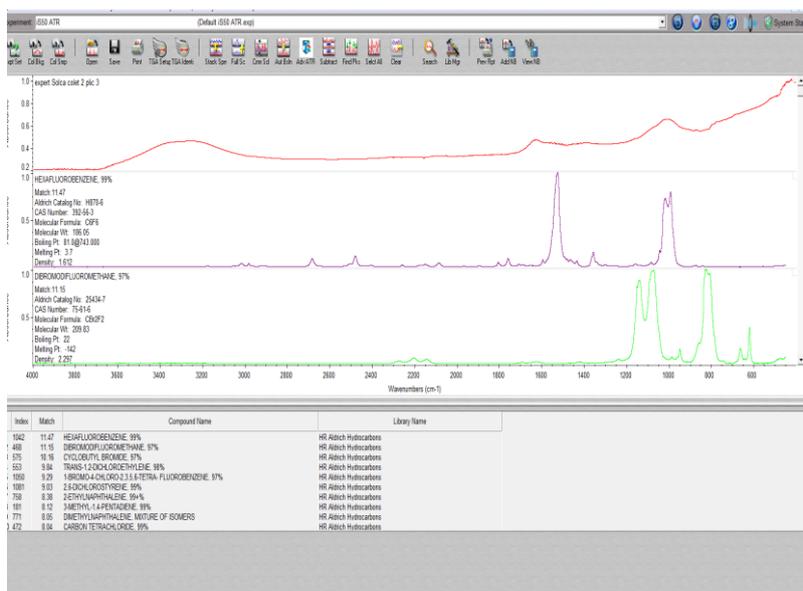

Fig. 9. IR spectrum for sample c), untreated with n-hexane.

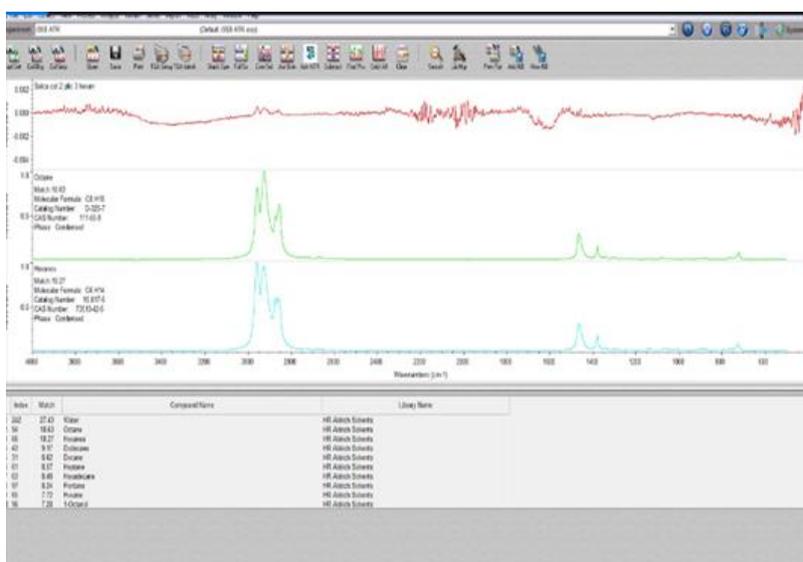

Fig. 10. IR spectrum for sample c), treated with n-hexane.

In this case, following the analysis carried out on the three samples, the ATR-FTIR analysis of n-hexane extract, there have been identified aliphatic hydrocarbons from the series of higher alkanols and aromatic hydrocarbons such as: pentane, hexane, heptane, octane, dodecane, cyclohexane, benzene, xylene, all these substances also being found in the chemical composition of petroleum products.

5. Conclusions

The ATR-FTIR spectral analysis method has proven to be an effective method for identifying the waveforms numbers specific to certain combustion accelerators and is particularly useful in investigating fire / explosion type events. The paper presents, in the second case under consideration, specific elements of petroleum products, which, together with other relevant data of the event, allow the confirmation of the Arson effect.

Abstract

Disasters represent a permanent threat to sustainable development and annually generate many human casualties and material losses; at the same time, the beginning of this millennium is characterized by an ever-increasing impact of human activities on Earth. It is also worth mentioning a paradox of contemporary society's attitude towards disasters: allocation of material and human resources to prevent and mitigate the effects of disasters has greatly increased, but at the same time the development of human society is a factor contributing to disasters and / or amplifying their consequences. People's health can be unexpectedly threatened both by natural disasters, whether in traffic, during leisure time or at work in different ways, either as a result of a traumatic event such as an accident at work. A quick intervention in the event of an accident can save a person's life or prevent aggravation of injuries suffered. Health, physical integrity or even the life of victims depend on how first aid is given. Everyone needs to know how to proceed to save someone's life or how to reduce the negative consequences upon injured persons.

Keywords: disasters; first aid; vital functions; resuscitation.

1. Introduction

A hazard is considered a disaster if there are at least ten deaths or 50 injured people and material losses of more than one million dollars (Alexander, 1993). They can be classified according to several criteria: way of development (genesis), event duration, affected area, number of victims, complexity of phenomena etc. (www.meteoalarm.eu).

1) Depending on genesis, hazards can be differentiated into:

a. Natural hazards, which in turn comprise two large groups of phenomena generated by endogenous and exogenous agents.

Endogenous hazards include volcanic eruptions and earthquakes, phenomena that by their amplitude often generate loss of life and material damage, in many cases.

Exogenous hazards part in: climate hazards (tornadoes, thunderstorms, lightning, hail, glaze frost, drought, etc.), geomorphological hazards (erosion, landslides) (Toth, 2018), hydrological hazards (floods), oceanographic hazards (ocean level rise), biological hazards (epidemics, invasions of insects and rodents), biophysical hazards (fire), astrophysical hazards (meteorites).

b. Anthropogenic hazards are generated by different human activities and include accidents in industry, agriculture and transport (Hogan et al., 1999). Technological disasters, especially those related to chemical and radioactive materials, have a bigger echo, leading to change of legislation in the field or initiation of new regulations.

2) Depending on the affected area, hazards are:

- Global, systemic hazards, such as climate warming tendency caused by artificial greenhouse effect, ozone depletion, the rising tendency of ocean level;

- Global hazards with regional effects such as desertification and soil erosion. These become global by cumulation (Toth, 2018);

- Regional hazards that affect large areas across continents and oceans and include storms, water, air and soil pollution;

* Corresponding author. Tel.: 0723684391; fax: 0254 546 277.
E-mail address: lorand.toth@insemex.ro

- Local and punctual hazards such as landslides, volcanic eruptions, earthquakes.

3) Depending on size of the effects (number of affected persons, material damage, environmental damage), the hazards are differentiated into (Toth, 2018):

- Low-impact hazards that cause small damage that can be remedied by local forces;

- Hazard with severe effects, causing disruptions in the functioning of society, major damage and injuries that require the intervention of civil protection organizations and other competent bodies;

- Disasters (catastrophes) that cause serious disruption or disturbances in the functioning of society and generate human casualties, material damage and environmental damage (Okumura et al., 1996). These effects outweigh the ability of society to respond effectively through the use of local resources, requiring intervention and aid at national and international level.

2. National / international approach to disaster prevention

The reform of public administration is part of the Romanian Government's action to promote a modern society, compatible with European standards. The reform implies enacting, implementation and assimilation of the administrative values set defining the European space, by the Romanian public administration system: transparency, predictability, accountability, adaptability and efficiency.

Evolution of society imposed, as a necessity "sine qua non", the enacting of legislative initiatives that would provide the legal basis for civil emergency management, with particular attention to disasters. Furthermore, Romania's option regarding NATO and EU integration has provided a bridge between bodies with responsibilities in the field – NATO's High-Level Emergency Planning Committee, as well as structures of European Union.

In Romania, the management of various types of crisis by domains (mobilization, war, emergency, siege, disaster, civil protection, etc.) is regulated by specific laws and their management is ensured through permanent or temporary structures on each domain.

In 2004, the Romanian Government adopted the legislative framework (GEO 21/2004 with subsequent amendments and completions) for the establishment of the National System for Emergency Situation Management for the provision of resources and actions coordination in emergency situations, in the conditions in which Romania presents great vulnerabilities to natural and anthropic disasters, such as (Toth, 2018):

- earthquakes - Bucharest is the European capital with the highest seismic risk and one of the 10 most exposed cities in the world;

- floods - annual events with great material and human damage;

- landslides - about 20% of the territory has favourable conditions;

- ecological accidents at and not only mining sites.

The normative act regulates the establishment of structures with attributions in the field of emergency management, at central and territorial level, namely coordination, planning and decision support, with temporary or permanent activity, placed in a hierarchical system according to administrative-territorial and domain of responsibility criteria. These structures ensure the unitary and permanent management of all activities regarding planning and implementation of measures to prevent, limit and remove the destructive effects of emergency situations.

The National Emergency Management System is organized by the public administration authorities and consists of a network of bodies, agencies and structures empowered to handle emergency situations, established by levels or areas of competence and has the necessary infrastructure and resources for fulfilling its duties.

Basically, the national system regards:

- committees for emergency situations;

- General Inspectorate for Emergency Situations;

- professional community public services for emergencies;

- operational centres for emergency situations;

- commander of action.

Internationally, there are several agreements and strategies for disaster prevention, including:

- The United Nations (UN), by Resolution 236 of 1989, decided to organize a comprehensive research program titled "The International Decade Natural Disasters Reduction" (IDNDR).

- The "Towards Partnerships for Disaster Reduction in the 21st Century" International Forum, which was held in Geneva in July 1999, essentially delivered a political message emphasizing the need to integrate risk management and disaster reduction in government policies of each state. The political process in Geneva included the enactment of two documents, namely: "A Safer World in The Twenty-Century: Risk and Disaster Reduction" (Burgess, et al., 1997) and the "A Geneva Mandate on Disaster Reduction", which highlighted the consensus among participants in all sectors involved - governments, international organizations, non-governmental organizations, private sector - on the need to continue global integrated research on disasters.

The International Strategy for Disaster Reduction was developed in 2000, focusing on increasing population involvement, linking with sustainable development, developing partnerships and networks. The objective of the International Disaster Reduction Strategy is to educate the public to increase collaboration with public authorities to build structures that are resistant to potential disasters that threaten them.

In 2002, the Johannesburg Implementation Plan (World Summit on Sustainable Development) included a new section - "An integrated, multi-hazard concept on vulnerability, risk assessment and disaster management."

The complex risk management strategy adopted in Istanbul in 2004 mentions systemic integration (risk assessment, emergency preparedness, disaster prevention and disaster risk financing) as well as reducing the exposure of states to economic losses.

In 2005, in Hyogo, Japan, the Hyogo Framework for Action 2005-2015 was adopted to build resistance of nations and communities to disasters.

Other global programs, which meet efforts of thousands of specialists trying to find solutions to serious problems and uncertainties surrounding environmental changes, are: The International Geosphere-Biosphere Program, the International Program the Human Dimension of Environment Global Changes, the Strategic Disaster Reduction Initiative, Climatic World Program etc.

3. Disaster risk management

The objective of risk management is to bring together all the elements and actors in the disaster management system, to develop disaster mitigation tools based on prevention and intervention strategies, transfer and mutual exchange of knowledge, education and decision-making techniques.

Disaster management considers the disaster manifestation stages and includes the following elements: assessment and evaluation of risks and vulnerabilities; response to disaster; appraisal of disaster; rehabilitation and reconstruction.

The assessment and evaluation of risks and vulnerabilities makes an estimate of the magnitude of each potential risk and importance of this risk for population and the environment (Băbuț, et al., 2011).

Disaster risk assessment is very important, as the hazards interact at different spatial and temporal levels, developing locally, regionally and internationally. Besides the individual study of potential hazards, it is important to have a multidisciplinary understanding and an integrated analysis of the different processes, given the fact that disasters are often complex.

Vulnerability assessment is a key component of risk management; qualitative and quantitative assessment of vulnerability of objects and systems exposed to risk of disaster is required.

The factors contributing to increased disaster vulnerability are:

- fundamental causes - poverty, limited access to resources, cultural model of population;
- lack of education, skills, local investment, low capacity of intervention of public institutions;
- degree of urbanization, environmental degradation, population growth, state of transition of cultural models;
- unsafe conditions / fragile environment - dangerous locations, buildings and high-risk infrastructure;
- fragile local economy – low standard of living / lack of information and public awareness.

Response to disaster is all actions taken by authorities and population in the face of disaster. It includes warning, security, communication and information management actions, logistics and supplies, post-disaster assessment, research and rescue of survivors, post-disaster assistance (assistance to the population, maximizing the number of survivors, restoring essential services, restoring damages) and emergency management operations.

Assessment disaster entails determining the impact of disaster on society and is an interdisciplinary process, its priorities being establishing the need for immediate emergency actions, to save and sustain the life of disaster survivors and identify opportunities to speed up the restoration of infrastructure, services and development. This is done considering various phases of disaster manifestation, namely:

Warning phase (actuating the population group for whom life-saving measures are taken and facilities to mitigate the impact of a potential disaster and activating arrangements in the preparedness plan from the perspective of appreciation);

Emergency phase (confirming the urgency reported and damage estimation, identification, characterization and quantification of population at risk of disaster, help to define priorities for action and resources needed to reduce immediate risks, identifying local capacity to respond, including organizational resources, medical and logistical support, help to anticipate serious future problems and support for immediate response management and control);

Rehabilitation phase (identifying the priorities of affected population, identifying government policies for post-disaster assistance, estimating additional support from national and international sources for mitigation, recovery and monitoring of these measures results);

Restoration phase (assessment of the destruction of significant economic resources and their implications for development policy, assessing the impact of disaster in current development programs and identifying new development opportunities created by disaster).

Rehabilitation and reconstruction comprise the longest period of the post-emergence recovery phase. Rehabilitation takes place in the immediate aftermath of disaster and is the transition between mitigation and reconstruction. The reconstruction period requires full restoration of services and infrastructure, building construction, restoration of destroyed infrastructure and, last but not least, economic revitalization.

4. Examination of the victim and cardio-pulmonary resuscitation

Before any procedure regarding the victim's examination, it is essential to ensure the safety of the rescuer, as well as the team's and not lastly the victim's. Once the safety conditions have been ensured, the rescuer must begin evaluating the victim's condition so that he can assist in the order of priority and severity of the present injuries. The rescuer must conduct a quick and thorough survey to assess changes in vital functions, endangering the life of the victim.

Primary examination aims to detect the presence of situations that can endanger the victim's life as well as to provide adequate emergency assistance (Chiorean et al., 2002).

In the victim's main survey, the rescuer must keep track of the following list of priorities:

1. Assessing the state of awareness;
2. Assessing the breathing;
3. Assessing blood circulation;

Assessing the state of awareness - a victim is aware if he/she reacts when stimulated. To do this, gently shake the victim's shoulders and ask out loud: "Can you hear me?" "Are you okay?" If the victim is unconscious, you must immediately call for more help. If he/she doesn't respond, the victim is unconscious and in potential danger of death.

Breathing assessment - first stage of respiratory evaluation is the release of the respiratory tract. Obstruction of airways is a very serious situation that can occur in unconscious victims by relaxing the muscles, by accumulation of secretions (vomit, blood, etc.) or by the presence of foreign objects such as teeth, prostheses, food, earth, leaves, etc.

After releasing the airways, approach the victim's face, examine the thorax while maintaining the airways open (Prentice and Charles, 2002). Check the breath for 10 seconds using the following three steps:

Look - if there is a vertical movement of the chest;

Listen - the flow of air that passes into the victim's airway;

Feel - the air expired by the victim.

Blood circulation assessment - arterial pulse is a peripheral manifestation of the heart's mechanical activity, consisting of a periodic expansive wave, synchronous with ventricular ejection, perceived upon palpation of an artery on the underlying tissue. In a victim with impaired circulation, it is possible to feel the pulse in large arteries, especially in carotid, femoral, radial or humeral. To find the pulse in the carotid artery, place two fingers (index and middle fingers) on the larynx (Adam's apple) and gently slide towards the outside of the neck to find a channel between the trachea and the sternocleidomastoid muscle. Gently palpate, without compressing, for 10 seconds.

Cardiovascular resuscitation is an important technique performed when the victim does not breathe and / or the heart stops beating (Azoulay and Sprung, 2004). Stopped breathing without a stopped heart allows intervention within 3 to 12 minutes, to have a chance to succeed in saving the victim's life (Saner et al., 2002).

Cardiovascular resuscitation implies (Beauchamp and Childress, 2008):

A) Opening and cleaning the nasal cavity/mouth and ensuring the airways are released by: tilting the head backwards and lifting the chest.

B) Resumption of blood circulation by external cardiac massage.

C) Resumption of artificial breathing movements by mouth-to-mouth breathing or mouth-to-nose breathing.

Artificial breathing. It is performed in both respiratory and cardiac arrest. The resuscitation manoeuvres begin with the release of upper respiratory tract (mouth, nose, oropharynx) (Bossart et al., 1998). Release of the upper respiratory tract is sometimes sufficient for the victim to resume breathing without the need for artificial respiration (Babbs, 2002).

The victim will be positioned in dorsal decubitus, the rescuer sits on his knees at the victim's head on the side and performs, in the following order, (fig. 1): 1. Head hyperextension; 2. Release of the upper respiratory tract; 3. Disjoint of mandible; 4. Nose pins - nose closure prevents the air powerfully inserted by the rescuer into the victim's mouth coming out through the nostrils, it being forced to fully enter the lungs. This manoeuvre can be performed with special pins from the aid kit or by hand.

After this preparation, the rescuer draws air in the chest (deep inspiration), followed by a willing apnea, then quickly applies, with wide mouth open, his lips over the victim's open mouth, which was previously covered with a piece of gauze or clean handkerchief and powerfully breaths the air from his lungs into the victim's airway (Ciontu, et al., 2006). Then the rescuer rises, performs a new inspiration, while letting the patient's nostrils and mouth open, so the air comes out of the lungs, and breaths air into the lungs again, repeating this sequence for 14-16 times / min. For varied reasons (the mouth of the victim cannot be opened, the presence of injuries to the victim's mouth, jaw fractures, the mouth of the rescuer is smaller than that of the victim), the mouth-to-mouth breathing is aborted and the breathing "mouth to nose" is initiated. This method generally retains the same working times described in the previous method.

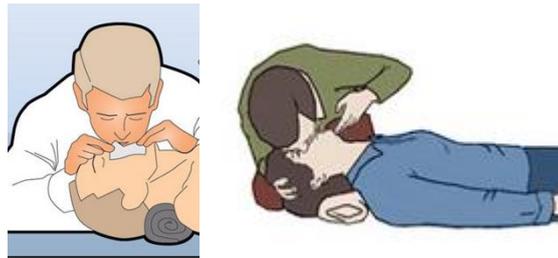

Fig. 1. (a) “mouth-to-mouth breathing”, (b) “mouth-to-nose breathing” artificial breathing

External cardiac massage. Resuscitation of a subject in cardiac arrest (fig. 2) is mandatory to be performed in parallel with artificial breathing, as cardiac arrest is invariably followed, in 20-30 sec., by respiratory arrest (Flabouris and Bridgewater, 1996). The victim will be placed in in dorsal decubitus position on a rough surface.

The rescuer sits on the side of the victim and transversely applies the left-hand bridge to the lower 1/3 of the stern and the other hand crosses the first. With two hands crossed and thumbs elevated to avoid compressing the ribs (which can fracture), rescuer’s shoulder line above the victim sternum, elbows in extension, helped by its own weight, the rescuer performs rhythmic pressures on the sternum (DeLorenzo, 1997). Each compression will be sharp and short (approx. 1 sec.) and will exert a vertical pressure of the sternum toward the spine so that the sternum is sunken by about 5-6 cm (Haukoos, et al., 2004). After each compression, the sternum is allowed to return to its original position without raising the hands of the sternum.

Fig. 2 External cardiac massage

Breathing may be delayed after the heart resumes its activity after external cardiac massage, so artificial respiration continues until the patient can breathe normally (Herlitz, et al., 2006). Even if the patient resumes respiratory and cardiac activity, it is forbidden to lift him from the horizontal position because at any time the cardio-respiratory arrest can reappear.

Resuscitation continues until:

- qualified help arrives and takes over resuscitation; or
- the victim gives signs of life: he moves, opens his eyes or breathes normally; or
- the rescuer is physically exhausted.

5. Conclusions

Disasters (catastrophes) cause serious disruption or disturbances in the functioning of society and generate human casualties, material damage and environmental damage. Evolution of society imposed the enacting of legislative initiatives that would provide the legal basis for civil emergency management, with particular attention to disasters.

Risk management requires systemic integration (risk assessment, emergency preparedness, disaster prevention and disaster risk financing) as well as reducing exposure of states to economic losses.

Prior to any first aid procedure, it is essential to ensure the safety of rescuers, as well as the team’s and, last but not least, the victim’s. Awareness is needed so that everyone knows how to perform first aid to save someone’s life, or to reduce the negative consequences for an injured person.

Abstract

Due to the continuous developments in both science and technology, arises a high importance in organizing human activity at the workplace. Two of the most aggressive factors in the workplace are noise and vibration. The noise problem is quite prevalent today because there are a lot more jobs available in industries with a high level of hazard, and so is the number of exposed workers. The purpose of this paper is to analyze the noise and vibration levels in the pipes manufacturing process measured at SC Pipes SRL from Iasi. Following the field measurements taken in the factory, it has surfaced that in some sections, the noise level has exceeded the maximum level of exposure set in Government Decision (GD) 493/2006. Regarding the vibration exposure measurements, it was found that all measurements were within exposure levels set in (GD) 1876/2005.

Keywords: noise levels, vibrations levels, pipes manufacturing

1. Introduction

The continuous development of industrial technology led to a more focused organization of human activity at the workplace. Noise and vibration represent some of the most aggressive physical factors in the workplace. The noise and vibration problems are still prevalent, altho, recently, the number of workers exposed have diminished thanks to the replacement of obsolete machines and equipment that produced intense noise with modern ones, where these pollutants are, usually, within allowed limits (Munteanu 2007).

Sound represents mechanical vibration propagating through an elastic gaseous, liquid or solid medium through which the source energy is transferred by progressive sound waves. Whenever an object moves or vibrates, a small proportion of the energy involved is lost to the environment in the form of sound (Kovacs 2017). Noise is an unwanted sound that is defined as a mixture of sounds, strong, discordant, unpleasant, being characterized by intensity (dB) and frequency (Hz). Noise and vibration are generally accepted, due to the professional obligations, but, in most cases, humans will carry on doing their work ignoring ambient noise and vibration (Munteanu 2007). Noise is a major problem for the work force, causing hearing loss, discomfort, sleep disorders, fatigue and hypertension. Although extra-auditory effects of exposure to high noise levels have been reported, noise induced hearing loss has been recognized for a long time as a primary effect of excessive noise exposure (Hong et.al, 2013). With the increase in intensity, noise is felt and can have an adverse effect on a person's professional performance. An unexpected or intermittent noise bothers more than a continuous one, and high pitch noises are more bothering than low frequency ones (Munteanu 2007).

Industrial vibrations are an oscillatory type of movement of solid bodies in an elastic environment, these can be found in most work environments and, like noise, have a negative effect on human body functions (Palmer and Bovenzi 2015). In practice, vibration studies gain a growing weight, due to increasingly prevalent trends (Zhao and Schindler 2014, <http://www.medtorrents.com>), like: (i) equipment with higher performance, higher working speeds and higher dynamic stability; (ii) making buildings as light and safe as possible; (i) protecting human operators. Due to increased power and working speeds of equipment, through the development of modern work techniques, a varied

* Corresponding author. Tel.: +0-074-283-4256;
E-mail address: monica.lohan@yahoo.com

number of sources of noise and vibration have emerged, which led to an increase in the number of persons exposed. Occupational exposure to vibration has many forms and quite frequent in the population. Vibrations can have adverse effects to human health which can manifest through rheumatological afflictions (Palmer and Bovenzi, 2015) or musculoskeletal disorders (Charles et al., 2018). By initiating measures to improve conditions in the work health and safety field, directives have been elaborated on specific areas, stipulating minimum requirements to ensure an optimal level of protection for workers (Kovacs 2017).

Risk identification and assessment is required to determine the protective equipment the workers are required to wear (Ivascu et al., 2014, Moraru et al. 2013), followed by proper use of equipment training (Darabont et al., 2017a, Babut et al., 2011). The correct implementation of the standards in effect (Darabont et al., 2017b, Bejinariu et al. 2017a) is also required.

In this context, the paper analyses the level of noise and vibration in the pipe manufacturing process. For this purpose, vibration measurements were made on the straightening machine, the analyzed area – the drawing roller area and the tube forming area, as well as the noise measurements in the first section of the analyzed company.

2. Methodological approach

Research has begun in the context sketched by competition, based on the idea of profit and sustainable development that imposes limitations through regulation and standards on noise and vibration, which involves additional cost; so, the context is previously the fierce confrontation between the idea of profit and the costs caused by the reduction of noise and vibration. The area of application is in the metallurgical industry, mainly in pipe making, which is under pressure of sustainable development (Corăbieru 2009).

The methodological approach was based on explanations and understanding, and, the main epistemological references of the paper being:

- the interpretativeist paradigm – to understand reality;
- the constructivist paradigm – emphasizing on building in anticipation of some tendencies;
- the positivist paradigm, used as an exception for deductive explanation (in relation to the theory).

As an epistemological approach, the paper has concluded between ethical and emical as follows:

- through the ethical approach, the general characteristics of noise and vibrations are invoked (intensity, frequency), by identifying the specific characteristics for each analyzed work in order to highlight the elements of general applicability (accepted level of noise, level accepted by vibrations);
- through the eco-type approach, the importance of the measured and analyzed noise and vibration characteristics were highlighted for each work station from the technological work flow, identifying the specific levels in the different groups of activities carried out in the pipe manufacturing process emphasizing the interpretative comparative side.

The two approaches are not entirely in opposition to each other, being presented during complementary research, relying on each other.

The methodological support for the study was provided by the specialized literature presented by (Mihai-Adrian et al., 2017, Darabont et al., 2017, Babut et al., GD 493/2006, GD 1876/2005):

- fundamental works by specialized personnel from home and abroad;
- periodical publications, analytical and informative;
- legislative acts of the Government of Romania;
- statistical yearbooks, official reports;
- European environmental directives;
- noise and vibration current legislation.

The research techniques were mainly based on comparative analysis, change analysis, prognosis and optimization of the equipment design on the technological flow of pipe making, modelling and simulation in the design of pipe-type products in order to achieve an explanatory and predictive construction.

The method plan is based on the inductive and the deductive method by mixing the qualitative and the quantitative approach.

3. Case study

The current paper analyses existing noise and vibration in the SC PIPES SRL company, a medium sized company with up to 300 employees and a yearly turnover of over 10 million €. Within the company, the pipe and profile making processes were followed and the physical emissions were measured and analyzed, with emphasis on determining the noise and vibration levels (Corăbieru and Minciună, 2018).

SC PIPES SRL manufactures steel longitudinally welded pipes from hot or cold-rolled strip, on German, Russian and Italian lamination lines. The company also runs cold rolled profiles, has high-quality technologies and its own research center.

The SC PIPES SRL company includes of 6 sections: Section I – 5 production halls, Section II - 8 production halls: Section III - 6 halls: Section IV - 11 halls, Section V - 5 halls: Section VI - 2 halls.

3.1. Determining the vibration level

Measuring the vibration level was done in the straightening machine and in the pipe formation areas. The straightening machine (Fig 1a) is an assembly, and, is part of the rolling line; the ribbon is straightened in order to obtain a correct sizing line and to avoid defects or tears. The workers that are handling this machine are subjected to noise and vibration, especially hand and eye protection (Bejinariu et al., 2017b).

In this sense, vibration determinations were made on the drawing rollers. Vibration measurement bulletin for the workplace: the straightening machine is shown in Fig. 1 (b).

Fig.1. Work place vibration measurements: the straightening machine (a) and the calibration bulletin (b)

The measuring method used was: momentary, with an exposure time of 8 hours. The vibration measurements were made on the Z and X axis. No exceedances for vibrations were found, however, compliance with HG 1876/2005, art. 13 and 15 was recommended.

The machine’s rolling speed gradually increases with each strip deformation step. Due to the speed increase on each step, there are noises and vibrations that need to be diminished or eliminated if possible. If the machine tuning isn’t done properly, the noise and vibration levels increase and can cause professional illness, discomfort, fatigue, stress, etc.

In this section, vibration measurements were made using the momentary measurement method, with an exposure time of 8 hours. The vibration measurement was carried out on the Z and X axis. Figure 2 shows the analyzed work area (a) and the vibration test report (b). No exceedances for vibrations were found, however, compliance with HG 1876/2005, art. 13 and 15 was recommended.

3.2. Determining the noise level

Noise measurement have were taken in section 1, work station and sales service. Resulting from these measurements, it was concluded that there were exceedances of noise levels and that there were some jobs in which the exposure was over the admitted levels. In these places, employee activity was forbidden according to HG 493/2006. Fig. 3 contains the determination bulletin.

Fig. 3. Workplace test report: Section I

3.3. Workplace health and safety policy

The core value promoted by SC PIPES SRL is the creation of a healthy work environment that ensures the development of the organization and the professional and personal development of the employees. The company's target is zero accidents. Prevention of Accidents and Occupational Diseases underpins the drafting of the Health and Safety Policy of SC PIPES SRL.

The main concerns for fulfilling the principles of the Health and Safety Policy are:

- Employee awareness regarding accident risk and workplace illness, related to the activities they are involved in and a continuous care for reducing and eliminating risks;
- Health and Work Safety trainings and workshops;
- Emergency situation simulations;
- Continuous employee consultation on workplace safety and health issues;
- Initiatives to motivate the employees in promoting safe working practices and contribution to the creation of safer jobs.

4. Conclusions

The measurements yielded the following conclusions:

1.Noise and vibrations aggravate and maintain pre-existing conditions such as anxious obsessions, nerve depression in depressed patients, gastro-duodenal conditions, and especially unexpected noise can cause major seizures and epilepsy.

2.Noise and vibrations directly reduce work capacity by reducing intellectual concentration, lowering precision and efficiency of movements, decreasing or distracting attention, increasing energy expenditure needed to perform a given physical effort, difficulty in perceiving verbal information (orders, assign task) voice and cerebral overload.

3.Measures to combat noise and vibration must be directed to removing or reducing the action of the indicated causes. If it is not possible to carry out radical measures, measures must be taken to isolate and absorb the noise from production. The sound absorbing material must have a maximum absorption coefficient. It is recommended that, where possible, noise work be carried out in the open air.

4.Proper machine balancing can remove the action of noise and vibration factors. It is possible to install on special elastic basis the machines and equipment that cause noise and vibration and at the same time to separate them with a layer of air from other rooms of the building.

5.Interpretation of the determinations carried out at SC PIPES SRL was made in accordance with GD 493/2006 and GD 1876/2005 and it was found that in the case of noise measurements in some workplaces the level of the exposure value at which the action is triggered was exceeded (Section 1 - Hall 2, collector, Hall 2 - 220-desk power station, 30L lines, 30xU-laminator, Hall 11-RAC 89-ovens, pump room, compressor station).

6.Following the interpretation of the results, it was found that some workplaces exceeded the limit value for exposure to noise. Thus, the activity of the employees is forbidden.

7.As far as the results of the vibration bulletins were concerned, it was found that all measurements were within the limits of exposure to vibrations.

Modern approaches in integrated management systems of quality, environmental and occupational health and safety

Doru-Costin Darabont^a, Costică Bejinariu^{b*}, Constantin Baciub^b,
Mihai-Adrian Bernevig-Sava^b

^a INCDPM “Alexandru Darabont”, 35 A, Ghencea Blv., Sector 6, 061692, Bucharest, Romania

^b “Gheorghe Asachi” Technical University of Iasi, D. Mangeron Blv., no. 67, 700050, Iasi, Romania

Abstract

Releasing of ISO 9001 and ISO 14001 standards in 2015 represents a big step forward in managing quality and environmental issues on an integrated manner, optimizing the resources spent by the organization for this scope. This set of instruments becomes complete by the releasing, in 2018, of ISO 45001 “Occupational health and safety management systems – Requirements with guidance for use”. The new international standard integrates the good practice gained by using former documents, such as ILO-OSH 2001 “Guidelines on occupational safety and health management systems” and OHSAS 18001 “Occupational health and safety management systems – Requirements”.

The strongest point of the triad represented by ISO 9001, ISO 14001 and ISO 45001 is the similar structure of these standards, based on the ISO 10 core clauses of the High Level Structure. This characteristic leads to a high potential to integrate the quality, environmental and occupational health and safety requirements in a single integrated management system.

Due to the novelty of these standards, it is necessary to develop new instruments to help organizations in implementing and assess the performance of the integrated management system.

The paper presents a high level checklist, aimed on auditing an integrated management system based on ISO 9001:2015, ISO 14001:2015 and ISO 45001:2018. This tool could be used for an integral audit, against all three standards, or just for a partial audit, against one or two standards.

In order to optimise the resources allocated for the audits, the checklist should be used together with an IT tool, also elaborated by the authors and described in the paper, which can provide several important functions such as automation of scores, synthesize of the results and digital archiving of the information.

Keywords: integrated management systems, occupational health and safety, quality management, environmental management, audit.

1. Introduction

Releasing of ISO 9001 and ISO 14001 standards in 2015 completed by ISO 45001 in 2018 represents a big step forward in integrated management of quality, environmental and occupational health and safety issues. The strongest point of the triad represented by ISO 9001, ISO 14001 and ISO 45001 is the similar structure of these standards, based on the ISO 10 core clauses of the High Level Structure. This characteristic leads to a high potential to integrate the quality, environmental and occupational health and safety requirements in a single integrated management system.

Considering the novelty of these three standards, the organizations need new instruments to facilitate the implementation and assessing the performance of the integrated management system. The high level checklist could be used for an integral audit, against all three standards, or just for a partial audit, against one or two standards. Also, the checklists could be combined with an IT tool, which can provide several important functions such as automation of scores, synthesize of the results and digital archiving of the information.

2. Overview of the integrated management systems

An integrated management system uses a similar approach of quality, environmental and occupational health and safety (OH&S) issues, optimizing the resources spent by the organization for this scope. It is based on the requirements of the following standards, see Fig.1:

- ISO 9001:2015 - "Quality management systems. Requirements" (with its Romanian version SR EN ISO 9001:2015);
- ISO 14001:2015 – "Environmental management systems – Requirements with guidance for use" (with its Romanian version SR EN ISO 14001:2015) and
- ISO 45001:2018 – "Occupational health and safety management systems – Requirements with guidance for use" (with its Romanian version SR ISO 45001:2018).

ISO 45001 standard replaces OHSAS 18001 standard which has acted as an international standard until 2018, when the new ISO standard has been released.

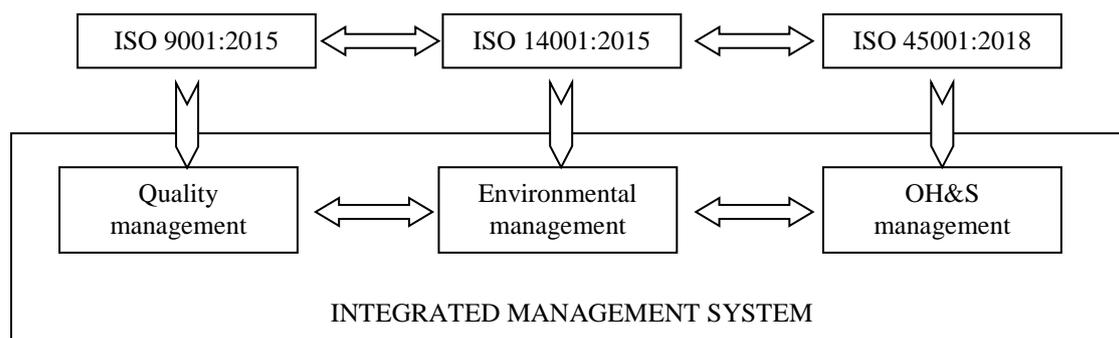

Fig. 1. Structure of an integrated management system

One of the main requirements of the organizations is to benefit by similar procedures for quality and environmental management as well as for OH&S management. In this scope, the structures of standards ISO 9001:2015, ISO 14001:2015 and ISO 45001:2018 are similar and based on the ISO 10 core clauses of the High Level Structure (Annex SL), which brings a common framework for all management systems. The 10 core clauses, common to all three standards, are presented in Table 1.

Table 1. Common structure of the standards, based on Annex SL

No.	Chapter
1	Scope
2	Normative references
3	Terms and definitions
4	Context of the organization
5	Leadership
6	Planning
7	Support
8	Operation
9	Performance evaluation
10	Improvement

Anyhow, there are some particular requirements of each standard which should be considered, such as:

- Requirements for products and services, in case of ISO 9001:2015;
- Environmental objectives and plans for achieving them, in case of ISO 14001:2018, or
- Hazard identification and assessment of OH&S risks, in case of ISO 45001:2018.

Thus, regarding hazard identification and assessment of OH&S risks, the standard requires the organization to "establish, implement and maintain a process for the on-going proactive identification of hazards arising" (SR ISO 45001:2018). As the standard does not recommend a certain method for hazard identification and risk assessment, the organization itself should adopt the method which is most appropriate for its size, territorial structure, type of activity, type of hazards, legal or organizational requirements etc. Generally, organizations prefer the methods considering risk as a result of three dimensions (Băbuț, G.B. et al., 2011). In Romania, a frequently used method for risk assessment is the method developed in 1998 by the National Research and Development Institute on Occupational Safety, which fully responds to the requirements of Government Decision no.1425/2006 regarding the approach of risk assessment (Darabont, D.C. et al., 2017).

3. Software tool for auditing the integrated management system

Analyzing the text of the standards, each requirement could be transposed in a specific item. Thus, three distinct high level checklists are obtained:

- Checklist for auditing quality management system;
- Checklist for auditing environmental management system;
- Checklist for auditing OH&S management system.

These checklists could be used together or separately, providing a high flexibility of the system.

Each item of a checklist should be assessed and it will obtain 0, 1 or 2 points, according to the requirement fulfilling level, as follows:

- 0 points, representing a non-conformity and showing that the requirement are not addressed;
- 1 point, representing a partial conformity;
- 2 points, representing a conformity, or showing that the requirements are fulfilled.

The conformity level (*CLi*) for each checklist is obtained as a percentage of the gained points from the maximum score (considering all the relevant items are noted with 2 points).

The overall conformity level (*CL*), characterising the integrated management system is obtained as the average of the conformity level (*CLi*) for each checklist used in assessment.

The software tool was elaborated using Microsoft Office Excel, considering the main advantages of this application: large number of users, flexibility, connectivity with Microsoft Word etc.

1	Company:		Auditor(s):

4. Conclusion

The strongest point of the triad represented by ISO 9001, ISO 14001 and ISO 45001 is the similar structure of these standards, based on the ISO 10 core clauses of the High Level Structure. This characteristic leads to a high potential to integrate the quality, environmental and occupational health and safety requirements in a single integrated management system, having as a result the optimization of the resources allocated by organization for implementing and maintaining the integrated management system.

The organizations need new instruments to facilitate the implementation and assessing the performance of the integrated management system. The high level checklists could be used for an integral audit, against all three standards, or just for a partial audit, against one or two standards. Also, the software tool provides several important functions such as automation of scores, synthesize of the results and digital archiving of the information.

Abstract

Protective helmets are very important components of individual fire-fighting equipment. They have different roles including: protecting the head from throwing objects, protecting from high temperatures or electrical shocks. In order to be used, they must ensure the absorption of shocks in the upper part of the head, to have penetration resistance, to have lateral crush resistance, to provide protection against hot liquids and high temperature resistance. The helmet material has to provide the same properties when is exposed to $90 \pm 5^\circ\text{C}$ for 20 minutes in the area of the upper head and ear, and at $180 \pm 5^\circ\text{C}$ for 5 minutes in the area of the neck protector. At the moment, fire-fighting helmets are made of high-quality polymers.

This paper aims to analyse the thermal behaviour of a new material useful for fire-fighting helmets: hot modelling material, under the form of a glass fibre-reinforced bismaleimide composite material, compared to a molded polypropylene injection. Thermal analysis will be performed using differential scanning calorimetry (DSC) and Dynamo Mechanical Analysis (DMA) and the thermal properties of the new material will be highlighted.

Keywords: Personal Protecting Equipment, firefighter helmets, bismaleimide, high temperature resistance

1. Introduction

Personal Protective Equipment (PPE) is the equipment intended to be worn or held by the worker to protect him against the risks that might endanger his health and safety at work, as well as any additional or accessory designed for that purpose, according to GD 1048/2006. PPE is part of the daily routine of all those working in the industry, construction and emergency services staff. Currently, Romania has one of the highest levels of incidents in Europe, with over 4,900 accidents at workplace being reported in 2016, of which 225 were fatal accidents, according to the Labor Inspection report (www.inspectiamuncii.ro).

One of the causes is the inappropriate choice and use of PPE (Bejinariu et al., 2017a). PPE includes the following components required for: head protection, leg protection, face protection, respiratory protection and body protection (Park et al., 2015). It should be noted that the use of protective equipment is the last priority in the process of preventing accidents at work; in principle, reducing or controlling risks at source should prevail (Mihai-Adrian et al, 2017, Babut and Moraru, 2018). Risk assessment is a first step in determining the type of protection required (Ivaşcu et al., 2014, Moraru et al., 2013), followed by the training for an appropriate use of the equipment (Darabont et al., 2017a, Babut et al. 2011), as well as the correct implementation of the standards in force (Darabont et al., 2017b, Bejinariu et al., 2017b).

Combating fire is often described as a very dangerous activity (Ghani et al., 2017). According to statistical data, the dangers that endanger the safety of firemen's life can be divided into several categories, namely: building demolition, flashover explosion, fall from height, electric shock, gas poisoning, road accidents and other accidents (Kang et al., 2016). The probability of meeting high heat environments contributes to the dangers inherent in this occupation. Situations such as "flashovers" and high intensity fire are examples of circumstances in which anti-fire personnel can expect to face a high level of radiant heat flow. To ensure adequate protection against bodily injury and fire blazes, PPE

is designed to isolate the wearer from the dangers of the environment and ensure the efficient performance of the work duties (Vigneswaran, and Arulmurugan 2014).

Appropriate head protection equipment is particularly important for the safety and protection of firefighters when they engage in small or large fires (Bălan et al, 2011). The helmet is designed to protect the head from flying objects, explosions, high temperatures, electrical shocks, and chemicals. Those helmets must meet certain specific thermal, shock, penetration or abrasion resistance requirements, in accordance with current standards.

In Romania, firefighting helmets in buildings and other structures must be tested and meet the mandatory performance requirements in accordance with SR EN 443:2008: shock absorption in the upper area of the head, penetration resistance, side impact resistance, radiant heat resistance, protection against hot liquids, as well as heat resistance. In general, a helmet consists of a cap and harness and other accessories. The cap is the visible part of the helmet made of materials resistant to temperature, vibration, impact and humidity. The most commonly used cap materials are high density polyethylene (HDPE), acrylonitrile-butadiene-styrene copolymer (ABS) or polycarbonate (PC).

Nowadays, new studies are being carried out and new materials are sought to improve the thermal and mechanical properties of the helmets. A good candidate for making the helmet cap is bismaleimide. This new material presents a number of advantages such as: high thermal stability, nonvolatility and low cost (Ursache et al., 2012). The purpose of this paper is to present the thermal properties of a new material, a glass fiber reinforced bismaleimide composite material (BISM COMP) obtained by some of the authors of this work, a material used to manufacture the helmet caps used by firefighters.

2. Experimental details

The material analyzed in the present paper was obtained by hot molding process, as a composite of glass fiber reinforced bismaleimide. The bismaleimide resin precursor (BMI) were prepared by reaction of 4,4-bismaleimidodiphenylmethane with 4,4-diaminodiphenyl methane. Silica cloth was impregnated with a 50 wt. % solution of BMI pre-polymer in N-methylpyrrolidone and allowed to dry for 24 h at room temperature and in a circulating air. The pre-pregs dimension 100x100 mm were packed over the female part of the steel mold coated with silicone release agent. The male counterpart of the mold was placed between the preheated plates (140°C). The first laminate samples were obtained in sheets consisting of a single layer and by pressing several layers followed by heating the samples were allowed to cool down to room temperature gradually under a pressure of 10 Kgf/cm² and the second type, of multilayer samples, were obtained (Ciubotariu-Ana et al., 2018) Thermal analysis was performed by differential scanning calorimetry (DSC) and mechanical-dynamic analysis (DMA). Tests were performed on two types of samples: samples from a fire-fighting helmet bought from commerce (HDPE) and samples made from glass fiber-reinforced bismaleimide composite (BISM COMP).

For DSC analysis, the DSC F3 Maia calorimeter (Fig. 1) supplied by NETZSCH, with a sensitivity of <1μW, temperature accuracy: 0.1 K and enthalpy accuracy - generally <1%, was used. The device was calibrated with Bi, In, Sn, Zn and Hg.

Fig. 1. DSC calorimeter used for experiments

The measurements were performed under Ar-protective atmosphere using corresponding correction curves. The DSC data was evaluated with Proteus software provided by NETZSCH. Small samples with a maximum mass of 25 mg were cut. After they have been cleaned from impurities, they were subjected to controlled heating with a 10K/min heating rate up to 400K for the HDPE sample, and 450K for the BISM COMP sample.

For DMA analysis, a dynamic mechanical analyzer (DMA) type DMA 242 Artemis supplied by NETZSCH was used (Fig.2), with a force resolution of 0.0005 N, amplitude range: ± 0.1 to 240 μm and amplitude resolution: 0.0005 μm using a three-point-bending specimen holder.

Fig. 2. DMA analyzer used for experiments

For analysis, a frequency of 1Hz and an amplitude of 20 μm were used. Experiments were conducted in inert gas atmosphere and consisted of controlled heating up to 420 K for the HDPE sample, and 470 K for the BISM COMP sample.

3. Results and discussions

The DSC thermogram illustrating the heating behavior of the HDPE sample is shown in Fig. 3.

During heating, it can be seen that the sample taken from a helmet bought from commerce has a minimum endotherm at 383.4 K, which is attributed to the melting of the material. For common commercial grades of medium and high density polyethylene, the melting point is typically between 280 and 300 K (Chianelli-Junior et al., 2013). The amount of heat absorbed during this transformation is about 1 J/g.

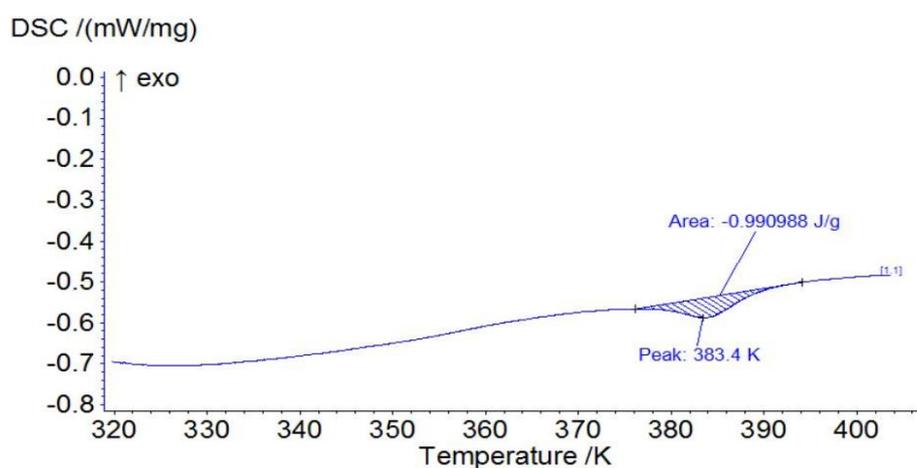

Fig. 3. DSC thermogram recorded during heating for the HDPE sample

In case of heating the sample made from BISM COMP, Fig. 4, the DSC thermogram shows no deviation from linearity that could suggest the presence of a transformation in the temperature range under analysis. It can be argued that the BISM COMP material is thermally stable up to 450 K

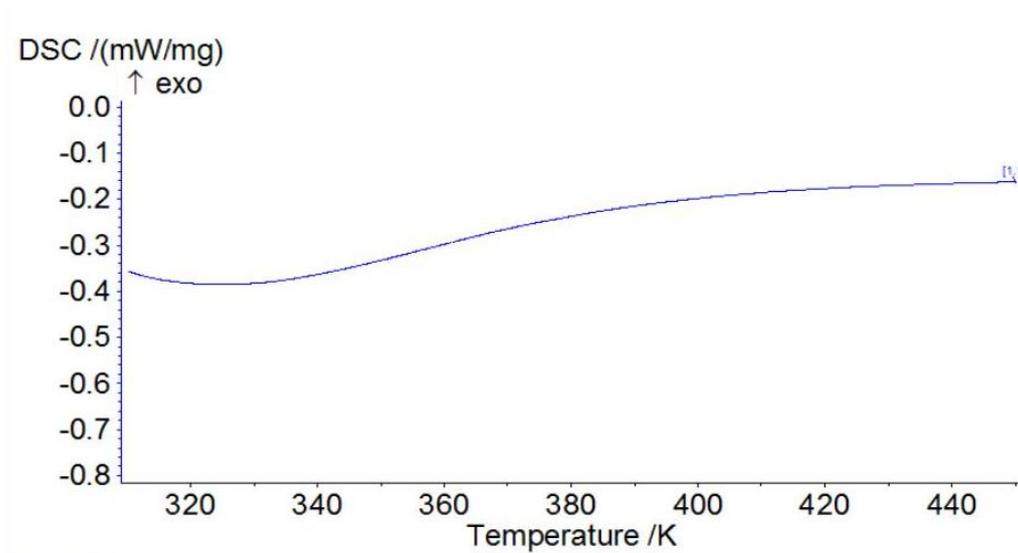

Fig. 4. DSC thermogram recorded during heating for the BISM COMP sample

To verify the visco-elastic behavior of the analyzed samples, DMA experiments were performed. For the analysis was chosen the variation of storage modulus (E'), and the internal friction ($\tan \delta$) with temperature. In Fig. 5 shows the variation of module E' for the two analyzed samples. For a better understanding of the dynamo-mechanical properties, an overlap of the elastic modulus (E') was realized for the two samples.

From Fig. 5 it can be seen that the modulus E' value for the BISM COMP sample has values approximately 9 times higher than HDPE. Also, during heating, the sample retains its stiffness in the temperature range of 300-450 K without taking any softening, a requirement imposed to protective helmets. The high levels of the elasticity modulus (about 11 GPa) of the resins bismaleimide are similar to those reported in the literature (Shibata and Hashimoto, 2017).

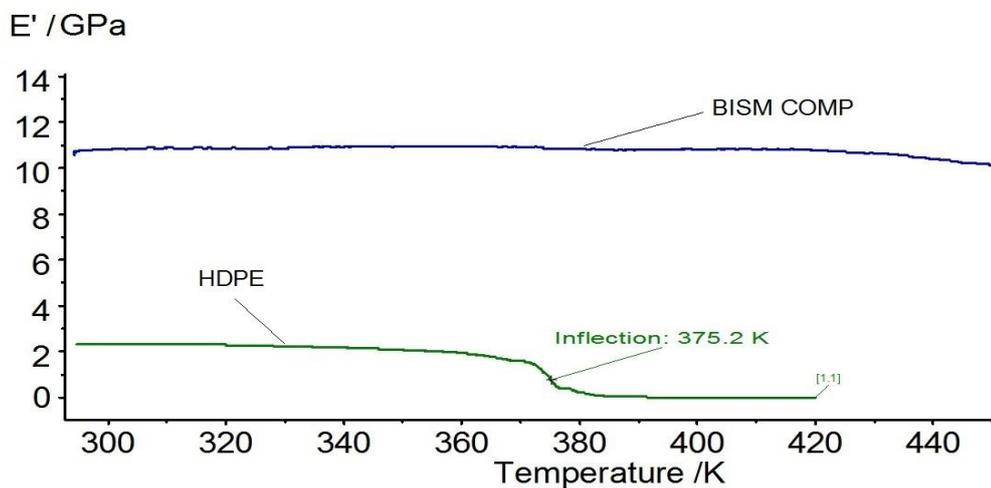

Fig. 5. E' variation with temperature recorded during heating for the HDPE and BISM COMP samples

On the other hand, the HDPE sample shows a decrease in the modulus between temperatures of 370 -380 K, confirming the recorded melt on the DSC thermogram in Fig. 3. Analysis of $\tan \delta$ curves is very useful in determining of the performance to stress and temperature of the samples. Fig. 6 shows the $\tan \delta$ curves corresponding to HDPE and BISM COMP samples.

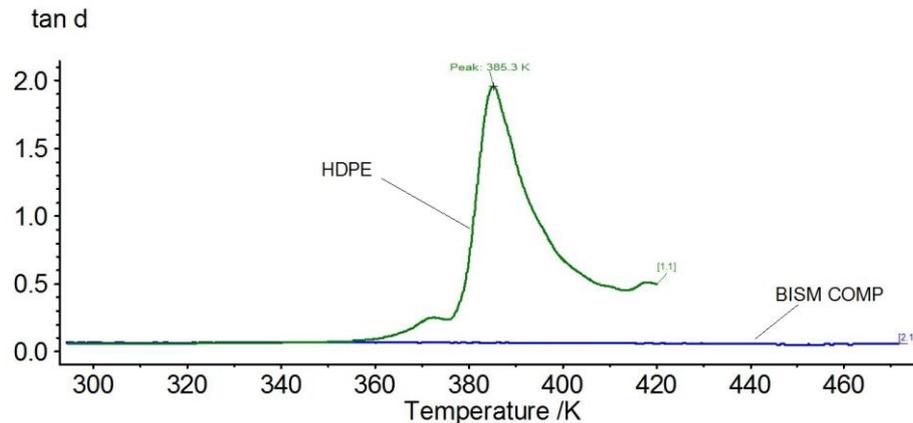

Fig. 6. Tan δ variation with temperature recorded during heating for the HDPE and BISM COMP samples

It is clear that in the temperature range studied between 300 and 460 K, the variance of tan δ for the BISM COMP sample shows low values. This can be attributed to improved interactions and modified stress transfer. It also explains the values obtained for stiffness by the BISM COMP material (Tian et al, 2017).

It follows that BISM COMP does not undergo any transformation in the area of the analysed temperature while the HDPE sample exhibits a maximum at 385 K, attributed to the melting of the material, according to the data obtained in Fig. 3 and 5.

4. Conclusions

In this paper we examined the thermal and mechanical dynamics of two samples of material for the fire helmets: a sample taken from a helmet bought from commerce, and a sample of a new material developed by the authors. In summary, the following conclusions were drawn:

- the new material, BISM COMP, exhibits improved thermal properties compared to the materials on the market, proving a superior thermal behaviour;
- during DSC analyses the BISM COMP sample did not show any phase transformation in the temperature analysed field, being thermally stable;
- during DMA analyses, the BISM COMP sample showed an elastic modulus approximately 9 times greater than the sample with which it was compared;
- improved thermal performance makes BISM COMP a good candidate for developing the cap of fire helmets to improve the user safety to high temperatures.

Abstract

"Decision no. 1048 of 9 august 2006 on the minimum safety and health requirements for the use by workers of personal protective equipment at work "may be considered as the legal provision which makes available, in its annexes, the risk assessment tool for the selection of individual equipment protection in order to achieve "the identification of the individual protective equipment necessary for the work stations in the unit and the elaboration of the necessary equipment for the workers with the individual protective equipment" (according to point 20, paragraph (1), article 15 of the Methodological Rules in 11 october 2006 on the application of the provisions of the Law on safety and health at work no. 319/2006).

Implementation in april 2018 of Regulation no. 425 of 9 march 2016 on personal protective equipment and repealing Council Directive 89/686 / EEC, provides elements that will allow "to monitor the maintenance, handling and proper storage of personal protective equipment and their replacement by the deadlines" with the requirements of point 19, paragraph (1) of article 15 of the Methodological Rules for the application of the Law on safety and health at work no. 319/2006.

Keywords: safety and health requirements, personal protective equipment, monitor the maintenance, replacement.

1. Introduction

The multitude of legal provisions in different areas such as employment relationships, occupational health, occupational safety and health or procurement puts the employer in difficulty when it comes to the correct and natural order of steps to be taken to comply with the requirements of current legislation.

If we consider the moment of employment, the Labor Code - republished, dated 24 January 2003, adopted by Law no. 53, art. 27, paragraph (1) clearly states that "A person may be employed only on the basis of a medical certificate, which establishes that the person concerned is fit to perform that work." Paragraph 2 adds that "Non-observance of the provisions of paragraph (1) entails the nullity of the individual employment contract. "

2. Evaluation for the selection of personal protective equipment

The employer, having the obligation to implement occupational safety and health measures and on the principle of "priority adoption of collective protection measures against individual protection measures", leads to the need to carry out an assessment before choosing individual equipment protective. This assessment, even if required by the Decision 1048 of 2006 and according to Art. 14, paragraph (2) comprises:

"(a) analysing and assessing risks that cannot be avoided by other means;

(b) defining the characteristics that the personal protective equipment must possess in order to be effective against the risks referred to in a) taking into account any risks that the equipment itself may create;

(c) comparing the characteristics of the individual protective equipment available with the features set out in b) ", she initiates in the first instance from a document and knowledge of the actual conditions of the work of the worker, as a working position and is complementary to the completion of the annex no. 3 of Decision no. 355 of 2007 on the health

* Corresponding author. Tel.: +4-0745-750-286.

E-mail address: cbejinar@tuiasi.ro

surveillance of workers. This appendix requires, prior to hiring and then periodically, the indication of the risks to which the worker is exposed, the description of the workspace, the level of effort, the overloading, the chemical, the biological, the carcinogen, the dust or the radiation that the worker comes into contact with, the microclimate as well as the means of collective protection and individual protection.

Implementation in April 2018 of the Regulation no. 425 of 9 March 2016 on personal protective equipment and repealing Council Directive 89/686 / EEC, provides for the elements to be used to monitor the maintenance, handling and proper storage of personal protective equipment and their replacement by the deadlines, with the requirements of point 19, paragraph (1) of Article 15 of the Methodological Rules for the Application of the Law on Safety and Health at Work no. 319/2006.

This Regulation, in Annex II: Essential Health and Safety Requirements, point 1.4. The manufacturer's instructions and information clearly state that "besides the manufacturer's name and address, the instructions to be provided with the PPE must include all relevant information on:

- (a) instructions for storage, use, cleaning, maintenance, repair and disinfection. The cleaning, maintenance or disinfection products recommended by manufacturers must not have any negative effects on PPE or on users if used in accordance with the relevant instructions;
- (b) the performance of the relevant technical tests to verify the levels or categories of protection offered by the PPE;
- (c) where appropriate, the accessories that can be used with the PPE and the characteristics of the corresponding spare parts;
- (d) where appropriate, the classes of protection appropriate to the different risk levels and the appropriate limits of use;
- (e) where appropriate, the month and year or period of end of use of the PPE or some of its components;
- (f) where appropriate, the type of packaging suitable for transport;
- (g) the meaning of any marking (see paragraph 2.12);
- (h) the risk against which PPE is intended to protect;"

As regards the setting of deadlines for the decommissioning of PPE, Regulation no. 425 specifies in point 2.4. in Annex II that 'if it is known that the projected performance of the new PPE may be significantly affected by the wear and tear phenomenon, an indelible and unambiguous marking indicating the month shall be affixed to each of the PPE placed on the market and their packaging the year of manufacture and / or, if possible, the month and year of use.

If the manufacturer cannot provide guarantees on the useful life of the PPE, his instructions must provide all the information necessary for the user or purchaser to reasonably determine the month and year of use, taking into account the quality level of the PPE. model and the specific conditions of storage, use, cleaning, maintenance and maintenance. If it is found that the process of considerable and rapid degradation of PPE performance may be caused by the wear and tear resulting from the periodic use of a cleaning process recommended by the manufacturer, the latter must, if possible, apply to each of the PPE introduced a mark on the market indicating the maximum number of cleaning operations that can be performed before the equipment has to be checked or cancelled. If such a marking is not applied, the manufacturer must provide that information in the instructions."

For PPE bearing one or more identification or indicators directly or indirectly related to health and safety, such markings or indicators should preferably take the form of harmonized pictograms or ideograms. They must be perfectly visible and legible and thus remain throughout the foreseeable useful life of the PPE. In addition, such markings must be complete, precise and comprehensible so as to prevent any misinterpretation. In particular, where such markings include words or phrases, the latter must be written in a language that can be easily understood by consumers and other end-users, as determined by the Member State in which the PPE is available on the market.

If the PPE is too small to allow the application of all or some of the required markings, the relevant information must be stated on the manufacturer's packaging and instructions."

For electrical insulating equipment, the manufacturer's instructions shall indicate in particular the exclusive use to which those types of PPE were intended and the nature and frequency of the dielectric tests to which they are subject during their useful life "and for protective equipment against substances and mixtures that are harmful to health and harmful biological agents "the manufacturer's instructions must also indicate the storage deadline of the new filters kept in their original packaging" and "the manufacturer's instructions must contain, in particular, a explanation of the codes (if necessary), a detailed description of the standard tests and all relevant information for calculating the maximum allowable wearing time under the various foreseeable conditions of use."

These provisions contained in Regulation no. 425 of 9 March 2016 allows for the schematic design of the risk assessment process for the selection of the individual protective equipment (Fig. 1) as well as the calculation, the determination of the duration of standard use not only "in terms of expenditure planning". (Antonov et al., 2013; Darabont et al., 2017)

The calculation of the normal use time may be influenced by the nature of the activity carried out or the properties of the individual protective equipment starting from disposable, up to eight hours / a work shift in certain environments up to four or five years in the case of helmets. With the exception of single-use protective equipment, the other categories may be normalized by a calculation that calls into question the time (storage or maximum permissible use), a value component influenced by the risk factors / hazards arising in the performance of the task and which can be eliminated / diminished by PPE and can lead to a degree of wear plus values related to maintenance tracking (proper washing and decontamination), handling (training of workers and proper use) and adequate storage (conditions to be met comply with the manufacturer's instructions).

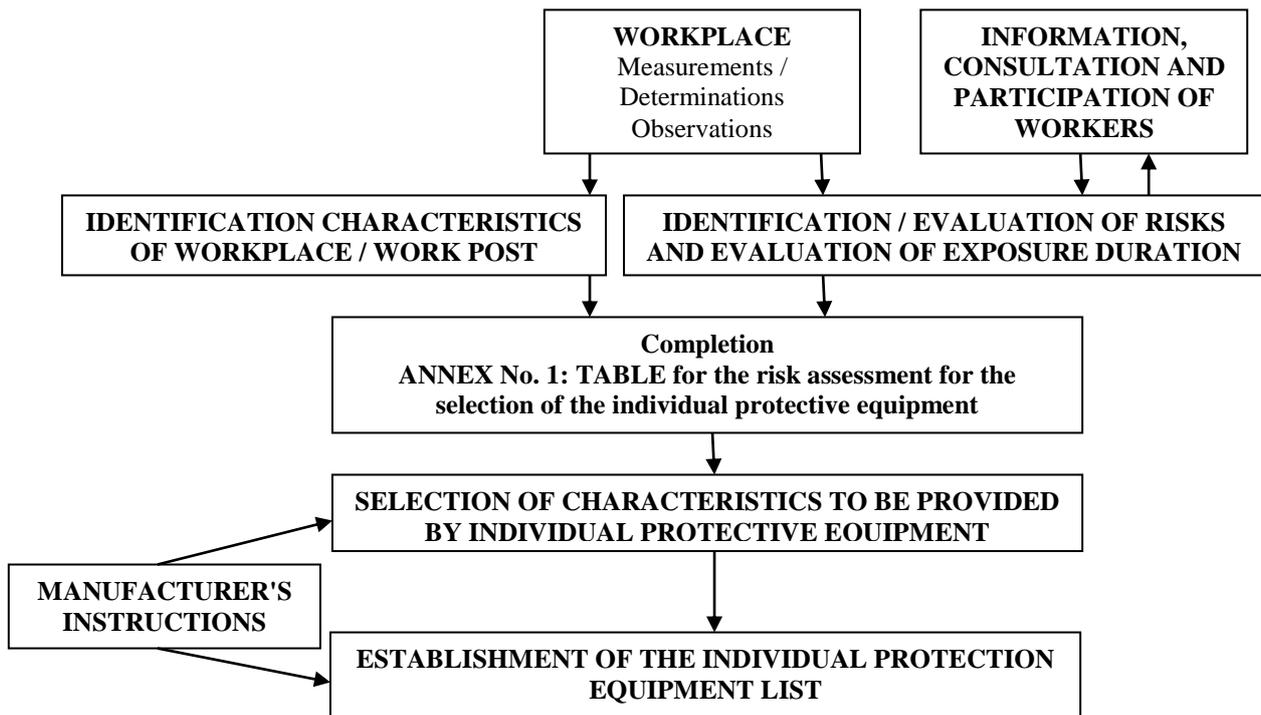

Fig. 1. Risk assessment process for the selection of personal protective equipment

The calculation of the normal use time may be influenced by the nature of the activity carried out or the properties of the individual protective equipment starting from disposable, up to eight hours / a work shift in certain environments up to four or five years in the case of helmets. With the exception of single-use protective equipment, the other categories may be normalized by a calculation that calls into question the time (storage or maximum permissible use), a value component influenced by the risk factors / hazards arising in the performance of the task and which can be eliminated / diminished by PPE and can lead to a degree of wear plus values related to maintenance tracking (proper washing and decontamination), handling (training of workers and proper use) and adequate storage (conditions to be met comply with the manufacturer's instructions). As far as the verification of the equipment before use is concerned, it requires at least visual inspection, but for some types the use, even if it is normalized, will be conditioned by marking or the existence of periodic tests carried out in specialized laboratories.

3. Conclusions

In view of the large number of legal provisions, the degree of subjectivity in identifying and assessing risks, and the lack of proposals for measures for all identified risk factors, the cumulative work carried out by some workers, the costs of carrying out the noxious determinations, and at least the estimation of the exposure duration plus the lack of awareness, consultation and participation of workers in the process of selecting personal protective equipment may lead to unjustified costs and the inappropriate use of PPE.

The selection of individual whipping equipment is a difficult, complex, observational, measurement and estimation process that, along with the technical knowledge of occupational safety and health workers, should be supplemented by information provided by workers. (Babuț et al., 2018; Mihai-Adrian et al., 2017)

Once the assortment has been selected, choosing a particular product from the manufacturers and distributors' offer should not principally introduce the financial connotations but compliance with product standards, compliance with the marketing requirements and the maximum allowable wearing time calculated by the manufacturer before the loss the quality of protection of that equipment, which will allow for the acquisition of the purchase costs in time of use.

Regulation no. 425 of 9 March 2016, the instructions to be provided by the manufacturer "with PPE", obligations taken over by distributors help the employers, those who make the selection and acquisition of PPE and the help of those who contribute to proper cleaning, fact which will lead to keeping the protection features longer.

Specifying types and test intervals will allow you to create graphs for their execution, scheduling, and cost breakdowns.

Placing on the market on 21 April 2019 only of individual protective equipment that fully complies with the requirements of Regulation no. 425 of 9 March 2016 will benefit to increase the security level of workers using PPE and, through the content of the manufacturer's instructions, will make a real contribution to the selection, acquisition, use, verification, and proper maintenance of PPE.

Abstract

Even if at first instance the audit was considered to be the financial field, the need for checks, examinations, the collection of data or information to allow "an opinion on the degree of correspondence between the observed and some predetermined criteria" became necessary various areas including health and safety at work. The opinion expressed in the examination of the information gathered, at least in the field of safety and health at work, can be reported to a certain standard starting from the "minimum safety and health requirements" contained in the legal provisions in force and applicable to a work system.

Keywords: occupational safety and health, audit, health and safety, minimum safety and health requirements.

1. Introduction

In most of the papers in the literature, the audit focuses on legal requirements in a particular field and / or where, depending on some considerations that are mainly relevant to the requirements of a market segment or size of that unit, it may have implemented a system to manage, it is an essential process in increasing the level of health and safety at work.

Considering the complexity of the audit process, we will use the term "occupational safety and health audit" rather than the "audit for safety and health at work" to allow the collection and examination of data and information from a wider spectrum, legislative areas.

2. Occupational safety and health audit – theory and legal requirements

Occupational safety and health at international level is regarded as an activity, an area that includes education, training, with the main purpose of identifying dangerous conditions, materials and practices at work, and helping employers and workers to eliminate or reduce risks associated.

Health and safety at workplace as a term, in practice, tends to simplify and reduce the complexity of this area. This often leads to a limited view of the audited work system and implicitly to the reduction of legal regulations applicable within that unit, the lack of specific documents.

The nature of the "systematic process" in occupational safety and health audit implies that its activity is systematic, independent and documented. (Baciu et al., 2006; Băbuț et al., 2014) Thus, depending on the subject of the audit, it should take the audit of compliance with the requirements of the legislation in the field of occupational safety and health, plus the related legislation, which allows the realization of the functional framework of the work system as follows:

- legislation on the functioning and the way of setting up of commercial companies;
- work legislation;
- aspect of occupational medicine;
- legislation in the field of emergency situations;

* Corresponding author. Tel.: +4-0755-252-527.

E-mail address: mihaibernevig@tuiasi.ro

- legislation on transport and traffic safety;
- specific legislation in fields of activity that lead us to the need for obtaining approvals, authorizations in respect of work equipment and professions / occupations for which there are special requirements for the organization of professional training (National Regulatory Authority for Energy, State Inspection for Boiler Control, Pressure Vessels and Lifting Installations, etc.).

Having in the foreground only one of the legal provisions applicable to all work places, respectively the provisions of the Methodological Norms of October 11, 2006, implementing the provisions of the Law on safety and health at work no. 319/2006 approved by the Decision 1425/2006 which at art. 15, paragraph 1, point 2, after the elaboration and fulfilment, "monitoring and updating of the prevention and protection plan" and in item 28 "monitoring the update of the warning plan, the protection and prevention plan and the evacuation plan" , together with paragraph 3, which requires a review of the risk assessment on safety and health at work:

- "whenever changes or changes occur in technology, work equipment, chemical substances or preparations used and work / workplace arrangements;
- "to discover the omission of risks or the emergence of new risks; "

If we remove from the context "monitoring", "tracking the update", "reviewing" "whenever changes or changes occur" or "finding out omission" together with at least two components of the table in Annex no. 7 The Methodological Norms of October 11, 2006, implementing the provisions of the Law on Safety and Health at Work no. 319/2006 which represents the Prevention and Protection Plan, respectively the action columns for the purpose of achieving the measure and the deadline, can lead us to the necessity but not the obligation to carry out an audit program in the field of safety and health at work. In audits planned after deadlines and targeted for clear goals, it will be possible to obtain results, evidence that can lead to the identification of opportunities to achieve improvements in the applicable health and safety aspects at work, all without having that place to implement a management system

If we remove from the context "monitoring", "tracking the update", "reviewing" or "finding out omission" together with at least two components of the table in Annex no. 7 The Methodological Norms of October 11, 2006, implementing the provisions of the Law on Safety and Health at Work no. 319/2006 which represents the Prevention and Protection Plan, respectively the action columns for the purpose of achieving the measure and the deadline, may lead to the necessity but not the obligation to carry out an audit program in the field of safety and health at work. In audits planned after deadlines and targets for clear targets, it will be possible to obtain results, evidence that can lead to the identification of opportunities to achieve improvements in applicable health and safety aspects at work, all without having that place to implement management system.

In the context of a small organizational and functional framework of a small or medium-sized unit but also applicable to large or very large units without fully meeting the requirements of an audit method compared to established methods (Workwell, Alberta, CHASE etc.) the method of auditing conformity with the provisions of the legislation in the field of safety and health at work based on the method of assessing the level of work safety elaborated by INCDPM Bucharest presents the most elements for identifying dangerous conditions, materials and practices for workers at work. The revised and improved version of this method allows for an effective, flexible and adaptable analysis of how general and specific legal requirements are known and applied within a work system. (Băbuț et al., 2018; Bejinariu et al., 2017a, b) This aspect permits to manage in a properly way the new risks, the organizations should adopt new approaches to continually improve their OHS performance.

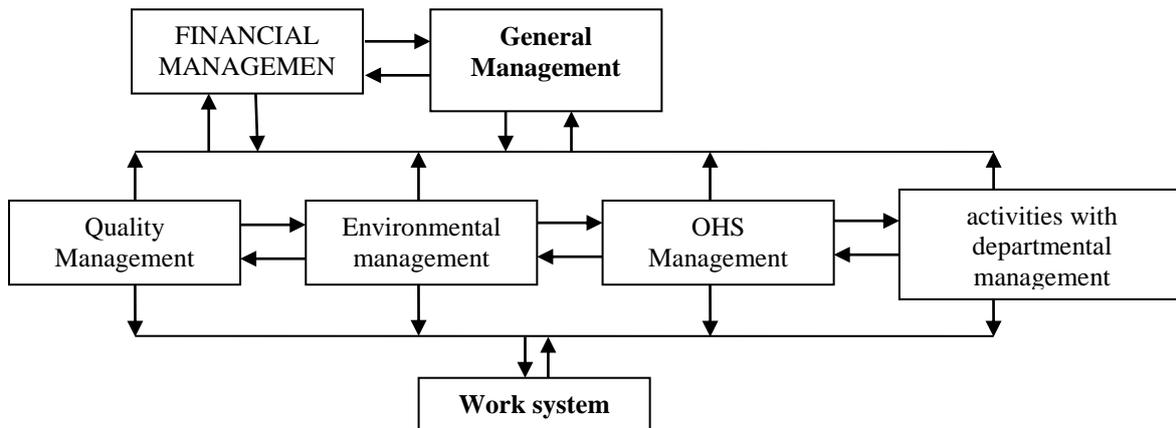

Fig. 1. Management Interdependence

Considering that management is in various forms in any activity carried out, depending on the size of the unit, both territorial, functional and as a number of activities and workers, it may have distinctly organized various types of management contained in the overall management of the unit / management being directly involved in meeting legal requirements and managing resources in relation to market requirements, the interdependence of the types is influenced by their need in relation to the size of the activity, the financial management and approved at the general management level, a process described briefly in Fig. 1.

3. Occupational safety and health audit – practice

Given that in practice the market only has an indirect role to influence the evolution of an enterprise and the culture of safety and health at work is still in the process it can be distinguished, in most cases, that regardless of the organization of the activity and implicitly of the management / the management of the implementation of a management system, except for the implementation of ISO 45001, does not lead to convergence of information, documents and organization in the field of occupational safety and health. This only makes the OHS management more difficult by duplicating staff and documents at the level of the work system which will lead to a general perception of distorted perceptions, mainly purely financial considerations. (Darabont et al., 1997, Darabont et al., 2001, Darabont et al., 2017)

The conditioning of the implementation of a management system in the procurement process does not guarantee its functionality due to the small size of some units and for the case of large or very large units that have opted for the implementation of a management system rarely make direct connection between the elements of the work system with aspects of occupational safety and health and managerial interdependence as a whole. (Mihai-Adrian et al., 2017)

Audit in the field of occupational safety and health, due to its complexity and diversity, will clearly be distinguished in two distinct categories, namely:

- audit of compliance with the requirements of the relevant legislation and requirements in related fields applicable at the level of a work system;
- audit of the occupational safety and health system. (Moraru et al., 2002; Moraru et al., 2014)

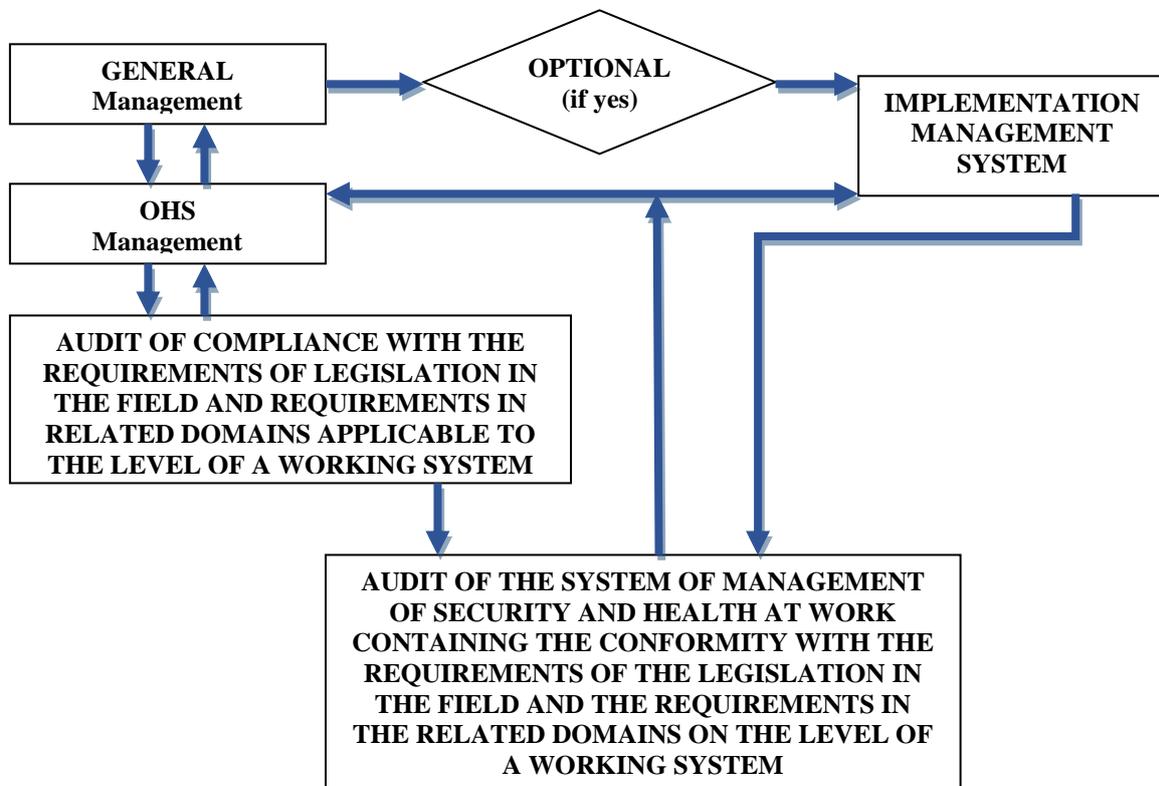

Fig. 2. Audit in the field of health and safety at work

The fact that literature puts them in distinct categories does not alter the practical reality of interdependence, conditional and complementary, which directly competes with the observance of legal requirements in an organized, planned, for realization and verification framework. The schematic presentation of the audit in the field of occupational safety and health is in Fig. 2, being part of the OHS management at the level of the work system, which in turn is a component integrated into the general management, and enter into the system of managerial interdependence in the case of larger units.

4. Conclusions

Regardless of the size of the work system and management activity, fulfilling legally binding requirements and applying them as accurately as possible can make a significant contribution to the development of a culture of occupational safety and health. Awareness of the complexity of the activity carried out and its organization in accordance with the legal requirements contained in the legislation in various fields is a quality of the specialized personnel, which can contribute, together with the education system at all stages and forms, to the awareness of the potential danger that is known before starting an activity and avoiding the occurrence of dangers.

Occupational safety and health audit allows for an x-ray on a work system to make the outcome obvious and to contribute to improving the safety and health of workers. Making it happen by people who understand the legal system and how to apply it to a work system can bring real benefits by streamlining the OHS management, reducing risk by proposing measures with real applicability, reducing spending and increasing credibility within the workforce enterprise.

In the context of what has been said, it can be said that the results of an audit of safety and health at work are all the more valuable as the practical and applicative impact on the audited work system will bring improvements.

Transformation of the geodynamic hazard manifestation forms in mining areas

Batugin A.S.^a, Kolikov K.S.^a, Ivannikov A.A.^{a*}

^aMISiS, Russia, 119049, Moscow, Leninsky Prospect, 4

Abstract

The problems of geodynamic safety assurance in mining are common for many countries with developed mining industries. Considerable results have been achieved in Russia in solving rockburst problem, yet in the last decades this problem is transforming into man-triggered seismicity problem. Induced earthquakes in areas where mines had been flooded, seismic activity in previously safe regions, re-activation of tectonic faults, violent man-triggered earthquakes in open pit operations have been registered. As a matter of fact, a number of mining regions with technogenic seismicity have emerged in Russia, where geodynamic events not only cause financial or physical damage, but also negatively affect the environment, bring about social tension, impose additional risk for hazardous industrial operations.

Manifestation of seismic events at the sites of closed mines, seismic activation of geodynamically hazardous zones including those located at a significant distance from mining activities, anthropogenic earthquake in the vicinity of a large coal pit - all of the above in Kuzbass - are considered in this paper.

In this context the centrepiece in geodynamic safety assurance and prevention of geodynamic hazards is geodynamic zoning. Advanced geodynamic monitoring of the rock massif and the earth's surface is required when mining in geodynamically unsafe areas or planning for the re-use of mine workings.

Keywords: rockburst, technogenic seismicity, geodynamic safety, geodynamically unsafe areas, social and environmental damage

1. Introduction

Geodynamic risk in mining is a genuine concern for many world's mining regions [Kozyrev and Lovchikov, 2013; Han et al., 2016; Jiang et al., 2014; Orlecka-Sikora et al., 2014; Zhirov et al., 2015; Malovichko et al., 2012; Marot et al., 2014]. Earlier geodynamic factor imposed hazard on mining sector only, yet in the last decades geodynamic events cause physical, environmental and social damage. Major rockbursts are manifested as man-triggered earthquakes that impose diverse effects on the environment.

An important feature of such geodynamic events is their suddenness, unexpectedness, and the fact that they create a new seismic background [Lomakin and Kholevin, 2002; Emanov et al., 2014]. Another distinctive feature is that epicentres of geodynamic events are located beyond the boundaries of the mining lease, and this rules out the possibility for the mine to exercise control over these areas for protective purposes.

First rockbursts in the mines of the USSR were recorded in 1950s in the Kizel coal basin. The origin and mechanism of these phenomena were understood by mid-1970s when control and precautionary measures were schemed out. As a consequence, the rock burst incidence in the mines of the USSR has drastically reduced by mid-1980s [Petukhov, 2004]. However, at approximately the same time heavy rock bursts began to occur that were referred to as tectonic rock bursts.

Tectonic rock bursts at the Russian mineral deposits caused quaking on the surface, shattering of buildings, they brought about surface subsidence, cracks, sunken streams, gross physical damage. On top of all this, considering that many deposits liable to rock-bumps are developed in heavily populated industrial areas, seismic threat of tectonic rock bursts for hazardous production facilities became evident. It can be stated therefore that a number of mining regions liable to induced seismicity have emerged in Russia. Such regions include Kemerovo Oblast with Kuzbass, the Urals, mining fields in Kola Peninsula, areas where potash salt is mined in Perm Oblast (Berezniki and Solikamsk cities). While other risks are a traditional threat for mines [Kaledina et al., 2016; Puchkov et al., 2015; Kachurin et al., 2017;

* Corresponding author. Tel.: +7-903-757-1047.
E-mail address: as-bat@mail.ru.

Morozov and Tatarinov, 2006; Rybak, 2014; Batugin et al., 2018; Nazarov et al., 2014], issues related to natural seismicity assessment [Balan et al., 2017; Kossobokov, 2013] remain unaddressed, and manifestations of geodynamic activity create new conditions in mining regions.

2. New forms of geodynamic hazard manifestation in mining areas (as illustrated by Kuzbass cases)

2.1. Technogenic earthquakes related to flooded mines.

Restructuring of coal mining sector was commenced in Russia in mid-1990s. A total of 200 unprofitable deep and surface mines has since been shut down.

Mine closure was performed either by flooding, or using dry and combined approaches. Where flood method was chosen mine pumping system was shut off and excavations were filled with water. In case of dry liquidation mine operations were stopped yet mine pumping system continued to operate. Combined method was preferred where water level in the abandoned mine had to be monitored to prevent potential water inrush to productive workings of neighbouring mines. Mass scale mine closure gave rise to new environmental risks in mining areas. Raising of water level in mines caused expulsion of water to the day surface and flooding of subsided terrain. Places were spotted where ground water was cropping out onto surface and/or discharging into surface water bodies. Part of the adverse environmental consequences was predicted by the federal environmental monitoring laboratories that were established in mining regions [Kharyonovskii et al., 2010]. Forecasts were made for changing geomechanical conditions triggered by mine closure [Fisun et al., 1997]. The question, however, if geodynamic phenomena may develop as consequent effect of mine flooding was left unattended by specialists.

Although initially no seismological monitoring was carried out in regions where mines were being shut down, the relation between mine flooding and seismicity can be traced by indirect indicators. Table 1 provides the dates mines were flooded in Kuzbass and dates of shallow-focus earthquakes. As can be seen from these data, there is a direct link between the beginning of mine flooding process and shallow-focus earthquakes that followed. Anzherskaya mine in Kuzbass, for example, was recovering a number of coal seams and by the date of closure it was over 700m deep. Mine flooding started in 1995, the average rate of water level raise was 10 m/month. By April 1997 water level in the mine raised by over 200 m. It was then that earthquakes occurred with epicenters located directly in the mine field. Thereafter geodynamic test range was established at the site of Anzherskaya mine to conduct field monitoring.

Indirect relation between mine flooding process and enhanced seismicity of the area could also be observed at the Kizel coal basin in the Urals. Flooding of mines there started in late 1980s. Since that time the burst of seismic activity in this region was registered after a lengthy (30 years) off-seismic period, according to Lomakin V.S. [Lomakin and Kholevin, 2002].

Table 1. Seismicity in Kuzbass vs. Mine Flooding Process

Kuzbass Region	Date of Earthquake	Earthquake Magnitude
Anzhersky	25.10.97	M=2.3
Anzhersky	30.10.97	M=2.3
Prokopyev-Kisselyovsky	1995	5-6 score, M=4.6

As to mechanism of earthquakes that happened after mine flooding, authors from different countries believe it is similar to that observed in large dam lake projects [Batugin and Klimanova, 2000; Srinivasan, 2000; Goldbach, 2009]. One of key mechanisms that triggers technogenic earthquakes when filling dam lakes is considered to be due to rise of fluid pressure in tectonic fault planes [Gupta and Rastogi, 1976]. Normal compression of fault limbs σ'_n is reduced by water pressure value p , while tangential shearing stresses τ_n in the fault plane remain unchanged:

$$\sigma'_n = \sigma_n - p = \sigma \tag{1}$$

$$\tau_n = \tau = \tau \tag{2}$$

As normal compression is reduced, confining force in the fault plane also decreases. At some moment the force of shearing stresses becomes great enough to overcome confining force and it is then that rock movement along fault plane occurs and seismic energy is released.

After mining operations are completed the rock material in abandoned space remains less compact with micro fissures capable to transfer hydrostatic water pressure. Such rock mass is also weakened by major disjunctive dislocations, their fault planes intersected by mining operations. Therefore, this mechanism may come into action following mine flooding, especially since quite often flood water level in abandoned mines is higher than that in dam lakes where earthquakes were registered.

2.2. Technogenic earthquakes in producing mine areas

In the vicinity of producing mines seismicity is observed with hypocentres located much deeper than the depth of mining operations. Similarly, seismic activity is triggered within rock mass areas far beyond the mine lease. The fact that seismic hypocentres are located at great depths and far away from mining operations is attributed to critical stress condition acquired by these areas due to mining activity and tectonic stress field [Petukhov, 2004].

Thus, technogenic seismicity around Polysayevo in Kuzbass were becoming more and more evident since 2006 in the vicinity of Oktyabrskaya and Polysayevskaya mine fields where coal mining was aggressive. In 2008-2009 a number of foreshock activation areas evolved. This was described in paper [Emanov et al., 2009]. Areas II, III, IV and V were related to mining operations, whereas areas I and VI were located beyond the boundaries of mining operations and had no connection to working excavations, see Fig 1. More than 25 years ago works on geodynamic zoning were completed in this part of Kuzbass. Modern crust blocks of various hierarchical ranks were identified and stress condition of the rock mass was assessed [Batugina and Petukhov, 1990]. According to data available for this region, there is a tectonic stress field with horizontally oriented axis of maximum compression, whereas boundaries of NW-trending blocks exhibit strike slip component.

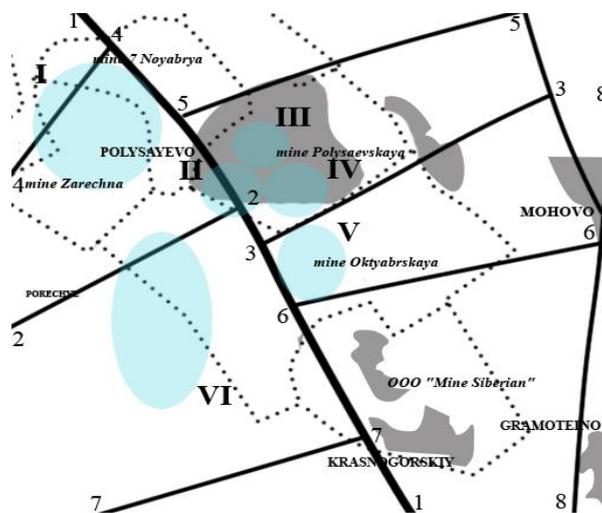

Fig. 1. Polysayevo district block outline with areas of seismic activity according to materials [Emanov et al., 2009; Batugina and Petukhov, 1990] (explanatory text).

Comparison between seismic activity areas and outline of modern block structure shows that seismically active zones II, IV, V are located next to boundaries of II rank blocks, particularly, in intersection node of II and III rank blocks boundaries. The seismically active area I is registered at III rank blocks boundary, where abandoned excavations of '7 November' and 'Komsomolets' mines are located. According to [Emanov et al., 2009] hypocentres of several seismic events are recorded at the depth of 2 to 3 km and were triggered by thrust faulting. Thrust faulting mechanism behind seismic events is the proof that it is modern stress field with horizontally oriented axis of maximum compression, that participates in seismic process, which is in line with geodynamic zoning materials.

2.3. Induced earthquakes in open mines

Heavy rockbursts and technogenic earthquakes were registered in recent decades in open mines of Russia and neighbouring territories [Kozyrev and Lovchikov, 2013; Emanov et al., 2014; Aitmatov, et al., 2004]. These events caused physical, social and environmental damage and were unexpected for specialists. Mechanism of these phenomena need to be studied, however there are some common features in tectono-physical nature of these events.

Tectonophysical research on the pattern of tectonic rock bursts in mines demonstrate that their hazard is linked to re-activation of major tectonic dislocations, optimally located in the rock mass relative to the axes of tectonic stress field [Batugin et al., 2016; van Aswegen, 2017]. Review of data obtained from geodynamic zoning of Kuzbass [Batugina and Petukhov, 2017] reveals that Bachat induced earthquake may be related to re-activation of major upthrow fault that undercut the pit at a great depth, see Fig 2. The depth of Bachat pit is approximately 300 m, its length being approximately 10 km and width 2 km. Mining operations include regular blasts with up to 350 t net explosive content.

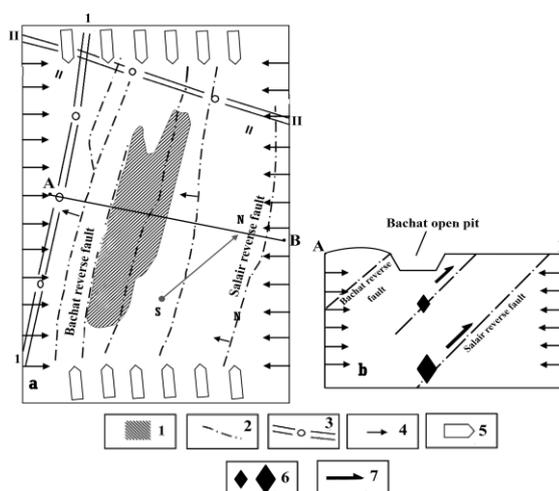

Fig. 2. Simplified tectono-physical layout of Bachat coal pit area: 1 – Bachat pit; 2 – tectonic dislocations; 3- second rank crust block boundaries; 4, 5 – direction of maximum compression for 2nd and 3d rank stress fields respectively; 6 – provisional hypocentres of aftershocks and the main shock; 7 – direction of thrust fault wall displacement brought about by earthquake

There is a series of major thrust faults in the vicinity of the Bachat pit (Tyrgansky, Bachatsky, Salairsky), dipping at 50-70 degrees towards SW. No detailed study has been ever made on the deeper strata of this part of Kuzbass, yet available regional geologic materials allow to suggest that upthrow faults extend to considerable depth and undercut the Bachatsky pit at the depth of several kilometres, see Fig 2-b. Direction of maximum compression in this part of Kuzbass is horizontal from SW to NE, i.e. approximately perpendicular to thrust faults trending.

Magnitude of Bachatsky earthquake in 2013 was $M=6.1$, whereas hypocentre was at the depth of 4 km. Mechanism of that event was thrust fault [Emanov, et al., 2014]. Drawing on the approach we stick to, it can be assumed that at the time of Bachat earthquake displacement might have occurred of the hanging wall of Salair or other major thrust fault under the pit optimally located in relation to direction of maximum compression, see Fig 2. Indeed, in the modern stress field the Salair fault behaves as classic thrust fault and may extend to the depth of several kilometres below the pit. During the earthquake a thrust fault occurred along the plane that by mode of occurrence concurs with the Salair thrust fault. In other words, during the earthquake and subsequent aftershocks major thrust faults got re-activated whereby their upthrown side was displaced in line with current stress field effect, see Fig 2.b.

3. Discussing the findings

Seismicity caused by flooding deep mines, activation of geodynamically risky areas outside mine boundaries, heavy rockbursts and technogenic earthquakes in the pits – all of these are fairly new phenomena not only for Russia but for other countries with mining industries. After shutting down and flooding mine excavations, seismicity was recorded at mine fields of Czech Republic, India, SAR, France [Marot et al., 2014; Batugin and Klimanova, 2000; Srinivasen et al., 2000]. This new risk has to be taken into account in mine construction and mine closure projects, especially in heavily populated industrial areas.

Induced earthquakes and heavy rockbursts outside mine takes or in abandoned areas of mine fields seem to be one of latent relationships between natural and technical systems. For example, a heavy rockburst at $10^8 J$ occurred in 'Mine 15-15' at Severouralsky bauxite deposit on 20.02.1987 in the district abandoned 10 years earlier. Paper [Cernik, 1964] describes heavy rockburst on October 15th 1929 at the Tirolean ore mine (Austria) recorded at levels VIII and IX in the area where no mining operations had been performed for 55 to 60 years. On October 22nd 1930 heaviest rockburst occurred in a footwall gate at VII east level, near 1st South fault where nobody had worked for 42 years. On June 11th 1959, March 19th and 30th 1960, March 27th 1961 heavy rockbursts occurred in the ore mines of Kolar deposit. Epicentres of all these events were located far from the ore body [Taylor, 1963; Batugina and Petukhov, 1991; Xiang et al., 2018]. In the period between 1910 and 1960 rockbursts were recorded at Příbram ore mines (Czech Republic) at 20 km distance to the East, 10 km to the North and 10 km to the South of mining operations. These rock bursts were in the form of earthquakes and were registered by seismographs in Prague, Prugonitse and Kladno.

As rockburst control measures presumably shall be focused on the areas where mining operations are conducted and assumably it is excavations, openings, headings etc., where such measures shall be applied, onset of geodynamic risks outside mine property makes it difficult to implement such measures. Furthermore, a local mine net of seismic monitoring is not enough for reliable identification of seismic buildup zones. Seismic activation zones and epicentres of heavy rockburst located outside mine lease boundaries put at risk industrial operations and civil facilities on the surface. Consequently, new approaches need to be devised to assess geodynamic risks.

Cases when the depth of induced earthquake hypocentre was considerably more than that of mining operations indicate that the top layer of crust acquires critical stress. Due to mining operations and development of cavities/large gobs in shallow parts of such areas the stress-strain balance is continuously disturbed, hence stress redistribution may propagate much deeper than the depth of mining operations. Within this context the location of earthquake hypocentres at a great depth below mine or pit can be attributed to the fact that mining operations were actually performed in the regional critically stressed zone.

Furthermore, the proportion between the size of the tectonic rock burst origin r and the size of this event's background, R , $r/R=10-30$ [Batugin et al., 2016; Xiang et al., 2018] allows to assess the size of crust blocks involved in induced earthquake lead up. Taking the magnitude of the Bachat earthquake as $M=6.1$, the size of earthquake source r must be at least 10 km. Then the event's background size R would amount to 100 - 300 km, which is commensurable with geodynamically active crust blocks of the 2nd rank – Figure 2. In this case it may be assumed that interrelation between grand crust blocks creates critically stressed zones either inside the blocks or at their edges. Considering that geologic processes develop fairly slow, energy confined inside the limit state zones takes enough time to redistribute in the ground thus no conditions provoke rock shattering. When mining works advance at a high rate and/or in case of mass scale blasts in pits, load increment rate may exceed the rate of load release, thus conditions are created for onset of adverse geodynamic events. Taking into account that critically stressed areas built up due to geodynamic processes embrace primarily shallow strata of Earth's crust, monitoring shall be envisaged as part of mineral resources recovery and earth's surface exploitation.

4. Conclusions

In addition to already known geodynamic phenomena (rockbursts and outbursts), new forms of geodynamic hazard manifestation have been observed in mining regions of Russia. No sufficient measures have yet been developed to address these risks. Technogenic seismicity brought about by mine flooding, seismic activation outside mine takes, heavy rockbursts and induced earthquakes in the pits cause not only physical, but also social and environmental damage, raise the probability of accident risk at hazardous industrial operations located in the region.

One of the reasons why in mining areas geodynamic hazard manifestation mode is changing may be interrelation between global tectonic processes and grand-scale engineering human activity. From this perspective, materials related to geodynamic zoning present interest for study. When mining in geodynamically risky zones, advanced geodynamic monitoring shall be established in mining areas and on the earth surface.

Abstract

The year 2018 brings new challenges to the use of current technologies. Since very old times the human kind craved upon reaching the furthest goals, usually those it only dreamed of. To be able to accomplish, the human invented and implemented ways to bring him closer to his ultimate goal, namely, knowledge. Augmented Reality (AR) is the mean by which an idea, a concept or even a thought can be translated into a more interactive manner for the user. This paper brings to the forefront the use of Augmented Reality in an area where the barrier between material world and imagination is overcome, so a multitude of applications can be developed. The range of applications can begin by simulating simple scenarios for learning purposes to an immersive and complex virtual environment which will educate users to be able to react in extreme or dangerous situations. Conclusions available in the end of the paper will uncover the perspectives offered by introducing the AR as an operating environment in maintenance applications.

Keywords: Augmented Reality; environment; application; technology; maintenance.

1. Introduction

Although the augmented reality is not a relatively recent discovery, it has only recently grown and made itself remarkable throughout the world wide within a rather short time.

Having an early quite modest stage because device processing power was still premature and could not provide means for the full performance of the Augmented Reality, with the development of technology and mobile devices, this kind of reality has come to the hands of the ordinary user getting him used to what would come next, namely the development of a new type of reality.

One of the first applications which used this concept and made itself known was the scanning of QR barcodes. With a smartphone's camera, such code can be scanned and the information contained can be decoded. Of course, the performance of augmented reality is not just about the ability to get information from QR codes but can be extended to introducing 3D objects in the scene with the help of a graphic engine. Objects can be either static or dynamic, which means that interaction with them will allow manipulation in a convenient way for the user.

At a first look, AR seems to be a fictional area but it has become possible and accessible to the general public with the evolution of smartphones and gadgets capable of delivering such technology. AR can show its true contribution to areas that require a high level of complexity, reduced accessibility in the event of a large geographic spread of equipment to be maintained, difficult know-how exchange between experts and technicians and high costs of intervention for maintenance.

As with the word “*only sky is the limit*” the development of applications that will use this concept is limited only by the imagination of the developer. This paper aims to develop an application that will offer support to the personnel responsible of activities in maintenance applications.

2. Concept

Paul Milgram defines Mixed Reality (MR) as an environment in which the real world mixes with the virtual one and the result is displayed in one form, MR being the border between the two. Although MR offers both reality and Virtuality Augmentation (VA), the paper brings to the forefront the use of Augmented Reality.

Augmented Reality is part of Mixed Reality (MR) (Fig.1) and stands as a new concept that combines both software and hardware technologies which intend to improve the work environment and the workflow resulting in an enhanced labour quality. The idea of AR implies the use of optical devices assisted by the processing power of electronic ones to allow the overlay of 3D or 2d graphic elements over real objects. The result obtained through implementing this concept will be an improved environment providing more information and functionalities, which will allow a more precise interaction with it.

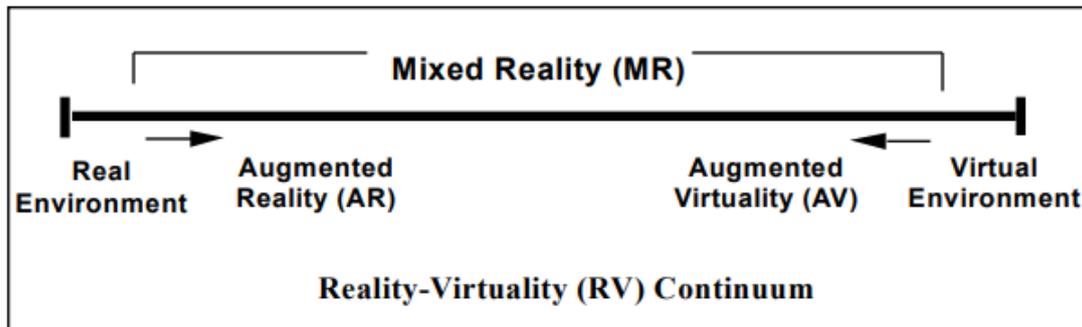

Fig. 1 RV Continuum

In fact, the AR is a live physical sight in which graphical elements developed on the computer are overlapped on real-world elements producing the semi-immersion of the user and stimulating his senses causing him to acquire new skills and support him in his activities.

3. Application

In developing such an application, key elements are needed to have a guaranteed success and to achieve the targeted purpose. Although the number and nature of the elements may vary from one application to another, their identification must be done correctly in order to have a final product with a great impact and increased utility.

Analysing the process which shall be supported by such an application must take place first and foremost because the data obtained can determine the type of objects to be designed and the type of interaction that will take place between user and application. Also, the analysis should consider the experts' opinion and the challenges they have faced over time. Not only the process analysis needs to be done in this manner, but also the development of the application. This must be done in close contact with technical process representatives who can provide a clear and accurate diagnosis over support information which shall be provided to the targeted personnel that will make use of the application.

This paper focuses mainly on the development of a maintenance application for the industry and also for the equipment that implies special attention and meticulous care, with the possibility of customizing according to the process needs and field of activity.

One way to develop an application which will deliver an augmented reality is using ArCore platform, the official and supported platform offered by Google. This platform targets Android compatible devices and will make use of its hardware for interpreting and understanding the environment. When using this library, every motion of the device is recorded and based on the input data coming from the sensors, the application creates a context similar to the real world but which allows alteration. At this point the basic setup is done and the next stage of development implies addition of new virtual elements in the scene.

For an experience rich in performance and high quality graphics ArCore can work with two compatible and powerful graphic engines, Unreal Engine and Unity 3D.

With the help of such an application, two major aspects are fulfilled, namely tele-maintenance and training of the designated personnel. By means of tele-maintenance, the information exchange takes place much faster and easier and the tasks are carried out more efficiently which in the end increases productivity. Also for productivity purposes, the application provides unconditional support to the service personnel training the with the correct skills necessary for the maintenance tasks.

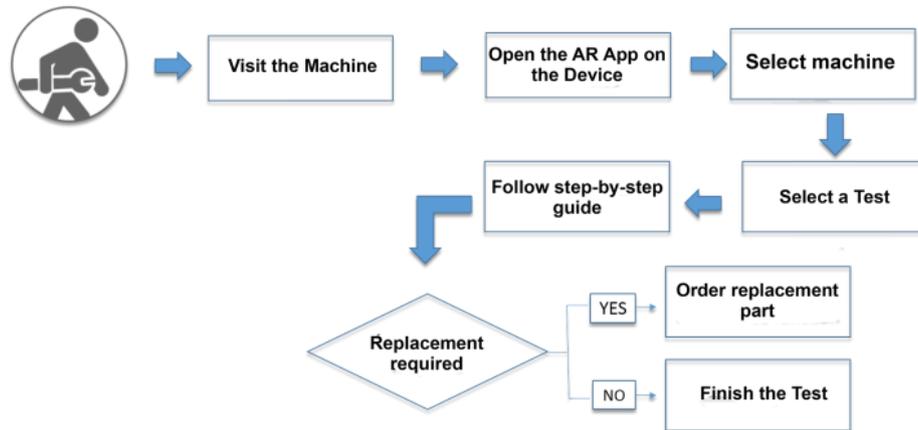

Fig.2 AR application workflow

The application aims to support the user by presenting a predefined interactive scene using a device capable of rendering augmented reality. The interactive scene presents itself as a graphical step-by-step guide for operating and manipulating a particular component in order to perform a maintenance operation, thus managing to provide the appropriate support (Fig.3).

Fig.3 AR application layout

4. Conclusion

This paper presents the development and the perspectives offered by an operating environment in Augmented Reality maintenance Applications that can be used by less experienced technicians or users in different situations that typically require specialized expertise in maintenance problem solving.

The perspectives offered by developing such an application comprises and is not limited to:

- A mixed reality and semi-immersive experience
- Information available at a click away
- Training of the designated personnel in solving technical problems
- solving situations and maintenance problems in a short time, without any other cost / cost reduction
- Improves customer satisfaction - assures the assistance of any type of user (technical and non-technical)
- reproduces scenarios according to the specifics of the company or the work environment
- Ensure a higher level of knowledge transfer (know-how)
- Reduces errors and periods of inactivity in complex operations
- Provides accurate maintenance in a short time

Thus, the Augmented Reality technology incorporates a portable device with just one click away for any maintenance work required for a company's specificity.

Application the fuzzy TOPSIS method to assess and select a contractor from the point of view of occupational safety management

Joanna Tabor*

Faculty of Management, Czestochowa University of Technology, Dabrowskiego 69, 42-200 Czestochowa, Poland

Abstract

The objective of this work is to analyse the possibility to use ordered fuzzy numbers within the frameworks of the TOPSIS method to assess the contractor using selected work health and safety management system criteria. Selection of a contractor is a decision-making problem for a decision-maker as it involves many criteria. In many situations, these criteria may at the same time be highly different: qualitative, quantitative, stimulants, destimulants. Fuzzy number orientation points to the type of criterion which we have to do with while carrying out our assessment. In order to assess and select the contractor, six different work health and safety management system criteria were used: (1) number of persons employed in hazardous work environment conditions, (2) rate of occupational risk assessments completed, (3) number of persons employed in hazardous conditions with reference to whom hazards have been eliminated or reduced over the year down to the level that complies with the standard, (4) indicator of the organisational preventive system usage, (5) training procedure and workplace instruction conformance level, and (6) number of benefits on account of working in conditions that are detrimental or hazardous to health. The criteria and their weights were established taking into account the nature of installation and maintenance works being planned. As a source of information, we used Z-10 annual working conditions reports submitted by companies to GUS [Polish Central Statistical Office], and work health and safety procedures submitted by five contractors. As a result of our research work, we have established that the use of ordered fuzzy numbers within the frameworks of the TOPSIS method makes it possible to streamline the contractors being reviewed from the point of view of selected criteria, and to select the company which meets the adopted work health and safety criteria to the greatest extent.

Keywords: Making decision; OHS management; Fuzzy Topsis

1. Introduction

In view of widespread use of outsourcing of various activities as part of companies' business, one of the key issues when selecting the contractor company is for the contractor to provide for work safety. The literature on this subject indicates that the subcontractor's high accident rate primarily results from poor knowledge of workplace conditions and procedures (Clarke, 2003), tendency for subcontractors to initiate high risk activities (Blank et al., 1995), insufficient training or experience in safety assurance issues (Kochan et al., 1994), improper identification of hazards or improper assessment of risks (Salminen, 1995), insufficient safety awareness (Hon et al., 2010), economic pressure, and poor organisation of work processes (Quinlan and Mayhew, 2000). Since accidents at work disturb the normal functioning of both the company and its subcontractor, the issue of optimum selection of the contractor has become one of the key business decisions within the integrated safety management system (Holubová, 2016; Majerník et al., 2017).

Although the decision-making process constitutes an integral part of the work health and safety management system, the use of multi-criteria decision-making tools in this area is still hardly practiced and rarely described in the literature on the subject. However, one can find various reviews of the methods themselves and their practical applications in the literature. As an example, the work by Trzaskalik (2014) contains analysis of the most frequently used methods in terms of selecting the optimum method for a given type of task, while the work by Zamani-Sabzi et al. (2016) contains statistical and analytical comparison of such methods when used in the fuzzy environment.

One of the most well-known and best described multi-criteria decision supporting methods is the TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) method. This is a tool that is used for linear ordering of variants in the decision-making process proposed by Hwang and Yoon (1981). One of this method's characteristic features is making use of the measure of relative distance from the best solution, which constitutes the pattern, and from the worst solution, which constitutes the anti-pattern, while its primary objective is to identify the variant which would be characterised by the maximum relative proximity to the pattern, and the minimum relative proximity to the anti-pattern. At the moment, the method that is used most frequently is the so-called fuzzy TOPSIS method introduced by Chen and Hwang (1992), which makes use of Zadeh's theory of fuzzy sets (1965) to solve available information ambiguity problems and assessment subjectivity issues. Currently, the basic application areas of the TOPSIS method include: logistics and supply chain management, production management, energy and resources management, and environmental management (Behzadian et al., 2012).

On the other hand, the Ordered Fuzzy Numbers model was proposed in 2002 by W. Kosiński, P. Prokopowicz, and D. Ślęzak (Kosiński et al., 2003). This model eliminates drawbacks of classical fuzzy numbers algebra based upon the extension principle according to Zadeh. A characteristic feature of the ordered fuzzy number is the fact that its orientation points to the type of the decision-making criterion which we have to do with. In case of the "loss"-type criterion, the fuzzy number's orientation is in the direction of the 0 value (the lower the value, the better); in case of the "profit"-type criterion, its orientation is in the direction of infinity (the higher the value, the better). Since quite different types of criteria, e.g. both stimulants and destimulants, tend to occur in the decision-making process, ordered fuzzy numbers seem to be a very good solution to such situations.

This work proposes an original application of the ordered fuzzy numbers and the TOPSIS method in the work safety management area.

2. Research methodology

The objective of this work was to verify the possibility to use ordered fuzzy numbers, as part of the TOPSIS method, to assess and select the contractor in terms of varying work health and safety management system criteria.

Assessment criteria and their weights were established, taking into account the specificity of the planned installation and maintenance works and characteristics of the machinery installation, maintenance, and repair sector (C33) from the point of view of some of the main hazards and reasons for accidents at work. The above-mentioned sector is characterised by high rates of persons employed in hazardous work environment conditions (for 2016: 84.4 per 1000 employees), work strain (59.2), and mechanical factors (19.8) which are higher than the average in the Industrial Processing section (respectively: 75.8; 24.3; and 11.7), with the following hazards being especially significant in this area: excessive workload (27.8), work with particularly hazardous machines (21.2), and industrial dusts (20.0) (CSO, 2017a). Also, accident rates are higher than the average: In 2016, the indicator of fatal accident victims was 0.032 (per 1000 employees), and the indicator of serious accident victims was 0.09; whereas the basic reasons for accidents at work in this industry, besides incorrect employee behaviour, comprise: improper organisation of work and/or workplace (16.9% of all reasons for accidents at work), lack or inappropriate use of the material agent (9.3%), and inappropriate condition of the material agent used while performing the work (9.1%) (CSO, 2017b).

Taking the above into account, six varying criteria were selected in our contractor assessments: C₁- number of persons employed in hazardous work environment conditions per 1000 employees; C₂- rate of occupational risk assessments completed (in %); C₃- number of persons employed in hazardous conditions with reference to whom hazards have been eliminated or reduced over the year down to the level that complies with the standard per 1000 employees; C₄- indicator of the organisational preventive system usage (in %); C₅- training procedure and workplace instruction conformance level - the score-based assessment on a scale of 0 to 10, and C₆- number of benefits on account of working in conditions that are detrimental or hazardous to health. On the other hand, weights of the particular criteria were subjectively determined at the following levels: $w_{C_1}=0.15$, $w_{C_2}=0.25$, $w_{C_3}=0.15$, $w_{C_4}=0.15$, $w_{C_5}=0.10$ and $w_{C_6}=0.20$. The highest weight was attributed to the rate of occupational risk assessments completed (0.25), considering that the specificity of the installation and maintenance works requires risk assessments to be performed much more frequently. The number of benefits on account of working in conditions that are detrimental or hazardous to health was also considered important, as it implied that hazard-prevention measures had already been taken.

As a source of information, we used Z-10 annual working conditions reports submitted by companies to GUS [Polish Central Statistical Office], as well as training procedures and workplace instructions submitted by five potential contractors from the machinery installation, maintenance, and repair sector. Contractor selection procedures were verified for conformance with procedures adopted by the selecting company (criterion C₅), whereas Z-10 annual reports were used to determine values of the remaining assessment criteria. Despite the fact that these criteria were not expressed verbally, fuzzy sets were used due to uncertainty of information. In our analysis, we used the approach proposed by Rudnik and Kacprzak (2015), within the frameworks of which fuzzy assessments are produced by extending assessment ranges by fuzzy uncertainty ranges, which does not require any additional experts being engaged.

Calculations should be performed in line with the following procedure:

(1) Create a fuzzy decision-making matrix X using ordered fuzzy numbers:

$$X = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1N} \\ x_{21} & x_{22} & \dots & x_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ x_{M1} & x_{M2} & \dots & x_{MN} \end{bmatrix} \quad (1)$$

Where: $x_{ij} = (l_{ij} \ 1_{ij}^- \ 1_{ij}^+ \ p_{ij})$ ($i = 1, 2, \dots, M; j = 1, 2, \dots, N$) are ordered fuzzy numbers (where: l – left, lower bound, p – right, upper bound). The fuzzy decision-making matrix is created based upon replacement of sharp assessments x_{ij}^* with assessments expressed using ordered fuzzy numbers x_{ij} .

(2) Create a standardized fuzzy matrix Z :

$$Z = \begin{bmatrix} z_{11} & z_{12} & \dots & z_{1N} \\ z_{21} & z_{22} & \dots & z_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ z_{M1} & z_{M2} & \dots & z_{MN} \end{bmatrix}, \quad (2)$$

where:

$$z_{ij} = \begin{cases} \left(\frac{l_{ij}}{\max_i p_{ij}} \frac{1_{ij}^-}{\max_i p_{ij}} \frac{1_{ij}^+}{\max_i p_{ij}} \frac{p_{ij}}{\max_i p_{ij}} \right) & \text{when } C_j - \text{"profit"} - \text{type criterion} \\ \left(\frac{\min_i p_{ij}}{l_{ij}} \frac{\min_i p_{ij}}{1_{ij}^-} \frac{\min_i p_{ij}}{1_{ij}^+} \frac{\min_i p_{ij}}{p_{ij}} \right) & \text{when } C_j - \text{"loss"} - \text{type criterion} \end{cases} \quad (3)$$

(3) Create a weighted standardized fuzzy matrix V :

$$V = \begin{bmatrix} v_{11} & v_{12} & \dots & v_{1N} \\ v_{21} & v_{22} & \dots & v_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ v_{M1} & v_{M2} & \dots & v_{MN} \end{bmatrix}, \quad (4)$$

where: $v_{ij} = z_{ij} \times w_j$ ($i = 1, 2, \dots, M; j = 1, 2, \dots, N$)

Scalar vector of weights: $w = [w_1, w_2, \dots, w_N]$,

where $w_N \in \mathbb{R}$ ($w_N > 0, n = 1, 2, \dots, N$) is the weight of the n -th criterion, whereby: $w_1 + w_2 + \dots + w_N = 1$

(4) Find pattern A^+ and anti-pattern A^- to assess each criterion, whereby:

$$A^+ = (v_1^+, v_2^+, \dots, v_N^+), \quad (6)$$

where: $v_j^+ = (\max_i l_{vij} \ \max_i 1_{vij}^- \ \max_i 1_{vij}^+ \ \max_i p_{vij})$, $j = 1, 2, \dots, N$ and

$$A^- = (v_1^-, v_2^-, \dots, v_N^-), \quad (7)$$

where: $v_j^- = (\min_i l_{vij} \ \min_i 1_{vij}^- \ \min_i 1_{vij}^+ \ \min_i p_{vij})$, $j = 1, 2, \dots, N$

(5) Calculate the distance of assessments of the particular variants from the pattern and from the anti-pattern using the following correlations:

$$d_i^+ = \sum_{j=1}^N d(v_{ij}, v_j^+) \quad \text{and} \quad d_i^- = \sum_{j=1}^N d(v_{ij}, v_j^-) \quad \text{for } i = 1, 2, \dots, M \quad (8)$$

where:

$$d(A, B) = \sqrt{\frac{1}{4} [(l_A - l_B)^2 + (1_A^- - 1_B^-)^2 + (1_A^+ - 1_B^+)^2 + (p_A - p_B)^2]}, \quad (9)$$

for: $A = (l_A \ 1_A^- \ 1_A^+ \ p_A)$; $B = (l_B \ 1_B^- \ 1_B^+ \ p_B)$

(6) Determine the synthetic measure of assessments of variants CC_i using relative proximity of assessments of variants to the pattern and to the anti-pattern:

$$CC_i = \frac{d_i^-}{d_i^+ + d_i^-}, \quad i = 1, 2, \dots, M \quad (10)$$

The lower the distance of assessment from the pattern, and at the same time the higher the distance from the anti-pattern, the closer the value of the measure is to 1.

(7) Create a ranking for M variants based upon linear ordering of synthetic measures: CC_i , where $i = 1, 2, \dots, M$.

The starting point for these calculations is the non-fuzzy (sharp) decision-making matrix of assessments of "i" variants with respect to "j" criteria.

3. Results

Table 1 juxtaposes information concerning values of the particular criteria C_1 - C_6 for the assessed alternatives (contractors) A_1 - A_5 , obtained from reports and based on verification of procedures.

Table 1. Input data for assessments of alternatives

	C_1	C_2	C_3	C_4	C_5	C_6
A_1	135	71	38	36	6	6
A_2	146	63	46	49	8	5
A_3	118	43	35	28	5	3
A_4	122	52	41	41	6	4
A_5	129	60	40	31	5	5

Based on the input data, using formula (1), the fuzzy decision-making matrix was created, which contained fuzzy values of assessments of alternatives against the particular criteria – Table 2. In line with characteristics of the selected criteria, “loss”-type criteria (the lower the value, the better) were C_1 - number of persons employed in hazardous work environment conditions per 1000 employees, and C_6 - number of benefits on account of working in conditions that are detrimental or hazardous to health, whereas the remaining criteria were “profit”-type criteria (the higher the value, the better).

Table 2. Values from the fuzzy decision-making matrix

	C_1				C_2				C_3			
	l_{11}	l_{11}^-	l_{11}^+	p_{11}	l_{12}	l_{12}^-	l_{12}^+	p_{12}	l_{13}	l_{13}^-	l_{13}^+	p_{13}
A_1	165	145	125	105	56	66	76	86	23	33	43	53
A_2	176	156	136	116	48	58	68	78	31	41	51	61
A_3	148	128	108	88	28	38	48	58	20	30	40	50
A_4	152	132	112	92	37	47	57	67	26	36	46	56
A_5	159	139	119	99	45	55	65	75	25	35	45	55

	C_4				C_5				C_6			
	l_{14}	l_{14}^-	l_{14}^+	p_{14}	l_{15}	l_{15}^-	l_{15}^+	p_{15}	l_{16}	l_{16}^-	l_{16}^+	p_{16}
A_1	21	31	41	51	5	5.5	6.5	7	7.5	6	6	4.5
A_2	34	44	54	64	7	7.5	8.5	9	6.5	5	5	3.5
A_3	13	23	33	43	4	4.5	5.5	6	4.5	3	3	1.5
A_4	26	36	46	56	5	5.5	6.5	7	5.5	4	4	2.5
A_5	16	26	36	46	4	4.5	5.5	6	6.5	5	5	3.5

Based upon fuzzy values of assessments of alternatives against the particular criteria, using formulas (2) and (3), we calculated fuzzy standardised values of assessments against the particular criteria – Table 3.

Table 3. Values from the standardized fuzzy decision-making matrix

	C_1				C_2				C_3			
	l_{11}	l_{11}^-	l_{11}^+	p_{11}	l_{12}	l_{12}^-	l_{12}^+	p_{12}	l_{13}	l_{13}^-	l_{13}^+	p_{13}
A_1	0.533	0.607	0.704	0.838	0.651	0.767	0.884	0.884	0.377	0.541	0.705	0.869

A_1	0.328	0.484	0.641	0.797	0.556	0.611	0.722	0.778	0.2	0.25	0.25	0.333
A_2	0.531	0.688	0.844	1.0	0.778	0.833	0.944	1.0	0.231	0.3	0.3	0.429
A_3	0.203	0.359	0.516	0.672	0.444	0.5	0.611	0.667	0.333	0.5	0.5	1.0
A_4	0.407	0.563	0.719	0.875	0.556	0.611	0.722	0.778	0.273	0.375	0.375	0.6
A_5	0.25	0.406	0.563	0.719	0.444	0.5	0.611	0.667	0.231	0.3	0.3	0.429

Then, taking into account the established weights of the particular criteria and using formulas (4) and (5), we calculated weighted fuzzy standardised values of assessments against the particular criteria – Table 4.

Table 4. Values from the weighted standardized fuzzy decision-making matrix

	C_1				C_2				C_3			
	I_{i1}	I_{i1}^-	I_{i1}^+	P_{i1}	I_{i2}	I_{i2}^-	I_{i2}^+	P_{i2}	I_{i3}	I_{i3}^-	I_{i3}^+	P_{i3}
A_1	0.08	0.091	0.106	0.126	0.098	0.115	0.133	0.15	0.094	0.135	0.176	0.217
A_2	0.075	0.085	0.097	0.114	0.084	0.101	0.119	0.136	0.127	0.168	0.209	0.25
A_3	0.089	0.103	0.122	0.15	0.049	0.066	0.084	0.101	0.082	0.123	0.164	0.205
A_4	0.087	0.1	0.118	0.143	0.065	0.082	0.099	0.117	0.107	0.148	0.189	0.23
A_5	0.083	0.095	0.111	0.133	0.078	0.096	0.113	0.131	0.102	0.143	0.184	0.225

	C_4				C_5				C_6			
	I_{i4}	I_{i4}^-	I_{i4}^+	P_{i4}	I_{i5}	I_{i5}^-	I_{i5}^+	P_{i5}	I_{i6}	I_{i6}^-	I_{i6}^+	P_{i6}
A_1	0.066	0.097	0.128	0.159	0.083	0.092	0.108	0.117	0.02	0.025	0.025	0.033
A_2	0.106	0.138	0.169	0.2	0.117	0.125	0.142	0.15	0.023	0.03	0.03	0.043
A_3	0.041	0.072	0.103	0.134	0.067	0.075	0.092	0.1	0.033	0.05	0.05	0.1
A_4	0.081	0.113	0.144	0.175	0.083	0.092	0.108	0.117	0.027	0.038	0.038	0.06
A_5	0.05	0.081	0.113	0.144	0.067	0.075	0.092	0.1	0.023	0.03	0.03	0.043

Based upon the weighted standardised fuzzy decision-making matrix, we identified the pattern using formula (6): (0.089 0.103 0.122 0.15; 0.098 0.115 0.133 0.15; 0.127 0.168 0.209 0.25; 0.106 0.138 0.169 0.2; 0.117 0.125 0.142 0.15; 0.033 0.05 0.05 0.1); and the anti-pattern using formula (7): (0.075 0.085 0.097 0.114; 0.049 0.066 0.084 0.101; 0.082 0.123 0.164 0.205; 0.041 0.072 0.103 0.134; 0.067 0.075 0.092 0.1; 0.02 0.025 0.025 0.033). Using formulas (8) and (9), we calculated the particular assessments' distance from the pattern and from the anti-pattern – Table 5, and then, based upon formula (10), we calculated synthetic measures of assessments CC_1 for the particular contractors A_1 - A_6 – Table 6.

Table 5. Assessment's distance from the pattern and from the anti-pattern

	Distances from the pattern						
	C_1	C_2	C_3	C_4	C_5	C_6	d_j^+
A_1	0.016	0	0.033	0.041	0.034	0.038	0.162
A_2	0.025	0.014	0	0	0	0.032	0.072
A_3	0	0.049	0.045	0.066	0.05		0.210
A_4	0.004	0.033	0.02	0.025	0.034	0.022	0.139
A_5	0.011	0.019	0.025	0.056	0.05	0.032	0.194

	Distances from the anti-pattern						
	C_1	C_2	C_3	C_4	C_5	C_6	d_j^-
A_1	0.008	0.049	0.028	0.025	0.017	0	0.127
A_2	0	0.035	0.058	0.066	0.05	0.006	0.215
A_3	0.025	0	0.019	0	0	0.038	0.083
A_4	0.02	0.016	0.039	0.041	0.017	0.017	0.149
A_5	0.014	0.03	0.035	0.009	0	0.006	0.094

Table 6. Final ranking of companies

	A_1	A_2	A_3	A_4	A_5
CC_1	0.439	0.750	0.284	0.518	0.327
No.	3	1	5	2	4

The final ranking of companies, as in Table 6, suggests that in view of such assessment criteria that were adopted, and such relation of their significance that was established, company A_2 turned out to be the best contractor to perform the planned installation and maintenance works from the point of view of work health and safety assurance, although it had the highest value of indicator C_1 , and a high value of indicator C_6 .

4. Summary

As a result of our research work, we have established that the use of ordered fuzzy numbers as part of the TOPSIS method makes it possible to arrange the analysed contractors in order from the standpoint of the established criteria, and to select the contractor who meets the adopted varying work health and safety criteria to the greatest extent. Obviously, the way these criteria are selected depends on what the decision-maker actually needs. In the same way, the significance relation between weights of these criteria may look different than in our research. One of advantages of this method is

its simplicity and possibility to make calculations using the most popular spreadsheets. Although the TOPSIS method is one of the most widely used and best described ranking methods, the use of ordered fuzzy numbers has broadened this method's application range to the areas that have been poorly represented so far, such as, for instance, the area of the work health and safety management system. We hope that this work will inspire its readers to search for further applications of the fuzzy TOPSIS method, both in this area and in the area of using ordered fuzzy numbers within the frameworks of other multi-criteria decision-making methods.

Limitations and error mitigation for mine climate models with no thermal history component

G. Danko^{a,b,*}

^aUniversity of Nevada, Reno, 1664 N Virginia St, Reno, NV, 89557, USA

^bUniversity of Miskolc, Miskolc-Egyetemvaros, 3515, Pf. 2, Hungary

Abstract

Currently available, commercial mine ventilation software models usually do not have the “thermal history effect” (also known as thermal flywheel effect) solver. It is well recognized that any mine climate model without thermal history component for thermal–humidity simulations will give erroneous result, however, such models are rarely available for the mine ventilation engineer. The goal of this study is to find the best way of using the simple thermal-humidity simulation models without the thermal history component for reduced simulation error in the thermal design of mine ventilation.

Three models are used for the testing a proposed simplification application for dynamic thermal-humidity simulations in underground mine. The first model is set up for the accurate solution, complete with the thermal history component, processing past and current temperature and heat flow data. Results from the first model are used as the reference for comparison. The second model is configured as a conventional mine climate model without including the thermal history component, simplifying the past temperatures with a step-change function and calculating the strata heat from the Gibson function type solution. The third model is set up according to a new, simplified, proposed method for error mitigation, using the superposition of two step-change solutions only. A long, single drift example is used for the numerical study for comparison of the three model results. Conclusions are drawn with recommendations to the engineers for improving the simplified, step-change-type numerical simulation tool for mine ventilation and climate design.

Keywords: mine climate; thermal simulation; temperature variation; thermal flywheel effects

1. Introduction

Air temperature and humidity are of great concern for safety and health of the miners at the work face in deep and hot underground mines. The thermal design of the mine must incorporate various heat, mass and momentum transport components such as advection, convection, conduction radiation and accumulation between the air, strata, machinery and people working underground (Danko, 2016). Traditional mine ventilation and climatic models (e.g., VnetPC and Climsim, 2018) can only be used with limited accuracy regarding the seasonal and daily maximum temperatures expected to be within regulatory limits, such as below 27 °C effective temperature in most countries. Following the early efforts (Vost, 1977), improved models have been emerging (Bluhm et al., 2001; Danko, 2013; Ventsim, 2018). In search for solution to dynamic simulations with time, the research community in mine climate has turned into the Computational Fluid Dynamic (CFD) tools (Cradle, 2012; Fluent, 1997), a difficult avenue in computational time and capacity. While CFD models are good choices for the laminar or turbulent air flow in the mine tunnels and shafts, the heat and moisture flow model in the strata must be coupled to the solution, a difficult task. Similarly, Porous-Media Transport Models for the strata, such as NUFT (Nitao, 2000) or TOUGH2 (Pruess et al., 1999) are likewise complex to be coupled for solving the conjugate transport problem for the air flow together with the rock mass around it. A new method is introduced for the coupled solution using the Numerical Transport Code Functionalization (NTCF) technique (Danko, 2006; NTCF, 2008, 2013) accelerating the computation by several orders of magnitudes.

Such solutions, however, may not be available commercially to the practicing designer or operator of a mine. The goal of the present study is show a simplified solution using the basic technique of step-change-type temperature history representation of the time-dependent temperature history in the rock strata everywhere and every time instant during the simulation time. The method is introduced in the course of a mine climate simulation example. First, a correct solution is described as Case 1, using the NTCF method for modelling the time-dependent heat flow in the strata with a 1-day time division for 12 years, coupled to the advection, convection and thermal accumulation model of the airway in a 10,000 m long drift in the mine. Second, the correct, NTCF model-element for the strata heat is replaced with a Step-Change-Function (SCF) model as Case 2, similarly to the method, used in a previous comparative study (Danko, 2013) for error analysis. Third, the SCF model element is refined with a Dual-Step-Change-Function (DSCF) model as Case 3 for comparison with the correct, NTCF-based solution as well as with the SCF solution for methods evaluation.

2. Model description

Air temperature and humidity variations are modelled in a 10,000 m horizontal drift driven in hard rock 1,000 m below the surface at $T_{VR}=44$ °C] virgin rock temperature. The thermal conductivity, density, and specific heat of the rock strata are 3 W/m/K, 2,700 kg/m³ and 845 J/kg/K, respectively. The cross section and the perimeter of the drift are 25 m² and 17.72 m, respectively, closely matching a metal mine in Nevada, USA. Line-averaged heat load from Diesel haulage transportation is assumed at a constant rate of 60.6 W/m accompanied by line-load-type water vapor emission of 3.27×10^{-6} kg/s/m from the engine. The drift wall is kept partially wet at 0.24 wetness factor. The entire perimeter is also split into dry and the wet segments of 74% and 24%, respectively, defining two different wall temperatures at each cross section, $T_{Dwall}(x,t)$ and $T_{Wwall}(x,t)$.

The air entering the drift is assumed to be heated by a forcing fan, dissipating 991 [kW] compression energy adiabatically into the air flow; and autocompression of 588.6 kW due to descending to 1,000 m depth through a vertical intake shaft. The heat transport in the 1,000 m vertical shaft is otherwise excluded, assuming perfect thermal insulation along its wall. The model arrangement is shown in Figure 1. The input air from the outside environment enters the horizontal drift section before the node of the heat sources from the fan and autocompression. The variable temperature of the air, following the measured, daily mean temperature, is accessed from the weather data for the region (Danko and Lu, 2018) for the entire time period of 12 years, defining a temporal discretization of 1 day and 4,383 time instants. The thermal model simulates the variable temperature field inside the drift along its length at 1,000 points (defining a spatial discretization of 10 m) in the air at 1,000 points; on the drift wall at 2,000 points (1,000 each for the wet and dry segments), and in the rock wall with 2,000 elements of continuous, analytical models between the wall points and the virgin rock area assumed to be at infinite distance in radial direction.

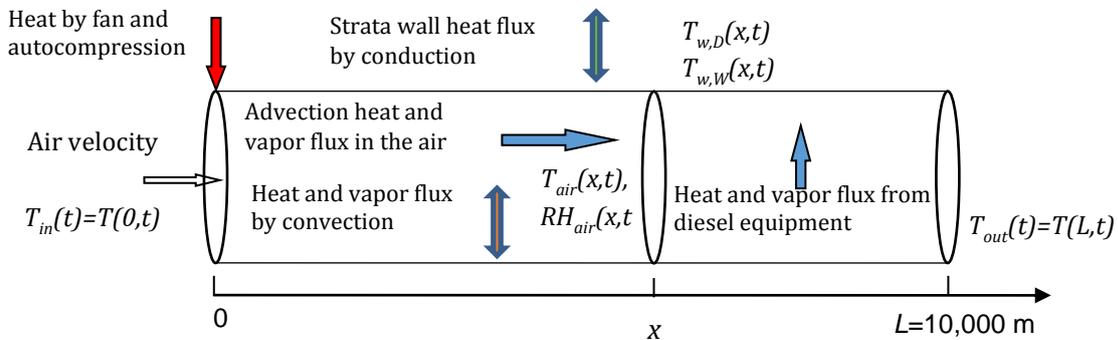

Figure 1. A single drift example with heat and water vapor fluxes transported by advection in the air, convection on the wall, and conduction in the strata.

a. Case 1. Wall heat flux model-element with the thermal history component

The NTCF modelling technique is used for calculating the time-dependent wall heat flux for the variable wall temperature with thermal history as follows (Danko, 2006):

$$q_w(t_i) = q_w(0) + \sum_{j=1}^i a_1(i,j)[T_w(t_j) - T_{VR}] \quad (1)$$

In (1), $a_1(i,j)$ are the elements of matrix $\mathbf{h}_1 = \{a_1(i,j)\}$, $\mathbf{h}_1 \in R^2$, an $M \times M$ matrix calculated by the NTCF procedure for a $[0, t_M]$ time interval for M time divisions (Danko, 2006). The full form of the \mathbf{h}_1 matrix is of a lower triangular, incorporating coefficients in row i for all $j \in [0, T_w(t_i)]$ wall temperatures as contributing history data for the $q_w(t_i)$ wall heat flux. In matrix-vector notations, (1) reads:

$$\mathbf{q}_w = \mathbf{q}_0 + \mathbf{h}_1[\mathbf{T}_w - T_{VR}] \quad (2)$$

where $\mathbf{q}_w = \{q_w(t_i)\}$ and $\mathbf{T}_w = \{T_w(t_i)\}$ are vectors of the temporal values of the variables.

b. *Case 2. Wall heat flux model-element with the SCF thermal history component*

The full NTCF matrix model can be used to emulate the SCF history by replacing the lower-triangular matrix with a diagonal matrix by summation in each line:

$$a_2(i, i) = \sum_{j=1}^i a_1(i, j); \quad h_2 = \begin{cases} a_2(i, i), & \text{for } \forall i \in [1, M] \\ 0, & \text{for } \forall i \neq j \end{cases} \quad (3)$$

Diagonal matrix h_2 ignores the history temperature values in the T_w vector, therefore, the expression in (2) may be used for q_w for the Case 2 model as $q_w = q_0 + h_2 [T_w - T_{VR}]$. Such a recognition helps testing the SCF model against the full NTCF model without changing the universal version of the core solution engine in the Multiflux model (Danko, 2016).

c. *Case 3. Wall heat flux model-element with the DSCF thermal history component*

The full NTCF matrix model can be used to emulate the simplified DSCF history by replacing elements of two strips in the lower-triangular matrix. As a simple example, one strip is chosen as the original value of the diagonal elements in h_1 ; while the other strip is defined as the average value of the remaining elements in each row for a given width of the trip, N . The algorithm of the h_3 matrix derived from the full NTCF matrix h_1 is as follows:

$$a_3(i, i) = a_1(i, i); \quad a_3(i, j) = \sum_{j=i-N-1}^{i-1} \frac{a_1(i, j)}{N} \quad h_3 = \begin{cases} a_2(i, i), & \text{for } \forall i \in [1, M] \\ a_3(i, j), & \text{for } j \in [i - N - 1, i - 1] \text{ for } \forall i \neq j \\ 0 & \text{elsever} \end{cases} \quad (4)$$

Dual-strip matrix h_3 modifies the history temperature values in the T_w vector according to the dual step-change-type history scheme, therefore, the expression in (2) may be used for q_w for the Case 3 model as $q_w = q_0 + h_3 [T_w - T_{VR}]$. Once again, the most universal version of the core solution engine in the Multiflux model is used without major modification in the comparison study. This technique eliminates the need for any software modification and possible mistakes in the execution of the study.

3. Numerical results

The daily average temperature variation results for the Cases 1, 2, and 3 models are shown in Figures 2a, 3a and 4a for the entire 12 year time period at the $x=0$ m intake, and at 1,000 m, 2,000 m, 5,000 m and 10,000 m distances from the entry point. Enlargements are shown in Figures 2b, 3b and 4b for the last 1.5 year time period. The Case 1 model results are used as the baseline reference. The absolute error in temperature in the Case 2 and Case 3 models relative to Case 1 are shown in Figures 5a and 5b, respectively. The temperature error in per cent in Case 2 and Case 3 models are depicted in Figures 6a and 6b, respectively.

The baseline humidity variations in the air from the Case 1 model are shown in Figures 7a and 7b in absolute humidity fraction and relative humidity forms, respectively. The relative humidity variations are depicted in Figures 8a and 8b from the Case 2 and Case 3 models, respectively. The relative per cent errors in relative humidity in the Case 2 and Case 3 models in comparison to the Case 1 model results are shown in Figures 9a and 9b.

Discussion of the results

The temperature solution $T_{air}(x, t)$ from the Case 1 model with the full NTCF function for the wall heat flux gives the most reasonable variation showing a time delay and amplitude attenuation with increasing length, shown in Figures 2a and 2b. The single step-change solution in Case 2, shown in Figures 2a and 2b, gives no time delay and noisy results. The error from the Case 2 model, depicted in Figures 5a and 6a, is significant in both absolute temperature and relative per cent values to be acceptable without criticism in engineering design or analysis. The errors are variable with time and alternate between positive and negative values. The error in relative humidity is also quite high in the Case 2 model, shown in Figure 9a.

The results from the Case 3 model for both temperature and relative humidity variations are much closer to those from the Case 1 reference model. Although only two distinct step changes are modelled, even a time delay is noticeable with increasing distance in Figure 2a and 2b. The errors are also much lower than those in the Case 2 model results.

Concluding remarks

- A hypothesis has been proven by the numerical study regarding achieving significant improvement in modelling accuracy by applying two distinct step changes, instead of only one, in the temperature history of the wall temperature of the drift.
- A model analysis with two distinct time steps is not excessive to perform manually. However, such an algorithm is not readily available for the user making the improved method in Case 3 difficult to implement in mine climate simulations.
- The implementation of the Case 3 model in the MULTIFLUX model is simple and straightforward on the basis of the availability of the full NTCF matrix solution for the wall heat flux. However, it would be quite counter-productive to scale back a fully-completed, Case 1 model into an approximate, Case 3 model.
- It is interesting to note that the run time of the Case 3 model in MULTIFLUX has been much longer than that for the Case 1 model or the Case 2 model. Difficulty in convergence may be caused by the mathematical fact that the wall temperature history is affected backward by averaging over the second step-change interval.

Developing a model of occupational health program

Zerbes Mihai-Victor^a, Cioca Lucian-Ionel^a, Neamu Vasilica-Silvia*

^a “Lucian Blaga” University of Sibiu, 10, Victoriei Bd, Sibiu, 550024, România

Abstract

The first author of this paper noted last year, in a workshop at the MSE 2017 international conference on OSH-related topics, that none of the experts involved and any papers on this topic did not focused on the occupational health component, focusing especially on occupational security. We affirm this because both the national legislation in force and the OHSAS 18001 standard deal with both aspects. Starting from this observation, the authors propose a model of occupational health program intended especially to help companies reduce the costs of absenteeism on case of illness and which could also positively change employee perceptions over the employer and why not in this context could lead even to thereof higher performance.

Keywords: occupational health; modeling; therapies; improving the health of employees

1. Introduction

Concern for employee health is often a neglected process, in some ways, by employers (we are talking, especially, about employers in Romania). It is not explicitly specified in the legislation that the employer should also consider this aspect. An example would be Article 27 of Section 4 named Internal Prevention and Protection Services under Law 319/2006 specifying: "The Internal Prevention and Protection Service may also provide for the supervision of the health of workers if they have staff with professional and appropriate material means, according to the law ". Another example could be that although in this law the word health or its variants is mentioned not less than 339 times and only about 1% this word occurs independently of the expression health and safety at work.

Throughout the experience in the field, we have heard, often, that health is the responsibility of the physician, in way of the health of the employee, is the responsibility of the occupational medicine doctor. So we (persons/employees/employers) have nothing to do and we should not get involved. It's not like this...?

Following a more detailed analysis of this phenomenon, we have concluded that the above-mentioned process, namely the concern for employees' health if brought to the spotlight, may become a factor, not negligible, of increasing the profit of an organization. We refer here in particular to the possibility of reducing the costs of paying sick leave for the employer (the first five days of temporary incapacity to work under Law No. 399 of 30 October 2006 for the approval of Government Emergency Ordinance No. 158/2005 on leave and health insurance benefits). Of course, we must also take into consideration the problems generated in the organizations by sickness absenteeism.

Taking these issues into account, we generated a model of occupational health program in order to facilitate the cutting down of the cost of absenteeism linked by the sickness in companies.

2. Conceptual modeling of an occupational health program

2.1. General aspects

At present, organizations are struggling for survival and supremacy on the market. The winners of this struggle were and are the organizations that have managed to create a discriminator in their sector of activity. Thus, successful models have emerged as sufficiently flexible and adaptable to market conditions, according to Zerbes, 2017. Marcu, 2002 defines the model as an ideal or material system by means of which the properties and transformations can be studied by analogy or by mathematical calculation to another more complex system and / or process. In other words, a model is a simplified representation of a process or system according to the definition of the "Iorgu Iordan - Alexandru Rosetti" Institute of Linguistics within the Romanian Academy, 2009.

* * Corresponding author. Tel.: +40-752-114-375; fax: +40-269-217-887.
E-mail address: mihai.zerbes@ulbsibiu.ro.

The objective of a model is to predict with a certain degree of accuracy the behavior of a system / process. The accuracy of a model depends, among other things, on: the accuracy with which everyone wants to know the system / process running, the time available, the necessary money, the accuracy of the input data, the calculation facilities, etc. Lobont said in 2002.

Taking into account all this and their experience, the authors of this paper have developed a model of health program meant to become, as we have already said, a discriminant for the organizations that will use it. The model, generically named IAP-IAP, is briefly presented below.

2.2. Brief presentation of the proposed model

The acronym IAP-IAP derives from the original model developed by the authors shown in Figure 1:

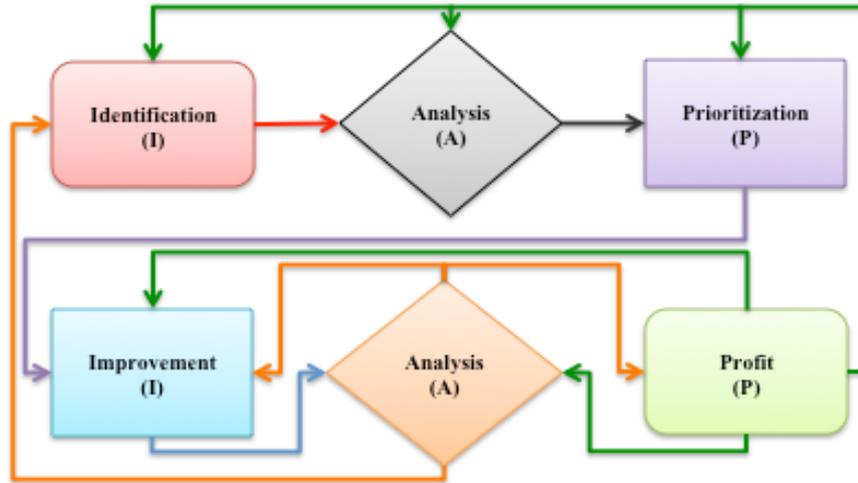

Fig. 1. The general model

Starting from the general model, we have developed a model specific to occupational health (OH) as follows:

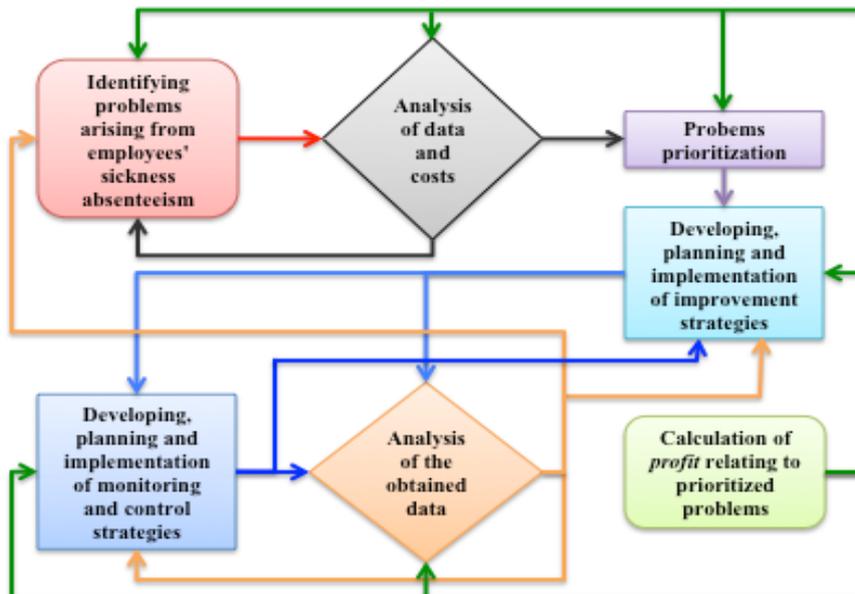

Fig. 2. OH specific model

2.3. Detailed model presentation

For a better understanding of the model and its mode of operation, we present the model in 3 distinct but complementary forms: graphic, tabular and mathematical. The graphic model is shown in Figure 3 as a flow diagram and aims to highlight the steps in which the modeling process takes place and the relationships between them.

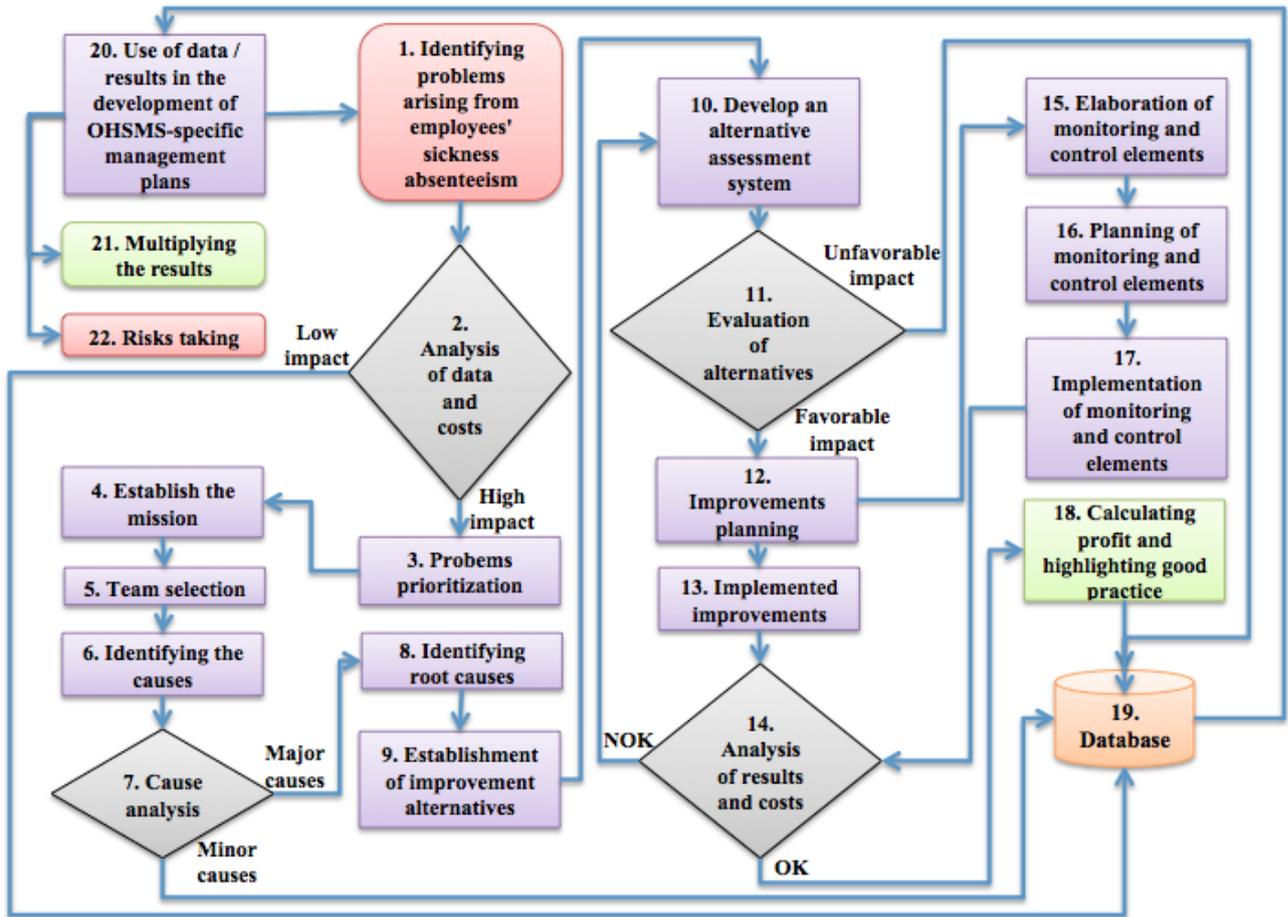

Fig. 3. Steps of the modeled process

Because the lack of space (due to the drafting restrictions) we only present the way of building the tabular model (table 1). We also took into account the fact that the specialists from the organizations that will adopt it can personalize the tabular model.

Table 1. An example of a table

Activities	Recommended methods, techniques and tools	Aim	Performance indicator	Weighting coefficient	Risk coefficient
A1	A	A1.1	PI.1.1	W1.1.1	R1
	B		.	.	
	C		PI.1.m	W1.1.m	
	.	A1.2	.	.	
	X	A1.n	.	.	
.
A22	R22

Mathematically expressed (Zerbes, 2017) the tabular model is presented as:

$$M_{OHP} = (\sum_{i=1}^{22} A_i)R_i \tag{1}$$

in which:

$$\sum_{i=1}^{22} A_i = \sum_{j=1}^m P_j W_j + \dots + \sum_{y=1}^x P_y W_y \tag{2}$$

therefore:

$$M_{OHP} = (\sum_{j=1}^m P_j W_j) R_1 + \dots + (\sum_{y=1}^x P_y W_y) R_{22} \tag{3}$$

where:

- M_{OHP} – OH program model
- $P_{j...y}$ – performance indicator
- $W_{j...y}$ – weighting coefficient
- R_i – risk coefficient

It should be noted that R_i - risk factors might vary from one organization to another depending on several factors such as experience, time priorities, organizational politics, etc.

2.4. Discussion

The conceptual model proposed by us has as its starting point the classical diagram of the process model presented in Figure 4 (Zerbes & Budău, 2005). Thus, it has defined the inputs, outputs, control elements and the mechanisms necessary for the functioning performance of the proposed model.

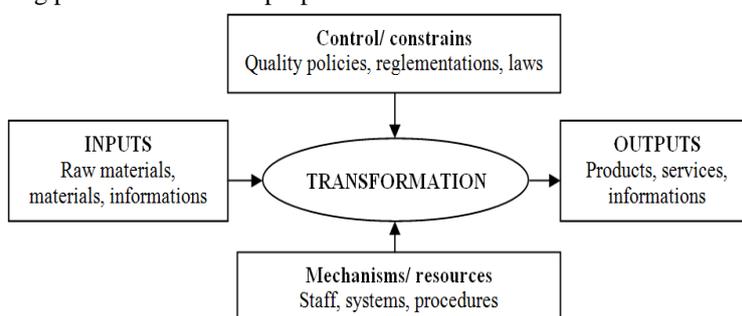

Fig. 4. The classical diagram of the process model

In order to facilitate the processes of regulating and implementing planned improvements, one can use the representation mode called tabular flow diagram (Table 2) to highlight the inputs, outputs and responsibilities associated with each activity in the process. For their establishment, organizations will appeal to internal and external experts, especially for consultants in the field. As we can see, we recommend that you determine the responsibilities to use the Deming cycle (PDCA).

Table 2. The tabular flow diagram

Inputs	Activities	Outputs	Responsibilities (human resources)				
			Plan	Do	Check	Act	Reporting
Resurse: • Material • Financiare • Informationale	Flow chart from figure 3	Rezultate: • Tengibile (rapoarte, procese verbale, instructiuni, dispositive, echipamente etc.) • Intangibile (cunostinte, experienta etc.)	Cine planifica activitatea?	Cine implementeaza a activitatea?	Cine monitorizeaza si controleaza activitatea?	Cine decide luarea masurilor de imbunatatire?	Cine raporteaza catre top management?

Regarding the documentation of the planning and implementation activities both of the improvements and of the control elements, we recommend that the organizations use the structure specific to the project management. In this respect, due to the fact that we are actually talking about a project to improve the health of employees, we will consider at least of the following aspects:

- Project title;
- Period of deployment;
- Possible funding sources;
- The project team (for each function involved, the job description will be drafted and a work contract if the team / function comes from the outside of the organization or an annex to them if the team / function is from the inside);
- Partners / collaborators (if it's applicable);
- Target group;
- Project justification (describe the situation of the target group before implementing the project, describe the causes and effects of the identified problem);

- Project beneficiaries (mention the direct and indirect beneficiaries of the project);
- SWOT analysis of the ability of the organization and / or team to solve the identified problem;
- The purpose of the project;
- The objectives of the project (the ways to reach the goal);
- Project results;
- The activities / work breakdown structure (details of the project activities according to the established objectives, pointing for each activity the sub-activities, the resources necessary for their implementation and the related duration);
- Budget (make budget by grouping costs by spending categories - human resource expenditures and material resource expenses);
- Implementation chart (Gantt diagram);
- Daily schedule and description of the activity / function;
- Daily schedule and description / target group (target group), etc.

We mention the fact that the stage of the occupational health program dedicated to the employee will consist in the implementation of integrative therapies and will be complementary to the medical services provided by the doctors of occupational medicine. Consequently, depending on the affections identified at the targeted employees, the program will include specific elements:

- allopathic medicine such as:
 - specialized medical check-ups (eg: cardiovascular, musculoskeletal, digestive system, etc.);
 - investigations;
 - medical tests;
- alternative medicine from practices:
 - Ayurveda;
 - traditional Chinese medicine;
 - homeopathy;
 - acupuncture, etc.
- complementary therapies such as:
 - physical therapy;
 - osteopathy;
 - massage;
 - reflexology;
 - presopuncture;
 - Bowen technique;
 - dietotherapy;
 - phytotherapy;
 - apitherapy;
 - hydrotherapy;
 - hirudotherapy;
 - psychotherapy;
 - sacrotherapy;
 - bioenergotherapy, etc.;
- personal development programs on topics such as:
 - nutrition education;
 - health education;
 - healthy lifestyle;
 - personal hygiene;
 - teamwork and teambuilding;
 - time management;
 - stress management;
 - physical education;
 - maintenance gyms;
 - yoga;
 - aikido;
 - tai chi;
 - qigong;
 - the music;
 - dance;
 - meditative painting;
 - eurythmia etc.

3. Conclusion

In conclusion, we believe in the efficiency of such programs. In the article *Occupational health programs and workplace absenteeism*, the authors (the same authors as the present paper) present such a program successfully implemented, in a company in Sibiu in the field of software consultancy.

We anticipate that such programs can increase the quality of life by improving service relationships with beneficial effects on all employees by increasing the level of trust in the team and management. Thus, the employer also will win by reducing especially staff fluctuations and increasing the company's profit. It is worth mentioning that without the direct involvement of top management in the organization such programs have no chance of success. However, the employer must first understand the benefits of using such a program and find out the strategies of awareness and motivation of employees who would participate in such a program.

Also, we must not forget the social benefits of such a program, first of all by improving the health status of the community they belong to employees. In this context, we recommend family involvement to increase motivation and ensure long-term compliance.

Finally, in the context of those presented in the paper, is the question from the introduction: Who is responsible for my health (as an individual / as an employee)?

Occupational health programs and workplace absenteeism

Zerbes Mihai-Victor^a, Cioca Lucian-Ionel^a, Neamu Vasilica-Silvia*

^a “Lucian Blaga” University of Sibiu, 10, Victoriei Bd, Sibiu, 550024, România

Abstract

Currently, at national level, there is no direct concern for occupational health. Moreover, in industrial organizations and not only the phrase "security and occupational health" is not yet well understood and used to its true value. In this article the authors show a facet of this component, namely how occupational health programs can influence the process of improving absenteeism at work. In this regard, the authors present a case study related to employees of a software consultancy company suffering from musculoskeletal disorders.

Keywords: occupational health; workplace absenteeism; musculoskeletal disorders

1. Introduction

1.1. General aspects

Productivity has always raised the same challenges / challenges for both multinational and national corporations as well as for small businesses. These challenges include the reduction of absenteeism, the increase in profit, the actions to be taken in relation to employees who are no longer performing, etc.

Following Corbett's 2003 study on productivity and profitability, it was concluded that organizations could be far more productive than they are. Of the CEOs who participated in this study, 53% said that organizations do not reach their productive potential. With this statement, 52% of the employees also agreed. Among the factors contributing to the deficit in organizations' profitability, specialized studies indicated that:

- 66% -71% of loss of profitability is due to physical and / or emotional health problems, stress, burnout of employees;
- 42% -59% of the loss of profitability is due to poor management strategies;
- 39% to 48% of the loss of profitability is due to the lack of effective training programs.

If past research and organizational policies were focused on profitability factors and losses, lack of effective marketing strategies, and lack of technology, the latest research provides information on the "hidden" causes of profitability losses, Davis & al.

Among the most important hidden causes are the fragile health statuses of employees. This state has the greatest negative impact on employee productivity and organization results. Employee health has effects on the performance from the workplace. These effects can be direct, such as absenteeism due to the impossibility of coming to work, or indirectly, the presenteeism of (Lowe, 2004), ie the unproductive state of the employee present at the workplace which cannot have maximum performance due to of disturbing factors such as: negative emotional states, stress, illness or general uncomfortable state due to headaches, stomach, back, etc. Due to absenteeism and presenteeism, companies face a lot of unproductive labor, ie working days lost due to presenteeism or absenteeism classes, and the costs of unproductive labor are often enormous. Stewart & Stewart's studies in 2003 found that 86% of all non-productive work time is due to strictly presenteeism work, a factor that increases the cost of organizations due to employees' remuneration at that time, as well as the increase in error rates in the workload thing. Thus, cumulative presenteeism hours with absenteeism generate the unproductive work time. To avoid unproductive work, one of the imperative conditions is to maintain and improve the health of employees. As a result, companies will benefit from sustainable work performance and increased overall profit.

1.2. Aspects regarding the affections targeted in the case study

In this research, we focused on musculoskeletal disorders (MSD) which represents an group of painful disorders of the muscles, tendons, joints and nerves. All parts of the body may be affected, but the upper and rear limbs being the most exposed. MSD occurs due to movements such as bending, straightening, grip, holding, twisting, tightening, crushing, kneading and stretching. These regular movements are not necessarily harmful in the course of daily activities. What makes them dangerous during work is repetitiveness, often forced, and especially, the speed of movements and the lack of rest breaks between them. Heat, cold and vibration also contribute to the appearance of MSD. In Europe, musculoskeletal disorders are the most common work-related health problems. A quarter of EU workers accuse back pain and nearly a quarter complain of muscle pain according to a study by the European Foundation for the Improvement of Living and Working Conditions in 2007. All musculoskeletal disorders interrupt work, reduce productivity and generate the absenteeism from medical reasons and of course chronic professional incapacity. MSD is a serious concern: it affects workers' health and increases the economic and social costs of businesses and European countries, according to the European Agency for Safety and Health at Work 2007. A previous report by the Agency mentions that some studies have estimated the cost of MSDs affecting upper limbs somewhere between 0.5% and 2% of Gross Domestic Product (GDP). MSD is still a significant and significant health problem. At European level, musculoskeletal disorders are the most common occupational diseases. In 2005, they accounted for about 39% of all occupational diseases according to the mandatory register. According to the latest figures provided by the European Working Conditions Survey, in the EU, back pain seems to be the most important work-related disorder, while in the new Member States, back pain is the second most exhausted. This is also one of the reasons for choosing our research topic, focusing on the spine specific affections, namely on kyphosis, lordosis and scoliosis.

The European Agency for Safety and Health at Work analyzed, for the first time, more careful, work-related musculoskeletal disorders in the 2000 reports, according to Buckle & Devereux, and Op de Beek & Hermanns, 1999.

1.3. Brief description of the organization where the research was conducted

For reasons of confidentiality we cannot present the name of the organization presented in the case study. It is a multinational company with more than 2500 employees at European level, the Sibiu branch with approximately 450 employees. The typical form of work in the company is office work. Thus, regardless of the job, each employee spends most of his working time at the office. For this reason, the company is equipped with ergonomic desks and chairs that support employees' health. Also, a system of occupational health and safety management is implemented at both company and branch level in Sibiu. However, MSDs is not missing from the company / subsidiary. The main causes of MSD identified in our research are briefly presented in Figure 1. We present in this paper only the results of the recovery program followed by employees from the chosen sample.

2. Case study

2.1. Methodology

The study was conducted according to the occupational health program model presented in the work *Developing a Model of Occupational Health Program in SIMPRO 2018*. Due to lack of space, we will briefly present only a part of the 22 steps of the model. Thus, in the last management analysis carried out within the organization targeted in this case study, the issue of employee absenteeism was also discussed. Following this analysis, the top management of the company decided to turn to external experts (the authors of this paper) to help them improve the costs regarding of absenteeism. Experts analyzed the documentation and formed a team of 7 members: 3 experts, 2 employees of the management company, 1 physical therapist and a fitness trainer. The team has developed the improvement program following the project management specific steps. The program is briefly presented below.

Duration of the program: 05.02.2018- 31.06.2019. Consequently, in this case study, will present only a preliminary phase, namely the results obtained after 2.5 months from implementation.

2.2. Participants

The sample chosen for the study included 20 of the 450 employees of the company who accumulated most of the sick leave due to the three types of MSD during the year 2017. The selection of the sample was made according to the following working procedure:

- the analysis of the statistical data on medical leave in 2017, which showed that the largest weight is due to MSD (Figure 2);
- analyzing data on employees who have absent on a sickness case basis due to MSD, which found that 50% of the 40 identified employees are responsible for 80% of the number of days off. Thus, of the 1102 days of sick leave (SL), 881 days were related to the 20 employees (table 1).

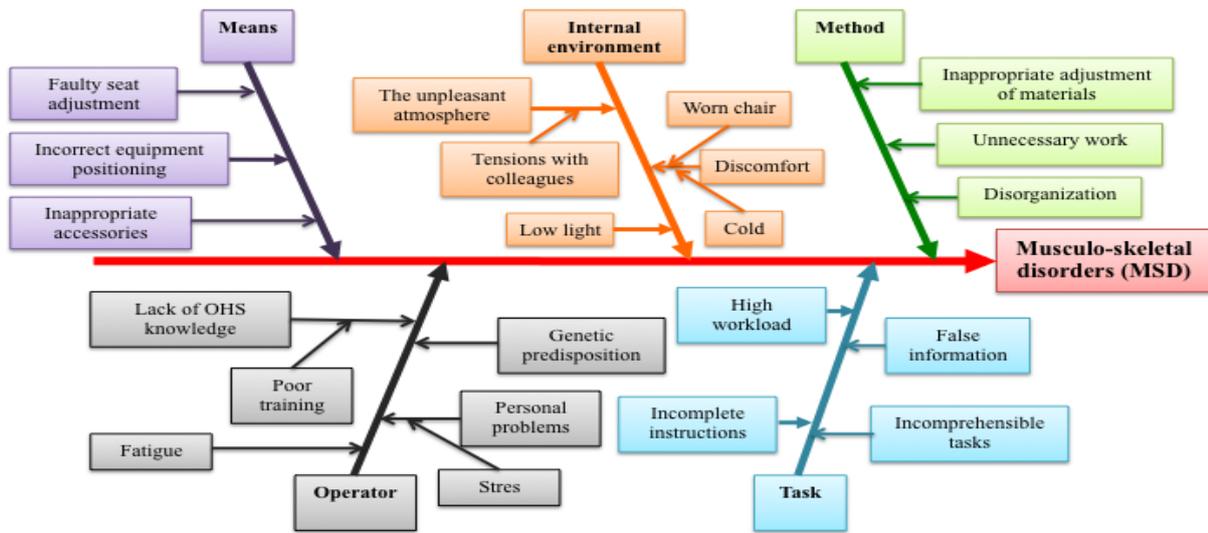

Fig. 1. The main causes of MSD

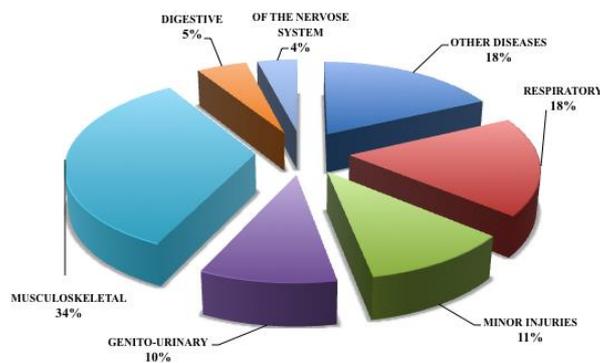

Fig. 2. Weight of sickness leave days

Table 1. Employees with MSD

Number of employees with MSD	% of total employees	Number of SL cases	Number of SL days	Related cost
40	8.89	160	1102	35,744 euro

2.3. Data collection

In 2014, Băbuț & Moraru says that workplace / workstation analysis is the fundamental element for identifying risk factors for preventing and protecting disease and establishing appropriate prevention and protection measures. From this perspective, the authors of this research collected the input data needed to improve the process in four ways:

- analysis of the documents from the doctor of occupational medicine;
- analysis of statistical data on medical leave in 2017;
- applying a questionnaire to identify employees' lifestyles;
- analysis of accident and occupational disease risk assessment files.

2.4. Aim and objectives of the program

The aim of the project is to reduce the number of medical leave for musculoskeletal disorders to a maximum of 10% of the total number of medical leave within 12 months of the implementation of the project.

The objectives are presented in Table 2 alongside their performance indicators, indicators that have been developed to facilitate the monitoring and control of program implementation.

Table 2. The objectives of program

Objectives	Performance indicators
A. Identifying the current health status of employees within 5 working days of starting the project	$I_a = T_{ea}/T_{pa} \leq 1$
B. Planning for specialist health check for identified employees within 15 business days of project start	$I_b = T_{eb}/T_{pb} \leq 1$
C. Implemented specialist health check for identified workers within 25 business days of starting the project	$I_c = T_{ec}/T_{pc} \leq 1$
D. Making a questionnaire on a healthy lifestyle within 30 days of starting the project	$I_d = T_{ed}/T_{pd} \leq 1$
E. Applying the questionnaire within 35 working days of the start of the project	$I_e = T_{ee}/T_{pe} \leq 1$
F. Analysis of data collected through the questionnaire and the results of the medical check-up within 40 working days of the project	$I_f = T_{ef}/T_{pf} \leq 1$
G. Subcontracting a fitness station for setting up and running a sports program within 45 working days of the start of the project	$I_g = T_{eg}/T_{pg} \leq 1$
H. Develop a program to improve musculoskeletal disorders within 50 working days of project start	$I_h = T_{eh}/T_{ph} \leq 1$
I. Implementation of the musculoskeletal improvement program in 140 working days since the start of the project	$I_i = T_{ei}/T_{pi} \leq 1$
J. Developing a fitness for maintenance program within 145 business days from the start of the project	$I_j = T_{ej}/T_{pj} \leq 1$
K. Implementation of the fitness for maintenance program within 240 business days from the start of the project	$I_k = T_{ek}/T_{pk} \leq 1$
L. Monitoring and control of employees' physical conditions throughout the project	$I_l = T_{el}/T_{pl} \leq 1$
M. Analysis of the data obtained from the monitoring and control of the employees' physical condition throughout the project	$I_m = T_{em}/T_{pm} \leq 1$
N. Drawing up the project documentation in the last 9 working days of the project	$I_n = T_{en}/T_{pn} \leq 1$

where:

- I - Performance Indicator
- Te - Time achieved
- Tp - Planned time

2.5. Activities specific to the MSDs improvement process

The results obtained from the analysis and interpretation of the collected data is summarized in Figure 3.

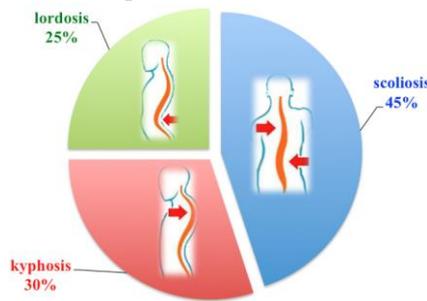

Fig. 2. Weight of sickness leave days

For the relief of these MSDs, three different exercise programs were developed, depending on the needs of each category of MSDs. The therapist recommends the frequency of treatment and takes into account, in particular, the severity of the condition. These programs will be supported for 18 weeks at a pre-booked fitness room (Table 3).

Table 3. Three different exercise programs

MSDs	Scoliosis	Kyphosis	Lordosis
Corrective exercises			
Maintenance exercises			

After supporting MSDs by employees for 18 weeks, they will follow maintenance programs for 19 weeks. Specialist personnel will personalize maintenance programs as soon as the employees complete the improvement step. The maintenance program will be performed 2-4 times a week, aiming at the formation of a reflex to correct the wrong attitude of the body.

2.6. Results

Currently, among employees with MSDs, the occupational health program for the improvement of musculoskeletal disorders has started for 2.5 months. During this time, they successfully supported 70% of the improvement stage, and then carry out the fitness program for maintenance. The sick leave statistics show considerable improvements, since only 2.5 months have elapsed since program implementation (Table 4).

<ul style="list-style-type: none"> In the months before the implementation of the Occupational Health Program, the presenteeism presented a very high percentage, equal to the percentage of productive time 37% 			<ul style="list-style-type: none"> 2 months after the implementation of the Occupational Health Program, the percentage of presenteeism decreased considerably, as well as the percentage of medical leave among the employees with MSDs from 19% to 8% 																																				

2.7. Discussion

The Occupational Health Program will be completed in June 2019 and employees will re-fill the Healthy Lifestyle Questionnaire for a detailed report on the consequences of implementing such an Occupational Health Program to be conclusive.

However, it should be noted that among problem employees, although this program will be completed within 10 months, they are recommended to implement a personal lifestyle maintenance program to maintain spinal health and to avoid the regression of MSDs.

It is also worth noting that only 50% of all people suffering from MSDs have participated in the study.

In order to justify the choice of such a project, we believe that it is necessary to highlight the losses of the company generated by the medical leave related only to the MSDs, thus by the year 2017, the number of 1102 days of medical leave due to the 40 persons suffering MSDs. These days cost the company 168,000 lei (35,745 euros), because the company is legally obliged to pay for each employee 5 days of medical leave per month according to Article 12 of GO 158, 2005.

So far, all objectives have been successfully achieved. In a free discussion with the participants, they have shown that they have changed their eyesight on the importance of health, both personally and professionally. Leadership was directly involved, a vital factor for the success of any project that is about to be implemented. The remarkable results to date provide the satisfaction of the management and the participating employees motivating them more strongly to support the project.

However, the results of implementing such a project, once finalized, will definitely be felt strongly in the long term, especially at the financial level, where by the end of 2018 an economy of nearly 60% of the amount paid for medical leave musculoskeletal disorders in 2017, when only 50% of employees with MSD participated in the study. For 2019, the reduction in MSD medical leave costs is estimated to exceed 70% of the initial costs, bringing the company a profit of over 25,000 euros.

3. Conclusion

The benefits of this Occupational Health Program are visible from the first year of implementation, but the cost of implementation will reduce the profits made at around. 3000 euros, so the profit becomes considerable especially from the second year of implementation.

Table 4. Costs and benefits of the implemented occupational health program

Benefits	Costs
<ul style="list-style-type: none"> • +20,234 euros that will no longer be paid for medical leave related to musculoskeletal disorders in the first year, this amount accounting for 57% of the cost of current medical leave • In the second year, at least 90% of the diseases being healed, at least 25,851 euros will be saved from the cost of the initial medical leave, this amount accounting for 72% of the current medical leave costs • Increasing employee productivity and company profit 	<ul style="list-style-type: none"> • Investments / sponsorships to implement the Occupational Health Program: approximately 17,147 euro • Working time of the team

Implementing such a program is undoubtedly one of the best decisions an organization can take, a decision that has considerable financial and human implications. Here are some advantages and disadvantages for implementing such a program:

Table 5. Advantages and disadvantages of occupational health programs

Benefits	Disadvantages
<ul style="list-style-type: none"> • Increasing employee productivity • Improving the quality of employees' lives employee awareness of workplace risks and the importance of occupational health • Stimulate employees for a healthy lifestyle • Increase the company's credibility • Increasing employee satisfaction at work • Improving the health of employees • Developing social relationships between colleagues within the company 	<ul style="list-style-type: none"> • Limited funds • Not all employees are willing to participate • The results are limited by the short time Need for staff availability • Constant motivation of employees for engagement

The success of an occupational health program depends primarily on the leadership of company and its involvement, especially the degree to which it is willing to engage in implementing and supporting the program, a factor without which any program would be successful. However, employee teams that make this change possible also influence success, and teamwork stimulates the prolongation of the program after the study. Thus, the motivation of both the management and the project team is crucial in the success of the program.

This program is intended to be practical proof of the potential that these occupational health programs can have, motivating not only management but also whole teams of employees to implement as many occupational health programs as possible to increase both employee productivity and profit company, and to take advantage of all the personal and professional benefits that accompany these profitable projects.

A propose approach for continuous improvement using ergonomics and quality management knowledge and methodologies

Bianca Cirjaliu^a, Anca Mocan^a, Maria-Elena Boatca^a, Anca Draghici^a *

^aPolitehnica University of Timisoara, Pta Victoriei 2, Timisoara 300222, Romania

Abstract

In the last years, quality management knowledge and methodologies support companies' continuous improvement strategies. In this context, the most popular organizational model is Lean Six Sigma and its practical exploitation is based on the structured approach DMAIC (Define, Measure, Analyse, Improve and Control) cycle. In each phase a set of tools and methodologies are applied, as brainstorming, cause-and-effect diagram and control charts. In the context of the present research Lean Six Sigma and DMAIC are integrated with Ergonomics approach (principles and knowledge) in order to create a synergistic effect aiming to support the continuous improvement processes by consider a holistic view of the human side of the production systems. Thus, the article will present the fundamentals of the proposed methodological framework that has been designed and which coherently applies the principles of both filed of science (ergonomics and quality management) and simultaneously ensuring gains in productivity and in workplace well-being.

Keywords: Ergonomics, Quality management, Lean Six Sigma, DMAIC cycle, holistic framework

1. Introduction

Continuous improvement process is embracing by companies to achieve operational and service excellence. This approach part of the performance management domain of organizations' interest because of the increase in competition and globalization. Therefore, companies need to adjust their strategic management and continuously improve performance in all areas (e.g., operations, organization) keeping up with strong competition on the markets they operate (Melton, 2015; Nunes, 2015; Cirjaliu and Draghici, 2016).

Lean Management and Six Sigma philosophies have been considered as the most adequate initiatives for the continuous improvement of organizations: Lean approach focuses on eliminating the sources of waste, aiming a continuous process flow (focus on operation management and business process management), while Six Sigma focuses on reducing the process variability (focus on quality management) (Nunes, 2015). These are complementary approaches and companies establish programs designed as Lean Six Sigma (Cirjaliu and Draghici, 2016). Therefore, Lean Six Sigma (LSS) concept represents a business philosophy and strategy to drive continuous improvement of production processes to reach higher customer satisfaction simultaneously with high profit rates; it supports good productive performance, based on the reduction of waste, variability and costs of production (Devane, 2004; Taghizadegan, 2010).

In the last years, companies that have implemented the LSS have started to search for other knowledge sources of improvements because operation managers sometime complain on employees working stress affecting productivity because of the strict duration and high quality of their demanded tasks. In addition, the achievement of the work of (Luz Peralta et al., 2016) was noted that often the ergonomics and safety are the background, as companies seek productivity and profit.

In this context, the present research proposes that ergonomic approach to be integrated simultaneously with LSS to diminish work stress but increasing the work productivity (eliminate the delays and avoid the stagnation of manufacturing processes) as suggested by the studies of (Nunes, 2015; Cirjaliu and Draghici, 2016). Both Ergonomics and LSS are system-oriented approaches. However, frequently ergonomic approach is neglected by managers and often is associated with Occupational Safety and Health (OSH) in the context of the risk management approach.

E-mail address: anca.draghici@upt.ro.

In the content of the present research there will be presented the proposed approach of integrating ergonomics principles and LSS (and not neglected risk management and OHS). This will assure the preliminary conditions for the creation of a decision-making support that will help operation management in the continuous improvement processes tailored to their specific needs (eliminating employees stress and increase work productivity).

The paper structure consists of: (1) literature review for the interest issues regarding LSS and ergonomics; (2) the description of the proposed approach of an ergonomics and LSS integration, by pointed the role of knowledge management to create the expected decision-making support. In the end some conclusions and future researches will be presented.

2. Literature review

2.1. Ergonomics – premise for the integration with LSS

Ergonomics is the interdisciplinary science that focuses on systems where the interaction between people and their environment occur. Ergonomics is a human oriented science focuses on the optimization of human energy consumption in the professional activities and thus, to well-being but simultaneously with maintaining overall performance (in terms of productivity) (IEA, 2018). Therefore, ergonomics can be characterized by (1) having a system approach; (2) being design driven and (3) focuses on performance and well-being (Dul et al., 2012; Richardson et al., 2017).

The literature review in the field of ergonomics has underlined that there is still a great knowledge potential that has been under-used, being one of the reasons that managers neglect ergonomics value. “Ergonomics is mainly associated with the workers well-being, being most often housed within the Occupational Safety and Health (OSH) department, therefore managers tend to inadvertently restrict its scope of intervention to OSH hazards, instead of benefiting from its help to organizational effectiveness, business performance or costs” (Nunes, 2012).

Nowadays, researchers and practitioners have recognized in disparate studies (in different industrial domains) the value of ergonomics knowledge that could support also, health and safety approaches, occupational risk mitigation. Ergonomics can add value to a company’ business strategy to reach the ultimate business goal of profit, or intermediate business goals related to profit drivers like cost minimization, productivity, quality, delivery reliability, responsiveness to customer demands, or flexibility (Draghici and Draghici, 2000; Jul and Neumann, 2009; Nunes, 2015; 2000, Cirjaliu and Draghici, 2016; Draghici et al., 2017). Therefore, it is necessary a paradigm shift, which requires a re-positioning from a primary health ergonomics approach to a more business-oriented ergonomics approach (Jul et al., 2012).

The integration of ergonomics principles in LSS matches this new paradigm.

2.2. Lean Six Sigma relevant aspects – premise for the integration with ergonomics

Lean concept was first introduced to interpret Toyota’s new production system that does away with mass production, to describe the highly efficient production system which uses less of every resource to produce the same number of products with competitive quality and cost (Behrouzi and Wong, 2011).

Lean Six Sigma results from the combination of two different but complementary management philosophies: Lean Management and Six Sigma (Albliwi and Antony, 2011). Lean Management is a production philosophy that evolved from the Toyota Production System (TPS) and appeared after the 2nd World War. Its focus on supporting companies achieving on time the delivery of the right product quality and quantity to satisfy customer demand. It is based on the following five principles (Cirjaliu and Draghici, 2016):

- Specify Value – it is necessary to specify what adds value from the end customer’s perspective, so that all the non-value activities can be identified and removed; in fact, for most production processes only a small part of the total production time and effort adds value for the end customer;
- Identify the Value stream – identify all activities that don’t aggregate any value to the final product;
- Create Flow - promote continuous flow in the process by eliminating wastes;
- Customer Pull – respond to customer demand; produce what customers want at the right time;
- Pursue Perfection – continually remove wastes, striving for a perfect process.

These five principles strongly underline that Lean Management focuses on the elimination of the non-value-added activities or wastes. From the practical perspective, there are eight different types of wastes: transportation, excessive inventory, unnecessary movements, over production, over processing, waiting time, quality/defects and intellect underuse (Fullerton et al., 2014).

From the praxiological point of view, to support the Lean Management philosophy implementation in reducing lead and set up times, inventories, equipment downtime, scrap, rework and other wastes there are many tools and techniques. Some examples are: 5S, Kaizen, Value Stream Mapping, Kanban and SMED. The Six Sigma methodology is a management program developed by Motorola Company, in the 80s, in response to an increase of the international

market competitiveness created by Japanese companies. To cope with this situation, Motorola felt the need to improve the process quality, due to an excessive amount of defective production parts (Salah et al., 2010; Cherrafi et al., 2016). Six Sigma seeks to achieve high levels of quality and low levels of variability, by detecting and removing defects causes (Salah et al., 2010). Because of this philosophy, the waste of organizations decreases, and the production variability is reduced as well improving production control and forecasts (Vinodh et al., 2011; Nunes, 2015). Its application is based on DMAIC (Define – Measure – Analyze - Improve - Control) cycle. From the practical perspective, in each DMAIC phase are used different methodologies and tools (e.g., brainstorming, Cause-and-effect analysis, control charts etc.).

The objective of the LSS implementation is to improve performance of production processes by reducing waste, variability, costs and satisfying customers (Jul and Neumann, 2009; Slah et al., 2010). Based on the DMAIC approach, LSS is a solution for problem solving that integrate, in a synergetic manner, tools from both philosophies. Furthermore, the simultaneously use of lean management and six sigma creates a more effective way to identify root causes of problems rather than focusing on the processes where the problems appear (Slah et al., 2010; Nunes, 2015).

3. The proposed framework of integrating ergonomics and LSS

The literature review has underlined different aspects related to psychological risks (and stress) that affect employees when their tasks are developed under the lean organization, and more when LSS approach is the way production processes are developed (Angelis et al., 2011; Desai et al., 2012; Stone, 2012; Koukoulaki, 2014; Cirjaliu and Draghici, 2016). In those previous researches there have been recognized the negative consequences in the working conditions due to the implementation and development of LSS in the production systems, such as: an increased work pace, workload and work intensification (Nunes et al., 2007; Hasle et al., 2012; Nunes, 2015) which affect the employees' well-being, namely originating fatigue, stress, tension and work-related disorders (Longoni et al., 2010).

Started from these negative effects on the organizations' employees (mainly of the direct productive workers at the operational level) that adopt LSS there have been conclude that a more comprehensive approach is required incorporating a ergonomics oriented approach, since higher productivity is expected with scarce resources, which can compromise the workers well-being and performance.

Practical observations of ours have underlined that LSS is mainly focused on organization's productivity (the system level) but leaves the internal work productivity ignored (the individual and working group level). Managers do not have a clear understanding of the relation between these two types of productivity. Internal work productivity regards the ability of workers to produce more output with no increase in risk of injury or errors, which is a core concern of ergonomics science (Nunes, 2015). As expected, ergonomic interventions can result in positive effects in production performance and this is because of the new created working conditions that support professional well-being of the workers. In addition, for maximizing organizational performance combining the internal working productivity concern in the overall organization's productivity goal is a required condition in the integration process of ergonomics and LSS.

Based on this idea a framework is proposed to help the integration of Ergonomics and LSS based on the DMAIC cycle, which was originated in Six Sigma. In fact, DMAIC is very convenient since it was generalized as an overall framework for process improvement. This generalization can go further; encompassing an integrated approach that incorporates Ergonomic principles, tools and methods. Figure 1 shows the corresponding framework. The proposed framework associates to the LSS procedures used in each phase of the DMAIC cycle an additional ergonomic perspective, as described in Table 1.

Table 1. DMAIC approach with ergonomic interventions

DMAIC cycle	Details on the ergonomic interventions
Define	ergonomic tools (e.g., checklists) and data from existing records (e.g., injuries, accidents) is used to characterize the initial situation of the working conditions and to identify new improvement opportunities
Measure	to complement the establishment of the baseline, ergonomic methodologies are used to evaluate the status of performance metrics in the beginning of the improvement process. These data will be compared to the performance metrics at the end of the process to evaluate the gain resulting from the improvement process
Analyze	ergonomic tools and methodologies are used to pin-point root causes affecting the working conditions. These root causes must be prioritized and selected for elimination on the subsequent step
Improve	the selection and implementation of solutions which eliminate or, at least, mitigate the effect of root causes incorporate ergonomic tools and methodologies which help to identify cost-effective solutions, test such solutions (e.g., using Human CAD modeling), and plan their implementation and deployment
Control	to sustain the gains achieved during the process, a continued monitoring process and training are required, which includes ergonomic tools and methodologies, as well as interventions to raise awareness

The validity of this framework is supported by several successful continuous improvement preliminary studies which were performed including ergonomics and using the DMAIC cycle (Nunes et al., 2007; Nunes, 2015; Cirjaliu and Draghici, 2016). Besides the validation of the framework, it can be concluded that the integration of ergonomics and LSS is possible and beneficial both for the production process and the workers.

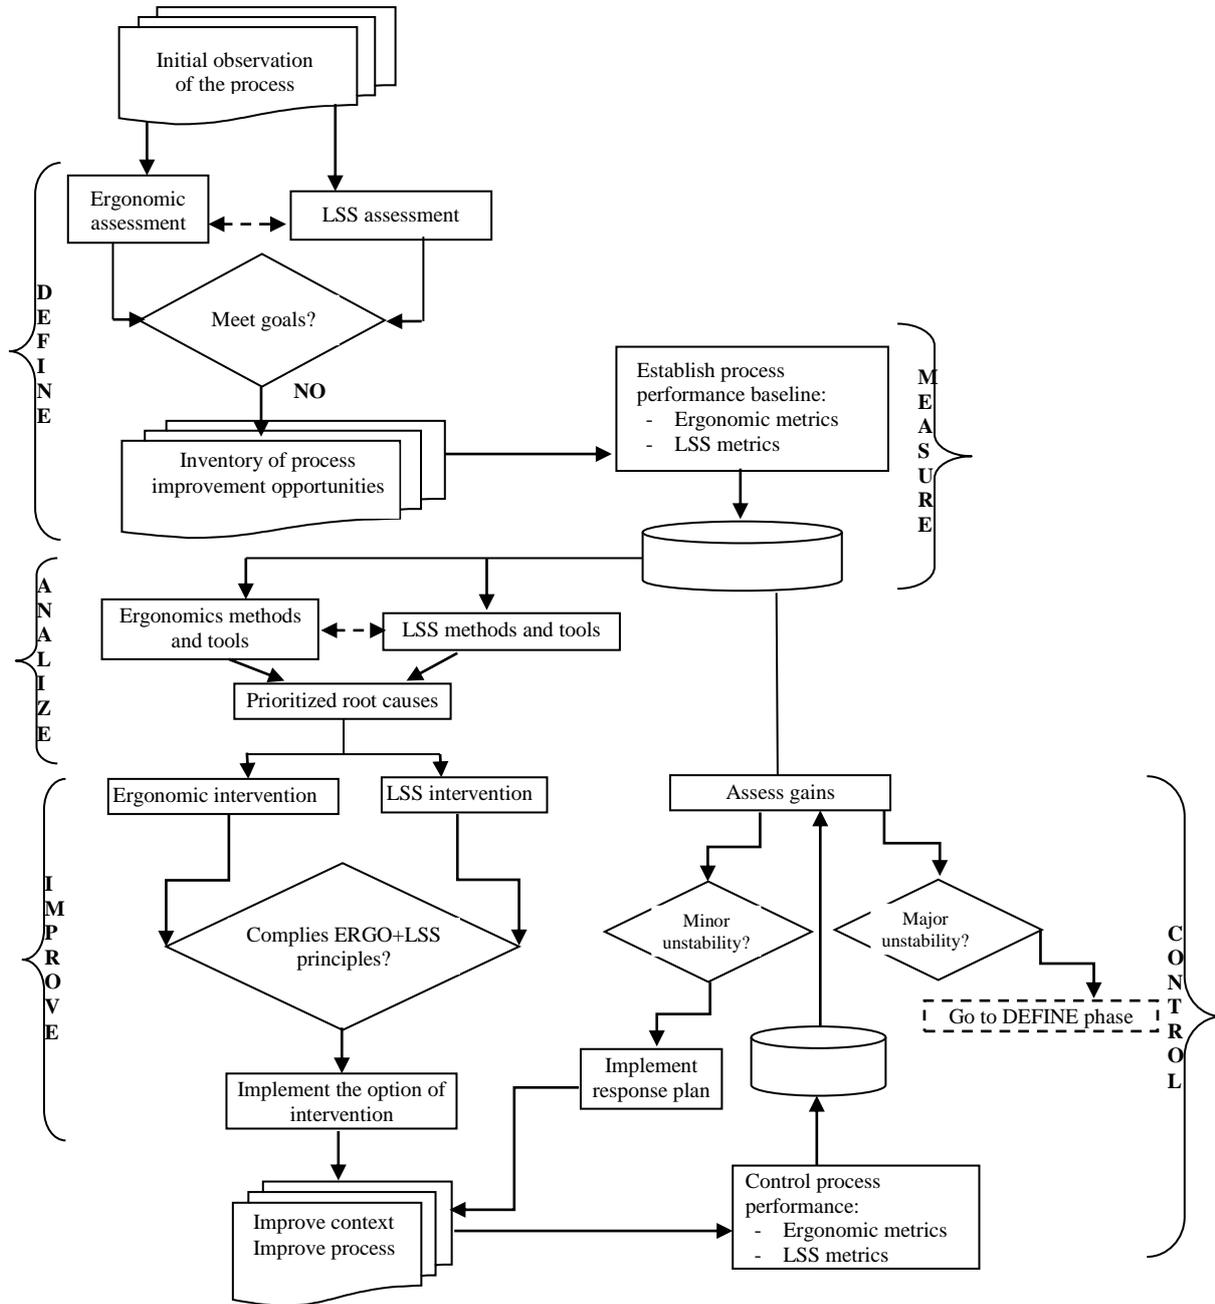

Fig. 1. The proposed approach for the ergonomics and LSS integration

The proposed approach of integrating ergonomics and LSS could be better implemented with a decision support system, as shown in Figure 2. The first knowledge base must be initialized with ergonomic and LSS domain knowledge, developed through a knowledge acquisition process from consultants, experts and from explicit sources of knowledge (e.g., create access to digital libraries). The data, information and knowledge regarding the organizational processes that must be improved have to be gathered and stored in the database, created based on organization evidences, reports, audits etc. The inference process will conduct the execution of the proposed decision support system, interacting with the user (through an adequate interface) providing orientation to the data collection stages, analyzing such data and providing results and advice, or help and guidance regarding the continuous improvement process.

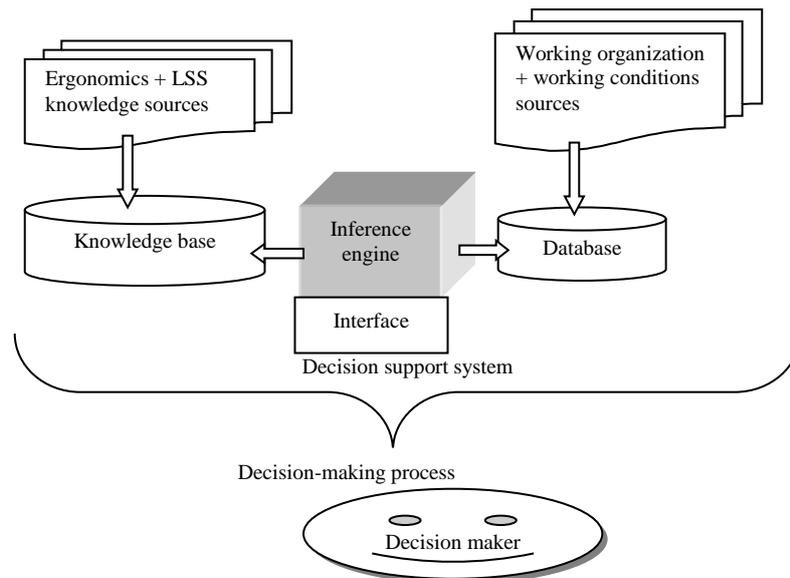

Fig. 2. The architecture of the decision support system based on the ergonomics and LSS integration.

Future researches will develop the reasoning process required for the inference engine as an artificial intelligence approach.

4. Conclusions

In the actual economic context, organizations have implemented continuous improvement approaches to increase competitiveness while facing great market competition, globalization and economic crisis. Managers and researchers have recognized that LSS is a very good approach for continuous improvement.

In the context of our research debate there have been presented (based on the literature review) some negative aspects that can appear when implementing LSS and developing an organization system based on this philosophy. The integration of ergonomics during the LSS implementation has the potential to obtain substantial gains in productivity and to simultaneously improve the working conditions. The proposed approach regarding the integration of ergonomics and LSS based on the DMAIC cycle was presented. The proposed framework associates to the LSS procedures used in each phase of the DMAIC cycle ergonomic tools and methodologies introducing an additional ergonomic perspective.

The proposed approach for the ergonomics and LSS integration (presented in Table 1 and Figure 1) has been developed based on an interdisciplinary research, combining the knowledge from different domains as: ergonomics, quality management, quality control, operation management etc. The proposed approach has demonstrated that ergonomic integration to LSS is possible and could support the continuous improvement processes in a much more proactive manner, by diminishing the work stress and increasing the quality of employees' professional life.

In addition, a decision support system architecture has been proposed to help the decision-making process in the execution of the integrated implementation of ergonomics and LSS continuous improvement processes. This decision support system is useful both for experts in continuous improvement and for managers which may have the awareness but usually lack the means to develop the required steps to implement continuous improvement.

Increasing the quality of occupational safety and health implementations through awareness training for those involved in implementing the Safety Observation Report

Alin Găureanu^{a*}, Anca Draghici^a, Hugo Weinschrott^a

^a Politehnica University of Timisoara, Pta Victoriei 2, 300222 Timisoara, Romania

Abstract

The occupational safety and health (OSH) management field is still a priority for all organizations. Following the observation and implementation of good practices and audits of OSH there have been findings that by questioning employees there could be brought added value to risk identification, sometimes more consistent and more effective than the results of risk assessments carried out by the laborious procedure performed by OSH specialists' domain. The article will present the characteristics and the steps of the Safety Observatory Report (SOR) through the awareness of OSH training. These will contribute to the preparation for the SOR implementation, which leads to the quality and efficiency of the data resulting from the application. Through the training program for the SOR implementation, the qualitative level of the data obtained is increased, is much more real, because they are coming directly from the source and not from the evaluations based on sterile or inappropriate check-lists. The research will underline that SOR could contribute to the increasing of the OSH culture, mainly for the employees, by making them aware that they are part of the system, and do not perceive it as an additional burden.

Keywords: Quality, Training, OSH Management, Safety Observatory Report (SOR), sustainability, safety risk assessment

1. Introduction

Since around 90% of all accidents are caused by unsafe actions, a worker-based safety program must be at the heart of any successful effort to eliminate the adverse effects on employees and sustainable economic development at the organizational level (Krug and Sommers, 2010). In the same time, management concern on OSH culture is a hot subject not only because of the law and regulations in the field, but also, because of the interest on creating work wellbeing and high levels of productivity.

Based on our own observations, in companies located in Timis County (highly industrialized area in the West Region of Romania) the existing programs to improve OSH aspects are mainly concerned with mature, and highly economic potential organizations that are driven by the principles of sustainability. Furthermore, companies cannot have OSH strategies and policies that are assumed and implemented effectively if they are based on sterile, unrealistic, outdated or inappropriate assessments of the organizations' realities that employees face daily. Therefore, they need to be aware of and involved in action to contribute continually to observe and propose measures, considering the human factor of each participant in the OSH system. Thus, employees must be considered the receivers and the primary filter of the observations and proposals related to OSH measures that are implemented in the organization practice.

Such a tool that allows and empowers the active role of employees in the OSH system is the Safety Observation Report (SOR). The purpose of the tool (and associated process) is to engage all employees in the observation of work in progress so that a maximum number of workers, with diverse experiences and perspectives, are involved in the process. This process also provides a method for identifying and documenting safe acts and safe workplace conditions. The main benefits of applying SOR are:

- Identifies and corrects unsafe situations;
- Prevention of injuries and property loss;

* Corresponding author. Tel.: +40-256-403610; fax: +40-256-403610;
E-mail address: gaureanu.alin@gmail.com

- Raises OSH Awareness and demonstrates leadership's commitment to OSH;
- Evaluates training effectiveness;
- Tests compliance with standards;
- Identifies and corrects weaknesses in OSH;
- Reinforces positive OSH Behavior and improves communication with employees in this field.

An example of SOR content that follow significant instructions is related to the following aspects:

1. Purpose: Performing workplace safety visits to identify and resolve unsafe situations;
2. Process description:
 - Message "I care / We care" - direct discussions with employees in and about their work environment, positive remarks, expressing concern, avoiding sanctions, focusing on effects. SOR is not an audit but an opportunity to interact with workers, providing training and communication perspectives. Questions to learn, not to teach;
 - Involvement on all hierarchical levels;
 - Filtered and centralized proposed actions are discussed monthly and quarterly in special committees;
 - Frequency of SOR from 1 to 4 per month based on assessed, planned or unannounced risks;
 - Visits are short 10-15 min. easy to manage findings;
 - It is done throughout the company's perimeter and in all work exchanges;
 - Examining individual operations and their deployment;
 - Identify safe and insecure practices (which can be instantly intervened);
 - Identify the root causes of unsafe conditions and practices;
 - Appreciate / thank and eventually reward / promote positive OSH behaviors and safe practices;
3. Analyze - Analysis and measurement of collection information:
 - Observation notes during and after the observation visit;
 - Questions and clarifications to get recommendations from operators on improving their OSH at work;
 - Filter and recommend removing / controlling unsafe conditions on a higher hierarchical scale;
4. Corrective actions - Correct prompt of the identified unsafe conditions:
 - Work instructions, use of personal protective equipment, risk assessment may be revised / updated;
 - Information and training of workers for any changes made;
5. Feedback - Offered to employees, direct directors:
 - Formalizing and monitoring corrective actions,
 - Analyzing the effectiveness of SOR after at least 12 months with adjustments to remain relevant.

The occupational safety and health (OSH) management field is still a priority for all organizations. Following the observation and implementation of good practices and audits of OSH there have been find that by questioning employees there could be bring added value to risk identification, sometimes more consistent and more effective than the results of risk assessments carried out by the laborious procedure performed by OSH specialists' domain. The article will present the characteristics and the steps of the Safety Observatory Report (SOR) through the awareness of OSH training. These will contribute to the preparation for the SOR implementation, which leads to the quality and efficiency of the data resulting from the application. Through the training program for the SOR implementation, the qualitative level of the data obtained is increased, is much more real, because they are coming directly from the source and not from the evaluations based on sterile or inappropriate check-lists. The research will underline that SOR could contributed to the increasing of the OSH culture, mainly for the employees, by making them aware that they are part of the system, and do not perceive it as an additional burden.

2. The premise of the research

In this research there has been considered two premises to outline the improvement of the qualitative aspect regarding the OSH implementation through the SOR tool. The first premise is based on the idea that employees are continually making significant contributions to the discovery and resolution of the hidden risks of injury. The second premise consider that employees can acquire perceptual skills, ready to offer viable solutions to reduce the risk of injury. Both premises have as a common scope: increasing efficiency of OSH activity starting from the bottom to the top of the organizational structure (from employees at the operational level to the top management). Employees and supervisors are actively contributing (on a continuous and realistic basis) to the shaping of OSH strategies, policies and engagements issued by OSH specialists and the organization's top management team. By creating and implementing appropriate and effective OSH procedures, the sterile compliance barrier is removed from existing systems or laws, conformation that inhibits links to the reality and needs of the enterprise, leading to new barriers to perception, misunderstanding, disinterest for prevention, and sustainability at all hierarchical levels. Table 1 presents the information and OSH prevention cycle, seen as a continuous cycle.

Table 1. Cycling OSH prevention by SOR

Top – bottom attributions	Hierarchical levels and OSH responsibilities	Bottom – top (SOR) attributions
Integrated management, responsibility, strategies, OSH policies, considering assessments, good practices (quality systems), legislation	Top and Middle Management	Analyzes integrates and correlates reports for consistency in quality policies integrated with SSH strategies
Internal SSH regulations, strategy takeover, and implementation tracking	OSH Specialist	Filter, quantify, analyze, conclude, report to management and risk assessor
Knowledge, implementation, guidance and supervision of internal policies and regulations	Leaders of workplace	Interviews, involves workers, observes risks and asks for possible measures
Performing and observing procedures with as few risks	Workers / Representatives	Identifies risks and proposes possible measures, actively participates

These convergences and interferences to the contributions to the OSH System Management are found as a guideline within the framework of regulatory acts in the field. These refer to the concept of participatory worker consultation, just as there will be seen that the SOR instrument is used. In Romania, the paragraphs in the OSH Law 319/2006 that consolidate this concept and regulate the workers' advisory aspect, forcing them to participate in OSH decision-making are shown in Table 2 (according to the European Directive 89/391/CEE transpose in the national legislation of OSH Law 319/2006).

Table 2. Legal obligation to use a kind of instrument like SOR

Directive 89/391/CEE, art. 11 – Romanian OHS Law 319/2006, art. 18	Directive 89/391/CEE, art.13 - Romanian OHS Law 319/2006, art. 23
<p>Consultation and participation of workers</p> <p>1. Employers shall consult workers and/ or their representatives and allow them to take part in discussions on all questions relating to safety and health at work.</p> <p>This presupposes:</p> <p>the consultation of workers,</p> <p>the right of workers and/ or their representatives to make proposals,</p> <p>balanced participation in accordance with national laws and/ or practices.</p> <p>...</p> <p>3. Workers' representatives with specific responsibility for the safety and health of workers shall have the right to ask the employer to take appropriate measures and to submit proposals to him to that end to mitigate hazards for workers and/ or to remove sources of danger.</p>	<p>Workers' obligations</p> <p>1. It shall be the responsibility of each worker to take care as far as possible of his own safety and health and that of other persons affected by his acts or omissions at work in accordance with his training and the instructions given by his employer.</p> <p>2. To this end, workers must in particular, in accordance with their training and the instructions given by their employer:</p> <p>...</p> <p>(d) immediately inform the employer and/ or the workers with specific responsibility for the safety and health of workers of any work situation they have reasonable grounds for considering represents a serious and immediate danger to safety and health and of any shortcomings in the protection arrangements;</p> <p>...</p> <p>(f) cooperate, in accordance with national practice, with the employer and/ or workers with specific responsibility for the safety and health of workers, for as long as may be necessary to enable the employer to ensure that the working environment and working conditions are safe and pose no risk to safety and health within their field of activity.</p>

In the practice of various companies, the communication and collaboration on improving OSH activity is often translated into mandatory “hazard” and “near miss” procedural reporting:

- Near miss means that the unplanned event resulting from an error or a malfunction during an activity or related to the disfunction of the working equipment that did not affect the workers, environment, equipment or activity, but through minor changes in circumstances, has the potential to easily produce such consequences in the last minute (circumstance impeded by injury);
- Hazard (dangerous situation) is a concrete, real and actual case, which only lacks the triggering opportunity to produce an accident at any moment.

The difference between the two situations is that if the “near miss” is an already consumed event and fortunately there were no consequences, “the hazard” did not happen, but by its status, it offers the opportunity to occur at any moment an event.

These concepts are a part of goal when using SOR tool, the spearhead of observations and continuous improvement of measures, both being internally solved. SOR tool is not intended to replace the risk assessment, but only to update these assessments by new observations that can be analyzed and considered by the evaluators according to art.15 paragraph 3, letter c) of Romanian OSH Law 319/2006.

3. The research approach

3.1. Aspects related to the employee's contribution to OSH

In the first statement, we can argue by presenting the purpose, namely the disclosure of possible accidents that are hidden under one major accident. These should be brought to light by closer observation of the potential risks that can turn the dangers into accidents at work. As have been seen in the example above and summarized in Table 3 it is not constructive to blame and sanction employees for unsafe practices, but it's important to improve the OSH system, according to (Manuele, 2011), who is fighting against Heinrich theories 300-29-1 and the domino (Heinrich, 1959).

Table 3. Approach to system blame - let's improve the system! by (Kleinstaub, 2007)

When Things Go Wrong	
Old approach	New approach
Human error is the cause of accidents:	Human error is a symptom of trouble deeper inside a system.
You are highly trained	You are human
and	and
If you did as trained, you would not make mistakes	Humans make mistakes
so	so
You weren't careful enough	Let's also explore why the system allowed, or failed to accommodate your mistake
so	
You should be PUNISHED	Let's IMPROVE THE SYSTEM!

In order for employees to feel useful and involved in this continuous process of adapting and streamlining OSH measures, they need to acquire skills in this regard by two ways of enhancing the quality of this process:

1. Active involvement as part of the system by increasing confidence in the benefits of its actions. As tools you can use:
 - OSH awareness raising processes at higher levels for a more coherent and uniform application;
 - Influencing workers' perception of their membership of the OSH system;
2. Increase the quality of periodical training through the following tools:
 - Presentation of thematic materials containing images or films;
 - Continuously refine the frames presenting the materials;
 - Appropriate establishment of the frequency of the trainings and the subjects to maintain a balance between the observance of the legal terms and the duration of those trainings, considering the specificities of the workplace and the level of perception of the employees so as not to affect the prevention, not to become disinterested and embarrassed by too dull repeatability or unattractive themes.

The paragraph 2) is part of other future studies. In the context of the research included in this article, we will only address the two instruments under number 1) paragraph.

3.2. SOR awareness training

As an appropriate implementation is specified, it is related to the level of preparedness of those who implement it. Therefore, before creating new tools and procedures that are beneficial for effective SSM management, consideration should be given to preparing participants for these changes. They need to know the SSM concepts, their importance and the role of each in the system. This is only possible through an awareness process involving all hierarchical levels, discussing less well-known aspects, novelties that can attract interest and mobilize explicit and applicative discussions.

Such courses may be provided either by the external partners or by the internal specialists, which may also be included in the provisions of art. 80 letter a) of updated HG 1425/2006, which stipulates that the employer must have appropriate training programs for job managers. Unless these job managers understand their position in the OSH management system, they will be able to convey them to the employees' discussions on the topic, of the understanding and governance of the OSH issue, thus enhancing their leadership status. In the absence of the awareness process before applying the SOR tool, there may be occurred some problems that will alter and hinder the observation process, targeting only a few areas of precarious security (Oswald et al., 2018).

3.3. Influencing the perception of workers

Another tool in raising the quality level of SOR implementation is the applied working method (research method) that refers to the stages of the observation so that the employees do not feel the pressor of regular discussions related to the SOR schema, they do not feel them as an additional task and perceive having an OSH mission in their interest in the organization system (feels attracted, tied and responsible with all participants in that system). "To become a good

observer, he needs to improve his observation skills and have to learn how to observe effectively. The actual observation includes the following key points (Hughes and Ferrett, 2013):

- Be selective;
- You know what to look for;
- Practice;
- Keep an open mind;
- Protect yourself from habit and familiarity;
- Do not be happy with general impressions;
- Record systematic observations.”

The need for processes of awareness and influence of perception will be distinguished from the conceptualization of SOR and the steps to be taken to achieve it.

4. The quality of SOR through conceptual similarities already demonstrated as effective

We can associate SOR as a collection tool for Root Cause Analysis (RCA)(Zhou et al., 2013; Ferjencik, 2010; Ferjencik, 2014). This analysis can be performed using the 5W Method (5 Way - Why?) which is derived from the Six Sigma methodology (following the Define – Measure – Analysis – Improve – Control cycle, DMAIC) (Tarvin and Tarvin, 2016). In this regard, we can recall a possible similarity in the Key Performance Indicators (KPI) approach, which has a top-down and bottom-up approach, as we can see from the SOR approach (Gerbec and Kontic´, 2017).

Practically, SOR tool comes to complete the work of (Hughes and Ferrett, 2013; p. 91 – Supervisors, point 4) and to argue with the multiple methods of continuous risk identification, leaving the analysis aimed at extracting information directly from the employees, and the reporting, analysis, evaluation, and resolution of these issues by the OSH specialists, assessors and managers through the methods already listed.

This SOR procedure is not the only a way of working, but it is also seen as a Safety Observation Tour (SOT) or Safety Observation System (SOS) or even Near Miss Reporting. All of them have the same purpose to involved employees into the OSH practice, to assume responsibilities for themselves and those around them, and to encourage employees at all levels to act and create a positive change (Krugh and Sommers, 2010). This expected behavior is expecting to have a positive impact on the OSH culture.

In support of the concept of increasing the quality of SOR tool implementation, the Safety Trail Observation Plan (STOP) (STOP ® Safety Training Observation Program Overview, 2016) has to be mention. Furthermore, under the same auspices of safety observation, even tools for the continuous improvement of operational safety in the nuclear energy industry (Cournoyer et al., 2011) have been developed with the help of the behavior-based safety observation program (ATOMICS-Allowing Timely Observations Measures Increased Commitment to Safety) within the Glovebox Safety Program (GSP).

By the employees’ assessment process and making them aware that they are part of the safety system, it is basically transferring responsibilities to them and others as they obtain a distributed security according to the Gaining Distributed Safety (GDS) / Distributed Safety Management (DSM) method as an observation Behavior-Based Safety Culture Assessment. This is based on an AsSeVi Survey Tool questionnaire developed in 2013 that aims to integrate coherently, responsibly, participation, commitment, compliance (Sheffick and Grillo, 2011; Amaya, et. al, 2018).

Prior to implementation and during the implementation of SOR procedure, there must be continuously analyze the cost balance needed to develop such programs for company profitability. “Customization is expected to require more resources; hence its realization depends on the capability, objectives and vision of each organization” (Karanikas et al., 2017). “Instead of providing robust safety knowledge, the SOR system was instead a tool that could be used to challenge their own performance” (Oswald et al., 2018).

Resource, staff and time investments to carry out these activities must not exceed the limits of the ALARP (As Low As Reasonably Practicable) management rules. The cost involved in reducing the risk further would be grossly disproportionate to the benefit gained (Jones-Lee and Aven, 2011; Ale et al., 2015; Nw Zealand Government, 2017). ALARP principles are also found in the motivation of elaboration of EEC Directive 89/391 “in accordance with Article 118a of the European Union Treaty, these directives must avoid imposing administrative, financial and legal constraints which would hinder the creation and development of small and medium-sized enterprises”.

5. Conclusions

SOR tool demonstrates that for a qualitative improvement in the application of OSH prevention principles, there must be a broader vision in an already established scientific spectrum. It is not an unpredictable invention, but it is an adequate application of prevention obligations under OSH legislation. To preserve the proven quality of the application, this must be accompanied by quality implementation through awareness-raising, continuous training through direct contact with every job, analysis, feedback and ongoing adjustments.

Some qualitative aspects of continuous training and improvement of participants in the SOR process, implicit in the OSH system in which everyone should feel involved, will be the subject of other papers. The objective of the future researches is aligned with the logo of (Kleinstauber, 2007): “If we can predict it: we can prevent it!”

Reducing the risk of slipping on ice by selecting appropriate protective footwear

Nicoleta Crăciun*, Alina Trifu

I.N.C.D.P.M. „Alexandru Darabont” 35 A, Ghencea Blv, Bucharest

Abstract

The existence of numerous jobs in construction, maintenance, interventions, etc., where workers have to operate in very cold environments, often results in the occurrence of various accidents due to slipping on frozen surfaces. Considering the risks to which workers are exposed, the article presents the results of studies on determination of the slip resistance on ice for different types of soles, while stressing the importance of properly selecting the footwear to prevent the risk of injury and occupational disease.

Keywords: coefficient of friction, ice, accident prevention, protective footwear

1. Introduction

One of the most frequent causes of injury and occupational diseases in many economic sectors is exposure of workers to very low temperatures. At national and international level, there are many jobs such as in construction, agriculture, commercial fishing, forestry, mining, energy, food, etc. where workers have to work a few hours a day in environments with low-temperature ($t \leq 10$ °C) or very low temperature ($t \leq -20$ °C).

Thus, in addition to the specific hazards of the work they perform, workers are exposed to the risks arising from exposure to cold.

The main risks that affect health by exposure to low and very low temperatures are: hypothermia, frostbite and accidents due to slipping. If some dangers encountered in such jobs may be avoided (e.g. by wearing clothing articles with thermal properties), others, such as slipping on frozen surfaces are more difficult to avoid and often cause particularly serious accidents. In relation to hand injuries, for example, when the same degree of injury will permit the worker to resume work, in case of injuries to the legs, it is necessary to interrupt the work over a much longer period of time due to the difficulty and even the impossibility of putting up one's footwear. If the accidents occurring on the toes are not always considered the worst, the accidents occurring on the paw of the foot at ankle level should be considered among the most serious.

Due to this fact, it is considered imperative to reduce work accidents caused by falling on frozen surfaces by developing criteria for the selection of the protective footwear. This necessity is imposed not only by the fact that the modes of manifestation of slip risks are very diverse, and inadequate protection against cold (such as the provision of inappropriate protective equipment) could introduce new risk factors that would change the worker's normal behaviour, rendering him more prone to errors and accidents, but also the lack of specific testing methods leading to the establishment of criteria for the selection of the footwear.

2. Identification of the risk factors specific to the movement on frozen surfaces

If for activities carried out in normal environments a number of problems have been resolved by the appearance of method standards and the setting of threshold values that allow the evaluation and determination of the protective features of the PPE used, the same cannot be said about the activities carried out in environments with low temperatures where the multitude of risk factors and their possible cumulative effects appear to further complicate measures to prevent accidents and occupational diseases.

Research in the field has demonstrated that accidents due to slipping are not purely random but rather predictable events with known risk factors that may be extrinsic (environmental factors), intrinsic factors (human factors) or mixtures (system factors).

If human factors include parameters such as walking behaviour, walking speed, weight, physical fitness and observation state (the ease with which slippery floors can be recognized as such), environmental factors include the characteristics of the surface on which the movement takes place, footwear types, contaminants, altitudes, lighting, etc.

In order to identify the main causes of the accident due to slipping, researchers from Finland and Germany followed both the phenomena of static friction (considered to be important to prevent slippage and dynamic friction) avoiding the fall of a subject due to intense movements of the body to regain balance) on different surfaces and lubricants.

Starting from the concept that the main risk factor for slippage is the sudden loss of foot and surface adherence, scientists in Finland and Germany have developed a conceptual scenario of the events that take place during the journey, from the contact of the heel with the soil, until the fall, is shown in fig. 1.

(https://books.google.ro/books?hl=en&lr=&id=TV3U-AHbFScC&oi=fnd&pg=PR6&dq=related:Oc-qLdFko84J:scholar.google.com/&ots=_FFqcXfrZI&sig=rr3ZZ4c_JgbTd-3IPwDujq7CETk&redir_esc=y#v=onepage&q&f=true)

Fig. 1. Conceptual scenario of events occurring during walking

At European level, the results of research on surfaces similar to those encountered in most occupational accidents have been materialized through both the appearance of method standards (such as EN 13287) and by the establishment of coefficients of friction on different surfaces (ceramic and steel) and contaminants (detergent and glycerine) below which slippage occurs.

Studies conducted at international level have highlighted the following factors specific to the footwear and general environmental conditions that affect slip resistance:

- ice surface characteristics, the ice slip risk is the property of this type of surface and can be amplified by the presence or absence of moisture - the water layer, which occurs mainly at relatively high temperatures, associated with the cold environment rather than what which PPE standards call "cold".
- the material from which the sole is made of;
- non-slip surface;
- the shape and height of the crampons;

In conclusion, identifying the characteristics that shoes should have in order to provide adequate protection for the movement on frozen surfaces is a challenge, both nationally and internationally.

3. Identifying the characteristics of the footwear to reduce the risk of slipping

In order to identify the protective footwear elements that could reduce the risk of slipping on frozen surfaces, researchers from the INCDPM developed a specific test method in which testing was based mainly on the setting of test conditions and selecting the protective footwear.

When determining the test conditions, the following was taken into account:

- potential temperature at place in which work was performed in:
 - **outdoor during winter in Romania** - Romania has a temperate continental climate with cold winters in which the cold air from the East brings temperatures up to $-20\text{ }^{\circ}\text{C}$ or even below (the record is -38.5 Celsius degrees at Bod, near Brasov, registered on January 25, 1942). The snow is not abundant compared to other European countries, due to the lack of rainfall and frequent temperature increases.
 - **enclosed spaces**, where workers, due to the specificity of the activity (food industry), are exposed to low temperatures between $0\text{ }^{\circ}\text{C}$ and $+10\text{ }^{\circ}\text{C}$ (in the case of fresh products) and temperatures below $-20\text{ }^{\circ}\text{C}$ (in the case of frozen products).
- the test conditions for the soles and the heel to be placed on the test surface according to EN 13287 (Personal Protective Equipment - Footwear - Testing Method for Slip Resistance).

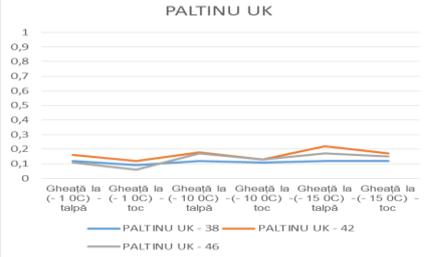

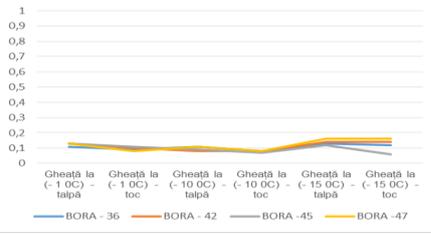

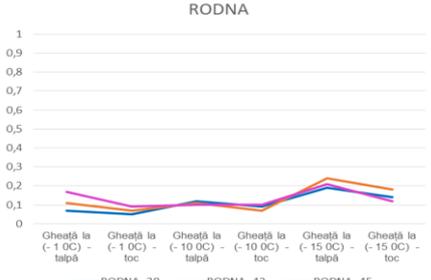

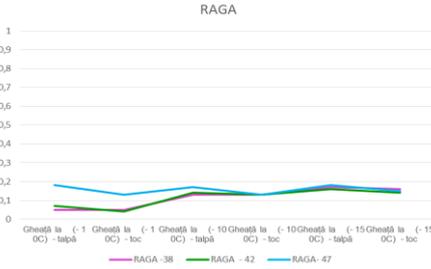

In order to identify the optimal protection features that should be provided by the sole to provide protection against slipping on ice, the shoe selection was made on the basis of the following criteria:

- to be made of different material;
- the sole has different profiles and sizes.

Results of the test series

Taking into account the criteria set above, 18 shoe models of different sizes with sole made of different materials were subjected to the sliding test on frozen surfaces (at $-1\text{ }^{\circ}\text{C}$, $-10\text{ }^{\circ}\text{C}$, $-15\text{ }^{\circ}\text{C}$). In table 1 are presented the results of the test series made on soles made of the same material but with different profiles.

Table 1. Results of slip resistance of dual-density polyurethane rubber soles

Sole profile	Characteristics	Obtained results
	<ul style="list-style-type: none"> - Double density polyurethane rubber - Hardness $62\text{ }^{\circ}\text{Sh}$; - Surface with cleats: - Previous: $\geq 0,50 \times L$ - Posterior: $\geq 0,32 \times L$ - Cleats height: $(4,85 \div 6,1)\text{ mm}$ 	<p>PALTINU UK</p> 
	<ul style="list-style-type: none"> - Double density polyurethane rubber - Hardness $56\text{ }^{\circ}\text{Sh}$; - Surface with cleats: - Previous: $\geq 0,49 \times L$ - Posterior: $\geq 0,30 \times L$ - Cleats height: $(3,4 \div 5,3)\text{ mm}$ 	<p>BORA</p> 
	<ul style="list-style-type: none"> - Double density polyurethane rubber - Hardness $66\text{ }^{\circ}\text{Sh}$; - Surface with cleats: - Previous: $\geq 0,55 \times L$ - Posterior: $\geq 0,33 \times L$ - Cleats height: $(3,4 \div 3,8)\text{ mm}$ 	<p>RODNA</p> 
	<ul style="list-style-type: none"> - Double density polyurethane rubber - Hardness $66\text{ }^{\circ}\text{Sh}$; - Surface with cleats: - Previous: $\geq 0,47 \times L$ - Posterior: $\geq 0,34 \times L$ - Cleats height: $(3,5 \div 4,0)\text{ mm}$ 	<p>RAGA</p> 

By analyzing the friction coefficient values obtained on ice slipping for the four models whose sole is made of double density polyurethane rubber, the following conclusions can be drawn:

- the coefficient of friction is influenced by the arrangement of the cleats;
- the coefficient of friction is influenced by the nature of the material, since it has been observed that at ice surface temperatures of -15 °C, the value of the friction coefficient is higher in the case of soles made of double density polyurethane rubber with higher hardness;
- the height of the cleats does not influence the value of the friction coefficient;

In order to obtain objective conclusions regarding the identification of the soles' characteristics that may influence the value of the friction coefficient on ice slip, all the values obtained on the sole size 42 were compared (see table 2).

Table 2. Results of slip resistance obtained on the sole size 42

Sole profile	Sole characteristics	Ice to -1 °C/sole	Ice to -1 °C/heel	Ice to -10 °C/sole	Ice to -10 °C/heel	Ice to -15 °C/sole	Ice to -15 °C/heel
	- Double density polyurethane rubber - Hardness 62 °Sh; - Cleats height: (4,85 ÷ 6,1) mm	0,16	0,12	0,18	0,13	0,22	0,17
	- Double density polyurethane rubber - Hardness 56 °Sh; - Cleats height: (3,4 ÷ 5,3) mm	0,13	0,1	0,08	0,08	0,14	0,14
	- Double density polyurethane rubber - Hardness 66 °Sh; - Cleats height: (3,4 ÷ 3,8) mm	0,11	0,07	0,11	0,07	0,24	0,18
	- Double density polyurethane rubber - Hardness 66 °Sh; - Cleats height: (3,5 ÷ 4,0) mm	0,07	0,04	0,14	0,13	0,16	0,14
	- cauciuc vulcanizat monodensitate - Hardness 67 °Sh; - Cleats height: (6,5 ÷ 6,8) mm	0,09	0,04	0,11	0,08	0,09	0,07
	- Monodensity vulcanized rubber - Hardness 67 °Sh; - Cleats height: (6,5 ÷ 6,8) mm	0,12	0,06	0,15	0,11	0,19	0,08
	- Monodensity vulcanized rubber - Hardness 64 °Sh; - Cleats height: (6,5 ÷ 6,8) mm	0,06	0,06	0,16	0,13	0,23	0,23
	- Double density polyurethane rubber - Hardness 62 °Sh; - Cleats height: 5,2 mm	0,14	0,1	0,23	0,19	0,22	0,2
	- double density polyurethane - Hardness 60 °Sh; - Cleats height: (5,0 ÷ 6,0) mm	0,14	0,10	0,23	0,19	0,22	0,20
	- styrene-butadiene rubber - Hardness 66 °Sh; - Cleats height: (7,2 ÷ 7,7) mm	0,06	0,05	0,17	0,10	0,20	0,15
	- styrene-butadiene rubber - Hardness 63 °Sh; - Cleats height: (5,0 ÷ 6,2) mm	0,12	0,03	0,14	0,11	0,18	0,13

Sole profile	Sole characteristics	Ice to -1 °C/sole	Ice to -1 °C/ heel	Ice to -10 °C/sole	Ice to -10 °C/heel	Ice to -15 °C/sole	Ice to -15 °C/heel
	- styrene-butadiene rubber - Hardness 63 °Sh; - Cleats height: (4,7 ÷ 5,3) mm	0,16	0,08	0,18	0,17	0,23	0,19
	- styrene-butadiene rubber - Hardness 61 °Sh; - Cleats height: (3,5 ÷ 4,7) mm	0,1	0,07	0,18	0,12	0,18	0,16
	- polyolefin thermoplastic polymers / polymers; - Hardness 59 °Sh; - Cleats height: (6,5 ÷ 6,8) mm	0,13	0,13	0,26	0,16	0,36	0,12
	- Polymer blend sole (vinyl polychloride and antistatic nitrile rubber); - Hardness 69 °Sh; - Cleats height: (6,0 ÷ 6,5) mm	0,09	0,05	0,12	0,09	0,14	0,15

Analyzing the values obtained after the test series, it can be said that the coefficient of friction value:

- is influenced by the nature of the material from which the sole is made - the soles made of " styrene-butadiene rubber" and "polyolefin thermoplastic polymers / polymers" have a higher slip resistance than those made from monodensity vulcanized; double density polyurethane rubber or blends of polymers;
- is influenced by how the cleats are positioned on the sole surface;
- it is not influenced by the height of the cleats;
- it is influenced by the condition of the walking surface; it has been found that regardless of the nature of the material from which the sole is made, the less frozen items (e.g., -1 °C) obtain the lowest friction coefficients, which implies a high risk of slipping

4. Criteria for selecting the protective footwear to reduce the risk of slipping

Since there may be a multitude of footwear models on the market, the selection of appropriate footwear to ensure a high level of protection against the risks at the workstation is only made after an appropriate assessment, taking into account:

- analyzing and assessing risks that cannot be avoided by other means;
- defining the characteristics that the personal protective equipment must possess in order to be effective against the risks against which it assures protection, taking into account any risks that the equipment itself may create;
- comparing the characteristics of the individual protective equipment available on the market with those identified in point b);
- the presence of the "EU" conformity marking accompanied by the number of the standard / standards whose requirements it meets.

Taking into account the above and the fact that the frozen surfaces are influenced by the working environment temperature, in the case of cool and cold environments, a shoe which will provide protection against cold, the marking of which must contain:

- size;
- manufacturer's identification mark,
- manufacturer's type designation;
- year of manufacture and at least quarter,
- the "EU" conformity marking - the presence of the conformity marking certifies that the footwear has been the subject of a certification procedure at a notified body and complies with the requirements of Regulation (EU) 2016/425 of the European Parliament and of the Council of 9 March 2016 on machinery individual protection and repealing Council Directive 89/686 / EEC
- the number and year of the standard that it complies with their requirements (eg EN ISO 20346:2014 - for protective footwear, EN ISO 20347: 2012 - for occupational footwear, EN ISO 20345:2011 - for safety footwear, etc.) as well as other symbols corresponding to the protection provided, such as:
 - the symbol "CI" - the specific marking corresponding to the insulation of the lower assembly against the cold;
 - one of the symbols:
 - "SRA" - which certifies that the shoes provide protection against sliding when moving on ceramic flooring covered with detergent solution;
 - "SRB" - which certifies that the shoe provides protection against slipping on steel (metallic) coatings covered with glycerine (viscous substances);

- "SRC" - which certifies that the shoes provide protection against slippage on both ceramic flooring covered with detergent solution and on steel (metallic) flooring covered with glycerine (viscous substances);

With regard to ice-slip protection, there are not enough studies at international level to substantiate a technical document (guideline, international or national standard, etc.) containing specifications, including labelling encodings. Therefore, in addition to the above-mentioned recommendations on shoe selection criteria, users may refer to the conclusions set out in Chapter 3, namely, to purchase footwear with "rubber" sole or "polymer compounds-thermoplastic polyolefin elastomers" sole.

4. Conclusions

Since at international level there are not enough studies to substantiate a technical document (guideline, international or national standard, etc.) containing specifications, including ice marking resistance coding, the article presents both the structural features of the sole footwear to provide protection against slipping on the ice as well as selection criteria for it.

Managing the activities of authorization to practice trades and professions in terms of safety and health at work

Băbuț Gabriel Bujor^{a,*}, Moraru Roland Iosif^a

^aUniversity of Petroșani, University Street, no. 20, 332006-Petroșani, Romania

Abstract

The fulfillment by the employer of the legal obligation to authorize in terms of safety and health at work the practice of trades and professions under specific legislation is currently encumbered by the lack of clear and coherent legal regulations setting the occupational categories to be approved, the authorization methodology and the competent regulatory authorities. This lack of regulation or even "legal vacuum" generated a lot of confusion in practice and led to conflicts between various stakeholders, with harmful effects in terms of ensuring safe and healthy workplaces. As a result, there is an urgent need to undertake a study establishing the constituent elements of the legislative and methodological framework to be adopted and implemented in Romania in order to achieve a modern and adequate management of the activities to authorize the practice of trades and professions in terms of safety and health at work. From this perspective, this paper analyzes the evolution of national law in the field of authorization of trades and professions in terms of safety and health at work, are identified the professional categories whose authorization is governed by specific legislation and is presented for each personnel category the authorization methodology applied by the appropriate regulatory authority. Studies and research have enabled the identification of other professional categories engaged in hazardous activities with high risk of injury and occupational disease, for which the opportunity of an internal or external authorization is required to be analyzed.

Keywords: management; authorization; trade; profession; safety and health at work;

1. Introduction

Authorizing to practice trades and professions in terms of safety and health at work is an activity of primary importance in ensuring safe and healthy working conditions especially for workers engaged in hazardous activities with high risk of injury and occupational disease (Băbuț and Moraru, 2018).

Authorization is always preceded and conditioned by the acquisition, development or completion of a set of knowledge, skills and competencies through qualification, training or specialization programs. While vocational training to pursue specific professions in the field of health and safety at work was the subject of normative acts and studies, both on national level (Băbuț et al., 2010; Moraru et al., 2014) and worldwide (Ricci et al., 2016; Tappura et al., 2019), the training required to authorize the occupations and professions from the point of view of safety and health at work did not benefit either from a clear and coherent legislative framework or from dedicated studies.

The analysis of the current state of knowledge in the field of authorization of trades and professions from the point of view of safety and health at work revealed that to this issue were devoted very few specialty studies, studies which generally concerned only a particular sector of activity (Fuentes, 2009; Furusten, 2013; Pupăzan et al., 2015).

As a logical consequence of the aforementioned aspects, there was a pressing need to carry out a study that, starting from the critical analysis of the current legislative framework and the current realities and trends in the labor market, to allow the achievement of a modern management of the activities to authorize the practice of trades and professions in terms of safety and health at work.

E-mail address: gabriel_babut@yahoo.com.

2. Legal requirements

The regulation of the activities of authorizing the trades and professions from the point of view of safety and health at work has been a constant concern of the national authorities with attributions in the field, the evolution of the legislative framework being influenced in particular by the scientific and technical progress.

The obligation of the management of the legal entity as well as of the individual legal person to take „*measures for the authorization of the exercise of the trades and professions stipulated in the norms of labor protection*” was introduced in the national legislation by the provisions of article 18, paragraph 1 (j) of the Law no. 90/1996 on Labor Protection - with the subsequent amendments and completions. This obligation was detailed by the provisions of Annex 1 of Order no. 578/DB 5840/1996 of M.M.P.S. and M.S. for the approval of the General Labor Protection Norms, which established the professional categories of personnel to be authorized and the regulatory normative acts (Table 1).

Table 1. Professional categories of personnel to be authorized according to the provisions of Annex 1 of Order no. 578/DB 5840/1996 of M.M.P.S. and M.S.

No.	Profession	Sector of activity
		Production and distribution of electricity
1.	Electrician	Mining industry
		Other sectors of activity
2.	Underground welding vulcanization, soldering, insulating table casting	Mining industry
3.	Energy staff for mining blasting gear	Mining industry
4.	AGR expert	Mining industry All sectors of activity with explosive environments
5.	Mechanics of extraction machinery	Mining and hydrotechnics
6.	Signal givers	Mining and hydrotechnics
7.	Mine igniter	Mining industry and other sectors of activity
8.	Technical leaders and managers of occupational safety compartments	Mining industry
9.	Mine rescuer	Mining industry and offshore activities
10.	Welders for mechanical pressure and lift installations	All sectors of activity
11.	Crane operators	All sectors of activity
12.	Translating mechanics	All sectors of activity
13.	Loaders	All sectors of activity
14.	Fireman	All sectors of activity
15.	Lifters	All sectors of activity
16.	Trolley mechanics	All sectors of activity
17.	Operator at laboratory in thermal power plants	Production and distribution of thermal energy
18.	Abrasive body mounting operator	All sectors of activity
19.	Manipulating trolley operators(motor, electric forklift) and electric car driver	All sectors of activity
20.	Authorized plumber (degree I, II, III) for design and use works execution of gas distribution	All sectors of activity
21.	Technicians and workers performing pre-stressing reinforcement work on concrete prefabricated elements	Construction materials industry
22.	Refrigerationist, refrigerationist master; intervention mechanics and electricians for refrigeration plants	Food industry and other sectors of activity
23.	Worker with radioactive source	All sectors of activity

The transposition into the national legislation of the *acquis communautaire* in the field of safety and health at work led to the repeal of Law no. 90/1996 and subsequent normative acts, including Order no. 578/DB 5840/1996 of M.M.P.S. and M.S. As a result, there is no longer a list of trades and occupations to be authorized from the point of view of safety and health at work, the list in Annex 1 of Order no. 578/DB 5840/1996 of M.M.P.S. and M.S. not being included, possibly in an updated form adapted to the new labor market realities, in a normative act in force.

At present, the authorization to practice trades and professions from the point of view of safety and health at work is regulated through the provisions of:

- article 13, letter I, of the Law no. 319/2006 on Safety and Health at Work - with the subsequent amendments and completions: „*in order to ensure safety and health at work and to prevent accidents at work and occupational diseases, employers have the following obligations: ... i) to take measures to authorize the exercise of trades and professions under the specific legislation*”;

- article 15, paragraph 1 (12), of the Government Decision no. 1425/2006 approving the Methodological Norms for the application of the provisions of the Law on Safety and Health at Work no. 319/2006 - with the subsequent amendments and completions: „the prevention and protection activities carried out within the enterprise and/or the unit are the following: ... 12. the records of the trades and professions stipulated by the specific legislation, for which it is necessary to authorize their practice”.

Failure to comply to the employer's legal obligation to take measures to authorize the exercise of trades and professions provided for by the specific legislation constitutes a contravention and shall be sanctioned by a fine from 4,000 to 8,000 lei, according to article 39, paragraph 4 of Law no. 319/2006. Also, the failure to observe the employer's statutory obligation to take into account the worker's occupational safety and health when he entrusts his duties is a contravention and is sanctioned by a fine of 3,500 to 7,000 lei, according to article 39, paragraph 5 of Law no. 319/2006.

In the absence of a legislative act containing a list of trades and professions to be authorized from the point of view of safety and health at work, employers face real difficulties in meeting the legal requirements listed above, being extremely difficult to cope with the specific legislation governing the licensing of trades and professions.

3. The notion of authorization: conceptual clarifications

A major impediment to the identification of trades and professions whose authorization is regulated by specific legislation is also the fact that neither Law no. 319/2006 and nor Government Decision no. 1425/2006 does not define the authorization. This concept is defined only in the specific legislation.

It should also be emphasized that the use of the notion of authorization is not generalized. This notion is used by I.S.C.I.R., A.N.R.E., I.N.S.E.M.E.X. Petroșani and Territorial Labor Inspectorates.

In specific legislation, the activity of assessing the competence and capability of an individual to pursue a trade or profession can also be found under alternative designations of certification or, attestation names that are more or less similar to the notion of authorization. These notions, although not defined in a legal sense, on the basis of the analysis of the specific legislation, can be said to refer to activities to verify the fulfillment of the conditions of professional qualification/specialization and assessment/testing/examination of practical and theoretical knowledge, competence and ability of a person to pursue a specific activity.

The repeal of some normative acts regulating the authorization to practice trades and professions and their non replacement with other normative acts tailored to the needs and expectations of all stakeholders in the field of occupational safety and health generated a lack of regulation or even a „legislative vacuum”. This state of fact has led to the perpetuation, sometimes at the express request of labor inspectors, of anachronistic situations generated by the continued use of some forms of internal authorization which are based on obsolete methodologies or procedures based on the provisions of some repealed normative acts.

It should be underlined that the notion of „internal authorization” has no legal coverage, being a typical Romanian way of adapting of both employers and the controlling authority to a non-compliant but real situation requiring a transitional solution which remained unfortunately final, like any improvisation.

4. Authorization of the trades and professions under the specific legislation

As it has already been mentioned, it is extremely difficult to draw up an exhaustive list of trades and professions for which there is specific legislation on the authorization of their exercise in terms of safety and health at work.

The starting point for this approach was the analysis of the current way of regulating the authorization of the trades/professions mentioned in Table 1. Thus, on the basis of a vast documentary study, the existence/non-existence of a legal obligation to authorize the practice thereof was verified for each trade/profession and, if it existed, the applicable specific legislation was identified. In addition to the trades/professions mentioned in Table 1, other trades/professions were identified for which the authorization for their exercise was regulated by specific legislation after the appearance of Order no. 578/DB 5840/1996 of M.M.P.S. and M.S.

The studies and researches carried out have been completed with the drawing up of the list of trades and professions for which it is necessary to authorize their practice from the point of view of safety and health at work, according to the legislation in force. For the drafting of the list, it was chosen to group the trades/professions according to the competent authority. This list is shown in Table 2.

Table 2. List of trades and professions for which authorization to practice them from the point of view of safety and health at work is required

No.	Trade/profession	Legal act	Competent authority
1.	Operator responsible for technical supervision of ISCIR installations/equipment - RSVTI operator	Order no. 130/2011 of I.S.C.I.R.	National Authority for Control and Approval of Boilers
2.	Fireman steam and hot water boilers	Order no. 2154/2009 of M.E.	Pressure Vessels and Hoisting Equipment (I.S.C.I.R.)
3.	Fireman hot water boilers and low pressure steam boilers		

4.	Fireman computer-controlled boilers		
5.	Central heating laboratory operator		
6.	Automatician for boiler supervision and maintenance		
7.	LPG containers filling operator		
8.	Pressure fluid bottler		
9.	Crane operator		
10.	Forklift operator		
11.	Lifter		
12.	Trolley mechanics (funicular operator)		
13.	Manual gas flame welder		
14.	Manual electric arc welder		
15.	Electric arc welder covered under flow layer		
16.	Electric arc welder with fuseable electrode in protective gas medium		
17.	Electric arc welder with non-fuseable electrode in protective gas medium		
18.	Operator welding pipes and fittings made of high density polyethylene (HD-PE)	Order no. 1001/2013 of M.E.	
19.	Non-destructive operator with penetrating radiation		
20.	Non-destructive ultrasound control operator		
21.	Non-destructive operator with penetrating liquids		
22.	Non-destructive operator with magnetic particles		
23.	Non-destructive operator by swirling currents		
24.	Non-destructive operator for leakage check		
25.	Authorized electrician		
26.	Project verifier [electrical installations]	Order no. 11/2013 of A.N.R.E.	National Regulatory Authority for Energy (A.N.R.E.)
27.	Quality technical and extrajudicial expert in the field of electrical installations		
28.	Authorized plumber in the field of natural gas	Order no. 83/2014 of A.N.R.E.	
29.	Construction project verifier	Order no. 2264/2018 of M.D.R.A.P.	Ministry of Regional Development and Public Administration (M.D.R.A.P.)
30.	Technical expert in construction		
31.	Technical manager with construction work	Order no. 1895/2016 of M.D.R.A.P.	State Inspectorate of Construction (I.S.C.)
32.	Transport manager		
33.	Driver (certain categories)		
34.	Safety adviser for the transport of dangerous goods by road		
35.	Driver for the transport of dangerous goods	Order no. 1214/2015 of M.T.	Romanian Road Authority (A.R.R.)
36.	Driver who carries out road transport with vehicles having overhanging masses and/or exceeding dimensions		
37.	Driver who performs road transport by trolleybus		
38.	Driver who performs paid national road transport of damaged road vehicles		
39.	Road safety auditor	Order no. 656/2016 of M.T.	
40.	Lecturer for transport managers		
41.	Lecturer for road law teachers and driving instructors		
42.	Lecturer for the transport of dangerous goods by road	Order no. 1213/2015 of M.T.	Ministry of Transport (M.T.)
43.	Lecturer for drivers		
44.	Safety adviser for the transport of dangerous goods by rail		Romanian Railway Authority (A.F.E.R.)
45.	Safety adviser for the inland waterway transport of dangerous goods	Order no. 1044/2003 of M.T.C.T.	Romanian Naval Authority (A.N.R.) / Romanian Maritime Training Centre (C.E.R.O.N.A.V.)
46.	Personnel working in the field of cold technology (refrigeration technician, installer of ventilation and conditioning installations, personnel operator for working with certain fluorinated gas equipment)	Order no. 2682/2011 of M.M.P.	Romanian General Association for Refrigeration (A.G.F.R.)

47.	Workers carrying out activities with ionizing radiation sources, respectively closed and open radiological installations and radioactive sources	Order no. 202/2002 of C.N.C.A.N.	National Commission for Nuclear Activities Control (C.N.C.A.N.)
48.	Security agent		
49.	Access control agent		
50.	Security agent for enclosures		
51.	Bodyguard agent	Law no. 333/2003 and G.D. no. 301/2012	General Police Directorate of the Municipality of Bucharest (D.G.P.M.B.)/County Police Inspectorates (I.P.J.)
52.	Security and order intervention agent		
53.	Value carrier agent		
54.	Security manager		
55.	Fireworker		
56.	Pyrotechnist	G.D. no. 536/2002	Territorial Labor Inspectorates (I.T.M.)
57.	Mine rescuer		
58.	Rescuer for surface industries		
59.	Control and rescue activity coordination staff	Order no. 1637/391/2007 of M.E.F. and of M.M.F.E.S.	National Institute for Research and Development in Mine Safety and Protection to Explosion - Petroșani (I.N.S.E.M.E.X. Petroșani)
60.	Rescue station mechanic		

5. Results and discussion

The comparative analysis of the data and information contained in Table 1 and Table 2 allowed us to highlight the following aspects:

- a number of 13 occupations listed in Table 1 (items 1, 7, 9-11, 14-17, 19-20 and 22-23) are in identical or similar form also in Table 2 (items 2- 5, 9-18, 25, 28, 46-47, 55 and 57-58), representing 56.52 % of the total number of occupations listed in Table 1;
- occupations from items 3 (energy staff for mining blasting gear), 4 (AGR expert), 8 (technical leaders and managers of occupational safety compartments) and 12 (translating mechanics) in Table 1 do not appear in Table 2 because they are not contained in the Classification of Occupations in Romania (COR);
- occupations from items 18 (abrasive body mounting operator) and 21 (technicians and workers performing pre-stressing reinforcement work on concrete prefabricated elements) in Table 1 have not been introduced in Table 2 because they use internal authorization procedures developed on the basis of the provisions of some repealed normative acts and adopted through own instructions for safety and health at work;
- according to the specific legislation in force, for the occupation from item 13 (loaders) in Table 1 the authorization was replaced by the acceptance of the staff and, as a result, this occupation is not found in Table 2;
- occupations from items 2 (underground welding vulcanization, soldering, insulating table casting), 5 (mechanics of extraction machinery) and 6 (signal givers) in Table 1 were not introduced in Table 2 because the specific legislation requiring staff authorization for these occupations was repealed;
- the occupations introduced in addition to Table 2, compared to Table 1, represent:
 - new occupations whose authorization is regulated by specific legislation [e.g., items 1 (RSVTI operator), 6 (automatician for boiler supervision and maintenance), 56 (pyrotechnist), etc.];
 - occupations requiring the attestation or professional certification of personnel for the purpose of their exercise [e.g., road transport specialized staff (items 32-38), security staff and bodyguard (items 48-54), etc.];
 - complementary occupations to those listed in Table 1 [e.g., 60 (rescue station mechanic)].

6. Conclusions

Authorizing the exercise of trades and professions from the point of view of safety and health at work has been, is and will remain an extremely problematic issue, proof of which is represented by the increased interest in this issue, which has been manifested lately by the articles posted on various specialized sites and conversations on this topic, often contradictory, on social networks.

Regrettably, despite the topicality of the subject and the importance of this issue, neither the national regulatory authorities nor the occupational safety and health specialists paid not the due attention, which was a major handicap in the drafting of this paper due to the absence of clear and coherent legislative regulations, as well as the extremely low number of bibliographic references.

To overcome this drawback in this paper, a holistic and systemic approach was used, converted in a research methodology that consisted of the following stages:

- the critical analysis of the evolution of national legislative regulations in the field of authorization of the trades and professions from the point of view of safety and health at work, as well as of the current realities and trends in the labor market;

- conceptual clarification and operationalization of the notion of authorization and alternative notions of attestation and certification;
- identification of the professional categories whose authorization/attestation/certification is regulated by specific legislation;
- the description, for each category of staff identified, of the authorization/attestation/certification methodology applied, of the specific requirements imposed (age, seniority, studies, health and fitness conditions, etc.) and the types of acts issued by the main national regulatory authorities with attributions in the field;
- identification of the malfunctions that occur with regard to the authorization of certain trades and professions and establishing, on this basis, the fields of activity for which it is necessary to adopt specific regulations leading to the elimination of these dysfunctions.

Through the information provided, as well as the comments and recommendations formulated, the work has set an ambitious goal, and wants to be a genuine legislative and methodological guide for all interested parties in authorizing the exercise of trades and professions from the point of view of safety and health at work.

The list of trades and professions for which authorization to exercise them from the point of view of safety and health at work proposed in the paper is not and does not claim to be exhaustive. Like any other human creation and this list is also perfectionable and therefore questionable, it is just a starting point, a topic of reflection, which aims to provide the foundation on which to develop a clear and coherent approach to the legislative framework and methodologically in the field of authorization of the trades and professions from the point of view of safety and health at work. As a result, we are inviting and challenging all occupational safety and health specialists to read this paper and to formulate on that basis both critical views and suggestions and recommendations designed to improve its content.

Abstract

Sustainable exploitation of coal in Jiu Valley can not be achieved without using methane drainage systems, given that the primary objective of these is to improve the safety and health of workers and ensure the proper environmental conditions underground, by reducing the concentration of methane in the mine atmosphere. It should not be neglected the valorization of drained gas which can play an important role in increasing the efficiency and profitability of mines. Studies and research on improving the efficiency of degassing coal seams in Jiu Valley focused, in particular, on the development of automated monitoring and management system for methane drainage networks. Despite progress achieved, qualitative and quantitative parameters of drained gas are still hard to keep under control due to inadequate knowledge about the phenomena related to migration of gas from massive to boreholes. Currently, the location of boreholes and setting the amount of depression on the borehole so that the highest possible gas flow to be captured is an area with prevailing empirical approaches that do not always achieve the objectives set. From this perspective, this paper aims to present, based on current the situation analysis, an original mathematical model of boreholes location for achieving an optimal management of methane drainage systems.

Keywords: methane drainage; borehole; coal; optimisation; quality; management;

1. Introduction

In order to increase the efficiency coal seam drainage in the Jiu Valley, studies and research carried out so far have focused on optimizing the design and operation of methane drainage systems, in this regard the following areas of research being outlined (Băbuț et al., 2018):

- development of a mathematical model and software for simulation of methane drainage systems (Băbuț and Moraru, 2017);
- development of an automated monitoring and management system for methane drainage networks (Băbuț and Moraru, 2014);
- development of an expert system for the analysis of methane drainage systems.

Studies in the first two areas of research are completed, the practical implementation of their results in the Jiu Valley mining units being conditioned by providing human, financial and material resources required. The third area of research is in an early stage of development, studies still being needed in this field.

Unfortunately, despite progress made in terms of simulation and automatic control of methane drainage networks, qualitative and quantitative parameters of drained gas are still hard to keep under control due to inadequate knowledge about the phenomena of gas migration massif towards the boreholes (Băbuț et al., 2017).

In conclusion, we can say that improving qualitative and quantitative parameters of the drained gas can not be achieved only through:

- critical analysis of the framework drainage schemes currently used in mines within the Jiu Valley;
- determination of the influence exerted on the drainage process efficiency by the drainage boreholes spatial distribution, their geometrical features, as well as the distance from the boreholes to the working face;

* Corresponding author. Tel.: +40 732 971 484; fax: +40 254 543 491.
E-mail address: gabriel_babut@yahoo.com.

- determining the value of the pressure drop on the borehole so that the captured gas flow to be as high as possible, for given characteristics of the vacuum pump.

From this perspective, the paper aims to present an original mathematical model for the location of boreholes enabling the optimization of degassing according to targets set by decision - makers.

2. Coal seam drainage through boreholes drilled in underground locations

Capturing methane through boreholes drilled in the underground is, like on worldwide level, the most used method (sometimes only) used for degassing coal seam from mines in the Jiu Valley coal basin.

The location of drainage boreholes, the parameters, how to achieve them, and their arrangement are determined in accordance with the "Drainage Project" (N.H.C.C., 2007). The drainage project is drawn by the ventilation - health and safety at work department, approved by the chief engineer of safety and health at work, also approved by the head of the branch, endorsed by the Department of Occupational Safety and Health at Work in the Hunedoara Energy Complex - S.A. and finally approved by a certified body (NIRD-INSEMEX Petroșani).

The position of the drainage boreholes and their inclinations and directions are checked by the supervisor of the drainage activity. Drainage boreholes are cased and cemented on a minimum length of 6 m and equipped with control valves and fittings. According to the sealing method used the drainage boreholes may be performed in two ways: the technique with concentric piping and the technique with the pneumatic fastener.

With the exception of these two techniques, in the Jiu Valley collieries there have been experimented also other methods, of which are to be mentioned the method to support the drainage boreholes along their length with the perforated metal columns in the last 10 m toward the base. This technique which prevents the destruction and shear of the borehole gave superior results to those obtained by the conventional methods, but because it is more expensive it was not introduced into current practice.

Drainage schemes which may be applied to Jiu Valley collieries, by type of structure and mining methods used are those contained in "Occupational Safety and Health Regulation of National Hard Coal Company - Petroșani" (N.H.C.C., 2007). In Table 1 are shown the geometrical characteristics of boreholes for drainage framework schemes applied in Jiu Valley collieries.

Table 1. Geometrical characteristics of boreholes for drainage framework schemes applied in Jiu Valley collieries

No.	Characteristics	UM	Value ranges of characteristic parameters in drainage framework schemes applied in Jiu Valley collieries								
			"A"	"B"	"C"	"D"	"E"	"F"	"G"	"H"	"I"
1.	Tubing-cementing diameter of the borehole	mm	100-125	100-125	100-125	100-125	100-125	100-125	100-125	100-125	100-125
2.	Tubing-seal-cementing length	m	6-10	6-10	6-10	6-10	6-10	6-10	6-10	6-10	6-10
3.	Number of boreholes in a location	pieces	1-2	depending on the panel length	2-6	4-6	4-8	1	2	9-16	5-10
4.	Borehole diameter	mm	65-86	65-86	65-86	65-86	65-86	65-86	65-86	65-86	65-86
5.	Borehole length	m	20-40	60-100	60-100	60-100	60-100	60-100	60-100	60-100	60-100
6.	Borehole's angle of inclination (α_g)	(°)	2°-4°	-	$\alpha_{2,4}=0^\circ$ $\alpha_3=10^\circ$ $\alpha_{1,5}=15-20^\circ$	based on relation $H-h=4 \cdot i_a$	10°-20°	$\alpha_4 = \alpha_s$	$\alpha_4 = \alpha_s$	$\alpha_1=10^\circ$ $\alpha_2=15^\circ$ $\alpha_3=25^\circ$	$\alpha_4 < 10^\circ$
7.	Borehole's angle of direction (β_g)	(°)	0-45°	10°	0-10°	40°-120°	45°-125°	90°	90°±10°	0-90°	0-90°
8.	Distance between the adjacent boreholes base	m	-	-	10	10	10	-	-	10	10

3. The current state of knowledge in the borehole characteristic determination field

Solving properly a methane drainage networks is more difficult than solving a mine ventilation network. The concept of resulting characteristic can only be applied to solve the ventilation systems, it can not be used for all the elements of methane drainage networks, given that these are more complex, consisting of three components having different characteristics: borehole - piping drainage system - vacuum pump. The borehole characteristic is the dependence between depression/pressure drop in the borehole and the gas flow exhausted from it.

Determination of the borehole characteristic represented the study subject for an important number of researchers. Thus, in a first stage, the high-scale coal seams drainage systems has been accompanied by the development of studies and research aimed at establishing empirical relationships describing the characteristic of the borehole. Empirical

relationships presented in the literature due to certain coefficients difficult to determine and to geological/mining conditions are difficult to use for analyzing efficiency of various schemes of boreholes location and drainage regime optimization.

Currently, benefiting from the advantages of using advanced informatics tools, research efforts made worldwide have targeted the following aspects:

- establishing the influence of the boreholes length and their applied depression to the qualitative and quantitative parameters of the drained gas (Chen et al., 2017);
- determining the effectiveness for methane emissions reduction of various schemes of boreholes location, taking into account in particular the influence of boreholes length and degassing time before and during panels (Karacan et al., 2007; Karacan et al., 2011);
- assessing the effect on the methane reduction efficiency of the distance from the first borehole at the working face in the specific case of the U ventilation system (Berger et al., 2010.);
- developing software applications for the study and analysis of operation of boreholes used for methane (Serdyukov et al., 2017);
- determining the effect of pressure drop applied on the boreholes upon the qualitative and quantitative parameters of captured gas and establishing adjustment procedures aimed at increasing the drainage efficiency of coal seams (Liu et al., 2018);
- optimization of the borehole length to maximize gas drainage (Zhang et al., 2018; Zhao et al., 2018);
- determining optimal parameters of the methane drainage system to reduce the methane concentration in the atmosphere of mine workings (Khodyrev, 2008; Ren et al., 2001);
- numerical analysis of horizontal boreholes location to reduce methane emissions in the mine atmosphere and increase the amount of coal extracted (Keim et al., 2011).

Analysis of the current state of knowledge in determining the borehole characteristic shows that the majority of studies and researches have considered only some of the parameters that influence the dependence of depression/pressure drop on the borehole and the drained gas flow thereof; it does not exist at the present time a mathematical model which takes into account all the parameters which determines the coal seams drainage efficiency, respectively the spatial distribution of boreholes, geometric characteristics thereof (length, cased length, diameter, angle of inclination), and the distance from boreholes to the working face.

Given the above, it will now be presented a mathematical model that will try to correlate all the parameters listed above to improve qualitative and quantitative parameters of drained gas.

4. Mathematical modeling of the boreholes location

Theoretical and experimental research carried in Jiu Valley coal basin (Moraru et al., 2013; Moraru and Băbuț, 2014; Moraru et al., 2016) and abroad (Balla, 1989; Ding et al., 2008; Pawiński et al., 1996; Zheng et al., 2016) have shown that the flow rate of a borehole can be expressed using the relationship:

$$Q_s = c_0 + c_1 \cdot x + c_2 \cdot x^2 + c_3 \cdot x^3 + c_4 \cdot h_s + c_5 \cdot h_s^2 \quad (1)$$

where:

Q_s is the borehole flow rate, m³/s;

h_s - depression, N/m²;

c_0, \dots, c_5 - the regression equation coefficients, determined from statistical processing of experimental data;

x - length from the borehole to the working face, m.

Equation (1) can be used to calculate the flow rate of a borehole, when the parameters x and h_s are known. When a number of simultaneously operating boreholes n_s , the total flow rate of the boreholes can be expressed by the equation:

$$\sum Q_s = \left[n_s \cdot (c_0 + c_4 \cdot h_s + c_5 \cdot h_s^2) + c_1 \cdot l \cdot \frac{n_s - 1}{2} + n_s \cdot x + c_2 \cdot \sum_{i=0}^{n_s-1} (x + i \cdot l_s)^2 + c_3 \cdot \sum_{i=0}^{n_s-1} (x + i \cdot l_s)^3 \right] \cdot k_s \quad (2)$$

where:

l is the distance on which the boreholes are drilled, m;

n_s - the number of simultaneously operating boreholes;

l_s - the distance between the boreholes, m; $l_s \cdot n_s = l$;

k_s - coefficient assessing the simultaneous operation of boreholes;

x - the distance from the first borehole to the face, m.

The coefficient k_s , of simultaneous operation of two or more boreholes can be calculated with sufficient precision, with the the relation:

$$k_s = d_0 + d_1 \cdot n_s + d_2 \cdot l_s \quad (3)$$

where: d_0, d_1, d_2 are the regression equation coefficients.

If in the equation (2) is used the equality $x = l_s$, it can be used as an objective function to determine the optimum values of the number of boreholes and the distance between them, values that will deliver a maximum drained flow rate. The optimization problem can be solved using the method of the alternatives; the calculation results can be presented graphically or tabular. This problem's solution is simplified by using the substitution $l_s = 1/n_s$.

Using the relation (2) we can determine the required number of boreholes, for a total drained flow rate ΣQ_s . In this case, equation (2) can be put in the form of:

$$D_0 + D_1 \cdot n_s + D_2 \cdot n_s^2 + D_3 \cdot n_s^3 + D_4 \cdot n_s^4 + D_5 \cdot n_s^5 - \Sigma Q_s = 0 \quad (4)$$

The values of the coefficients $D_0, D_1, D_2, D_3, D_4, D_5$ are obtained by transforming the equation (2), taking into account equation (3). Equation (4) can be solved using numerical calculation methods. Since the solution to this equation is not an integer, the result is adopted as the next whole number to the solution obtained by computation.

5. Drainage regime optimization

For the optimization of the quasi-stationary drainage regime it is necessary to assess the total flow of boreholes for the entire duration of their operation. Solving the problem can be simplified if we accept the hypothesis of replacement of two boreholes changing each other (the second borehole connects to the drainage network when decoupling the first borehole), with a borehole having doubled operating time.

The flow variation rate in the case of the use of said type of borehole may be represented by a curve with two points of maximum flow rate:

$$Q_{s0} = c_0' + c_1' \cdot x + c_2' \cdot x^2 + c_3' \cdot x^3 \quad (5)$$

where: c_0', c_1', c_2', c_3' are the regression equation coefficients.

Conventional borehole flow rate dependence of distance for a given value of the depression may be expressed in the form of a trigonometric series:

$$Q_{s0} = a_0 + \sum_{k=1}^N a_k \cdot \cos(k \cdot \pi \cdot x \cdot l^{-1}) + \sum_{k=1}^{N-1} b_k \cdot \sin(k \cdot \pi \cdot x \cdot l^{-1}) \quad (6)$$

where: a_0, a_k, b_k are the trigonometric series coefficients.

To determine the coefficients a_0, a_k, b_k it can be used an approximate alternative of the harmonic analysis, respectively the 12 ordinate method. The range of length $2 \cdot l$ is divided into 11 equal parts, and the flow is divided into 12 points (12 ordinates) and is determined by the relationship (5). In general, the determination of the borehole's flow rate using the relationship (5) is done for a minimum value of the depression.

The individual flow rate of a borehole, taking into account the value of the depression at the entry of the borehole, will be given by:

$$S_0 = S_{s0} + A_1 \cdot (h_s - h_{sm}) + A_2 \cdot (h_s - h_{sm})^2 \quad (7)$$

where: h_{sm} is the value of the depression at the entry of the borehole for which the values given by the relation (6) were obtained.

To obtain coefficients A_1 and A_2 , equation (1) can be used. For this purpose, it is necessary to calculate the value of the flow for a fixed value of the distance from the borehole to the face and for different values of the depression and to repeat these calculations several times, for different values of the distance from the borehole to the working face.

The total flow of the boreholes running simultaneously can be described by the relationship:

$$\begin{aligned} \Sigma Q_s = & a_0 \cdot n_s + \sum_{k=1}^6 a_k \sum_{j=0}^{n_s-1} \cos[k \cdot \pi \cdot (x + j \cdot l_s) \cdot l^{-1}] + \sum_{k=1}^5 b_k \sum_{j=0}^{n_s-1} \sin[k \cdot \pi \cdot (x + j \cdot l_s) \cdot l^{-1}] + \\ & + A_1 \sum_{j=0}^{n_s-1} (h_0 - h_{sm} - j \cdot p_{SF} \cdot l_s) + A_2 \sum_{j=0}^{n_s-1} (h_0 - h_{sm} - j \cdot p_{SF} \cdot l_s)^2 \end{aligned} \quad (8)$$

where:

h_0 is the depression at the first borehole level, N/m^2 ;

p_{SF} - the specific pressure loss due to frictional resistance, N/m^2 .

To optimize the quasi-static drainage mode, the following objective functions can be used (Băbuț et al., 2018):

$$l + 0,5 \cdot \int_0^l \left(\frac{d \Sigma Q_s}{dx} \right)^2 dx \rightarrow \min . \quad (9)$$

$$l^{-1} \cdot \int_1^l \left\{ \left| \left(\sum Q_s \right)'' \right| \cdot \left\{ 1 + \left[\left(\sum Q_s \right)' \right]^2 \right\}^{\frac{3}{2}} \right\} dx \rightarrow \min. \quad (10)$$

6. Conclusions

Increasing the efficiency of coal bed degassing and implicitly improving the qualitative parameters of captured gas can not be obtained without a thorough knowledge of the dependence between the depression/pressure drop at the borehole and the exhausted gas flow from there.

In order to contribute to solving this problem, for the geological and mining conditions specific to the Jiu Valley mines, a research methodology has been used in the paper which involves going through the following stages:

- description of the methods and procedures for achieving the drainage of coal strata through underground drilling boreholes, specifying the geometrical characteristics of the boreholes for the drainage frame schemes used in the Jiu Valley mines;
- the analysis of the current state of knowledge in the field borehole characteristics determination, based on a comprehensive documentary study;
- the development of an original mathematical model for the location of the boreholes to allow optimization of the drainage regime.

Unfortunately, the lack of resources required to carry out experimental studies have given the research presented in the paper a preponderantly theoretical character, the research objectives envisaged being only partially fulfilled. Thus, it can be mentioned that a critical analysis of the drainage schemes used in the Jiu Valley mines could not be carried out, which further determined the impossibility of assessing the influence it exerts on the drainage, efficiency of the spatial distribution of the boreholes, their geometrical characteristics, and the distance from the boreholes to the working front. Also, the validity of the mathematical model proposed in the paper could not be verified by experimental studies.

Despite these limitations, it can be argued that the mathematical model proposed in the paper for the simulation and optimization of the borehole location represents a modern and original approach to this problem, which attempts to correlate the vast majority of the parameters that exert influence on the efficiency of the coal seam drainage.

The use of the mathematical model presented in the paper allows the calculation and optimization of the main parameters of the drainage of coal seams through boreholes and can contribute, by reducing the methane emissions in the atmosphere of the mining works both to improving the safety and health of the workers, and to increasing the degree of valorization of drained gas and extracted output.

Abstract

The use of working equipment and means of protection is a technical safety measure used against electrical hazards during the operation and maintenance of electrical installations. The study presents the results of the research on the identification of the technical and safety requirements specific to a category of protective equipment - the insulating sticks. They are designed to provide a safety distance during the maintenance of electrical installations. The identification of the technical and safety requirements allowed the testing of new and used electrical insulating sticks for assessing and attesting the technical and safety performance during their use.

The behaviour of this category of equipment has been assessed at mechanical, thermal and electrical requirements in order to identify changes or deflection from the normal technical and functional characteristics.

The technical and safety requirements applicable to insulated electrical sticks are intended to provide the criteria underlying the management of the protective equipment required by both manufacturers and users in order to adopt high-tech and safety solutions to ensure their compatibility with electrical installations and to ensure the safe maintenance of these working equipment.

Keywords: risk, safety, work equipment, insulating electrical sticks, management;

1. Introduction

One of the most important objective at national level is to ensure the conditions for the competitiveness of the producers of work equipment on the market and to guarantee the free circulation of Romanian products within the European Union (EU), considering Romania as a member state, by ensuring the technical and health and safety requirements applicable to all work equipment, in order to implement the policies provided by the free movement of products contained in the EUROPA 2020 strategy. (Antonov et al, 2017)

As a consequence of the need to ensure compliance with the safety and health requirements set out in Annex 1 of Directive 2009/127/EC, and Directive 2014/35/EU, the research study focuses mainly on the analysis undertaken to identify the technical requirements and safety features specific to a category of protective equipment, in order to increase the compliance rate of work equipment in use, according to new manufacturing technologies and the methods used are:

- Identifying the safety and technical requirements applicable to electrical insulating sticks, which are within work equipment category, and which is the subject of the project analysis;
- Establishing the health and safety requirements applicable to electrical insulating sticks, according to the legal provisions set out in Annex no. 1 of Executive Order (EO) no.1146/2006, which adopts European Directive no. 2009/104/EC (Work equipment directive);
- Establishing the health and safety requirements applicable to electrical insulating sticks, in accordance with the legal provisions set out in Annex 1 of the EO no.409/2016, which adopts the Machinery Directive no. 2014/35/EU (Electrical Equipment Design Directive);

* Corresponding author. Tel.: 0213131729/int 209; fax: 0213157822.
E-mail address: gbuica@protectiamuncii.ro.

- Establishing the health and safety requirements applicable to electrical insulating sticks, according to the legal provisions set out in the specific safety standards analysed in the project.

The electrical equipment and protective devices can be evaluated using the quality function deployment (QFD) method. This provides the tools to evaluate by an overall index the correlation between the customer requirements and the quality characteristics (Leba M., et al, 2014).

Insulating sticks are work equipment that provides protection of workers against the electrical hazards, by providing an insulation level that is required to safely perform live or dead working.

Insulating sticks consist of one or more hollow tubes and / or filled with foam fitted with couplings between them and at the head, in order to attach accessories and / or various types of work equipment. In use, we also identified insulating sticks for round bars.

The insulating sticks have an insulating element and a handle separated by a hand guard made of insulating material that must be shockproof, with a larger diameter than the handle. For technical reasons, the bottom of the insulating rod is provided with a cap.

In electrical installations, insulating sticks can be used to carry out a series of operations by means of attached working equipment or accessories, such as: (SR EN 50508, 2009), (SR EN 62193, 2004), (Buica, 2010)

- Verifying the presence / absence of voltage by using the attached voltage detector or the single phase systems with the monopolar indicators;
- Earthing and short-circuiting by mounting earth and short-circuit mobile devices;
- Capacitive load discharge;
- Mounting rigid or flexible protectors on live parts of electrical installations that can be reached during maneuvers or work;
- Performing electrical operations (connection and disconnection of disconnectors or other equipment operated by the insulating sticks, fuse replacement with an attached tool, testing and measurement, lifting of signal flaps mounted on electric cables);
- Removal of foreign objects from or near live parts;
- Removal of victims from or near live installations.

2. Analysis and evaluation of insulating sticks used in electrical installations

Identifying, analysing and assessing the risks of injury and occupational disease generated by work equipment are the basic tools of risk management to reduce and eliminate by technical and organizational measures. The benefit of risk assessment allows identification of the problems faced by users, which requires the adoption of preventive measures (Antonov et al., 2016).

The study has as its starting point the analysis and evaluation of electrical insulating sticks used in electrical installations for transport, distribution and use of electric energy. Various categories of insulating sticks have been identified: simple, made of removable or telescopic insulating modules, components of earthing or earthing and short-circuiting devices.

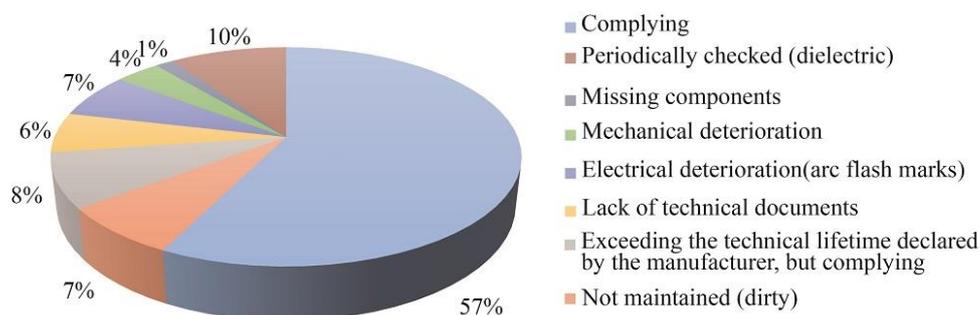

Fig. 1. Percentage results on the evaluation of insulating sticks in use.

Fig. 1 shows the percentage of the technical condition and the conformity of the insulating sticks in use. The insulating sticks from 17 high-voltage electric power stations (400, 220, 110, 20, 6 kV), 9 hydropower plants and micro-hydro power plants, 1 wind farm and 3 economic operators were analysed.

In this respect, we analysed and evaluated:

- Technical state of insulating sticks (inspection by visual inspection), mode of use, storage mode;
- Compatibility with the electrical system in which it is used;
- The existence and content of the technical documentation of the pairs and the documents attesting to their compliance certification;
- The existence and content of periodic inspection reports (dielectric rigidity);

- Documents on risk management generated by these working equipment.

Based on the evaluation of the technical condition, the existence and the content of the technical documents (technical instructions for use, periodic inspection reports) it was found out that from the total of working equipment evaluated: 57% meet the criteria established in the evaluation, do not show technical nonconformities, have technical documents; 10% of the working equipment has technical documentation, it is tested periodically but it was dirty; 4% of the insulating sticks had no technical documents but were in compliance; 28% of the insulated sticks evaluated were identified as non-compliant. From this percentage, 8% had missing components; 7% had traces of flashovers and arc flashes; 6% were mechanically damaged (cracks, scraps, damaged hand guard).

The risk management of protective equipment and insulating sticks has been analyzed through the existence and content of management documents, which employers have to develop, hold and operationalize. The following was analyzed:

- Technical safety and health data sheets for the purchase of insulating sticks;
- Instructions for use / technical books;
- Procedures for testing the protective equipment or insulating sticks in use;
- Annual plans for testing the protective equipment in use;
- Checking registers, according to art. 5 of EO no. 1146/2006;
- Type verification reports and periodic verification reports.

The analysis of the management documents showed the following data, presented in fig. 2 (percent).

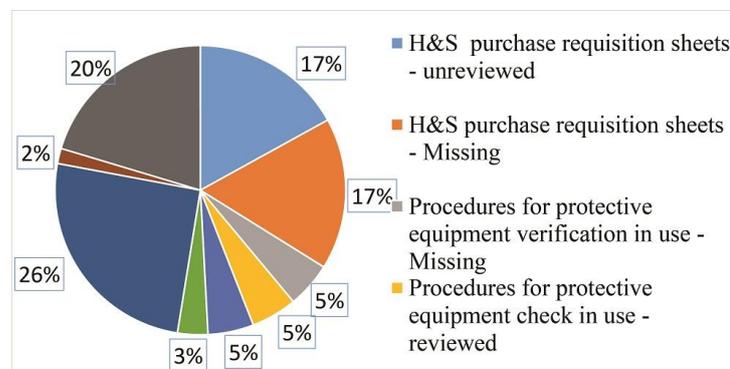

Fig. 2. Results on analysis of management documents

It is noted that in some companies' management the documents of specific risk generated by the protective equipment are partially completed or totally missing. This situation can become a negative determinant regarding the monitoring of safety quality of work equipment in use, and may contribute to generation of work accidents, complementary to the specific risk factors for the occurrence of technical events in electrical installations. Improving safety conditions through more efficient management of risks generated by safety equipment can be achieved through the effective involvement of top management, decision-makers and health and safety department, in conjunction with the concrete implementation of specific management documents.

Risk management generated by protective equipment, as well as the occupational health and safety management system are the key component which has to be integrated in the company's general management system and its implementation should be made by integration in other management systems which are relevant for the organization, such as quality, environment or social responsibility. (D. Darabont et. al., 2017).

3. Technical and safety requirements applicable to insulating sticks

In order to ensure the use of safe working equipment, the designer and the manufacturer must certify the compliance with the national and European provisions and standards, national technical regulations, users' health and safety documents (their own Health and Safety Instructions for workers) and good practice (Antonov et al., 2017).

For this purpose, the insulating sticks must meet the requirements laid down in EO no.1146/2006 on minimum safety and health requirements for the use of work equipment by workers; safety objectives / assimilated requirements of the EO no. 409/2016 laying down the conditions for making available on the market of low voltage electrical equipment that adopt the provisions of Directive 2014/35/EU.

The conditions of use (field of use, precautions in use, maintenance, storage and transport conditions) and the technical characteristics (dimensional, mechanical, electrical and thermal properties) were taken into account in determining the technical and safety requirements applicable to insulating sticks, corroborated with the results of the analysis and evaluation of insulating sticks in use. Table 1 presents the minimum technical and safety requirements applicable to insulating sticks (Buica, 2010).

Table 1. Technical and safety requirements applicable to insulating sticks

S/N	Technical and safety requirements on work equipment	Legal provision		Testing condition

For technical and safety requirements which test conditions and methods have not been identified for, testing methods have been developed.

Testing methods have been validated by testing several new and in use insulating sticks from different manufacturers.

In this study, in order to certify the, technical quality and safety performances of the insulating sticks, 6 models of new insulating sticks (42 specimens) were evaluated and tested for chemical, electrical, mechanical and thermal properties, in order to identify changes or deviations from the technical characteristics and normal operation.

Two models of telescopic insulating sticks, 6 insulating sticks made of modules, but with different coupling systems and 2 simple insulating sticks models were tested. All 6 models are used in electrical installations with rated voltages between 6 and 400 kV. Other 36 insulating sticks, already in use, were also evaluated and tested.

The new equipment batches were subjected to the requirements specified in table 1, depending on the field of use, the technical characteristics and the manufacturer's specifications, based on logical schemes for the application of the procedure for the assessment and diagnosis of the safety of work equipment and the means of protection.

Based on the technical and safety requirements applicable to insulating sticks, additional tests have been proposed and verification methods have been developed. In order to verify the dielectric characteristic in use, mechanical, chemical, thermal, climatic and dielectric tests have been performed.

Microclimate conditions can decisively influence the safety of insulating working equipment, in terms of insulation degradation, which leads to a high risk for workers. (Pasculescu, V. M. et al., 2016).

To prevent this risk, additional requirements have been imposed and / or verification procedures have been developed and applied by testing on a part of the specimens. The requests for environmental conditions were performed after the mechanical tests, and after conditioning in extreme environments. It was checked that the dielectric characteristics were maintained within the established limits.

Batches of used working equipment have been subject, depending on field of use, technical characteristics and manufacturer specifications, to visual inspection and dielectric tests.

Protective working equipment have been checked to identify visual defects (eg. missing parts, cracks, bumps, foreign inclusions, etc.) and to technical condition, mainly related to maintenance (traces of punctures, the flashover, dirt, moisture traces, mold, unauthorized modifications made by users, etc.). At 11% of the working equipment, cracks and blows were identified, and the working equipment did not pass the dielectric test.

Verification of the dielectric characteristics was performed in accordance with testing and working laboratory procedures, but taking into account the verification methods indicated by the manufacturers in the technical documents. During the tests, the leakage current, the flashovers and the local heating were monitored. It has been found that specimens that have lost the dielectric characteristic also show visible local heating (P Dašić et al., 2017). A comparison was made within values of leakage current degradation recorded during periodic safety tests and for some working equipment there was a greater decrease of dielectric characteristics for those stored in undeveloped environments. Figure 3 shows the results of dielectric characteristics tests for the insulating sticks batches in use.

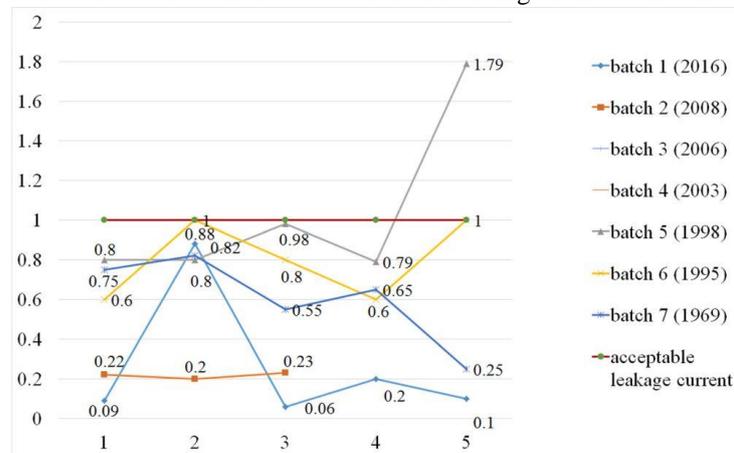

Fig. 3. Leakage current – insulating sticks in use

The results highlighted the quality of the materials of insulating sticks, respectively of the insulating hollow tubes and insulating materials and adhesive joint systems, as well as the way of using, maintaining, transporting and storing them.

There were other studies that investigate the comparative performances of new and used insulated sticks, with and without weather sheds fitted, under wet conditions. The tests investigated the time dependency of leakage current across the insulating surfaces when voltage stress was continuously applied for up to one hour, with the dry condition used as a reference baseline for comparison. This is seen as being representative of the practical situation in which a field operator must work (Williamson, Saha, 2002).

The results of the evaluation of insulating sticks in use are information on how to manage occupational hazards, the efficiency of selection and procurement procedures, the maintenance procedures and to establish the most appropriate technical diagnostic and inspection / control measures for a higher safety level of working equipment.

Awareness and involvement of top management is essential in the development of organizational risk management and to increase the risk awareness at different levels of the organization (G. Babut, R. Moraru, 2006).

4. Conclusion

Insulating sticks must be designed and manufactured in such a way as to protect against electrical hazards in use in electrical installations.

The purpose of the study was to identify the technical and safety requirements for insulating sticks, in order to establish the necessary conditions for checking and testing new and used work equipment, in order to attest the technical and safety quality during their use.

The study also aimed at identifying the conformity assessment tools and technical diagnostics necessary to certify the conformity of insulating sticks, in order to develop power risk management methods, both for the most appropriate control measures in use and for selecting and acquiring them.

The technical and safety requirements applicable to insulating sticks are intended to provide the criteria underlying the management of the protective working equipment, required by both manufacturers and users, in order to adopt the best technical and safety solutions, to ensure their compatibility with electrical installations, and to ensure safe use and safe maintenance of this work equipment.

In addition, the management of risks generated by the working equipment and the means of protection in use allows for a safer and healthier work environment and to increase the competitiveness of companies on the market.

Abstract

Maintenance activities are essential for maintaining the safety and reliability of the equipment and the working environment, it has a decisive impact on occupational safety and health, being a high risk activity that needs to be done safely, with adequate protection for maintenance workers and of other people present at the workplace. These activities include operations from very different sectors and from all types of work environments. This study highlights the impact of maintenance – as a high risk activity – on the safety conditions of the maintenance workers’ protection, within the post-accident evaluation and analysis of several organizations from Arad county.

Keywords: maintenance, risk, prevention, work accident, health and safety at work, statistic.

1. Introduction

In accordance with the European Standard 13306, maintenance is referring to "the combination of all technical, administrative and managerial actions over the lifecycle of a piece of equipment - a building, a work equipment or means of transport - in order to maintain or restore it in a state in which it can perform the desired function". Maintenance activities - Preventive and Corrective Maintenance - includes operations from extremely diverse sectors and across all types of work environments: inspection, testing, measurement, replacement, adjustment, repair, maintenance, troubleshooting, component replacement, service, lubrication, cleaning.

Maintenance is essential in maintaining the safety and reliability of the equipment and the working environment, it has a determining impact on occupational safety and health, being a high risk activity that needs to be done safely, with the proper protection of maintenance workers and of other people present at the workplace.

The lack of maintenance or inappropriate maintenance can lead to dangerous situations, accidents and health problems.

2. Workers’ protection in maintenance activities

In order to characterize and assess the time course of workers’ protection in maintenance activities (maintenance, repairs, cleaning, inspection - code 16-52, code 16-53 and code 16-55 from FIAM), the absolute statistical indicator was used "The number of accidents produced during 01.01.2011 - 30.09.2016", in organizations from Arad County.

Postaccident analysis and assessment allowed to highlights the dangerous actions and conditions that led to injury, in terms of injury occurrence and severity, of all data that may lead to the establishment of measures to prevent the risk of injury during maintenance activities.

During the analyzed period, during maintenance activities in Arad county, 33 work accidents were recorded, 30 accidents with temporary work incapacity, 3 fatal accidents, (fig.1).

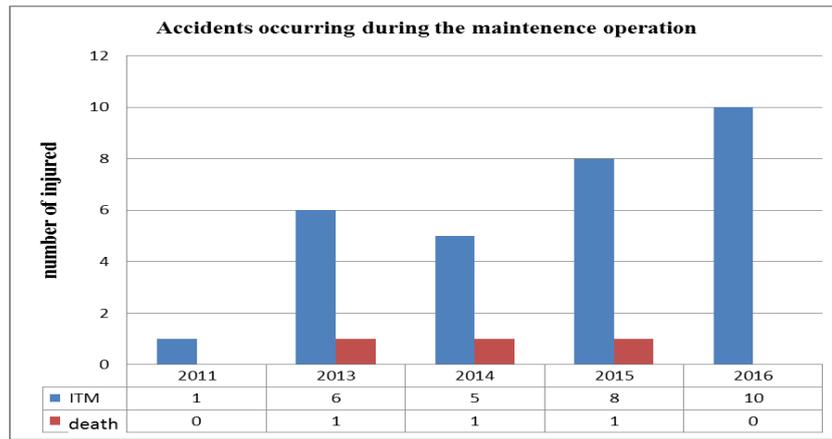

Fig. 1 Work accidents during maintenance activities

Compared to the total number of work accidents registered in the county, 458 cases, the work accidents in maintenance activities represent 7.2%.

The distribution of work accidents analyzed in relation with CAEN codification, regarding the economic activity that took place in the economic activities: manufacturing industry (section C, division 14; 16; 17; 22; 24; 25; 27; 28; 29 ; 30; 31), 32 cases; wholesale trade (section G, code number 45) one case - (figure 2).

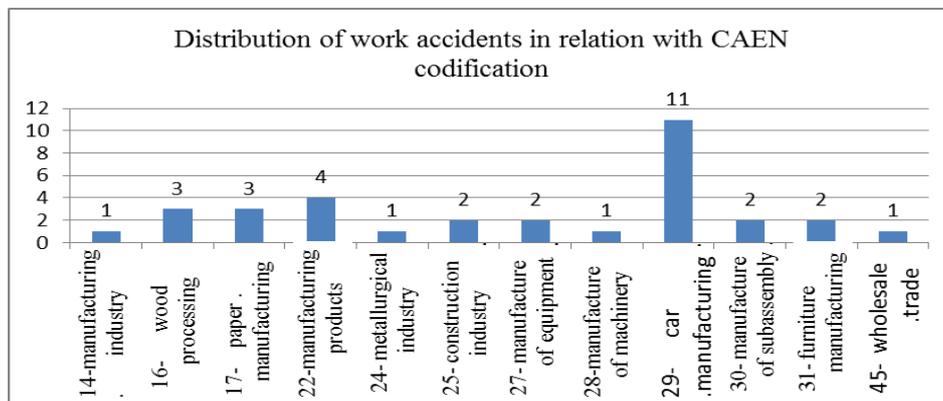

Fig 2 – Number of accidents / div. code C.A.E.N. "accident activity"

In the analysis carried out, we can notice that maintenance activity is found in 12 sectors of activity, compared to the 88 sectors of activity (divisions) that include the CAEN codification.

Regarding the working environment or all the factors where the victim was working at the time of the accident, the distribution of work accidents shows that most accidents occurred in production areas, factories, workshops - 30 cases; in maintenance areas, 1 case; storage 1 case; forest areas 1 case - (figure 3).

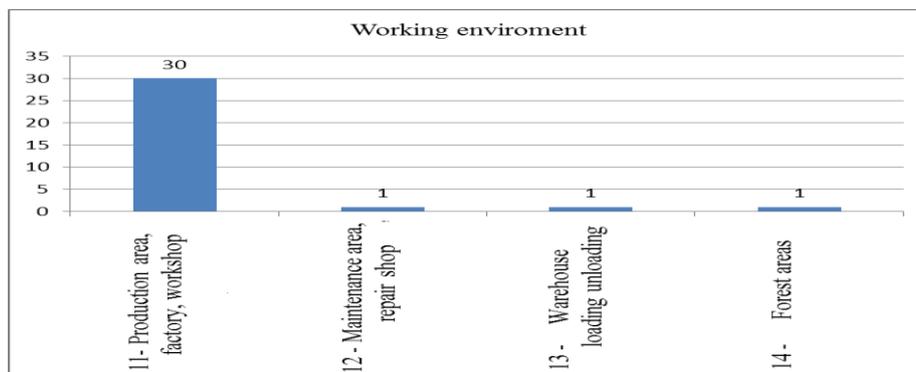

Fig 3 – Number of accidents / code „working environment"

3. Analysis of identification data and injured information.

Regarding the professional status, 98.1% of the injured persons were permanently working and full-time workers. The injured persons were 100% male; regarding marital status, 27 injured (81.81%) were married, 2 injured (6%) were unmarried, and 3 injured (9.09%) were divorced.

The criterion on the age of the injured person (Figure 5) shows that most of the injured belong to the age group 25-35 15 persons, the age group 45-55 9 persons, the age group 18-25 4 persons, age group 35-45 3 persons, and for the age group 55-65 2 persons.

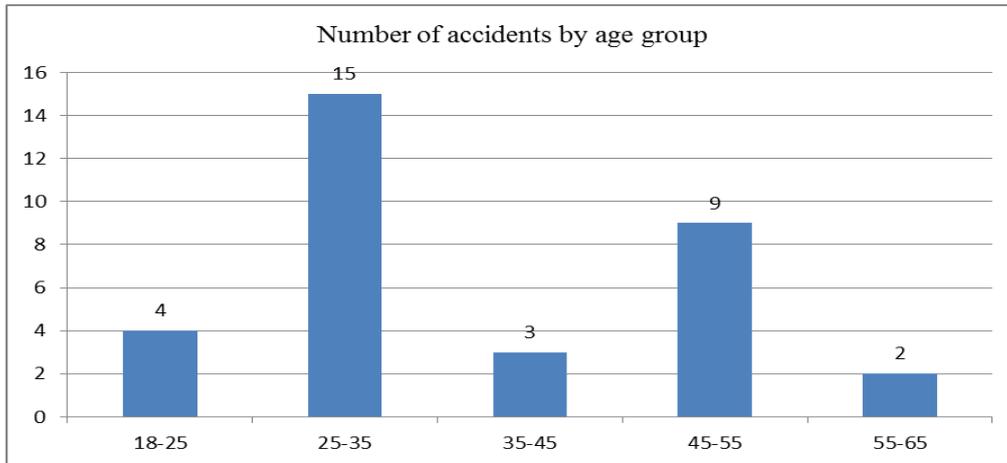

Fig 5 – Number of accidents / code, "injured age group"

4. Data analysis of the time when the accident occurred.

Regarding the distribution of work accidents over the months of the year (Figure 6), there is generally a relatively uniform distribution with an increase in June, July and August 4, 5, 4 accidents, the factor being the "occasional or mobile point".

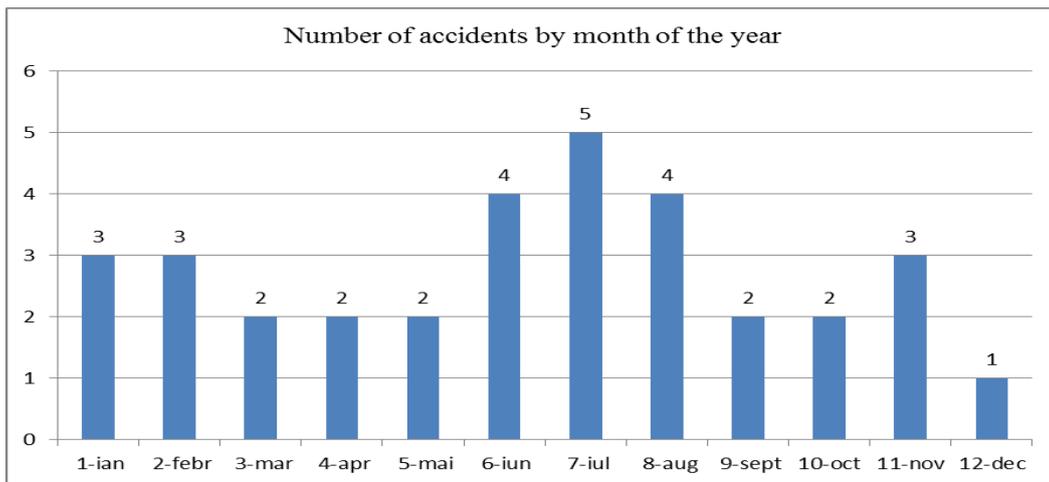

Fig 6 – Number of accidents / code "month of the year"

The "day of the week" criterion (Figure 7) shows a steady increase from the first day of the week on Monday, Tuesday (5 respectively 6 cases), with the peak on Wednesday 8 cases, followed by a steady decrease towards the end, so Thursday, Friday, Saturday and Sunday with 6, 4, 3 and 1 accident.

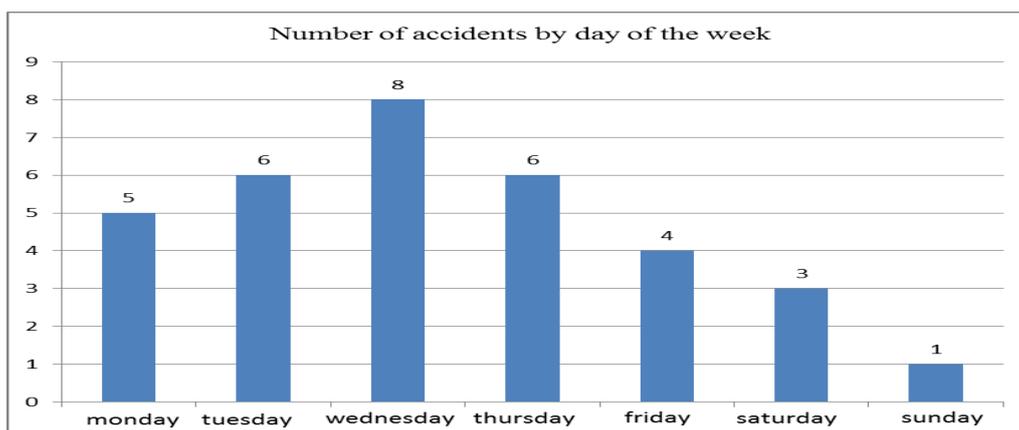

Fig 7 – Number of accidents / code "day of the week"

The "time of day" criterion (Figure 8) shows the distribution of work-related accidents over the hours, so it is noted that after an hour of work on shift 1, the number of accidents is 2 at 9 o'clock, double in the next hour to 4 accidents, followed by a decrease at 10, 11 and 12 (3, 2, 3 accidents). A significant increase of 5 accidents at 13 o'clock followed by a decrease and maintenance at 14, 15 with 4 accidents. In the second shift, the accident distribution is in the form of a curve beginning at 20 o'clock (1 accident), followed by a significant increase at 21 (3 accidents) and a decrease at 22 with 1 accident.

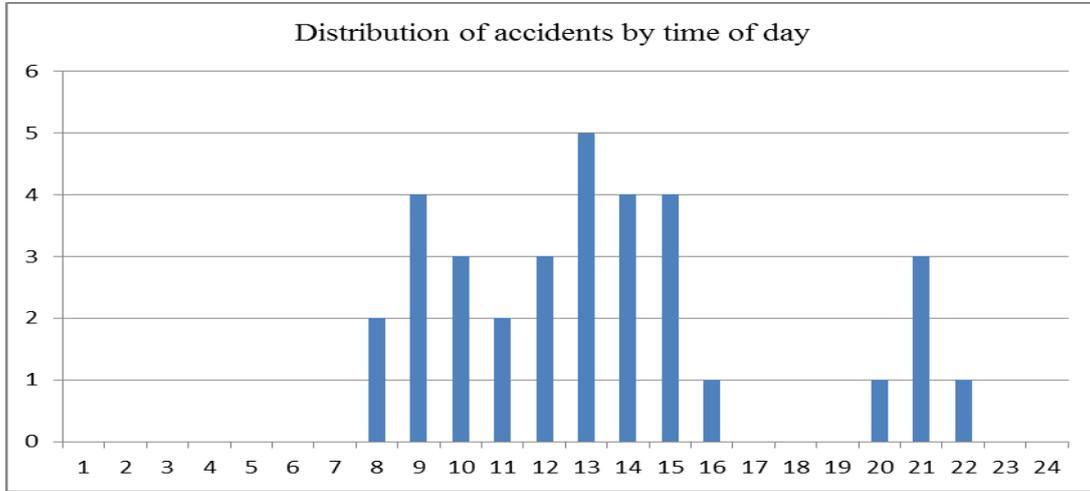

Fig 8 - Number of accidents / code "time of day"

5. Cause analysis in the labor accidents' dynamics.

In order to determine the most efficient measures to prevent the risk of injury in the maintenance activity (maintenance, repair, cleaning), we only approached the analysis of the causes depending on the "executor - the man involved in the work activity" and the "work task – the number of actions established and transmitted to the executor by the manager of the workplace", causes that are highlighted in "lit. (k) the cause of the event" in the event's investigation report and which are the main causes (*according to their importance in the work accidents' dynamics*), whose removal in the phase of risk factors, their occurrence could have avoided.

The analysis of the causes depending on the "executor" (Figure 4.11) highlights the inadequate behavior of the worker, reflected by his work capacity deficiencies, deficiencies that led to wrong actions or omissions, to an event-accident following:

- inadequate orders, code maneuvers 23.03 - 10 cases;
- not performing operations essential to work safety on time - code 23.02 - 8 cases;
- non-use of protective equipment, code 23.01 - 6 cases;
- exposure, outside work tasks, by displacement code 23.12 - 4 cases;
- falls from the same level by slipping, code 23.16 - 4 cases;
- falls from a high place, due to unbalance, code 23.20 - 2 cases;
- falls from a high place by slipping, code 23.21 - 1 case.

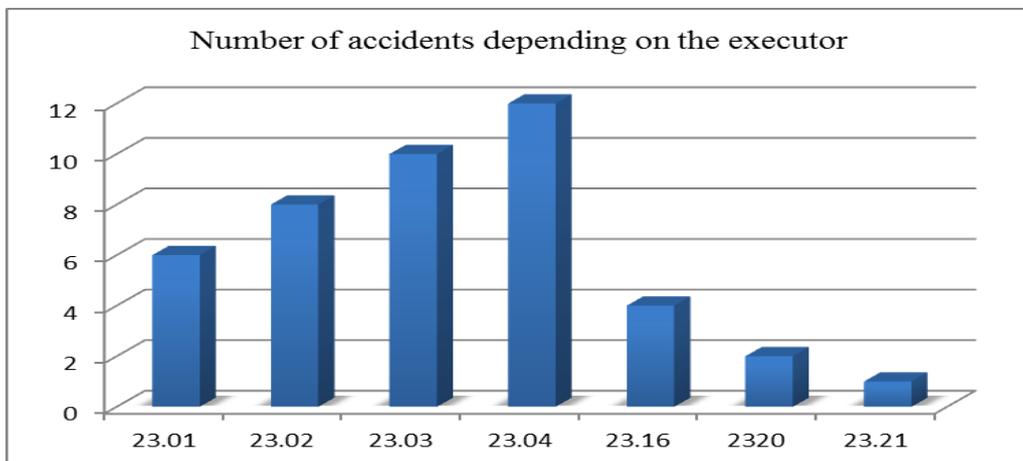

Fig 9 – Number of accidents / code, "depending on the executor"

The cause analysis depending on the "work task " (figure 10) highlights the inappropriate content of the work tasks under the report:

- omissions in pre-work tasks, code 23.092 - 8 cases;
- errors in pre-work tasks, code 23.093 - 8 cases;
- tolerance of technological discipline deviations, code 23.098 - 1 case;
- not securing the coordination of some work tasks performed in complex tasks
- accepting inappropriate production means, code 23.101 - 1 case;
- other causes, code 23.107 - 11 causes.

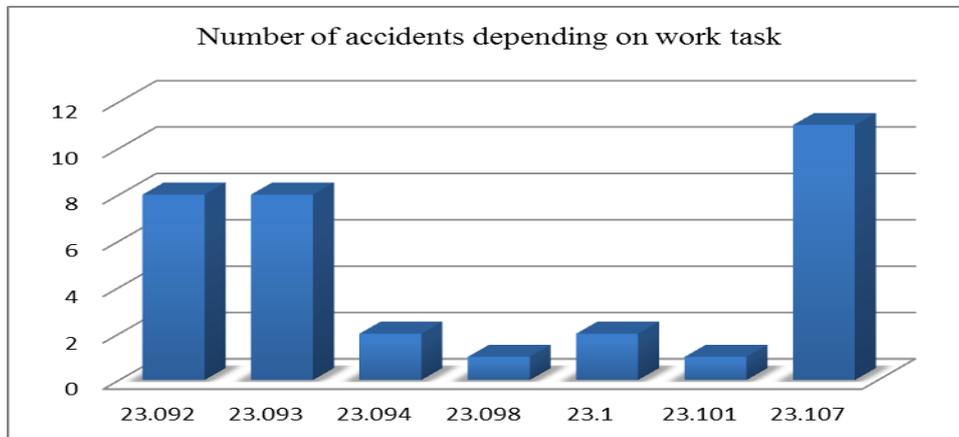

Fig 10 – Number of accidents / code, "work task causes"

6. Conclusions

The post-accident analysis and evaluation shows that the work injuries suffered by maintenance workers took place in very different activity sectors, in 13.63% of the activity sectors, compared to the 88 activity sectors (divisions) of the CAEN code.

Regarding the working environment, a multitude of types of working environments resulted (from code 011 to code 034, from position 15 FIAM, figure 4.6) where the group 011 predominates - productive area with 30 cases, factory , workshop, followed at a great distance by group 012 - maintenance area 1 case, repair workshops, group 013 - warehouses, loading / unloading 1 case and group 034 - forest areas 1 case.

Regarding the type of maintenance, the analysis showed that the "corrective/reactive" maintenance predominated, which restored the operating status of the damaged system, in 23 cases (69.6%), while the "preventive" maintenance with planned, proactive actions, through which the control of the deterioration process leading to system failure was found in only 10 cases (31.1%).

Maintenance is an activity that includes work near an ongoing process and in direct contact with the work equipment, this aspect being highlighted by the variable "deviation" as the last abnormal event leading to an accident, namely:

- deviation from checking the injured person, mainly caused by problems with the work equipment, eg: groups 10-30, with 3 cases;
- the loss (total or partial) of control over something, eg groups 40-50, with 14 cases;
- movements of the body, eg groups 60-70, with 10 cases, etc.

Regarding: professional status, the majority of 98.1% of the injured persons were permanent and full-time workers.

The injured persons were 100% male; with regard to civil status it is highlighted that 27 injured (81.81%) were married. The criterion "injured's occupation" reveals that most of the injured belong to the major group 7 - skilled craftsmen and workers (major subgroup 72 - working in metal constructions 12 cases, 75 - food industry 1 case); major group 8 - machine operators (major subgroup 81 - fixed installations operators, 4 cases, 82 - metalworking machinery operators 6 cases); Major group 9 - Unskilled workers (subgroup 92 - unskilled labor workers 1 case, subgroup 93 - unskilled construction workers 5 cases); major group of 3 technicians, foremen (subgroup 31 - technicians 1 case, subgroup 33 informatics and communications technicians 1 case); the major group 1 Subgroup 13 - 1 case; as well as 00 - unspecified 1 case.

The criteria for " the age of the injured person" shows that most of the injured belong to the age group 25-35 15 persons, the age group 45-55 9 persons, the age group 18-24 4 persons , the age group 35-45 years 3 persons and for the age group 55-65 years 2 persons.

The "injury location" criterion reveals that the most affected area was: *the upper extremities area* - 20 cases; *head area* 7 cases; *lower extremities area* - 6 cases.

The "month of the year" criterion generally shows a relatively uniform distribution with an increase in June, July and August of 4, 5, 4 occupational accidents, the factor being the "occasional or mobile point".

The "Day of the Week" criterion shows a steady increase from the first day of the week on Monday, Tuesday (5th respectively 6th), with the peak on Wednesday, 8th, followed by a steady decrease towards the end of the week , Saturday and Sunday with 6.4.3 and 1 accident.

The "Time of the day" criterion shows the distribution of work accidents over the hours, with an increase at around 9 and 13, when the most accidents occur (11 cases).

Regarding the causes of the injury, the prevention measures must focus on the components "executor" and the "work task".

Regarding the "executor" component, the need to promote a culture of prevention, acquiring knowledge and health and safety trainings at work must be an absolute priority in the occupational health and safety management system in the enterprise.

As far as the "work task" component is concerned, the activity of the managers must be informing and verifying the way work instructions in the maintenance activity are applied and also upon occupational safety and health norms.

Management of dangerous substances released by machinery, condition to ensure safety and workers' health and environmental

Anca Elena Antonov*, Georgeta Buica^a, Constantin Beiu^a, Raluca Aurora Stepa^a

INCDPM “Alexandru Darabont”, 35A Blvd Ghencea, 6th county, Bucharest 062692, Romania

Abstract

The research is aimed at identifying the applicable safety requirements for the prevention of occupational risks in the management of dangerous substances related to the use of machinery. For the use of machinery in conditions of economic performance and a maximum level of safety, it is necessary to ensure that the conditions set by the manufacturer regarding the putting into service, use and interventions under the conditions of safety work and guarantee of technical and environmental requirements, including measures and means of protection against the action of dangerous substances used or produced by machines. The prevention of this specific risks can be achieved by avoiding the use of dangerous materials and substances or by using less dangerous substances. The specific occupational hazards impact of machines can be reduced by applying modern principles in conformity assessment, taking into account the provisions of the Machinery Directive which imposes an obligation on manufacturers to ensure compliance with safety and health requirements both technical point and on safety work environment. The research paper aims to develop a risks management methodology based on the dangerous substances produced and/or used by the machinery to ensure compliance and to provide the premise for increasing employers' competitiveness.

Keywords: risk, safety, machinery, dangerous substaces, management

1. Introduction

The modern economy is the result of industrialization and economic and social progress, requiring modern, high-performance, high-performance working equipment and installation facilities to ensure high economic efficiency. To use working equipment in conditions of economic performance and a maximum level of safety, it is necessary to ensure that the conditions set by the manufacturer regarding the putting into service, use and maintenance in proper conditions are met and to guarantee the technical and environmental requirements, including measures and means of protection against accidents and occupational disease. An important national objective is to ensure the essential safety and health requirements applicable to all working equipment, in order to implement the policies provided by the free movement of goods contained in the EUROPA 2020 strategy, namely to guarantee the free movement of Romanian products within the European Union (EU) (Antonov et al., 2017).

Another objective is to ensure the safe use of working equipment (WE) from which the machinery belongs, in order to prevent the risks of accident and occupational disease, as well as to protect the working environment and the environment, by putting into service of compliant products, including measures and means of protection against the action of hazardous substances used or produced by machinery. The prevention of risks from emissions of hazardous substances can be achieved by avoiding the use of hazardous materials and substances or by using less dangerous substances. Working equipment must be designed and built in such a way to be able to perform its function and be used, adjusted and maintained without the working being exposed to risk when such operations are carried out under the conditions laid down by the manufacturer, and taking into account any foreseeable misuse that can be predictably expected. Working equipment must be delivered with all essential components and accessories so that it can be adjusted, maintained and used in complete safety.

In order to prevent risks from emissions of hazardous substances, the machinery manufacturer and employers, as a user of the working equipment, must identify the hazards and carry out the assessment of the foreseeable risks resulting from the dangerous substances produced and/or used by the machinery, in order to guarantee the health of workers at work. This process must cover, as far as possible, any potential hazard that may arise from the exposure of individuals at any stage of machinery life cycle. The research study focuses mainly on the analysis undertaken to identify the measures to be taken to increase the compliance rate of WE in use and to prevent risks from emissions of hazardous substances.

The methods used are:

- identification of professional risks applicable to the machinery, which is the subject of the study analysis;
- establishing the essential safety and health requirements applicable to machinery, in accordance with the legal provisions set out in Annex no.1 of EO no.1029/2008, which adopts the Machinery Directive 2006/42/EC (Machinery Directive);
- establishing the safety and health requirements applicable to machinery, in accordance with the legal provisions set out in Annex no.1 of EO no.1146/2006, which adopts Directive 2009/104/ EC (Work equipment Directive);
- establishing the safety and health requirements applicable to the machinery in relation to the risks generated by the emissions of dangerous substances, according to the legal provisions set out the specific safety standards analyzed in the study.

2. Work accident statistics in agriculture and processing industries

Statistical data on work-related accidents at national level in Romania are based on the data provided by the National Statistics Institute (NSI) for the period 2013-2016 (NSI TEMPO, 2018). It was taken into account in the analysis of the statistical data related to the work accidents and the information provided in the Romanian Labor Inspection through the Activity Reports for 2013-2017. Also, from the statistical data provided by EUROSTAT and from the analyzes based on the SEAM methodology (European Workplace Accidents), it can be identified work accidents as a result of maintenance operations in several European countries (EU OSHA, 2010; EUa, 2001). Accidents at work have an increasing tendency not to occur during normal operation, but during repair, maintenance, cleaning, adjustment, etc. (Dobra R et al., 2013; EUb, 2010).

An analysis of the results of the Spanish National Survey on Working Conditions (2007) indicates a greater exposure of maintenance workers to noise and vibrations affecting hands, arms and the whole body as compared to other workers. They are also more exposed to dangerous substances, vapors and emanations (Garcia Morilla et al., 2003).

Approximately 25% of all electrical accidents with injuries are caused by portable electrical equipment. Damaged conductors from working equipment annually cause around 2000 fires. A major cause of these accidents and fires is the failure to carry out inspections and maintenance. (EU-OSHA and b) The research shows the results of the processing of statistical data regarding the work accidents produced at national level, by macro-regions, development regions and counties, respectively economic activities as a number of collective accidents, according to Fig. 1.

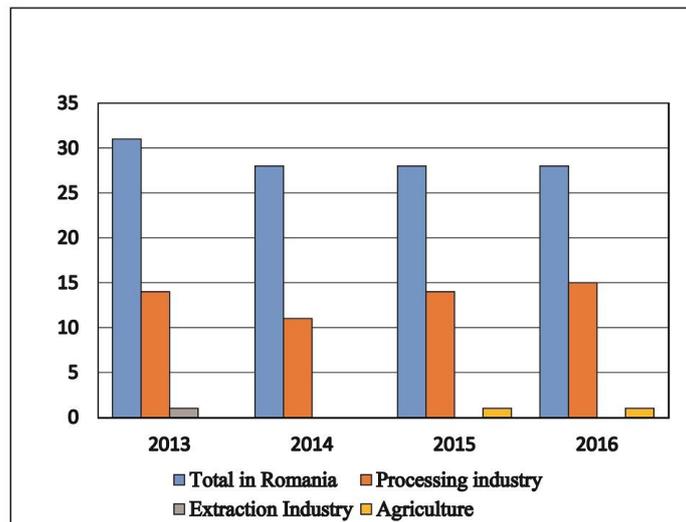

Fig.1. Collective accidents at work at national level during 2013-2016

Fig. 2 shows the situation of work accidents on categories of accidents, macro-regions, development regions and counties specific to agriculture, the mining and processing industries, in the period 2013-2016, according to the NSI registration. (NSI TEMPO, 2018).

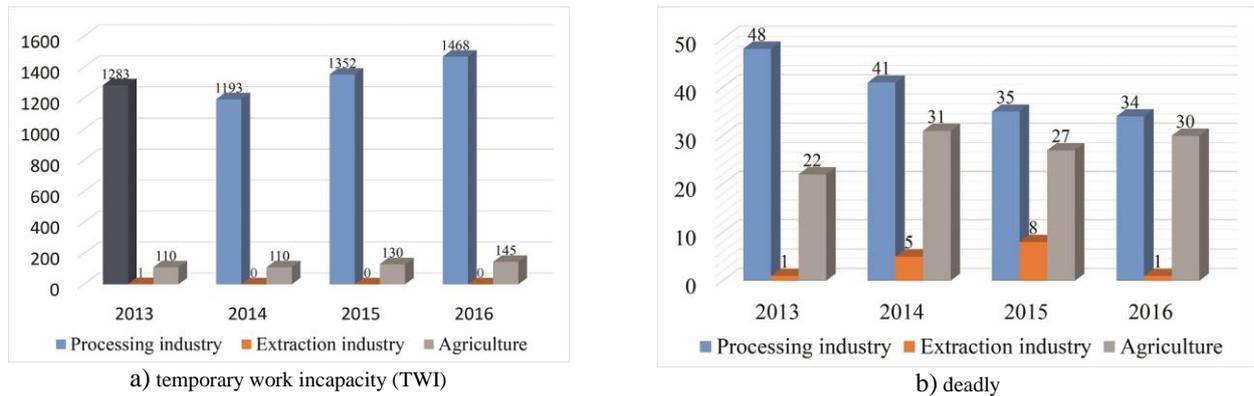

Fig.2. Accidents at national level during 2013-2016.

In the research study, the results of the processing of statistical data on work-related accidents at national level are presented (NSI TEMPO, 2018). According to the data available at the national level (NSI), processed by the authors of the research study, the above graphs, shows the distribution of the accidents at work produced in Romania, the statistics and the data collected from the activity reports of Labor Inspectorate during 2013 -2017 does not highlight the direct causes of occurrence of these accidents, the results of the accident investigation produced in these sectors of activity being recorded and declared in the files drawn up at the employers level, at Territorial Labor Inspectorates and, as the case may be, at the National Labor Inspectorate. Analyzing the statistical data, it was found that the agriculture, extractive industries and processing industries remain in the first places in terms of number of injured in work-related events. Statistical data on national accidents at work shows that there is an increase in the number of accidents at work during 2013-2016 in agriculture and extractive industries, with a decrease in the processing industries in the case of TWI, respectively an increase in the number of dead workers in the agriculture and processing industries. In order to ensure safe machinery in use, the designer and the manufacturer must ensure the compliance with national and European legislation, applicable national and European standards and national and Occupational Safety and Health (OSH) documents developed by employers (Antonov et al, 2017).

3. Identifying the applicable safety requirements to prevent risks from hazardous substances

From the studies carried out on the evaluation of the risk level and the working conditions during maintenance operations in the 4 categories of working equipment, it was found that the most significant are the mechanical and electrical risks, which may influence the characteristic factors of the emission of hazardous materials and/or substances (Dobra R et al, 2013). Identifying, analyzing and assessing the risks of injury and occupational disease generated by working equipment are the basic tools of risk management, in order to reduce and to eliminate these risks by technical and organizational measures. The benefit of risk assessment allows to identify the problems faced by users, which requires the adoption of preventive measures (Antonov et al, 2016).

The main source of a technical event with consequences, both at the employer's and worker level, is the working equipment. Risks related to the impact of workers' health are generated by a multitude of machinery-specific risk factors and workplace organization. A category of risks that affect the workers' health and can generate a work event is due to the emissions of hazardous materials and substances produced by the machinery. Dangerous materials and substances include both chemical and biological materials and substances classified as toxic, corrosive, irritant, carcinogenic, mutagenic, teratogenic, pathogenic or asphyxiating (EC b, 2010). The level of risk depends on the properties of the hazardous substances, the likelihood of being personal, the exposure to occur and the degree of exposure. The effects on workers' health caused by emissions of hazardous substances by machinery may be on short or long term and depend on reversible or irreversible nature. Dangerous substances may appear in any physical state (gaseous, liquid, solid) and may affect the human body by inhalation, ingestion, contact with the skin, eyes and mucous membranes or penetration through the skin, which can be generated from any part of the machinery substances present in the machinery or materials that result directly or indirectly from materials and/or chemical or biological agents processed or used by the machinery or, as the case may be, used on the machinery. Airborne emissions of dangerous substances may enter in the body by inhalation or other ways when deposited on the surface of the body or ingested. Emissions of non-airborne hazardous substances may enter in the body by ingestion or in contact with the skin, eyes or mucous membranes. The prevention of risks from emissions of hazardous materials and substances can be achieved by avoiding the use of hazardous materials or substances or by using less dangerous substances.

The machinery manufacturer must identify hazards and assess the foreseeable risks from hazardous substances. Risk assessment should extend, wherever possible, to all potential hazards of exposure of workers in all different life phases of the machinery. The machinery manufacturer must design the production process to avoid or reduce emissions. Where

emissions of hazardous materials and substances cannot be avoided or reduced sufficiently, the machinery must be equipped with necessary equipment to retain, evacuate or precipitate hazardous materials and substances in order to protect workers against exposure. Where dangerous materials or substances are flammable or may form explosive mixtures with air, the necessary precautions shall be taken to avoid the risk of fire or explosion during their retain or evacuation. The safety and health requirements applicable to machinery for airborne emissions, in order to prevent risks from hazardous materials and substances, are provided in the applicable safety standards of SR EN ISO 14123-1: 2016 and aim at the necessary measures to be taken by the designer and the manufacturer of the machinery, in order to eliminate and to reduce the emissions that can come from different sources as much as possible, namely: processing, grinding, sanding, milling; evaporation or thermal convection; hot metal processing; material handling; spraying; leaks; waste; maintenance; dismantling; combustion of fuels; machinery for mixing food or metal processing. In the same way, the safety and health requirements applicable to machinery for non-airborne emissions aim at the necessary measures to be taken by the designer and manufacturer, in order to eliminate and to reduce as much as possible the emissions that may occur under certain circumstances, namely: migrants coming from open sources, which lead to secondary emissions; machinery openings; doors for inspection; manipulation of materials; manipulation of machine parts; incorrect operations; leaks or breaks.

Table no.1 presents the machinery risks related to the emissions of hazardous materials and substances in compliance with the applicable essential requirements provided by, Annex 1, chapter 1 and, as the case may be, 4, 5 of EO no.1029 / 2008 and under reference of harmonized standard SR EN ISO 14123-1: 2016

Table 1. The technical and safety requirements applicable to machines that produce and / or use hazardous materials and substances

Nr. crt.	Technical and safety requirements	Legal provision		Technical and verification conditions	
		EO no.1029/2008	EO no. 1146/2006	SR EN 14123-1:2016	SR EN 14123-2:2016
1.	Emissions of hazardous airborne substances	1.5.13	2.5	5.1	3
		1.1.3	2.6	4	4
		3.5.1	2.13	6	5
		3.5.3	2.15	8	
2.	Emissions of hazardous substances which are not airborne	5.5	2.17, 2.18	5.2	
			3.3.1.1	4, 6, 8	
3.	Fire	1.5.6	2.18	-	-
		3.5.2	3.16		
		5.6	3.3.1., 3.3.5		
4.	Explosion	1.5.7	2.18	-	-
			3.3.1, 3.3.5		

Where it is foreseeable that leakages, accidental spills or uncontrolled losses of hazardous substances may occur, the manufacturer must indicate the measures to be taken to limit the consequences and, respectively, to regain control of the situation as soon as possible. This information should refer, as appropriate, to emergency procedures, safe disposal of the substances and to protective equipment and devices in such way to allow the complete identification of the places where loss of substances occur and to make the necessary repairs. The manufacturer must provide adequate information on the necessary personal protective equipment and hygiene measures.

4. Management of hazardous substances emitted by machines, a condition for ensuring the safety and health of workers

The impact of machine-specific occupational hazards due to emissions of hazardous chemical mixtures and/or substances not may or not be reduced by applying modern principles in conformity assessment, certification or technical diagnosis and inspection, taking into account the provisions of Machinery Directive 2006/42/EC that sets the obligation for manufacturers to ensure compliance with the applicable safety and health requirements, both technically and in terms of workplace and environmental protection, provided that the production process is designed to avoid or reduce emissions. The management of hazardous substances emissions from machines is a condition to ensure the safety and health of workers and environmental protection. Equipment play an important role in injuries of workers or private individuals.

Specific data for Romania could not be found, but data is available for the USA. A study published in 2015 by the Centers for Disease Control and Prevention in the reporting period (1999-2008) reveals the number and percentage of contributing factors associated with the top five chemicals released - Hazardous Substances Emergency Event Surveillance System, nine states. (CDC, 2015)

Table 2. Number and percentage of contributing factors associated with top five chemicals released — Hazardous Substances Emergency Events Surveillance system, nine states, period 1999–2008

Factor	Carbon monoxide		Ammonia		Chlorine		Hydrochloric acid		Sulfuric acid	
	No.	(%)	No..	(%)	No.	(%)	No..	(%)	No.	(%)
Equipment failure	200	(45)	242	(46)	86	(32)	47	(22)	89	(41)
Human error, unspecified	185	(42)	133	(25)	99	(37)	87	(41)	74	(34)
Others	59	(13)	154	(29)	85	(31)	77	(37)	52	(25)
Total	444	(100)	529	(100)	270	(100)	211	(100)	215	(100)

The general public represented 48% of the injuries for carbon monoxide, 23% for ammonia, 48% for chlorine, 31,9 for hydrochloric acid and 15 % for the sulfuric acid, while the unknown injured represented between 0,1 % and 0,5 %. The rest were employed persons, (CDC, 2015)

In order to manage the specific risks due to emissions of hazardous substances, the machine manufacturer or the employer who uses this equipment at the workplace must carry out a specific risk analysis, also taking into account the risks that are additional to the major/main risk. Reducing the risk of fire involves taking several combined measures.

The research study identified the necessary conditions for developing a risk management methodology based on the hazardous substances produced and/or used by the machines, in order to ensure compliance and to provide the premises for increasing company's market competitiveness. The developed methodology leads to the application of the procedures for checking the reduction of the health risks due to the hazardous substances from the machinery, which must comply with the principles and technical requirements stipulated in the harmonized standard SR EN ISO 14123-2: 2016. The test methods are chosen according to the air sampling and analysis methods for the pollutants adapted to the nature of the pollutants emitted. The choice of test methods to measure the emission of airborne hazardous substances must comply with the principles and technical requirements laid down in harmonized standards SR EN 1093-1:2009 and SR EN 1093-(2 ÷ 11) + A1:2008 series.

For the assessment of workers exposure to substances that become airborne after being emitted while operating/testing/doing maintenance for the machinery, techniques for measuring the concentrations of these substances in the breathing zone of workers in the machine area shall be applied. The results of the measurements shall be compared with the occupational exposure limit values (OELVs) established by the national regulations regarding the exposure of workers to chemical agents. Where national OELVs are not available, measurement results may be assessed against OELVs used by other countries or internationally recommended. Sampling methods and analysis techniques should be adapted to the nature of the pollutants emitted. Emissions of non-airborne substances cannot be measured by measuring their concentration in air, in which case other assessment criteria may be established based on the measurement techniques laid down in harmonized standard SR EN ISO 14123-2:2016 or by verification procedures developed by testing /analysis laboratories. Taking into account the steps leading to the implementation of the established verification procedures used in order to comply with the requirements of the harmonized standard SR EN ISO 14123-2:2016, the risk management methodology for hazardous substances produced and/or used by the machines developed in the research study considers the following: identification of hazardous chemicals; identification of the risks of emissions of hazardous chemicals produced or used in machine; characterization of significant emissions of identified hazardous chemicals; identifying the critical, relevant factors that can generate an emission and that should be addressed in order to avoid or lower emissions; establishing the characteristic parameters, which can be qualitative, in direct relation to the identified critical factors; collecting data on characteristic parameters by checking the results of on-the-spot tests / measurements, laboratory tests, measurements, examinations or calculations, as appropriate. Within the methodology developed by the research team, account is taken of both the types of emissions (that fall into the categories: zero or insignificant, localized or total, where emissions can be identified from several possible points) as well as the relevant factors and characteristic parameters such as: design, performance determined by the technical solutions adopted, materials, energy. The risk management methodology for hazardous substances produced and/or used by machines aims at making the conformity assessment and certification process more efficient and ensuring the necessary conditions for the safe use of work equipment and the management and control of occupational hazards at the users level, in order to improve the level of safety and health at work and the OSH management activities respectively.

Specific tools for conformity assessment, inspection, certification and compliance through technical diagnostics of work equipment, of which the machines are part, are required within the company management system, allowing for the technical framework necessary to control and guarantee the fulfillment of the specific security requirements related to hazardous substances, in conjunction with the specific requirements identified based on the risk analysis performed according to the harmonized standard SR EN ISO 12100: 2010. Risk management for specific processes e.g. metal and woodworking with their specific work equipment should start at the design and manufacturing level to ensure the necessary conditions for placing on the market of safe products with an adequate level of safety under the conditions intended use set out in the instructions in the Technical Manual/User Manual/Instructions.

Conclusion

The research study aimed at developing the necessary tools to ensure compliance of machinery and other work equipment intended for placing on the market or in use at employers' level with the Machine Directive 2006/42/EC, in conjunction with Directive 2009/104/EC, the Law No.319/1996 on Occupational Safety and Health and the Social Directives on the exposure of workers to chemical and biological agents. The research addresses the need to ensure compliance with the essential health and safety requirements set out in Annex no.1 to Directive 2006/42/EC, in conjunction with the minimum safety and health requirements of Directive 2009/104/EC and the technical rules laid down through the safety standards applicable to machine with regard to the risks related to the emissions of hazardous substances produced and / or used by the machine.

The research study aimed at identifying the applicable safety requirements for the prevention of hazards caused by hazardous substances in order to manage the hazardous substances related to the use and maintenance of the machine, in relation to the tuning, repair and cleaning operations, including situations arising after events, major repairs and upgrades.

The risk-management methodology for hazardous substances produced and / or used by the machines developed in the study will allow compliance and provide the premises for increasing the competitiveness of employers in the market economy in order to help the safe use of the machines and the effective control of professional risks at the user level. The tools developed in the research study aimed to create the framework necessary to improve the level of safety and health at work in the workplace and the level of OSH management activities, respectively.

Analysis of the methods of exploitation applied to Romanian salt mines

Chiuzan Emeric^{a*}, Găman George^a, Tomescu Cristian^a, Matei Adrian^a, Drăgoescu Răzvan^a

National Institute for Research and Development in Mine Safety and Protection to Explosion, INSEMEX, 32-34 G-ral Vasile Milea street, Petroșani, 332047, Romania

Abstract

Salt is a vital food that has begun to be consumed since the Neolithic period. The history of salt is tumultuous and involves, among other things, the liberation of a people from foreign occupation. Man began to consume salt since the Neolithic period, when he began to diversify his diet and eat vegetal products. Man learned to use salt and became dependent on it probably in the Neolithic, when the transition has been made from an exclusively carnivorous diet to a diet with vegetable products. In 2018, in Romania, three methods of extraction of dried salt are applied, namely: i) method of operation in small rooms and square bunk pillars; ii) method of operation with small rooms and square pillars; iii) small room method and rectangular bunk pillars.

Keywords: exploitation, method, salt;

1. Introduction

Nowadays, in Romania are 6 underground salt mines in operation, belonging to teh National Salt Society located in Bucharest. The 6 salt mines presented in Fig. 1 are: Cacica, Ocna Dej, Praid, Slanica Prahova, Ramnicu Valcea and Tg. Ocna. Besides these, salt is also mined with the humid method in Ocna Mures, Tg. Ocna, Cacica and Ocnele Mari (Tamas et al., 2015).

Fig. 1. Romanian salt mines in operation

Three hypotheses have been drawn up concerning the origins of salt:

- The first one admits that salt dissolved within marine waters and the one from the earth's bark originates from the primordial atmosphere of our planet.
- The second one states that salt was generated by substances released from volcanic eruptions.

*Chiuzan Emeric, Tel.: +40-254-541-621; fax: +40-254-546-277.
E-mail address: emeric.chiuzan@insemex.ro.

- The third admits that salt originates from substances from decomposing miners from the earth's bark. Some authors state that marine salts started to deposit in a system of lagoons of various dimensions and low depths, in hot climate, slow subsidence of the lagoons bottoms and the presence of a system of large barriers. Small and intermittent lagoons which retained from marine waters calcium and magnesium carbonates, which deposited as dolomites, into the large Transylvanian lagoon (represented by Transylvania and Maramures basins), waters full of sodium chloride and potassium and magnesium salts deposited as salt by cooling down (Fig. 2).

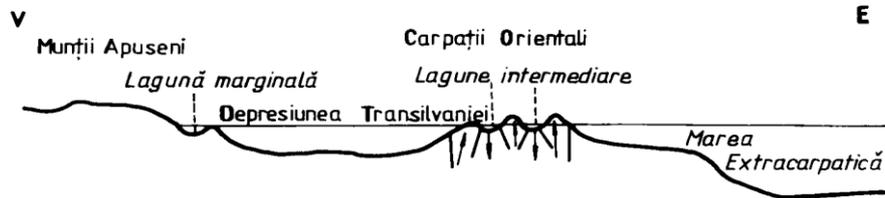

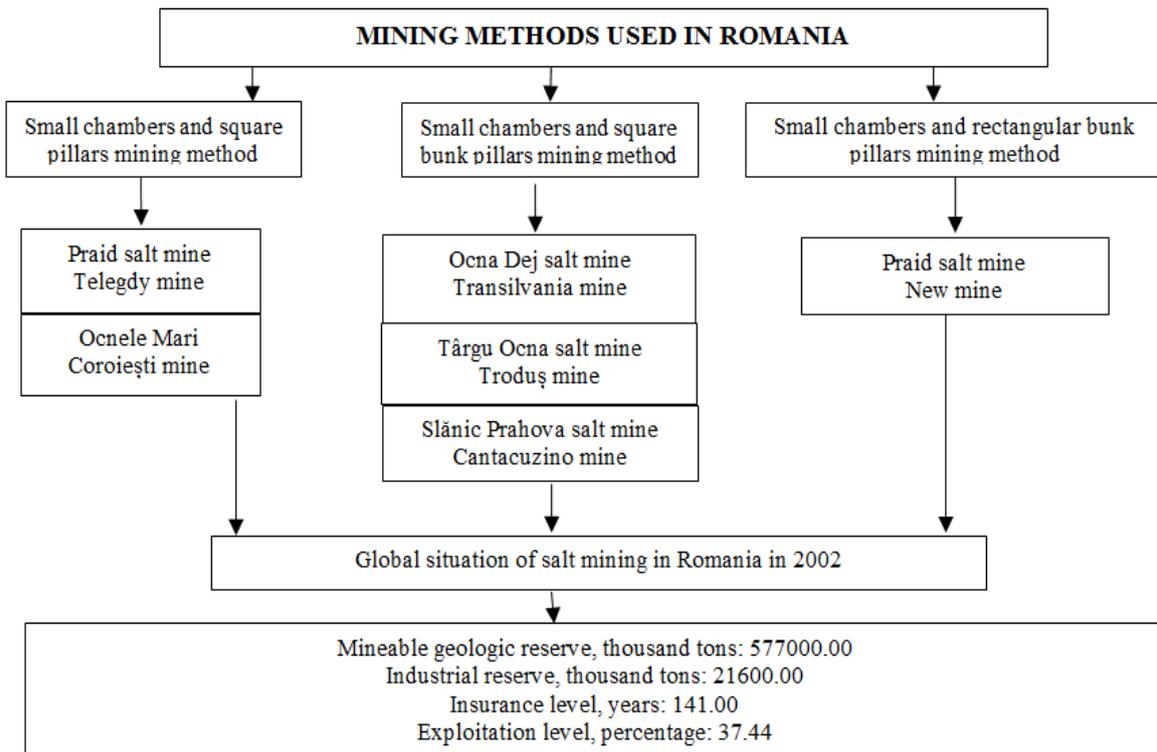

Fig. 2. Configuration of intermediate lagoons

2. Salt mining methods. Generalities.

In 2017, in Romania were applied only three salt mining methods, namely (Table 1):

- Small chambers and square bunk pillars mining method;
- Small chambers and square pillars mining method;
- Small chambers and rectangular bunk pillars mining method.

Table 1. Mining methods used in Romania

2.1. Small chambers and square pillars mining method

The method consists of excavating-blasting of chambers, between which are abandoned parallelepipedic pillars with square base. The exploitation direction is in advance (Fodor, 2015). The chamber-pillar system forms a well-established operational system, the chamber ensuring the space required for extracting the raw material and the pillar the stability of the salt massif. This method involves supporting the roofs of the exploitation chambers and the square pillars, but do not exclude this support when there occur instability phenomena (exfoliation, fissures of roofs and pillar etc.)

In the absence of these phenomena, the rock mass from the roof and pillars has to be maintained in balance, by a proper sizing of the mine's resistance elements, so that the salt between the pillars and roofs to unjustifiably increase operating losses.

Dimensions of the chamber-pillar are gap correlated for 30 m. The gap is the distance between the central vertical axis of two neighbouring chambers, separated by a pillar.

The exploitation method with small chambers and square pillars used in most salt mines has a series of advantages (Chiuzan, 2018; Oprina, 2015):

- The use of machinery is light, taking into account the gauge of the chamber;
- There may be opened a larger number of active work faces located at the same horizon;
- The ventilation network is diminished a lot, not being required special works for each chamber;
- There can be easily avoided waste or low-quality salt areas from the deposit (Leba et al., 2014).

Fig. 3 shows a horizontal section through an exploitation system, where (lp) stands for the width of the pillar, (lc) for the width of the chamber, (e) for the gap. The exploitation coefficient is depending on the gap: inversely proportional with the dimension of the pillars, directly proportional with the dimension of the chambers. Fig. 4 presents the chamber-bunk rectangular pillar system, where g-thickness of the roof, h-height of the chamber, l-width of the chamber, f-pillar.

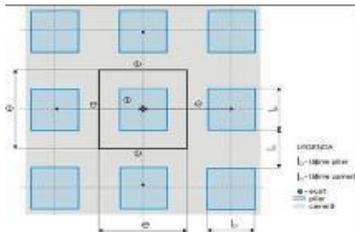

Fig. 3. Horizontal section

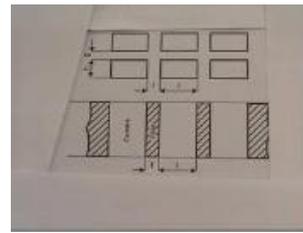

Fig. 4. Horizontal section through the chamber-rectangular pillar system

2.2. Small chambers and rectangular pillars mining method

This method differs from the one presented before only by the shape (rectangular in section) and dimension of the pillars and chambers. Horizontal and vertical gap is larger than for the previous method. This mining method consists in the excavation in the salt massif of chambers of 20 m width and 8-12 m height, separated by rectangular shaped salt pillars (Covaci et al., 1999). These pillars shall take the load of covering rocks, ensuring the stability of the excavation and of the surface. The mining method does not involve the support of chamber roofs and abandoned pillars, but does not exclude it when instability phenomena occur. The exploitation method is developed by MINESA - I.C.P.M. Cluj and it is exclusively used in Praid salt mine – new sector (lower horizons) and is characterised by the following (ICPM Cluj projects, 1986-2014; Popa et al., 1993):

- Roof (pillar) of the salt deposit has a minimum of 30 m thickness;
- Floor pillar of the salt deposit has a minimum of 25 m thickness;
- Marginal pillars for the new sector of Praid salt mine shall have a thickness of 30 m min.;
- Pillars (roofs) between horizons have a min. 8m thickness;
- Pillars between chambers are prisms with width of 20m, length of 40-100m and height of 8-12 m;
- Exploitation chambers with straight roof, width of 20m, height of 8-12 m and length of 20-300m.

Work procedure is the following:

- There is performed the main ventilation gallery (Cioclea et. al, 2015; Cioclea et al., 2014), of 6sqm, connected to the ventilation rising;
- Using the URAL-33 cutter (Fig. 5) is cut a channel in the floor, having 1.8m in depth.
- Workface is perforated using RADA-TELEMAC or SECOMA perforation installation (Fig. 6.);
- Perforated boreholes are loaded with explosive;
- Workface is blasted in two steps (240mp or 200mp);
- Workface is ventilated for 1 - 2 hours;
- Roof and walls of the chamber are lined of the freshly blasted slice using the HAULOTTE nacelle (Fig. 7) and the previous slices are verified;

Fig. 5. URAL-33 cutter

Fig. 6. SECOMA perforation installation

Fig. 7. HAULOTTE nacelle

Fig. 8. CASE front loader

- Resulting oversized rocks are broken with hammers or by blasting;
- Resulting salt is loaded using the front loader type STALOWA VOLA/ JCB/ CASE (Fig. 7) into 10t AUSA type dumpers (Fig. 8);

Fig. 8. AUSA dumper

Fig. 9. Rolling collector equipped with grill, mesh size 0.40 X 0.40 m

- Salt is transported to the rolling collector equipped with grill, mesh size 0,40 x 0,40m (Fig. 9.) through which it is discharged and transported to the surface;

For ensuring the continuity of the extraction process, the exploitation activity is performed concurrently in at least 3 exploitation chambers, in each one being performed a distinct work phase, according to the methodology described before.

Quantity of salt resulting from a cycle is:

20m x 12 m x 1.8 m x 2.16 (t/mc, spec. weight) = 933.12 tons

20m x 10 m x 1.8 m x 2.16 (t/mc, spec. weight) = 777.60 tons.

2.3. Small chambers and abandoned square pillars, with straight roof mining method

The exploitation method is in compliance with the framework project developed by MINESA - I.C.P.M. Cluj and has the following characteristics:

- Roof (pillar) of the salt deposit has a minimum of 30 m thickness;
- Floor pillar of the salt deposit has a minimum of 10 m thickness;
- Marginal pillars range depending in the exploitation depth, from 22m (for h=80-120 m) to 29m (for h=280-400m);
- Pillars (roofs) between horizons have a min. 8m thickness for a depth of 80-100m and 10m for 280m depth.
- Pillars between chambers are prisms with square base (10-18m), 8m height, the dimensions of the base increasing once with the exploitation depth
- Exploitation chambers have a straight roof, width of 12-16m, height of 8 m and length of 20-300m, depending on the size of the exploitation field;
- Work technology is the following:
- Using the cutter is performed a channel having 1.8m in depth into the floor;
- Workface is perforated (128m) with RIPAMONTI EX-180 perforation installation, mounted on a CATERPILLAR 312 C, executing a number of 185 of blasting holes (40mm diameter);
- Boreholes are loaded with explosive, which is initiated using electrical detonators with ms delay.
- Workface is blasted in single step;
- Workface is ventilated for 1-2 h for exhausting blasting gases;
- Roof and walls of the chamber are lined of the freshly blasted slice and the previous slices are verified;
- Resulting oversized rocks are broken with hammers;

Resulting salt is loaded using the front loader type LIEBHERR 541 into dumpers and is directly transported to the processing installation;

Quantity of salt resulting from a cycle is:

16m x 8 m x 1.8 m x 2.16 (t/mc, spec. weight) = 497.66 tons

2.4. Proposed mining method with small chambers and square pillars and shearer cutting

This mining method proposed to be applied is with small directional chambers and square pillars, with straight roof, with descending mining, cutting with the point-driven shearer (Pasulescu et al., 2015a, and Pasulescu et al., 2015b), loading into mining dumpers with the shearer, auto transportation to the surface.

Chambers and mined integrally from a single positioning of the shearer, into a 5m height and 8m width slice.

The main phases of salt extraction are:

- Performing the directional ventilation gallery (Suvar et al., 2014; Suvar et al., 2012) (approx. 1.6-2.0 km on w wing of the deposit) to the margin of the horizon's exploitation field, at the limit of the pillar and putting the ventilation under the mine's general depression;
- Performing the cross-sectional preparation gallery for the exploitation panel to the perimeter limit and putting it under the general depression;
- Cutting salt form opening and preparation works is performed using the point-driven shearer and it is loaded with the shearer in mining dumpers;
- After cutting and exhausting salt from the galleries and/or chambers, roofs are lined so that not to remain any unstable surfaces;
- All digging/cutting works shall be executed under the control of the deposit, the identification/determination of perimeter pillars limit.

Advantages of this mining method are the following:

- Easy performance of the mining exploitation structure, as well as easy leading and monitoring mining works;
- Early identification of solutions required by changes occurred within the deposit during the works;
- Ensuring the control and protection of the deposit, of the performed mining works;
- Easy control of the mine structure;
- Reducing to minimum the possibility of execution mistakes, knowing and respecting the coaxial character of the pillars from the chambers and the crossing of protection pillars;
- By removing blasting, disappear faults occurring within the salt massif.

The point-driven shearer has cutting ends rotating transversally. The cutting arm pivots horizontally over the workface. Once the cutting heads penetrate the workface, the cutting depth is set (Pasulescu et al., 2012; Pasulescu et al., 2014).

Before every horizontal cutting, the cutting head is set up for the cutting thickness, penetrating the front over an additional depth. The cutting depth and thickness are determined depending on the physical and mechanical characteristics of the salt.

Workface penetration is carried out by adjusting the arm or movement of the shearer, while the cutting arm pivots horizontally.

The loading mass, during cutting, has to be located on the floor in order to load the salt while the shearer advances. After the initial penetration of the workface, by the movement of the arm is cut a channel on the floor over the entire cutting length and the cutting thickness is set and the arm is pivoted horizontally.

This new salt mining method by cutting with the shearer is successfully used in a series of European mines, such as: Spain-Iberpotadh (potassium mine), Poland Polkowice-Sieroszewice, Bulgaria etc.

3. Conclusions

Currently, in Romania and used three underground salt mining methods, namely:

- Small chambers and square bunk pillars mining method;
- Small chambers and square pillars mining method;
- Small chambers and rectangular bunk pillars mining method.

Praid salt mine applies two mining methods, namely:

- Small chambers and square pillars mining method. This mining method is used in Telegdy sector.
- Small chambers and rectangular bunk pillars mining method. This method is used in the New Mine sector.

Using the shearer for mining salt is proper for deep mining, and would substantially improve the mining climate, also the physical productivity, and the biggest advantage would be the almost complete removal of the seismic effect in the pillars.

Besides underground salt mining, salt is also exploited using the humid method in Ocna Mures, Tg. Ocna, Cacica and Ocnele Mari.

Underground environment optimization using specialized programs

Morar Marius Simion ^{a*}, Cioclea Doru^a, Cioara Cristian Raul^a, Păsculescu Vlad Mihai ^a

National Institute for Research and Development in Mine Safety and Protection to Explosion, INSEMEX, 32-34 G-ral Vasile Milea street, Petroșani, 332047, Romania

Abstract

Worldwide consumption of raw materials is growing, this is due to the explosive growth of population, and the industrial development in certain regions of the world.

In the process of underground coal mining are utilized a complex network of vertical, horizontal and inclined mine workings with the purpose of extraction, transportation and evacuation to the surface. Associated system of mining works have the air network to ensure the oxygen necessary for workers, diluting explosive gases and/or toxic substances and preparations to evacuate heat and humidity from the underground.

For pumping air flows using special fans, with high capacity, located on the surface in the main ventilation station.

Ventilation mining is an extremely sensitive and complex that encompasses many disciplines in the service of achieving and maintaining security conditions underground.

In this regard solving ventilation networks using specialized programs, is a huge step forward that allows skilled practitioners to view real-time network changes and what is more important, can anticipate any disruptions in the ventilation system.

The fans operation depends on the network parameters aerodynamic ventilation and structures that main station ventilation. Knowledge of specific local network parameters leads to the optimization of air flow distribution.

Keywords: optimization, fans, management, ventilation networks, aerodynamic parameters;

1. Introduction

Ventilation mining is an area extremely sensitive and complex incorporating a multitude of disciplines, in this sense, solving ventilation networks using specialized programs is a huge step forward that allows to view real-time changes in the network.

The network of mining works necessary for exploitation of mineral substances useful presents a high degree of complexity, have different shapes and sections respectively, can attain lengths of tens of kilometers.

In order to obtain optimal conditions of work in the underground has to be ensured through primary protection ventilation. The work of mining ventilation aims to achieve three main objectives:

- Concentration of oxygen, the underground staff required;
- Diluting explosive gas and/or toxic in the network of mining works;
- Acquisition of heat exposure in the network of mining works, due to human activity and geothermal gradient.

For good ventilation at each job level mining is necessary optimized the distribution debits on each branch of the local network.

In this sense it is necessary to resolve network at a mine ventilation.

For this presentation was chosen the ventilation network of the Lonea mining unit and I'm used specialized program 3D Canvent.

The software has a graphical representation of the network ventilation and the quantities involved.

* Morar Marius. Tel.: +40-254-541-621; fax: +40-254-546-277.
E-mail address: marius.morar@insemex.ro.

2. Presentation and solving the ventilation network

The ventilation network of Lonea mining unit is very complex. The ventilation network comprises four routes of entry of fresh air, namely: skip shaft I, skip shaft II, Auxiliary mine shaft located inside and Valea Arsului Shaft located in the central north of the mine. Also have three main stations ventilation namely: the expansion rate of raises 840, Valley of raises ventilation shaft ventilation Valea Arsului and Jieț whilst also includes underground mine arranged across the eight horizons: 250; 300; 350; 400; 440; 460; 500 and 615.

These works consist of main transverse galleries, galleries directional diagonal galleries, galleries cross number, inclined planes, stopes and connecting rising.

The entire ventilation network comprises 339 junctions (nodes) and 424 branches.

For providing the best solution available for such a complex ventilation network, we have used the Hardy-Cross method for successive approximation. This method represents the grounds of expert software CANVENT designed in Canada. This software helped us to provide the solution for the ventilation network as well and optimization of the air flow distribution within the ventilation branches.

Solving the ventilation network related to Lonea mining unit made necessary to run several stages:

- Marking the junctions of the ventilation network on the spatial diagram;
- Determining the geodesic coordinates of the identified junctions;
- Inputting the geodesic coordinates of junctions and the existing branches into the database of the software (Fig 1);

3. Conclusions

The ventilation network given as example belongs to Lonea mining unit and includes 4 shafts, 3 ventilation raises, 8 levels and several underground workings (cross-sectional galleries, directional galleries, diagonal galleries, inclines, connection raises and working faces).

The optimization of the underground environment has been accomplished with the 3D Convent specialized software.

With 3D Convent, was found the best solution for solving the mining ventilation network.

We have been able to perform simulations on this software that involved certain changes which might come up in the ventilation network.

Giving solutions for the ventilation network with the help of specialized program allows the best possible solutions irrespective of its complexity.

Implementation of the 3D Convent specialized program afforded effective distribution of air flow rates in each branch and thus a better distribution of air in workplaces and reducing costs through effective distribution of circulated air.

The impact of the integrated technical system on the quality of construction works

Bușe Florian^{a*}, Bușe Gheorghe-Florin^a

^aUniversity of Petrosani, 20, University Street, Petrosani, 332006, Romania

Abstract

The integrated technical system consists in the development of a production technology on the path design – execution – testing – experimentation – homologation.

The constructions, as products of human activity, presents a series of characteristics such as: high capital requirements; influenced by a high number of variables, unpredictable due to its long lifetime; has to fulfill the needs of two-three generations which makes standardization difficult and extends the time of experience gathering needed to optimize the products; there are also craft works, despite the technology advancement, where the quality is given by the qualification and skill of the workers; it is difficult to appreciate an optimum ratio between the increase of execution costs for quality improvements and the reduction of the exploitation costs; no defects or scraps are allowed (especially related to stability, resistance, durability and exploitation safety).

An integrated construction system means construction design, works and assembly (material and parts supply, construction equipment, qualified workforce) at European level, according to an established schedule, starting from precise cost calculations which do not modify for the entire contract, etc. The construction integrated system uses an advanced technology and is a complete construction system which provides resistance, durability, excellent thermic isolation and sound protection. The result is a predictable and efficient product considering both the used resources and the implied costs.

The integrated technical system provides maximum efficiency of the maintenance costs on the entire lifetime of the construction, ensuring substantial cost saves regarding energy, repairs of design modification.

Keywords: integrated technical system, construction integrated technical system, construction works, construction quality, technical efficiency of construction equipment;

1. Introduction

An integrated technical system consists in creating a partnership network composed of organization systems from the domains of research, technology development and innovation, mechanical technologies in constructions, chemical technologies in constructions, mechanical systems execution in constructions, pneumatic-hydraulic systems execution, electronic and automatization systems execution for the development of a technologic line towards achieving a product with industrial applications in constructions.

The most quality characteristics are imprinted to the project in the design stage. These are less expensive and easy to modify or replace. In the design stage there can be reviewed certain ideas from the conception stage without significant additional expenses (Bușe, 2017).

Having the right materials and equipment at the quality levels suggested in the design stage removes the risk of getting a low quality product (Ilieș and Crișan, 2008).

The execution stage may contribute to keeping, improving or lowering the project quality. If we have a good design documentation, following all the prescriptions leads to a good project quality, while disrespecting these data leads to a lower quality project. A project with quality deficiencies may be improved if, during the execution, the inconsistencies which lead to this lower quality are traced, and there are suggested modifications of the design documentation which to improve the project quality. One of the most important stages for configuring the quality of a future project is the maintenance stage where we may follow the project operation and the implications of the possible quality deficiencies (Toma and Margarit, 2002).

* Buse Florian.
E-mail address: prof_buse@yahoo.com

All the deviations from the required quality of a project lead to additional costs, lower or higher depending on the stage when the deviations are solved (Zafiu and Gaidoş, 2001).

2. The integrated technical system in constructions

The integrated system in constructions represents the most advanced technology in construction systems, giving all the benefits required by a modern technology, design of the most advanced standards. Various design options, high level resistance and excellent capacity of energy loss isolation make from the integrated system in constructions an important technology for present and future constructions.

An important role in keeping the designer requirements and their retrieval in construction quality is given by the integrated or applied technical system (TS). It has to create the balance between the used resources and the performance of the construction, expressed by the methods of evaluating the results of the construction production process (CPP) (fig. 1): work and, consequently, construction quality, production expenses, work execution deadlines, environmental impact, security requirements fulfillment, work protection and safety.

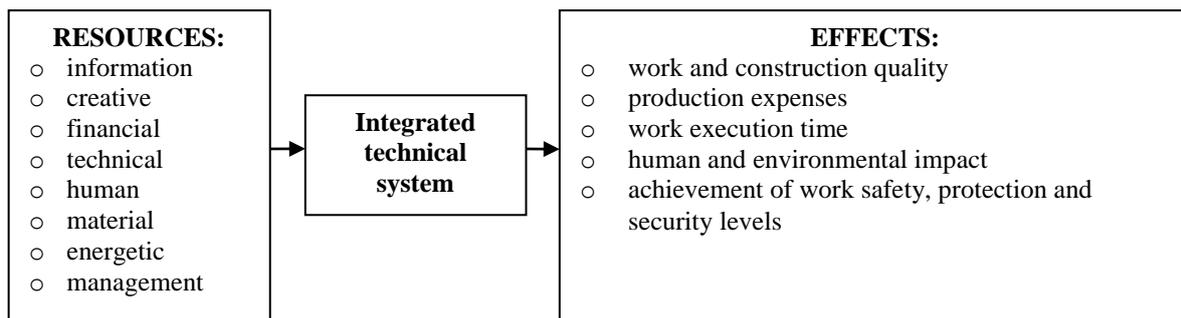

Fig. 1. Construction production process

The integrated TS is determined by the interdependences between the factors from every CPP component (fig. 2): technology and metrology equipments, materials and energy resources, human factors, technology procedures applied, environmental factors.

If we refer to construction quality, we may consider that it covers, due to the integrated TS, the quality of every factor. As it results from the diagram type cause-effect (fig. 3), named also Ishikawa diagram (fishbone diagram), neglecting the quality of any of these factors up to a certain degree will affect the quality of the construction (Zafiu, 2004).

Next we will analyze shortly the main factors of the TS: technologic equipment, materials, human factors and technology procedures.

The term "technologic equipment" usually refers to the technical endowment used for construction executions represented mostly by technical machines.

No construction activity can take place without the required technical equipment. There are some work categories where the technical processes and its results depend entirely on the capacity of the used equipments, such as concrete works, roads or railroads, etc. Therefore, the problem of the construction technical equipment becomes extremely complex, being connected to the applied procedures and having a large set of specific importance.

Therefore, we consider the requirements for performance level ensured by the technical equipment on two basic trends:

- The fidelity of ensuring the technical quality for the processed and used materials, respectively their capacity of executing specific works in their domain, at the quality level for construction technical requirements;
- The reliability and maintainability, operation safety, ergonomic qualities and environmental protection quality.

Each of the above aspects are found directly or indirectly in the quality of the construction.

It is obvious that the fidelity of ensuring the technical quality for the processed and used material is found directly in the quality of the construction. Especially since it is known that the technical equipment is involved directly in the two components of the construction production process (fig. 2): the processing of materials and construction components in industrial units specialized for production and using them in site works for construction execution.

The low reliability and maintainability influence the construction quality as a result of breaking the normal development of the technical process, which may lead to the impossibility of keeping under control the quality parameters of the work or to the work depreciation in time.

The lack of operation safety may lead to failures which don't affect only the development of the technical process by temporary breakdowns with negative effects on quality, but also lead to partial depreciations of the construction, which will have to be repaired.

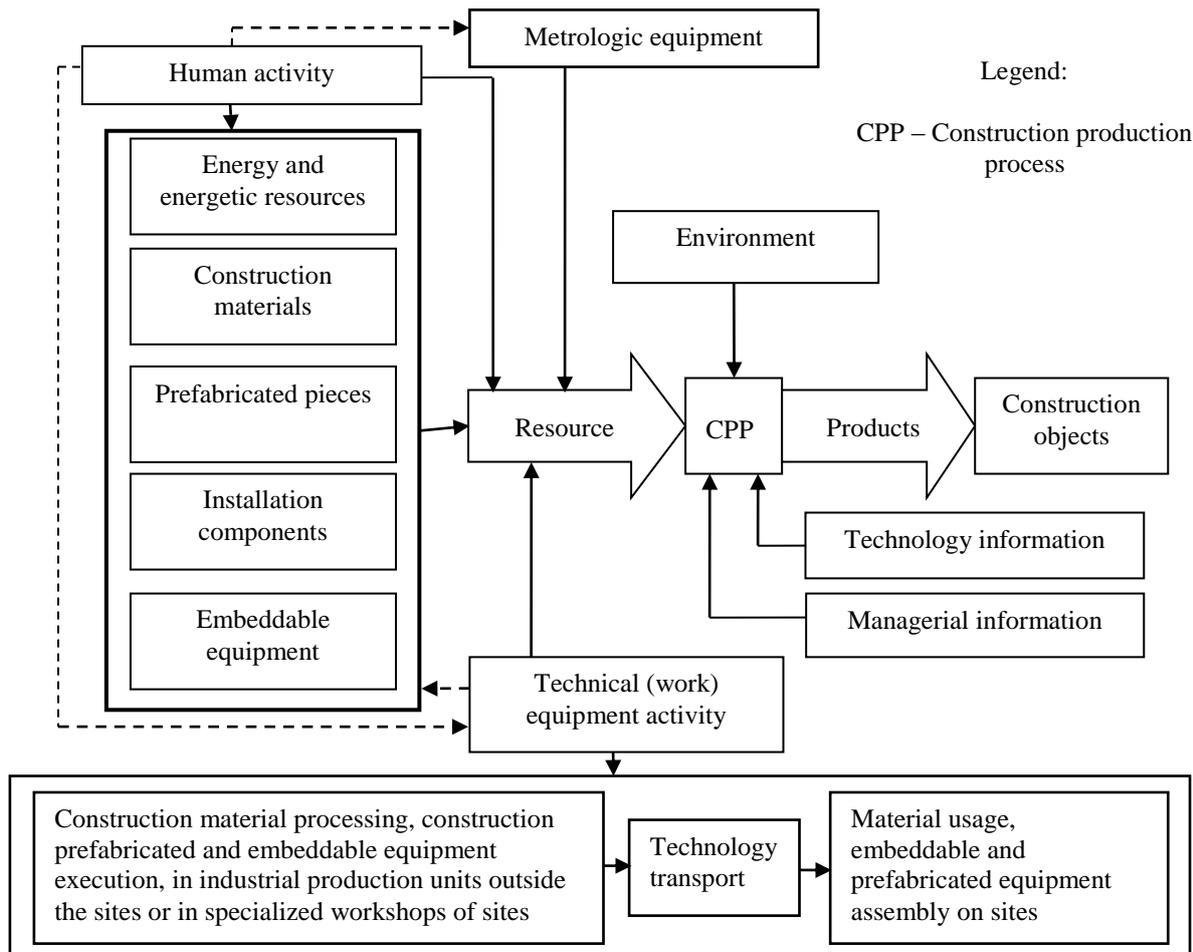

Fig. 2. System factors of every CPP component

This presumes that the technical equipment are permanently maintained, repaired and modernized in order to match the requirements and guarantee the operation safety at nominal parameters.

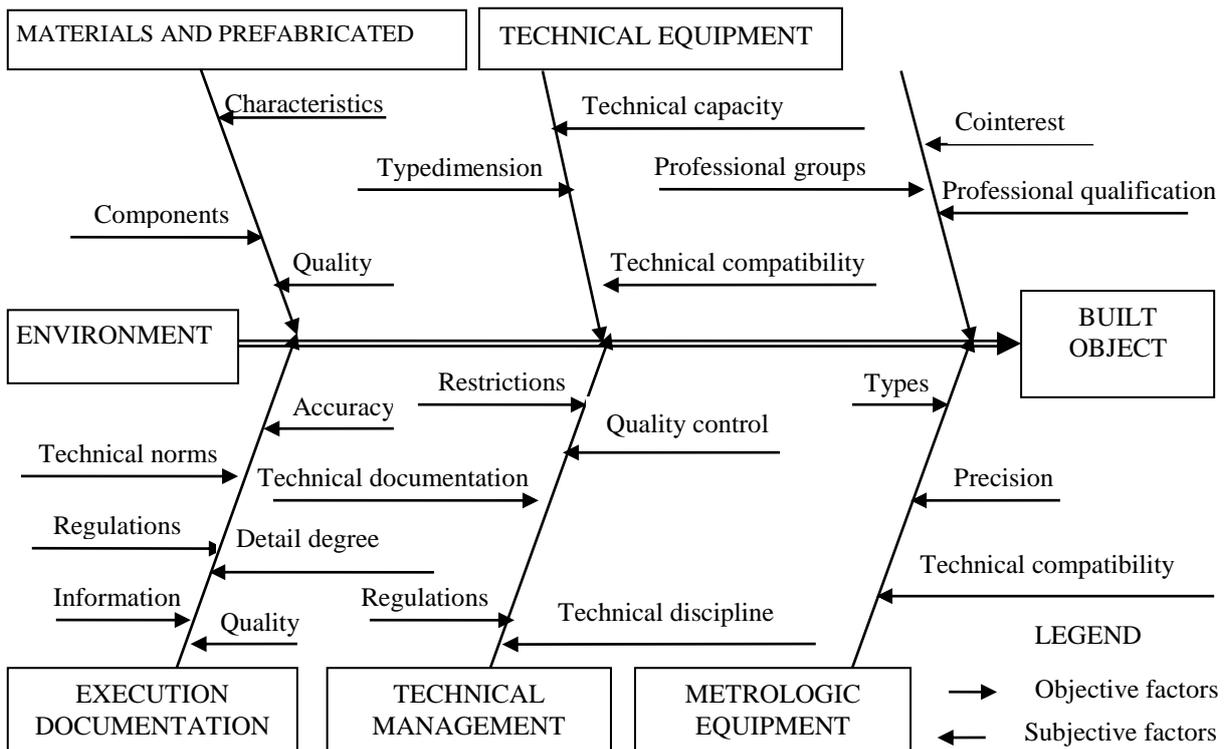

Fig. 3. Cause-effect type diagram

Ergonomic and environmental protection features act indirectly through the human factor, subject of stressing requests with negative effect on the quality of the technical process development and, consequently, on the quality of the construction.

The practical implementation of these requirements is done through a series of actions which consists in the work on the technical documentation and specific regulations:

- the instructions of putting into operation of the equipment, taking into account their complexity, working regime, work nature and other specific factors;
- the instructions for protection, grinding and operation, and also for adjusting to normal parameters;
- the greasing schemes and the maintenance and repairing instructions for technical equipment;
- the procedures for equipment disposal by retrieving and reusing the components;
- the technology for repairing, refurbishing and reusing the used parts
- the technology for reusing other materials resulted from dismemberment.

These issues are part of the terotechnics and terotechnology domain.

3. The use of terotechnics and terotechnology in constructions

Terotechnics is the multidisciplinary science which deals with the complex of actions done to ensure the operation at nominal parameters and in safe conditions of the technical equipments, passing through the entire cycle from conception to recycling (fig. 4).

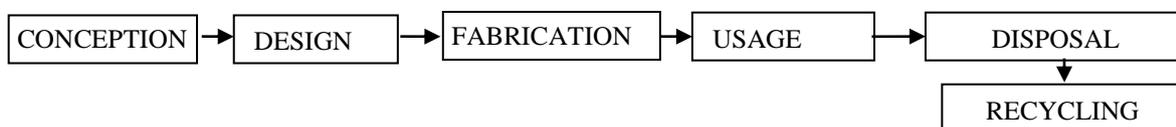

Fig. 4. Technical equipment cycle

Terotechnics deals with the specific matters known as: reliability, maintainability, tribotechnics, ecology and environment, mechanic-energetic design and ergonomomy.

Terotechnology deals with applying the organization variants for maintenance, repairing and upgrading the technical equipment and takes into consideration their selection criteria, for reducing the stationary times and intervention costs, by technology preparation in advance and ensuring new or refurbished spare parts (Zafiu, 2005).

Specific regulations are needed furthermore, for getting the desired quality in construction through technical equipment, both regarding its implication in work and by ensuring the normal operation and exploitation conditions on site. The specialists in the field of construction technical equipment agree that their technical certification is the activity which confirms the technical capacity of the equipments to perform quality works and to fulfill the safety requirements, so the work can be done in safe conditions and the technical processes at the required quality level. Surely, the concepts of performance and quality cannot exist without the basic requirements from the regulated domain regarding work security, safety and protection for men, but also in the domain of environmental protection, for construction works where technical equipment has a decisive role (Antohe, 2004).

Therefore, we support the need to further develop some authorized organizations, who can perform the generic activity of "technical certification".

The control activity for technical certification of technical equipments in construction takes place according to the regulations in the construction quality field, on three main directions which ensure their operation: user security and protection control, environmental security and protection control, work quality capacity control.

The certification of the technical capacity of construction equipment is done by:

- the conformity certification for new equipment without CE mark;
- technical inspection for the equipment kept in operation after passing the standard lifetime or for second-hand acquisitions.

Current concept improvements of the technical equipment structure lead to constructive solutions which allowed the use of board computers and automatic regulation systems of functional parameters, such as:

- the implementation of sensors, to give information on environment and equipment condition;
- the use of information processing and interpretation resources;
- the introduction of artificial intelligence in equipment lead systems.

This was occasioned by the generalization of hydrostatic actions and was concretized by:

- automatic regulation of work parameters of hydrostatic pumps depending on the work equipment opposition, in order to keep the motor moment constant;
- automatic commanding through the board computer of the work technical parameters, not depending on the machine position;
- the association of some measurement and control devices (MCD) with construction installations, both for the continuous regulation of some work parameters and for the automatic control of work quality;
- the assurance of preventive maintenance through integrated, operational systems which to evaluate continuously the technical condition of the machine.

Taking into consideration the CPP characteristics, the design of technical equipment has to keep in mind, beside the negative effects of the operation environment, a series of constructive particularities:

- the high degree of mobility on site;
- the difficulties in providing the command execution precision;
- the intense interaction between the equipment and environment, to help locating the work areas, etc.;
- the need of superior specialization of operation through intense training;
- the conceiving of the man-machine interference, depending on site specifics;
- the distinction of particularities depending on the work conditions: temperature, dust, humidity, rain, wind, shocks, vibrations.

Therefore, there are three main factors in order to ensure the technical conditions for equipment use:

- the workforce quality – the more advanced are the equipment the more skilled has to be the mechanics, both for operation and for maintenance;
- the processed materials quality – the technical compatibility between the equipment and the processed material properties;
- the work conditions – keeping minimal work conditions for processes, according to the requirements from the equipment use technical instructions.

4. The role of technical project in construction execution

The technical project (THP) aims to create the technical-economic documentation for construction execution which will basically solve the following issues (Zafiu et al, 2004):

- the analysis of the technical process and finding mechanization alternatives;
- the selection of the mechanized alternative for the construction-assembly works (C+A), based on the technical-economic indicators and pointing out the backup alternatives;
- the choice / design of the auxiliary devices used;
- the elaboration of technologic plans for work mechanization and the technologic files on basic activities and complex processes;
- the schedule of mechanized execution of construction works considering the resources needed and their technologic usage, but also the schedule optimization in order to fit the technical-economic parameters of the works;
- the elaboration of the requirements regarding work safety, work and environmental protection.

THP will be done in order to give the technical information needed for the general coordination of construction works through project management, quality management and safety, work and environmental protection management.

THP is the main documentation source for the elaboration of procedures from the quality manuals, but also for the other documents needed to implement the construction quality system.

The execution details (ED) are part of the technical project (TP) and represents the documentation given by the designers, needed to clarify constructive details so the construction to fulfill all the parameters according to the project, legislation and construction certification.

Through THP the objective and the nearby constructions can be traced, during work execution. THP has to follow all the TP requirements and the ED regarding the work quality control and, if necessary, to extend by introducing additional controls.

In order to guarantee a safe, quality construction, the THP has to provide activities regarding the work execution surveillance and technical quality control, during the execution process.

THP provides the norms to be followed in work execution, having in mind the following requirements: personnel safety, location safety, execution procedure safety, technical equipment operation safety.

THP will give technical solutions and will make recommendations in order to reduce, during the construction works, the effects on the environment caused by: noise, terrain vibrations, air pollution, surface water pollution, underground water pollution, ground pollution.

In order to supervise the construction process and the execution quality, there will be established:

- the validity of design hypothesis;
- the identification of the differences between real terrain conditions and design conditions;
- the detailed planning of actions in order to establish if the construction works are done according to the THP and to the technical regulations in the field.

The level and quality of the surveillance and monitoring has to be at least the ones in the project, according to the safety parameters and coefficients.

There will be identified the elements which were the base for the project development and were influenced by the surveillance and monitoring activities.

The inspection, control and field and lab tests requested by the technical process surveillance and by monitoring the construction behavior during works must be established together with the THP development, which should include a „Program for the quality insurance of the execution”.

The THP development should consider the aspects from the technical certifications, issued by certification organizations, given to certain technical equipment, materials and procedures, which fulfill the norms of certification procedures. The THP is written by the constructor, depending on his technical endowment and the workforce needed. The following aspects are taken into consideration: the ease of work execution, fitting the scheduled costs, respecting the execution schedule, respecting the imposed quality norms. The specialized technical personnel who takes place to THP development should be certified by professional authorities (Ceașu, 1992). Respecting the technical documentation for execution should be stated clearly in the THP.

5. Conclusions

The construction quality should have a complex scientific approach, since the implications of low quality are bigger compared to other products.

The construction quality is not only a problem of the constructor, it is a national problem and lately European or worldwide problem. Therefore, the E.U. assigned the European Committee for Standardization to establish norms which to acknowledge the organizations and labs which certify quality in all member states.

The total quality management system targets all the aspects of company activity and states quality as strategic element.

The total quality management strategy is materialized in the integrated effort at all company levels in order to increase the client satisfaction through continuous practical improvements.

The paper presents the quality importance for constructions, the causes of lower quality, the quality cycle and the quality system in construction. At the end there are described the information sources, the methods and technics used in quality planning, insurance and control for construction works.

Efficiency of industrial ventilation installations

Rădoi Florin^{a*}, Gherghe Ion^a, Chiuzan Emeric^a, Matei Adrian^a, Drăgoescu Răzvan^a

^aNational Institute for Research and Development in Mine Safety and Protection to Explosion, INSEMEX, 32-34 G-ral Vasile Milea street, Petroșani, 332047, Romania

Abstract

Effective and efficient air distribution is an important aspect of industrial ventilation.

When the air flows through a ventilation column, the pressure required to push or draw air through it, depends not only on the internal frictional force but also on the dimensions, length and shape of the pipe, the roughness of its walls, the nature of the obstructions inside, speed and air density.

The air movement introduced into ventilated rooms can be controlled and conducted as direction and sense of movement. In rooms, overpressure or under pressure may be created as necessary.

Designing and building an individual ventilation system, should harmonize comfort requirements with the user's ventilation system management, without adversely affecting other system functions.

Keywords: ventilation, optimization, efficiency;

1. Introduction

The quality of the environment in which the staff perform their activity has a complex influence on them, both in terms of microclimate conditions and in labour productivity.

For many categories of premises, where significant disasters occur (production rooms, laboratories, etc.), the quality of the environment cannot be guaranteed only by the heating system. In order to remove toxic odours, there is a need for a "controlled" introduction of airflow. The nature and amount of harmful emissions, their mode of propagation, the building system of the enclosures, the values at which indoor air parameters are prescribed for comfort or technological reasons, the admissible limits to which the concentrations of various harmful substances must be reduced, have led to the use of a wide range of industrial ventilation facilities.

Industrial ventilation systems have a great diversity in terms of composition, (Doru C., et al., 2013) equipment fitting, component type, size of installations according to the volume of air flow rates, thermal (heating or cooling) power and generated pressures, as well as the way of air exchange in rooms, the temperature, pressure and humidity levels achieved in the rooms.

The type of building to which an industrial ventilation plant is intended is given its specific imprint on the installation, in particular through the solution adopted, the technical design (appearance, route, leakage, parameter assurance, noise level, automation, operation and maintenance etc.).

Automatic regulation installations for industrial ventilation facilities ensure that the indoor air parameters (temperature, relative humidity, air speed, CO₂ concentration) are preserved at any time of the year. Automatic adjustment is required for economic reasons, but also because manual adjustment of various parameters is not possible. Automation installations regulate the heat flow (hot / hot water, chilled water, steam) that feeds the heat exchangers of the air handling units (heating batteries, cooling batteries) or the airflow rate of the installation (fresh air, air recirculated, exhaust air).

2. Applicable ventilation systems

The adopted ventilation system must take account of the technological process, (Rădoi F., et al., 2016) density of sources, and propagation of harmful agents and the intensity of harmful agent's release.

* Radoi Florin. Tel.: +40-254-541-621; fax: +40-254-546-277.
E-mail address: florin.radoi@insemex.ro.

Systematic natural ventilation – in case of heated workshops without a release of noxious vapours, gases or dust with high heat releases and less releases of moisture, mainly applied in the form of mixed ventilation or along with other systems.

General exchange mechanical ventilation – applied when it occurs a release of harmful substances and the systematic natural ventilation is insufficient.

Local exhaust ventilation – used in order to improve working conditions in certain areas adjacent to sources of heat, strong radiant sources or to prevent entry of cold air through exterior doors.

Local air intake ventilation - when there are concentrated sources of harmful releases and general ventilation is insufficient even in large volumes of air.

Local absorption and exhaust ventilation - for example in industrial ablutions.

Emergency ventilation - automatically turns on in case of large accidental releases of harmful substances occurrence as a result of technological equipment failures.

Industrial air-conditioning- is required by the manufacturing processes, the need for precise conditions, in case of high precision processing, testing, and calibration.

3. Optimization of industrial ventilation installations

The problem of industrial ventilation has risen due to the serious pollution problems of both the industrial areas (and their surrounding areas) and the industrial premises. It is obvious that before addressing an industrial ventilation study, the question is whether there is no simpler means of suppressing the causes of pollution or of reducing pollution by modifying the production process or the design of the industrial plant. It is preferable to treat the causes that lead to pollution and thus to eliminate it even from the design, and only when this is not perfectly possible, it is necessary to limit the effects of the pollution.

In order to be able to choose the correct ventilation system, (Alexandru Cristea, 1971) a complete analysis of the workplace to be ventilated must be carried out, so that the solution chosen to not only fix the problem of the exhaust, but also to be well received by the user, respecting the thermal comfort of it.

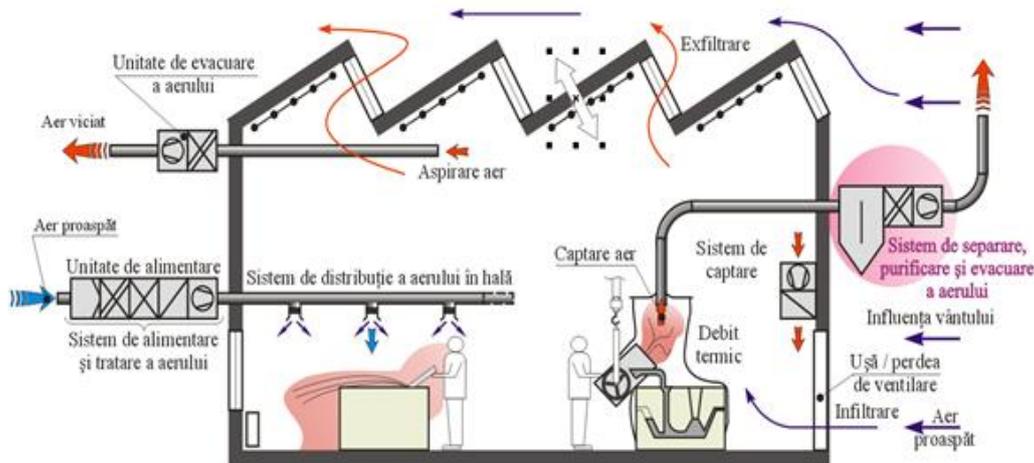

Fig. 1. Schematic diagram of an industrial enclosure

Thus, in an industrial area, the comfort of the workplace is influenced by the following factors:

- the presence of an air stream;
- an acceptable temperature gradient;
- soil temperature (too low or too high);
- the existence of an asymmetric radiant heat field, due to the presence of cold windows, heat sources only by one part of the operator's body or relative humidity level.

Choosing an industrial ventilation solution can be done by completing the following sequence of steps:

- clear definition of the building and its working stations, (Matei, I., et al., 2000) the type of industrial process being carried out, the personnel employed, the environmental restrictions, the temperature and the conditions for keeping the building in good condition;
- determination and classification of sources of pollution, their physical and chemical characteristics;
- the choice of the technical solution for capture and ventilation, considering: the possible evolutions of the industrial process and the changes that these developments can bring with regard to the ventilation system and the possible incompatibilities between different pollutants (e.g. dust and humidity, acids and bases, etc.) that require their separation;
- determination of parameters (air velocity, flow, heating) and calculation of the installation (determination of losses, load, diameter, installed power, etc.), choice of circuit elements (air inlets, required piping, fans, automatic, etc.), the physical location of the component parts, commissioning, reference values, maintenance;

- the ventilation scheme adopted must ensure that the air moves in the sense of harmful propagation;
- the collection and disposal of harmful substances at the site where they occur (use of local absorption plants in the case of concentrated poisons or the provision of emergency facilities in case of accidental leakage of toxic substances), in order to avoid their spread;
- introducing fresh air as close as possible to people's work area, respectively the ventilation system ensures uniformity of air parameters throughout the room in order to avoid clutter of harmful substances;
- use of overpressure or depression to limit the spread of noxious substances in or from other rooms or to avoid cold air drafts.

The selection and sizing of air intake and outlet holes, (Olga Bancea, 2009) is very important to ensure comfort conditions or working conditions and production processes and has two stages:

- ensure a good air circulation in the room so that air can be treated at all points, there are no areas where the air stagnates, no overheating air, air movement will not lead to the spread of noises, etc. The movement of air in a room takes place depending on the location of the inlet and outlet holes. Movement of air must be done at the same time, in the same way as the natural movement of the particulates (gases, vapours, dust) released. For heavier particles than air, evacuation will take place in the lower part of the room, for lighter particles at the top.
- the actual choice of the types of air inlet and outlet pipes is made considering the type of building (civil, industrial), the aesthetics of the room, the location of the machinery and the machinery. Depending on the amount of air flow calculated, the size of the room (length, width and especially height), type of air jet (isotherm, hot / cold non-isotherm), a number of air ducts of a certain type are chosen; or of two constructive types. Based on the chosen constructive type and the geometric dimensions (the distance between two adjacent holes, the height of the mouth from the floor), the kinematic (jet air velocity at the work area / stay, the air velocity in the plane of the discharge mouth) / cold, temperature difference between room air and jet) and jet type (with the influence of the ceiling, without the influence of the ceiling), based on the diagrams or calculation programs of the manufacturing companies, determine the size of the discharge opening type. The choice of drain holes is simpler because the suction speed damping is inversely proportional to the square of the speed and the influence of the movement in the suction plane is no longer felt at distances greater than $2De$. (De is the equivalent diameter of the suction mouth). The suction holes can have airflows, as a rule, up to 2000 m^3 . Their dimensioning is also based on the room noise level. For social-cultural buildings, the air velocity in the plane of the suction mouth is $v = 2-3 \text{ m/s}$. For industrial buildings, usually the speed is $v = 3-5 \text{ m/s}$.

The local suction installations with the air velocity generate a limitation of the spread of the hazards, while at the same time ensuring the minimum openings necessary for the development of the technological processes. The devices used must ensure that the release is as complete as possible, do not obstruct the production process and allow the worker to be in a normal position so as not to be between the source of the harmfulness and the aspiration opening. These installations are made up of the capture device, air duct and fan. Devices for the capture of harmful substances in the immediate vicinity of the harmful outbursts may be: open, semi-closed or closed.

Fume cupboards are local aspiration devices located above, sideways or under sources. (Niculescu, N., et al., 1982). *Figure 2* shows the main types of hoods.

- The classic fume cupboard (*Figure 2a*) depending on the source of the source of the hazards, can be made with a square, circular or rectangular suction section. Its edges must exceed the perimeter source with $(0,3 \div 0,4) y$, where y represents the distance from the source. In order to smooth out the speed in the suction section, the opening angle of the cupboard $\alpha \leq 60^\circ$ and at the bottom a levelling band with the width $(0,1 \div 0,2) y$ can be mounted at the bottom;
- The fume cupboard placed near the wall or above the furnace door (*Figure 2b*) limits the draft air suction and is not influenced by the direction of air movement in the enclosure;
- The compartment fume cupboard (*Figure 2c*) is used for sources of long-range hazards, each compartment being provided with individual evacuation;
- The central and peripheral suction fume cupboard (*Figure 2d, e*) is used for working benches with different sizes and the surface of the source is variable;
- Folding fume cupboard (*Figure 2f*) allows to change the distance from the source and manipulate the parts and materials with transport devices (tread beams) by rotating the capture device 90° ;
- The telescopic fume cupboard (*Figure 2g*) allows, depending on the required technological operations, a change in the distance from the suction plane;
- Accumulator fume cupboard (*Figure 2h*) used for accidental leakage of high-rate hazards, allowing for momentary capture and evacuation.

The air captured at the workplace must be evacuated to the outside and, if necessary, cleaned according to the regulations in force. The drainage is done using the tubing. Methods for calculating the duct and the ventilator are based on the determination of the air flow resistance in the ducts and the definition of the ventilator operating conditions (flow, pressure, etc.). In general, piping dimensioning results as a compromise between economic restrictions (investment, operation - operation), standardized diameters, load losses, minimum transport speeds, the presence of corrosive pollutants, etc. The air velocity in the piping should be chosen for each installation, depending on the nature and properties of the pollutants. Transport speed is an essential factor for dust-containing exhaust systems, it must be above a minimum level to avoid dusting and time-blocking of the piping. It is even greater as the mass of particles is higher.

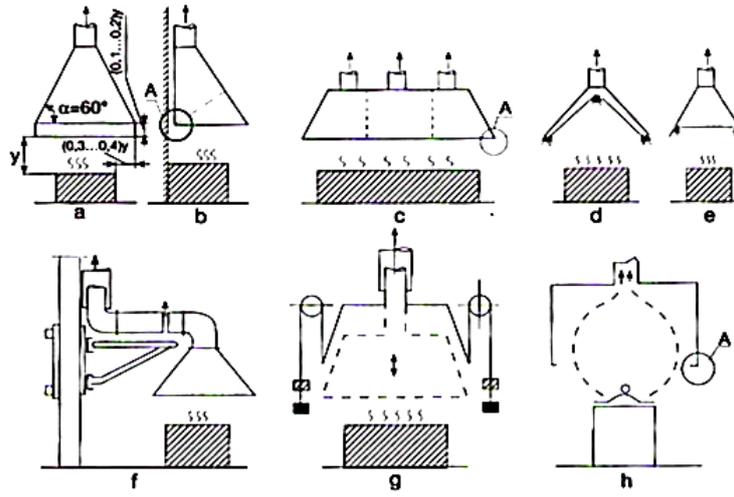

Fig. 2. Types of hoods

4. Conclusions

1. Industrial ventilation systems aim to ensure the conditions of air purity and microclimate corresponding to human activity and the nature of the technological process. The fulfilment of these requirements contributes to the maintenance of the work capacity, the elimination of the professional illnesses, the increase of labour productivity, the quality of the products, etc.
2. When designing the local suction devices, the following factors shall be considered in order to determine their type, shape and dimensions: the shape and location of the machinery; nature and manner of deployment of technological processes; nature, quantity and mode of generation of harmful substances; the dimensions and constructional shape of the production rooms.
3. The main sizes involved in defining ventilation and air conditioning systems are: air pressure, air speed, temperature and humidity.

Abstract

Explosions produced in urban areas are less likely to occur, but when they occur, they may pose a particular risk to buildings and occupants. When the charge is detonated in the immediate vicinity of major structural elements, major local failures can occur, which in turn can expand and generate generalized collapse (also called progressive collapse). Progressive collapse, which in many cases causes more casualties than the shock wave or the fragmentation effect (explosive charge or detachment from building elements), can be prevented by various measures that aim at reducing exposure, for example by increasing the distance security and vulnerability reduction by using systems with high redundancy and continuity between elements. The ability of a structure to withstand extreme actions without being affected at a disproportionately high level with the causal action is called robustness and is also required by the design rules in force (eg EN 1991-1-7, 2006). Awareness of these risks requires appropriate measures in the design and execution of building strength structures. Explosion calculation is, however, a difficult task (compared to other types of calculation), both in terms of evaluating the action (eg the maximum value of the resulting pressure or its variation on an element or structure) and the effects on the material or element, for example the effect of load speed on mechanical properties of steel or explosion-structure interaction.

Keywords: metal structures, explosive effect, measurements;

1. Introduction

Blasting charger can affect any type of structures depending the used. Explosives by the positioning of the charge and the type of the charge and specific structural characteristics of the targeted building. Over their lifespan, the buildings may be subjected to a variety of actions. Design and execution of buildings should take into account that some of these actions may reach extreme values, much higher than those currently used at initial design. Therefore, the buildings must be able to resist such events without being damaged disproportionately compared to the original cause. In such situations, the structure can be severely damaged, leading to partial or complete failure, e.g. the Ronan Point building, in London, in 1968. Explosions caused by gas accumulations have great significance, given the large number of residential buildings (and other types of spaces) where it is currently used. Hazards can be caused both by external distribution networks and the devices that use the gas inside. For example, in the United States, the average probability of producing a gas explosion is about 1.8×10^{-5} / year (NISTIR 7396, 2007). Studies conducted in the UK showed similar values of the order 2.3×10^{-5} / year to 1.86×10^{-5} / year. In other countries, e.g. Romania, there are no public data about such events, and this makes it difficult to assess the risk of such events based on the number of dwellings. The second important issue is the maximum pressure in the rooms affected by the explosion. Studies conducted after the accident in the Ronan Point building showed that these pressures rarely exceed the value of 17 kPa. Even if this value is much higher than "ordinary" loads, it is less than the amount recommended in EN 1991-1-7 (Mainstone RJ, 1974), namely 34 kPa. The pressure resulting from gas explosions is therefore very high compared to permanent or live loads (occupancy, wind, snow), which rarely exceed 4-5 kPa. The presence of voids limits first pulse intensity and pressure fluctuations of the second phase presents a reduced significance for the structural response. Unlike internal gas explosions, external explosions are usually produced from intentional causes, the source being both classic explosives (TNT, C-4, Semtex) but also improvised charges, like those based on ammonium nitrates, a chemical fertilizer widely

E-mail address: attila.kovacs@insemex.ro.

used in agriculture. Because of the intentional nature, these events cannot be modelled using a Poisson distribution model, which is widely used to model the random occurrence of rare events (NISTIR 7396, 2007). Explosions caused by explosives, known as detonations, create shock waves that propagate at high speeds from the point of detonation. In terms of the effects on the structure, distance between the source of the explosion and structure plays a very important role. When the explosive charge is placed at greater distance from the structure, failure usually occurs due to excessive bending. The pressure released by the shock wave can be considered as uniformly distributed on the surface of the element. An explosion at a very short distance from the building causes a localized failure, like punching or shear failure. This is caused by the rigidity of the structural element, which produces inertial resistance to blast. Punching or shear-type failure occurs before structural element is able to respond by bending. The study presented in the paper investigated the response of beam-column steel elements subjected to close-in blasts. The research focused on the evaluation of typical steel frames response when subjected to direct effects of a blast and the direct calculation of blast loads for further numerical simulations. Two 3D frame specimens were tested inside a bunker using different charge weights, located at different distances. A numerical model was also validated using the advanced nonlinear dynamic analysis software Extreme Loading for Structures (US Departments of the Army, Navy and Airforce, 1990). The study is part of a research program devoted to the design of structures to sustain extreme loading events without collapse (Karlos V, Solomos G., 2013).

2. Blasting design and blasting scenarios

2.1 Description of specimens

Two 3D specimens were designed and constructed for testing under blast effects inside a bunker. Specimens were extracted from a typical moment resisting steel frame structure, see high-lighted areas in Fig.1.a. Due to space limitation in the bunker, the specimens were scaled down from 8.0 m span to 3.0 m span. First specimen (see Fig.1.a, Fig. 2.a) includes a column (blast induces deformations in the major axis direction), two half-span longitudinal beams rigidly connected to the flanges of the column using extended end plate bolted connections and one half-span transversal beam, connected to the column web using a simple clip angle connection.

The specimens were placed in a reinforced steel-country bunker fixed in every fire connection possibility.

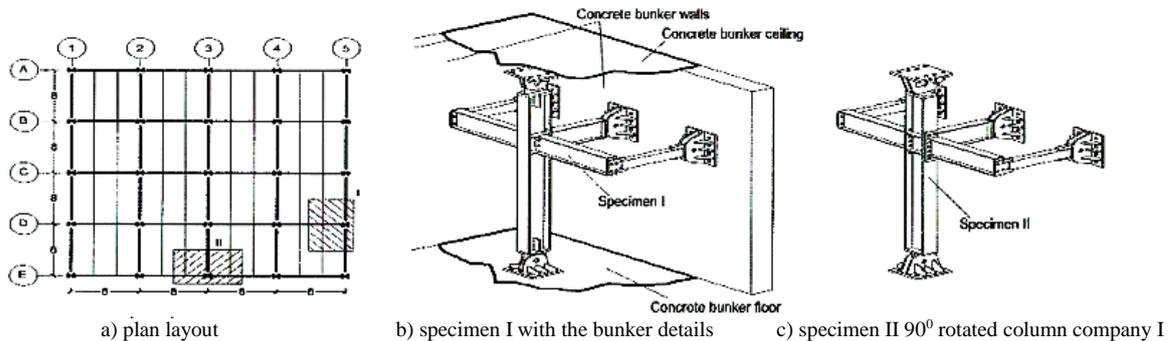

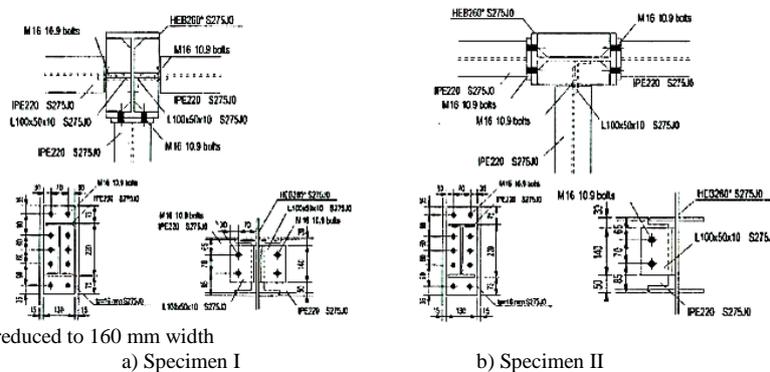

Fig. 1. Plan layout of the reference multi-story building with the position of the specimens extracted for testing and 3D views of specimens

* flange of HEB260 column reduced to 160 mm width

Fig. 2. Details of the specimen's designs

Second specimen (see Fig. 1.b, Fig. 2.b) includes a column (blast induces deformations in the minor axis direction), two half-span longitudinal beams connected to the column web using simple clip angle connections and one half-span transversal beam, connected to the column flange using extended end plate bolted connections. For both specimens, lateral restraints made from tubular profiles were used at the ends of longitudinal beams.

Steel material in plates and profiles was S275J0 and bolts were grade 10.9. Table 1 summarizes the measured material properties of the specimens.

Table 1: Average characteristic values for materials in steel profiles, plates and bolts

Element	f_y (N/mm ²)	A_{gt} (%)
	yield strength	Total elongation at maximum stress
Beam flange IPE220, $t = 9.2$ mm	345	28.0
Beam web IPE220, $t = 5.9$ mm	353	30.4
Column web HEB 260, $t = 10$ mm	407	27.0
Column flange HEB 260, $t = 17.5$ mm	420	27.0
End plate, $t = 16$ mm	305	17.1
Bolt, M16 class 10.9	965*	12.0

Note: * 0.2% offset yield point

2.2. Blast effects

The main hazard components of an explosion are blast (overpressure), fragmentation, and thermal effect. In our study, only first issue has been of interest. As seen in Fig. 1.b, the peak pressure value depends very much on the distance of the detonation point from the structure of interest. Thus, the peak pressure value, and also the velocity of the blast wave, decrease rapidly by increasing the distance between the blast source and the target surface. The effect of distance on the blast characteristics can be taken into account by the introduction of scaling laws (Hopkinson B., 1915). These laws have the ability to scale parameters, which were defined through experiments, in order to be used for varying values of distance and charge energy release (Richards AB, Moore AJ., 2005). The experimental results are, in this way, generalized to include cases that are different from the initial experimental setup. The most common blast scaling law is the one introduced by Hopkinson (Tagel-Din H, Meguro K, 2000) and Crazn (Kaneko H., 1997). According to Hopkinson-Crazn law, a dimensional scaled distance is introduced as described by Eq. (1):

$$Z=R/(W^{1/3}) \tag{1}$$

where: Z is the scaled distance, in $m/kg^{1/3}$, R is the distance from the detonation source to the point of interest [m] and W is the weight of the explosive [kg TNT or equivalent TNT].

As the scaled distance reduces, the peak overpressure increases. For example, in case of Murrah Federal Building in Oklahoma City, which collapsed in 1995 as a result of a blast produced by a large truck bomb (1814 kg equivalent TNT), located at a distance R of 1.5 m, the scaled distance was $Z= 0.12 m/kg^{1/3}$, which resulted in a very large peak overpressure, estimated at 20 000 de kPa. The scaling law from Eq. (1) should be corrected when blast test is done inside a bunker. A more general expression to evaluate the peak pressure (or peak overpressure) and the variation with the distance (Eq. (2)), is the one proposed by Richards and Moore (Dinu F., Mărginean I. Sigauan A., Kovacs A., Ghiciei E., Vasilescu D, 2016):

$$P = Ax(R/w)^b \tag{2}$$

where: P is the peak overpressure (kPa), A is the site constant (evaluated experimentally), a is site exponent (evaluated experimentally, is always negative), b is the site exponent for the charge weight (evaluated experimentally), R is the distance from the detonation source to the point of interest [m] and W is the weight of the explosive [kg TNT or equivalent TNT]. Using experimental calibration tests, Eq. (2) can be used in case of bunker tests. In the study, calibration blast tests were performed first, in order to evaluate the site exponents A , b and a . Then, the specimens were subjected to blast of increasing intensities, obtained by increasing the charge weight and/or reducing the distance from the blast to the specimen.

3. On-field experiments on specimens

Fig. 3 shows the first specimen tested in the bunker. In order to evaluate the site exponents A , b and a , and then the pressure inside the bunker, two Kistler pressure sensors were mounted on a special frame, at 4-meter distance from the specimen, in front of the bunker venting. Explosive material used in the testing has a TNT equivalence of 1. To note that the effects of gravity loads on the columns and beams were not considered in the test.

First four blasts used charges $m_{1,1} = 125$ g, $m_{1,2} = 250$ g, $m_{1,3} = 500$ g and $m_{1,4} = 1000$ g, located at 0.27 m from the beams mid-length, freely suspended (see Fig. 3). Last blast used a charge weight $m_{1,5} = 1000$ g, located at the external face of the column, at mid-height, see Fig.3. The pressure measured after each explosion were $p_{1,max} = 20$ kPa, $p_{2,max} = 40$ kPa, $p_{3,max}=80$ kPa and $p_{4,max}= 175$ kPa. The peak pressure during last explosion attained the maximum value, $p_{5,max} = 1400$ kPa.

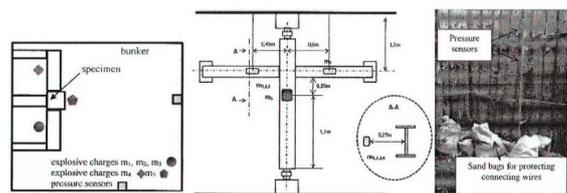

Fig. 3. Plan design and test set-up for specimen 1

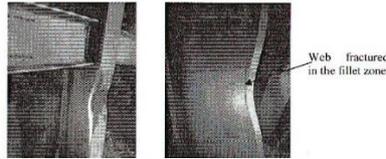

Fig. 4. Specimen 1 after blasting

While for first four explosions there were no visible deformations at the level of the specimen, the last charge, ms, caused severe local deformations of the column near the source, and the web complete fractured at the contact with the flange, in the fillet zone, for a length of 300 mm.

For calibration of experimental set-up, a charge with weight $m = 125$ g was detonated at a distance $d = 0.27$ m from the position of the pressure sensors. The value of the peak pressure was $p_{calibration} = 1400$ kPa. With the values of the pressure measured during each detonation, the following specific coefficients of the bunker were determined: $A = 3850$, $a = -0.73$, $b = 3.87/3 = 1.29$. The peak pressure value of the blast wave, decrease rapidly with the distance between the blast source and the target surface, as seen in Fig. 5. Apart from the pressure measurements, also the permanent deflection of the specimen was measured in several points.

Second specimen was tested for three charges. First charge had a weight $m_{1,2} = 500$ g, located at distance $D_1 = 0.5$ m from the specimen and $H = 1.0$ m height from the base of the column. No visible effects were recorded, nor in the beams or in the column. The test continued with detonation of a charge of $m_{2,2} = 1815$ g, located at the same distance and height ($D_2 = 0.5$ m, $H = 1.0$ m). Web of the column has been deformed plastically out of plane for approximately 22 mm, but without any visible cracks (Fig. 6.a). The third detonation was produced by a charge blast of $m_{2,3} = 1815$ g, located at same height but closer distance, $D_3 = 0.20$ m. The web of the column has been completely removed within a length of almost 600 mm around the point of detonation, see Fig. 6.b.

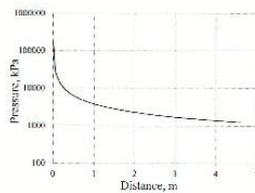

Fig. 5. Peak pressure vs. DISTANCE between the blast source and target surface

a) Damages consist in plastic deformations in column web after blast $m_{2,2}$

b) complete brake of the web after blast $m_{2,3}$

Fig. 6. Result of the free positioned charge after blasting

To note that, because the effects of gravity loads were not considered in the test, the column did not failed. However, in real conditions, the gravity loads are always present in the structure, and therefore such damage would be similar to a complete loss of bearing capacity (removal of the column). The permanent deflections of the specimen were measured in several points after the test and were used for numerical model validation.

4. Results interpretation

The performance of the steel specimens undergoing close range detonations was also predicted using ELS (CODEC, 2012) (see Fig. 7). ELS utilizes a nonlinear solver based on the applied element method (Dinu F., Mărginean I. Sigauan A., Kovacs A., Ghicioi E., Vasilescu D, 2016) which is a derivative of the finite element method and the discrete element method. In ELS, the structure is modeled as an assembly of small elements, which are assumed to be connected by one normal and two shear springs located at contact points distributed around the element edges. The average normal strain is calculated by taking the average of the absolute values of strains on each face. When the average strain value at the element face reaches the separation strain, all springs at this face are removed and elements are not connected any

more (until they collide). Columns, beams, and plates were modeled as solid elements and could undergo deformations at the interface between the discretized elements. The constraints, made of tubular sections, were also modeled as solid elements. The bolts were modeled using individual springs: one for normal stresses and two for shear stresses. The column bases and transversal beam end connection to the bunker wall were considered pinned, and all displacements were prevented.

The shaded areas presented in Fig. 7 (left) indicate the surface of the elements loaded with the blast pressure.

Due to the dynamic, impulsive character of the blast load, strain rates effects in the material are very important. The rate dependency has been considered by means of the following relationships (Dinu F., Mărginean I. Sigauan A., Kovacs A., Ghicioi E., Vasilescu D, 2016):

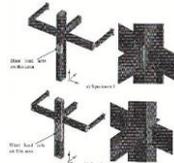

Fig. 7. Numerical models of specimens

Fig. 8 and Fig. 9 display the deformed shape of the specimens and the displacement history (along Y axis). Comparisons between numerical and experimental results show a very good agreement. The permanent deflection of the columns is very close to the measurements done after the test. Also, the extension of damage in the columns are very similar, with the same location and extension of fracture lines.

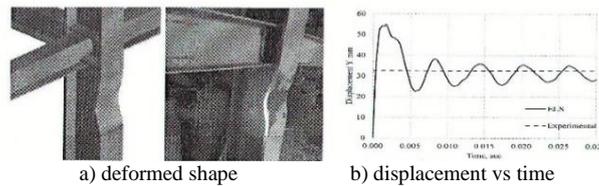

Fig. 8. Specimen I, comparison between free eyes examination and measurement

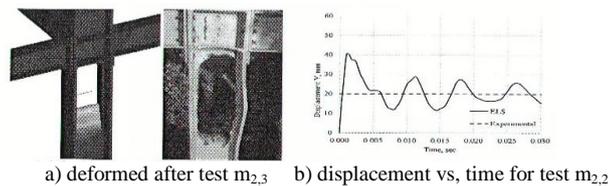

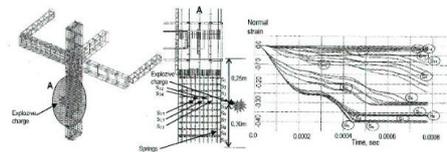

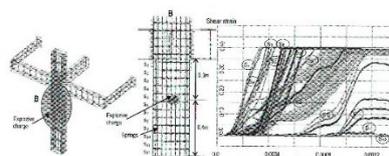

Fig.9. Specimen II, comparison between free eyes examination and measurement

The blast load pressure and therefore the blast effects decrease very rapidly with the distance from the explosive charge. For close-in detonations, the effects can concentrate in the area of the element adjacent to the explosive charge, while the effects on the remaining structure can be neglected. Thus, Fig. 10 .a and Fig. 10 .b show the shear strains in springs located in the fillet zone of the column web, within a length of 50 cm for specimen I and 60 cm for specimen II, respectively, measured from the bottom side of the beams. It can be seen that, even for small charges (maximum weight 1815g equivalent TNT), the local damages are extreme, but localized to the area close to the point of detonation.

a) specimen I behavior

b). specimen II behaviour

Fig. 10. Evolution of stain in the columns restarted

5. Conclusions

The study presented in the paper focused on the evaluation of close-in blast effects against steel frame structures. Two specimens were tested for charges of different weights and located at different distances to the specimens. The specimens were extracted from a six-story moment resisting frame structure, designed to meet the seismic design requirements for special moment frames. The variation of blast pressure with time and distance has been evaluated for bunker test conditions. The results showed that charges located at close distance can produce large damages in the members, with complete fracture of the section walls. Thus, for the specimen loaded against the strong axis (charge normal to the column flange), the blast caused sever local bending of the external flange, and fracture of the web at the contact with the flange, in the fillet zone. In case of specimen loaded against the weak axis (charge normal to of 600 mm, before structural element to be able to respond in bending. The later situation can be extremely dangerous, especially for buildings with perimeter steel moment resisting frames and interior gravity frames, if the loads cannot be distributed to the adjacent structural members. In the test, the complete failure of the column was prevented only due to the absence of any gravity loads. Numerical models that were calibrated using test data indicated a very good agreement, giving the possibility to extend the research to full scale structures, using different blast loading conditions. This project was continued in a larger scale on the basis of these results, meanly to expose se complex structure with much more elements (essentially using the same type of steel specimens). This structure was changed with extra weight to reproduce the real situation and to have information on the response of individual elements and the structure to blasting demotion.

Abstract

Anthropic activities involve the extraction of the transformation and use of natural resources.

During the process of extraction at the surface or underground of useful minerals, particles or gases resulting from the natural rocking or release from the rock mass appear in the working environment.

The process of transforming useful mineral substances is carried out on the surface in enclosed enclosures, involving the use of complex technological processes. During the course of these technological processes, explosive or toxic gases, dusts, mists, dusts or dusts may be released or may enter into the atmosphere.

To protect workers from underground mining works, the particles or gases produced during the extraction process are discharged into the atmosphere. Noxes of industrial nature in enclosed spaces are discharged into the atmosphere for similar reasons of worker safety.

In addition, other types of anthropogenic activities are being carried out to remove pollutants into the atmosphere. The first measure to ensure optimal microclimate conditions in enclosed spaces to protect workers is to provide good ventilation.

Pollutant substances found in the atmosphere can migrate over long distances reaching industrial dwellings or enclosures with fresh air introduced naturally or mechanically through ventilation systems. As a result of the exposure of short or long-term workers to toxic or explosive hazardous substances, workers may suffer from acute poisoning or occupational disease. When workers are surprised, the case of fires or explosions generated by flammable or explosive substances, the morbidity is extremely high.

This paper aims to analyze explosive environments interacting with industrial ventilation systems.

Keywords: environment, security, systems, ventilation;

1. Introduction

A discovery emerged in 1891 when Le Chatelier discovered the law to determine the limits of explosivity.

The lower explosive limit LIE (LEL) is the lowest concentration of gas or vapor in the air capable of generating the explosion in the presence of an efficient ignition source. This is considered to be the same with the lower limit of flammability LII (LFL). At a lower air concentration than LIE (LIE), the gas mixture is too weak to burn or produce the explosion even if the source of initiation is present.

The upper explosion limit LSE (UEL) is the highest concentration of gas or vapor in the air capable of generating the explosion in the presence of an efficient ignition source. This is considered to be similar to the upper limit of flammability LSI (UFL). At a higher air concentration than LSI (UEL), the gas mixture is too concentrated to burn or produce the explosion even if the source of initiation is present.

Le Chatelier's law was used by Coward and Jones in 1952 in his famous work on the explosive triangle.

In 1965 Zabetakis determines and publishes technical data on flammability limits, auto-ignition temperatures and combustion rate for 200 combustible gaseous substances.

In 1975, Hertzberg tried to establish in depth the theory of flammability but at an academic level, hard to use by practitioners. Later, this area was thoroughly deepened, and new laws emerging governing the phenomenon of flammability / explosiveness and factors influencing it.

E-mail address: adrian.matei@insemex.ro.

2. Flammability / Explosiveness of explosive substances

2.1. Le Chatelier Principle

Le Chatelier found that the lower and upper explosion limit of the air-methane mixture may change if other explosive gases are present. In this case, the lower LIE limit of explosive of the resulting mixture is calculated as follows: installed ventilation conditioning;

$$LIE = \frac{100}{\frac{C_1}{L_{i_1}} + \frac{C_2}{L_{i_2}} + \dots + \frac{C_n}{L_{i_n}}} \quad [\%] \quad (1)$$

where:

C1 Cn - the percentage concentrations of each explosive gas in the mixture;

Li 1 Li n - the lower explosive limits of each explosive gas in the mixture.

The upper LSE explosion limit of the resulting mixture is calculated as follows:

$$LSE = \frac{100}{\frac{C_1}{L_{s_1}} + \frac{C_2}{L_{s_2}} + \dots + \frac{C_n}{L_{s_n}}} \quad [\%] \quad (2)$$

where:

C1 Cn - the percentage concentrations of each explosive gas in the mixture;

Ls 1 Ls n - the upper explosive limits of each explosive gas in the mixture.

Lower and upper explosion limits define the explosive range within a straight segment comprised of 0% fuel gas and 100% air and 100% fuel gas and 0% air, fig. 1.

Fig. 1. Explosive range

2.2. Explosive chart Coward -Jones

In his work "Limits of flammability of gases and vapors" published in 1952 under the aegis of the Bureau of Mines, H. F. Coward and G. W. Jones, they first presented the form of explosive triangle. Coward-Jones's explosive triangle was a 2D representation of the explosive atmospheres consisting of simple methane and air.

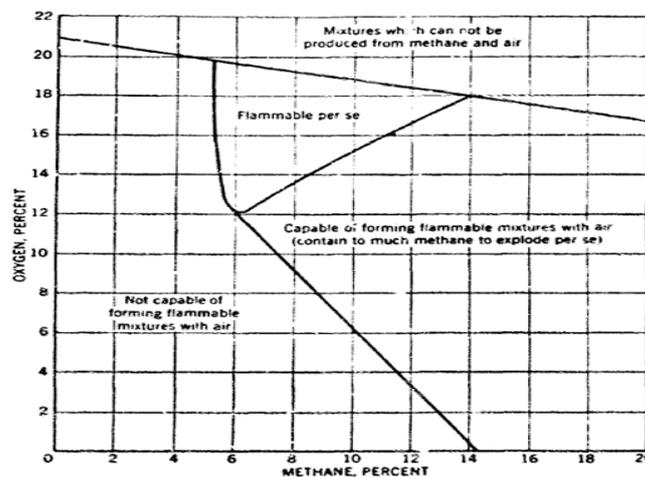

Fig. 2. Explosive Triangle - Coward - Jones

3. Analysis of factors influencing explosive environments

3.1. Energy dependence

Le Chatelier and Boudouard note that in this phenomenon the combustion heat on the volume unit at the limit of the air to alkenes mixture is approximately a constant at the lower limit of flammability / explosivity. Burgess and Wheeler showed that the heat released by one mole of blend at the lower limit is almost constant for many fuel-to-air mixtures at normal temperature and pressure. So they came to the following addition:

$$x_L \cdot \Delta H_C = K \quad (3)$$

where :

x_L is the percentage of combustion at the lower limit of the mixture,

ΔH_C is the combustion heat of the fuel which is approximately 10,5 kCal/mol,

K is the constant that for Burgess and Wheeler has $K = 1059$ for methane, Spakowski sets $K = 1040$, Hanley proposes $K = 1120$ while Ramiro proposes $K = 1042$.

White and Zabetakis later proposed a correction as follows:

$$x_L \cdot \Delta H_C + \Delta H = K \quad (4)$$

where:

ΔH is the fraction of energy absorbed by ambient air.

3.2. Temperature dependence

White has shown experimentally that the lower and upper limits are influenced by temperature. Rowley estimated temperature dependence as follows:

$$x_L \cdot \Delta H_C + \Delta H = 100 \cdot c_p \cdot T \quad (5)$$

where:

c_p is the specific heat at constant air volume.

Later, the temperature difference was expressed relative to the relationship as follows:

$$\frac{x_L(T)}{x_L(T_0)} = 1 - \frac{c_{p,gaz-aer-amestec}}{x_L(T_0) \cdot (-\Delta H_C)} \cdot (T - T_0) \quad (6)$$

Zabetakis simplified the dependence on a constant one as follows:

$$\frac{x_L}{x_{L,0}} = 1 - \frac{0,75}{x_{L,0} \cdot \Delta H_C} \cdot (T - T_0) = 1 - 0,000721 \cdot (T - T_0) \quad (7)$$

Britton and Frurip have established linear temperature dependence as follow:

$$\frac{x_L(T)}{x_L(T_0)} = \frac{T_{AFT} - T}{T_{AFT} - T_0} = 1 - \frac{T - T_0}{T_{AFT} - T_0} \quad (8)$$

3.3. Dependence on chemical composition

Jones was the first to note that at any specified temperature, the ratio at the lower limit, the amount required for the stoichiometric reaction, is approximately constant. He proposed a series of fuel cell constant.

Some values are shown in Table 1.

Table 1.

Nr. crt	Substance	Jones's constant
1	Methane	0,52
2	Ethane	0,57
3	Propane	0,59
4	Methyl Chloride	0,67
5	Ethyl Chloride	0,61
6	Propyl Chloride	0,61

Lloyd generalizes Jones' law by obtaining an expression of the form:

$$x_L = 0,55 \cdot x_{st} = 0,55 / (1 + 4,773 \cdot C_o)$$

$$x_U = 3,5 \cdot x_{st}$$

Zabetakis proposes a relationship based on the square root thus:

$$x_U = 6,5 \cdot \sqrt{x_L} + 4,8 \cdot \sqrt{x_{st}}$$

3.4. Dependence on the fuel substance

When more gases are involved, Le Chatelier's law is the only tool to make a prediction of the flammability of the mixture. Le Chatelier issued the following law: "If we have more gases each with explosive limit concentrations, then if we homogenize them we will get a mixture of combustible gases with the concentration limit at the explosive limit"

This law can be written as:

$$\frac{x_1}{x_{L,1}} + \frac{x_2}{x_{L,2}} = 1 \tag{9}$$

Mashuga identified the hypotheses resulting from Le Chatelier's law, and are further exposed:

1. the calorific capacities produced are constant;
2. the number of moles of gas is constant;
3. the pure gas combustion kinetics is independent and unchanged the presence of other combustible gases;
4. The increase of the adiabatic temperature to the limit of flammability is the same for all gases.

3.5. Pressure dependence

An increase in pressure has a low effect on the lower limit, although the upper limit can be enlarged; however, the magnitude of the reaction to the flame front is impaired. Based on experimental data on natural gas (85-95% methane and 15-5% ethane) by Jones, Zabetakis, suggested that the limits vary linearly with the initial pressure logarithm. This is

$$x_L = 4,9 - 0,71 \log P \text{ (atm)}$$

$$x_U = 14,1 - 20,4 \log P \text{ (atm)}$$

Fig. 3. shows the variation in flammability under overpressure conditions.

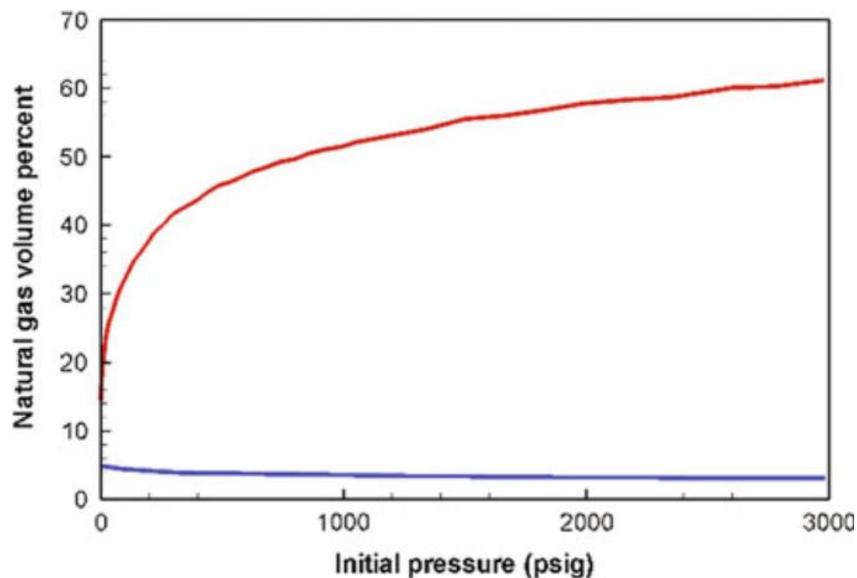

Fig.3. Flammability curve – overpressure

Fig. 4. shows the variation of flammability under low pressure conditions under atmospheric pressure after Lewis and Von Elbe.

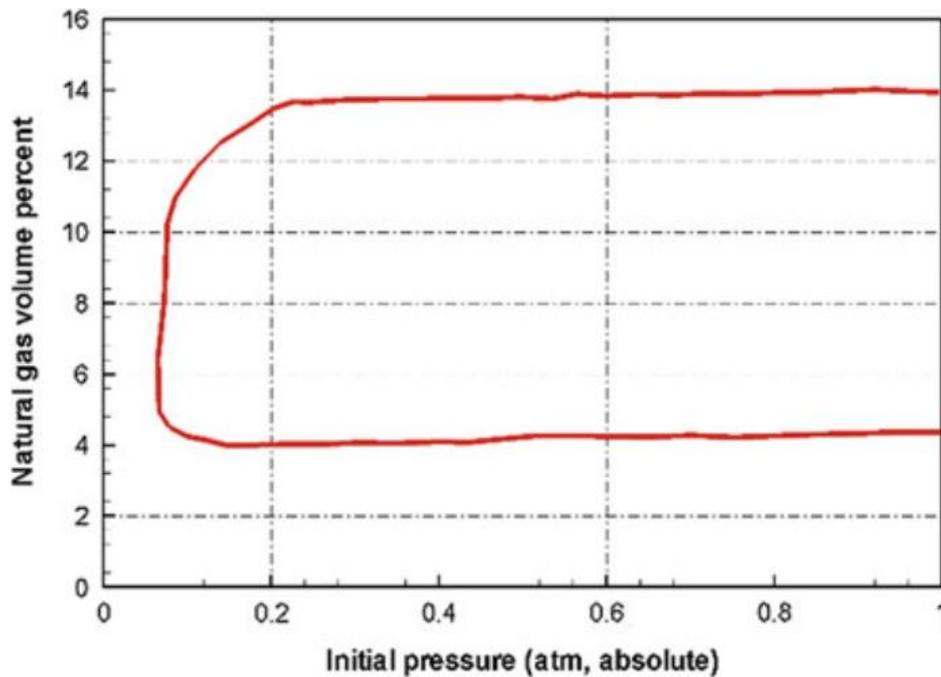

Fig. 4. Flammability curve - Lewis and Von Elbe

Currently, professional methods in the field of flammable atmospheres consisting of gas mixtures and dilution gases are given in ISO 10156/2010, which contains test methods and methods for determining the flammability of gas mixtures.

The calculation methods use the flammability limits and the Tci coefficient for flammable gases and vapours.

Tci values are given for pressures under atmospheric pressure with air as an oxidant, also referred to as the maximum permitted MXC concentration.

In contrast, the coefficients of equivalence in nitrogen (K) for gas mixtures are calculated with the relation:

$$K_{i,j} = \frac{MX \cdot C_{i,j} \left(\frac{100}{T_{ci}} - 1 \right)}{(100 - MX \cdot C_{i,j})} \tag{10}$$

Table 2 gives the coefficients in equivalent nitrogen.

Table 2.

Gaz	N ₂	CO ₂	He	Ar	Ne	Kr	Xe	SO ₂	SF ₆	CF ₄
K _i	1	1,5	0,5	0,5	0,5	0,5	0,5	1,5	1,5	1,5

Table 3 shows the Tci values for common flammable gases.

Table 3.

Gaz	H ₂	CO	Metan	Etan	Butan	Etilena	Propan	Propena	Acetilena	n-Hexan
T _{ci}	5,7	20	8,7	7,6	5,7	6	6	6,5	4	3,5

4. Conclusions

Explosion is the particular case of combustion at the level of explosive mixtures of combustible gases and / or combustible vapors and / or combustible dusts with air where the oxidation reactions occur rapidly and violently with heat, light, and light generation high pressures.

Technical data on the flammability / explosiveness of combustible substances, their properties, the main factors of influence are presented.

Lower and upper explosion limits define the range of explosive that is within a straight segment between 0% fuel gas and 100% air and 100% fuel gas and 0% air.

Factors influencing the explosive nature of combustible substances are generated by dependence on: energy, temperature, chemical composition, fuel substance and pressure.

Abstract

The first measure for ensuring optimal occupational health and safety conditions in underground minerals exploitation is the achievement of proper ventilation (Teodorescu C., et al, 1980). For ensuring proper ventilation of each mine working, there is imposed the optimization of air flow repartition in each branch of the network, fact which involves the mine's entire ventilation network solving (Hargreaves D.M., et al, 2007). In hard coal exploitation, opening, preparation and exploitation works undergo a nonlinear continuously and differentiated process of specific aerodynamic parameters degradation. Following the changes in time of aerodynamic parameters of mine workings, specific ventilation parameters also change, leading to the ventilation network's deviation from the aerodynamic point of view, compared to the standard situation (Patterson A. M., 1992). The ventilation network's deviation is directly proportional to costs required for air circulation and inversely proportional to the efficiency of the ventilation network's aeration. In order to assess the efficiency of ventilation networks (Băbuț, G.B., and Moraru, R.I., 2018), a new parameter has been introduced, namely the ventilation network's standard deviation. In this paper is presented the theoretical basis and the determination of the standard deviation applied for Lupeni mine unit ventilation network.

Keywords: efficiency, modelling, software, solving, ventilation, ventilation networks;

1. Lupeni Mine Unit Ventilation Network

Lupeni mine unit is equipped with two main ventilation stations: Shaft 1 East and Central Rising.

Underground mine workings are ventilated under the depression of the Main ventilation station Central Rising, fitted with two axial fans type VOKD 1.8.

Underground mine workings which are ventilated under the depression of the Main ventilation station Shaft 1 East is equipped with two axial fans type VOD 3.0.

Fresh air entrance in underground is performed through 5 mine workings: Stefan shaft, shaft no. 12, shaft with skip, coast gallery horizon 650 and auxiliary shaft south.

Central Rising and Shaft 1 East circuits are extended over 5 horizons: horizon 300, horizon 360, horizon 400, horizon 480, horizon 650.

2. Lupeni Mine Unit Ventilation Network Solving

For solving the ventilation network of Lupeni mine unit was used VENTSIM Visual Advanced software, designed and developed in Australia.

A number of 386 junctions and 481 branches have been inserted into the software's database. Figure 1 presents the 3D spatial ventilation network of Lupeni mine unit.

After the ventilation network's solving (Cioclea D, et al, 2012; Cioclea D, et al, 2014; Gherghe I., 2004), the following results have been obtained:

Air flow at the level of the longwall with undermined coal bed no. 1, seam 3, block II, sublevel II was 3.2 m³/s; Air flow at the level of the longwall with undermined coal bed no. 1, seam 3, block II, sublevel III was 3.2 m³/s; Air flow at the level of the longwall with undermined coal bed no. 11, seam 3, block V, was 4.0 m³/s; Air flow at the level of the

longwall no. 3, seam 3, block V, was 3.7 m³/s; Air flow at the level of the longwall no. 2C, seam 3, block V, was 6.6 m³/s; Air flow at mine level was 83.7 m³/s; Air flow at the level of the main ventilation stations was 85.4 m³/s.

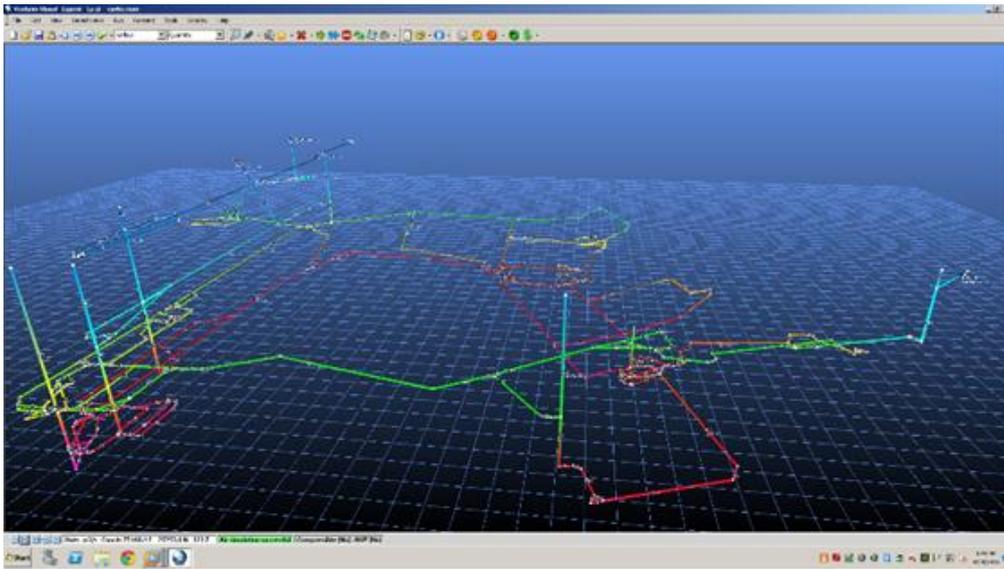

Fig. 1. Lupeni mine unit ventilation network in 3D system

3. Methods for Determining the Ventilation's Efficiency

For the classification of ventilation networks in terms of efficiency (Cheng J., et al, 2010; Cheng J., et al, 2011) are used several methods, namely: Equivalent orifice method, Ratios method, Temperament method.

3.1. Equivalent Orifice Method

The equivalent orifice of a mine is a ventilation parameters using which there may be characterized the ventilation capacity and it represents a fictional orifice A, performed into a thin wall, through which at a pressure difference on the two sides of the wall equal with the mines depression "h", will be circulated the same amount of air Q as the one circulated through the mine.

3.2. Ratios Method

This method is characterized by the efficiency of the mine's general ventilation and takes into account the size of ratios:

$$\frac{Q_{sc}}{Q_{ef}} \text{ and } \frac{h_{ef}}{h_t} \tag{1}$$

in which:

- Q_{sc} - air flow short-circuited in underground, m³/s;
- Q_{ef} - air flow which ventilates the work fronts, m³/s;
- h_{ef} - depression of the mine, determined by measurements, N/m²;
- h_t - theoretical depression of the mine, determined by calculation, N/m².

3.3. Temperament Method

In order to classify the manner in which a mine working's ventilation is achieved is used the T temperament term. Temperament represents the easiness with which the fluid passes the mine working.

4. Standard Deviation

Underground hard coal exploitation involves the performance of a complex of opening, preparation and exploitation workings in order to extract and transport the useful minerals to the surface. Once with the increase of the mine workings usage, their aerodynamic parameters negatively change, having severe consequences from the point of view of air flowing on their alignment. The degradation in time of aerodynamic parameters of mine workings leads to the

change of the ventilation network's aerodynamic parameters. The change of aerodynamic parameters of mine workings in relation with the initial value represents the ventilation network's deviation (Cioclea D., 2015).

4.1. Standard Deviation of a Ventilation Network

The standard deviation of a ventilation network is defined as the change in time of aerodynamic parameters specific for a ventilation network in relation with the aerodynamic parameters specific for the same ventilation network in standard conditions.

For determining a parameters which is applicable for any ventilation network, regardless of its' structure and complexity, there has been used the term of ventilation network in standard conditions.

The ventilation network in standard conditions represents the structure of a ventilation network evolving at a certain time, which is characterized by the fact that all active mine workings have associated the aerodynamic parameters specific for the moment of entrance into exploitation.

Aerodynamic parameters specific for the entrance into exploitation of a mine working and the ones established through the technical project. Aerodynamic parameters specific for a mine working at a certain time during exploitation air determined through flow and pressure measurements performed on site.

4.2. Establishing the Standard Deviation of a Ventilation Network

For assessing the ventilations efficiency at a certain moment is used the A_s parameter which represents its' standard deviation. The standard deviation of a ventilation network is defined by the ratio between the equivalent orifice of the ventilation network at a certain moment A and the equivalent orifice of the ventilation network in standard conditions A_0 :

$$A_s = \frac{A}{A_0} \cdot 100 \quad (2)$$

in which:

A - equivalent orifice of the ventilation network at a certain moment (m^2);

A_0 - equivalent orifice of the ventilation network in standard conditions (m^2).

Equivalent orifice of the ventilation network at a certain moment A is determined using the approximate Eq. 3:

$$A \cong \frac{1,2}{\sqrt{R}} \quad (m^2) \quad (3)$$

Equivalent orifice in normal conditions may be calculated using the exact Eq. 4 (i.e. for two ventilation stations):

$$A = 1.2 \sqrt{\frac{Q_m^3}{Q_{s1} h_{s1} + Q_{s2} h_{s2}}} \quad (m^2) \quad (4)$$

Equivalent orifice of the ventilation network in standard conditions A_0 is determined using the approximate Eq. 5:

$$A_0 \cong \frac{1,2}{\sqrt{R_0}} \quad (m^2) \quad (5)$$

Equivalent orifice of the ventilation network in standard conditions (i.e. for two ventilation stations) may be also calculated using the exact Eq. 6:

$$A_0 = 1.2 \sqrt{\frac{Q_{0m}^3}{Q_{s01} h_{s01} + Q_{s02} h_{s02}}} \quad (m^2) \quad (6)$$

In these conditions, the standard deviation of the ventilation network A_s is:

$$A_s = \sqrt{\frac{R_0}{R}} \cdot 100 \quad ; \quad A_s = \sqrt{\frac{Q_m^3 (Q_{s01} h_{s01} + Q_{s02} h_{s02})}{Q_{0m}^3 (Q_{s1} h_{s1} + Q_{s2} h_{s2})}} \times 100 \quad (7)$$

4.3. Characterization of Ventilation Networks Depending on the Standard Deviation

The standard deviation of a ventilation network is a non-dimensional parameter which establishes the level of deviation from standard conditions.

In order to characterize ventilation networks in relation with the standard deviation is required the establishment of periods defining concrete states specific for the ventilation network.

Therefore, ventilation network may be split into three categories:

- a) Ventilation network with optimal standard deviation characterized by $A_s > \frac{2}{A_0} \cdot 100$
- b) Ventilation network with acceptable standard deviation characterized by $A_s = \frac{1}{A_0} \cdot 100 \div \frac{2}{A_0} \cdot 100$
- c) Ventilation network with unacceptable standard deviation characterized by $A_s = 0 \div \frac{1}{A_0} \cdot 100$

If the ventilation network is assessed from the standard deviation point of view in different categories, then is chosen the assessment which takes into account the exactly calculated equivalent orifice.

5. Lupeni Ventilation Network Solving in Standard Conditions

For solving Lupeni ventilation network in standard conditions was used the database of VENTSIM Visual Advanced (User Guide, 2014) for solving the ventilation network in normal conditions. Figure 2 presents the 3D ventilation network of Lupeni mine unit solved for standard conditions.

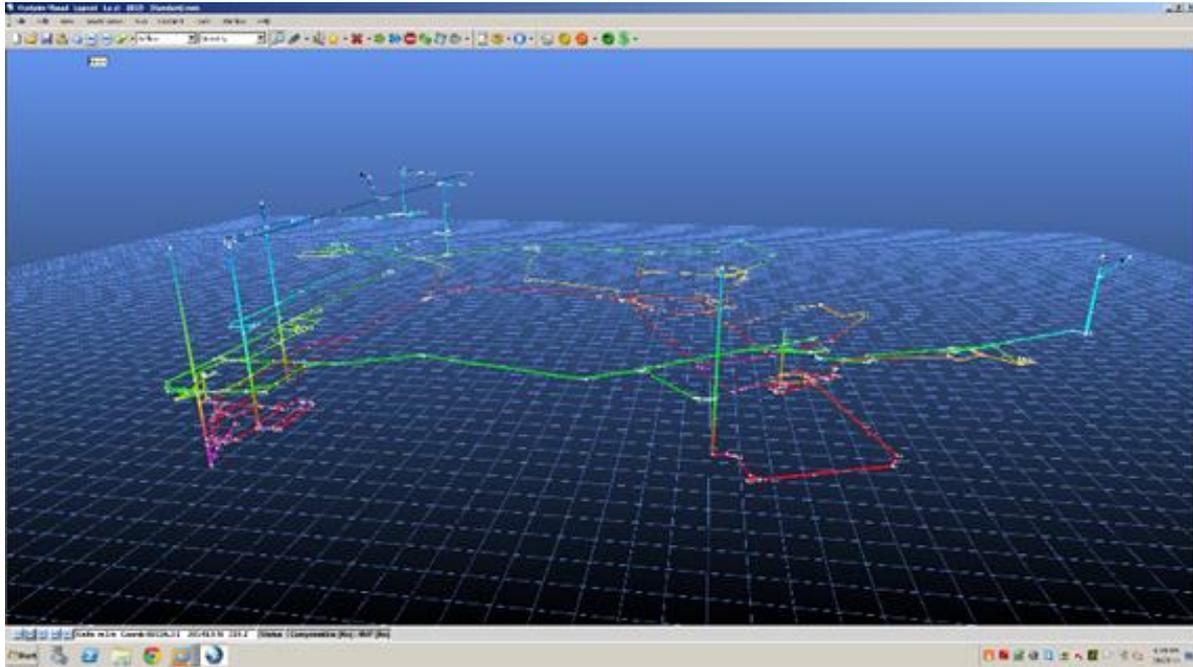

Fig. 2. 3D standard ventilation network of Lupeni mine unit

After the ventilation network's solving for standard conditions, the following results have been obtained:

Air flow at the level of the longwall with undermined coal bed no. 1, seam 3, block II, sublevel II was 3.4 m³/s; Air flow at the level of the longwall with undermined coal bed no. 1, seam 3, block II, sublevel III was 2.8 m³/s; Air flow at the level of the longwall with undermined coal bed no. 11, seam 3, block V, was 8.0 m³/s; Air flow at the level of the longwall no. 3, seam 3, block V, was 8.6 m³/s; Air flow at the level of the longwall no. 2C, seam 3, block V, was 15.3 m³/s; Air flow at mine level was 107.6 m³/s; Air flow at the level of the main ventilation stations was 108.6 m³/s.

6. Determining the Standard Deviation for Lupeni Mine Unit Ventilation Network

For determining the standard deviation of a mine is required the knowledge of aerodynamic parameters specific for the ventilation network, respectively of operational parameters of active fans. The aerodynamic and operational parameters are required both for the ventilation network solved in normal conditions, as well as for the ventilation network brought to its' standard condition.

6.1. Standard Deviation Calculation

For calculating the standard deviation is determined the equivalent resistance of the ventilation network in normal conditions:

$$R = \frac{R_1 \cdot R_2}{(R_1 + R_2 + 2 \sqrt{R_1 \cdot R_2})} \text{ (Ns}^2\text{/m}^8\text{)} \tag{8}$$

Particularly for Lupeni mine unit ventilation network we have the following: $R = 0.26753 \text{ (Ns}^2/\text{m}^8)$

The equivalent resistance of the ventilation network in standard conditions is calculated using Eq. 9:

$$R_0 = \frac{R_{01} R_{02}}{(R_{01} + R_{02} + 2 \sqrt{R_{01} R_{02}})} \text{ (Ns}^2/\text{m}^8) \quad (9)$$

Particularly for Lupeni mine unit ventilation network we have the following: $R_0 = 0.05846 \text{ (Ns}^2/\text{m}^8)$.

Based on previous results is determined the ventilation network's equivalent orifice in normal conditions:

$$A \cong \frac{1.2}{\sqrt{R}} \text{ (m}^2); A \cong 2.32004 \text{ (m}^2) \quad (10)$$

The equivalent orifice in normal conditions is exactly calculated using Eq. 11:

$$A = 1.2 \sqrt{\frac{Q_m^3}{Q_{s1} h_{s1} + Q_{s2} h_{s2}}} \text{ (m}^2) \quad ; A = 1.93973 \text{ (m}^2) \quad (11)$$

The equivalent orifice of the ventilation network in standard conditions is calculated using the approximate Eq. 12:

$$A_0 \cong \frac{1.2}{\sqrt{R_0}} \text{ (m}^2); A_0 \cong 4.96308 \text{ (m}^2) \quad (12)$$

The equivalent orifice in standard conditions is exactly calculated using Eq. 13:

$$A_0 = 1.2 \sqrt{\frac{Q_m^3}{Q_{s01} h_{s01} + Q_{s02} h_{s02}}} \text{ (m}^2); A_0 = 3.78194 \text{ (m}^2) \quad (13)$$

Based on the previous results is determined the ventilation network's standard deviation:

Thus, there may be determined the standard deviation based on the approximate mathematical Eq. 14:

$$A_s \cong \sqrt{\frac{R_0}{R}} \cdot 100; A_s \cong 46.75 \quad (14)$$

Also, by using Eq. 15 which uses the values of exactly calculated equivalent orifices for the situation of normal and standard conditions ventilation networks.

$$A_s = \frac{A}{A_0} \cdot 100 \text{ or } A_s = 51.29 \quad (15)$$

6.2. Ventilation Network Characterization in Relation with the Standard Deviation

In order to characterize the ventilation network in relation with the standard deviation, there are firstly calculated the ratios $\frac{1}{A_0} \times 100$ and $\frac{2}{A_0} \times 100$, using the equivalent orifice in standard conditions with approximate value:

$$\frac{1}{A_0} \times 100 = 20.149; \frac{2}{A_0} \times 100 = 40.297 \quad (16)$$

or by using the equivalent orifice in standard conditions with exact value:

$$\frac{1}{A_0} \times 100 = 26.44; \frac{2}{A_0} \times 100 = 52.883 \quad (17)$$

For the value of the standard deviation $A_s = 46.75$, calculated using the value of the approximate equivalent orifice, results that Lupeni mine unit ventilation network frames into category a) "Ventilation network with optimal standard deviation".

Also, for values of the standard deviation $A_s = 51.29$, calculated using the value of the exact equivalent orifice, results that Lupeni mine unit ventilation network frames at the upper limit of category b) "Ventilation network with acceptable standard deviation".

If the ventilation network is assessed in terms of standard deviation into different categories, then is chosen the ventilation network assessment which takes into account the exactly calculated equivalent orifice.

Therefore, the final assessment of Lupeni mine unit ventilation network in terms of standard deviation is: The ventilation network frames into category b) "Ventilation network with acceptable standard deviation".

7. Conclusions

In order to assess the efficiency of the ventilation network was inserted the A_s parameter, representing its' standard deviation.

Results obtained after solving Lupeni mine unit ventilation network in normal exploitation and in standard conditions highlight the fact that a total flow of 85.4 m³/s respectively 108.6 m³/s is circulated in the ventilation network, through the two main ventilation stations: Central Rising and Shaft 1 East.

The assessment of Lupeni mine unit ventilation network in terms of standard deviation highlights the fact that the ventilation network frames into category b) "Ventilation network with acceptable standard deviation".

Abstract

This article describes the practical way of realizing the demolition of metallic structures using the computer modelling of the works for the preparation of structures according to the chosen demolition concept, so that the blasting works and demolition are executed under conditions of efficiency, quality and security.

Keywords: demolition by blasting works, metal structures, explosive shaped charges, computer simulation;

1. Introduction

The restructuring of the steel industry in Romania has led to the closure of many productive units, the main reason being the high production costs and the high level of pollution. In recent years, with the reduction or stopping of the primary production flow - of which belong the agglomeration sections as well as Siemens - Martin furnaces, an ample process of greening these industrial platforms has begun.

For this purpose, many demolition activities were carried out, part of which was done by blasting works. From a technical point of view, the most interesting demolition works are those of metal structure, such as furnaces. Because of the complexity of these structures, a mechanical demolition would have been difficult, which is why demolition was done by blasting.

In most cases, the demolition of metal constructions by blasting works involves more problems compared to the situation of demolition of classical constructions. This is due to the complicated equilibrium systems of these structures, to the safety measures to be taken, to the particularities of the type explosive and initiating materials used as well as their location.

The article describes the practical way of realizing the demolition of a Siemens - Martin furnace, using the computer modelling of the works for the preparation of structures according to the chosen demolition concept, so that the blasting works and demolition are executed under conditions of efficiency, quality and security.

2. Furnance assembly description

The iron casting furnaces (Fig. 1) have a weight of up to 2 000 tons and consist mainly of a furnace body, a cleaning bag and a flanged pipe.

(1). The actual body of the furnace consists of the inner brick work made of refractory brick, followed by the cooling elements and the outer steel sheet armour.

Support pillars of the access platforms and the loading device, of 4 to 7 pieces, are arranged equidistant around the furnace body. The pillars are quenched, made of 30 to 40 mm thick steel. Bridges between these pillars are developed to access the main furnace installations. The number and height of the pillars, respectively the number and height of the platforms, differ according to the volume and year of the furnace construction.

3. Furnace blast demolition

3.1. Considerations on demolition by blasting

The successful completion of many demolition works by blasting various metal constructions led to the conclusion that by properly studying and preparing the structures, by modeling the data on the resistance and stability requirements, they can be demolished using explosives under conditions of success and full safety.

When demolishing a structure, the following requirements may appear:

- the structure must be fall down in a given direction;
- the structure must fall on itself;
- the structure must be overturned with a shortened length in a certain direction.

The choice of one of these variants is conditioned by the physical state of the construction, the existence of objectives in the vicinity of the demolition construction, the possible effects of demolition on these objectives. The demolition process chosen must meet the following requirements:

- directing the fall to protect the nearby active constructions and maintain the production process;
- protecting buildings near the target, against seismic action, shock wave, and throwing concrete or metal pieces under the effect of the explosion.
- destroying the integrity of the construction, so that the dismantled elements can be transportable or loaded with mechanical means;

The basic idea of a demolition is that the destructive effect on the objects to be protected is negligible, the number of elements destroyed by the blast being as small as the quantities of explosives that shoot at once. The explosive necessary to dismantle a certain constructive parts, is dependent on the type of explosive used, the material to be blast, the type of construction to be demolished, and the geometry of the load location (Laszlo et al, 2005).

3.2. The furnace demolition process

The demolition of the furnace was done by fall it down simultaneously with the other construction elements - the pipe and the cleaning bag. In view of the demolition of the furnace and the orientation of its fall in the desired direction it was chosen the solution of the sectioning of the constructions in two planes, by creating detachable cuttings.

Thus, a first detachment was carried out in the upper area, in the four metal posts supporting the platforms and the furnace loading device between the +6.0 m elevation and the +13.00 m elevation (shaped charge explosive apply on the metallic structure).

The largest opening of the cut was oriented from the direction of tip over to the back of the furnace

A second detachment cut was carried out in the lower zone by the creation of cutting sections in reinforced concrete support pillars of the cleaning bag above +1.0 m from ground level (dynamite explosives placed in the perforated holes in the reinforced concrete pillars).

4. Preparatory stages for demolition of structures

In order to overturn the furnace, pipe and cleaning bag, a series of preparatory works were carried out (Laszlo et al, 2014).

Furnance body

- pre-cutting of the outer tubing supported by the furnace and the foot of the estacade;
- decommissioning of the walls as well as the roof of the furnace hall;
- separating the connections between the furnace platforms and the lift tower;
- decommissioning of all facilities and equipment between +/- 0.0 m and + 13.0 m level around the 4 main pillars;
- decommissioning the floor from the + 6.0 m elevation of the furnace hall in front of the pillar pair in the downward direction (Fig. 2);
- in order to overturn the furnace, it was created a cut on the pair of front pillars in the direction of fall by three breaking sections between the elevation + 6.0 m and +13.0 m (Fig 4);
- for the creation of the cut, the metal pillars were first omitted by oxyacetylene flame cutting with 2 x 0.50 m profile on the front and rear sides (Fig. 3, a);
- on the other two lateral sides of the post, a cut of the profile is executed in front of the front and rear sides (Fig. .3, b);
- on the pair of rear pillars opposite to the fall direction, the profile on the two side faces and the rear face was cut at the level of the front lower section of the front pillars (Fig. 3, c);

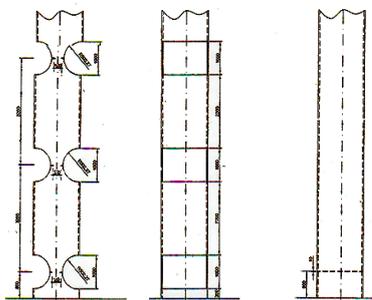

Fig. 3. Preparing metal front pillars (a, b) and rear (c)

Fig. 4. Completing the preparation of metal pillars

Cleaning bag

- the first pair of pillars from the falling direction and the third pair of pillars (Fig. 5) were previously cut off to the cleaning bag. From the end of the drain mouth was cut 2 m in height;
- for the creation of the detachment cut, in order to overturn the cleaning bag, fracture sections were created, in which purpose holes were drilled in pillars as follows:
 - pile pair, 1.5 x 1.5 m section, from the drop direction, a group of 4 x 3 holes starting at 1.0 m from the base of the pillar, a second group of 4 x 3 holes drilled at a distance of 1.0 m from the first group of holes and a third group of 4 x 3 holes drilled at a distance of 1.0 m from the second group of holes (Fig.5);
 - the pile pair, with the 1.5 x 1.5 m section opposed to the fall direction, is slanted by mechanical means on the back, at + 3 m distance above ground level, by 1/3 of pillar thickness, and the unveiled metal structures are cut.

Fig. 5. Prepare concrete columns for supporting the purge bag

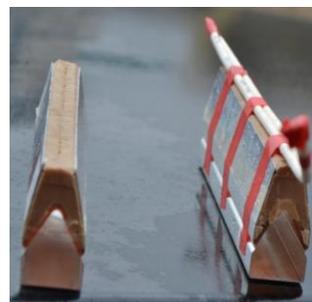

Fig. 6. Shaped charge explosive type CCL 30 - 200

5. Explosive charges. The type of explosive, mode of application and initiation

Explosive charges are dimensioned according to the type of material and section of the construction elements to be sectioned. For the cutting of the breaking sections on the metal profiles, shaped explosive charges CCL 30-200 have been used. These loads are delivered in the form of bars with a length of 0.200 m and have an explosive load of 0.230 kg. (Figure 6). A dynamite explosive was used to cut the columns of the cleaning bag support.

5.1. Explosive charge construction and initiation mode

Since the thickness of the posts of the pillars was 40 mm, two explosive loads applied on both sides of the soles were used. To fix the shaped loads CCL 30-200, it was intended that they be symmetrically placed so that the cumulative action of the explosive work in the same plane (Fig. 7). To ensure the simultaneous initiation of the shaped explosive charges on the two faces of a cutting section, have been initiated at both ends with a 12 g / m detonating cord line overlapping on the shaped explosive bar. In a breakage section on a metal pole, the two-sided detonating lines were chained from one load to the other and initiated with a detonator of the Nonel non-electric system. The destructive effect of the shaped explosive charges was previously verified by a test shot on a representative profile cut from the structure of the metal support pillar. (Fig. 8).

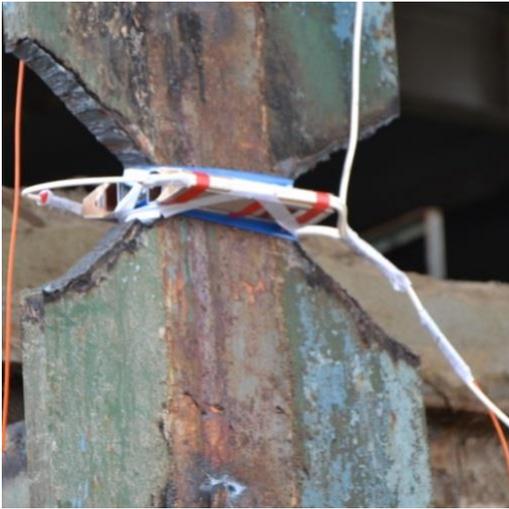

Fig. 7. Explosive application method on metal pillar profile

Fig. 8. Testing the destructive effect of the shaped explosive

5.2. Explosive charge on the furnace metal pillars in the direction of fall (Laszlo et al, 2014, Laszlo et al, 2005):

- metal profile thickness, $Gt = 0.040$ m;
- cutting length of one-sided section, $L = 0.380$ m;
- number of cuts in a breakage section, $Nc = 2$;
- number of breaking sections per pillar, $Nb = 3$;
- the shaped explosive charge applied in mirror, two pieces on each side of the profile. Total 8 pieces at one breaking section;
- number of shaped charges per pillar $N = 8 + 8 + 8 = 24$ pieces.

5.3. Explosive charges on concrete pillars from the cleaning bag (Laszlo et al, 2014, Laszlo et al, 2005):

- pillar pair with 1.5×1.5 m section;
- burden, $W = 0.350$ m;
- the distance between holes in a row, $a = 0.30$ m;
- number of vertical rows, $N = 3$;
- number of holes per pillar, $N = 12 + 12 + 12 = 36$ holes;
- hole length, $lg = 0.90$ m;
- explosive charge per hole, $Qh = 0.150$ kg Dynamite;
- explosive charge per pillar $Qp = 5.400$ kg Dynamite.

Upon demolition of this furnace, 48 pieces of shaped charges were used. = 11,400 kg. CCL type 30-200 and 10.8 kg. of Dynamite explosive type. At the execution of the blasting, the explosive charges were protected with wire net and geotextile cloth. The purpose of these protections was to minimize the phenomenon of throwing pieces of material under the action of the explosion.

5.4. The order of detonation of explosive charges

In order to fall over the assembly of furnace, pipe and cleaning bag, was used the following order to initiate the explosive loads:

1. Breaking sections of the front row pillars, those supporting the cleaning bag.

2. Cutting sections of the front row pillars, those supporting the furnace.

As can be seen from the delay order, it was chosen to first detonate the cleaning bag support pillars and then the metal pillars from the furnace falling down direction.

This was because, prior to the commencement of the furnace movement, it was necessary to move the center of gravity of the pipe towards the direction of the furnace overturning. Since the pipe is support on the cleaning bag, by blasting the cleaning bag pillars in advance, the pipe it has been moved to the direction of overturning together with the whole assembly.

6. Static modeling of the furnace assembly, pipe and cleaning bag

In order to verify structures in terms of resistance and stability requirements, after loosening or removing some sections, the data was processed through a structural analysis program - Axis VM 12. (Laszlo et all, 2014).

In the spatial analysis of the structure, the static scheme was introduced with the sectional characteristics related to the cross-sections of the component elements, and on the parts that were reduced from the pillars section (in the place of the explosive loads), the sectional characteristics of the cutting details have been taken into account. In the calculations, only the assumption of own weight loading was taken into account without any external disturbance of the structure. In the modeling it was considered that there are no stresses due to a forced assembly and when demolition is performed the structure of resistance has no connection with the other equipment in the area, being considered free in the structural analysis.

After checking the resistance structures according to the new constructive data, it was found that they meet the conditions of resistance and stability. After modeling the situation of the realization of the detachable cuttings using the energy of the explosives, it was found that the structures would overturn in the intended direction (Fig. 9,10,12).

Fig. 9. Molded shape after furnace decommissioning by classical methods

Fig. 10. Molded preparatory work for overturning the furnace

Fig. 11. Static modeling of the furnace assembly,

Fig. 12. Furnance assembly after blasting operation

7. Conclusions

The constructive assemblies of the furnaces and generally the constructions made of metallic structure, will be in the future the object of demolitions activities by blasting works.

The static modelling of the structures can determine the preparatory work consisting in the cutting of the non-important elements and the reduction of the section of the supporting elements, which will reduce the size of the explosive loads. In this way massive structures can be demolished only by using several tens of kilos of explosive.

Practical experience also highlighted the superior net results obtained by using shaped explosive charges in order to cut metal structures. With the use of these loads, small explosive quantities are involved but which have a maximum effect in terms of sectioning and a minimum effect from the point of view of the air shock wave and noise.

Also, using the computer modelling of the works for the preparation of structures according to the chosen demolition concept, the blasting works are executed under conditions of efficiency, quality and security.

Abstract

An industrial ventilation system is started each time in a work place occur noxious, in order to maintain a safe, healthy, productive and comfortable environment in conditions of work hygiene, health and safety of workers, where this need is determined not only by the human occupation level, but also by other factors, such as production processes.

For choosing a proper ventilation installation, there is needed an analysis of the workplace to be ventilated so that the chosen solution to solve the problem of noxious exhaust and to respect the comfort of the workers.

In this paperwork, there are presented different types of fans used in industrial ventilation, the operational parameters, the air state parameters and the aerodynamic parameters of ventilation pipes, because they have the greatest influence on the operation of a ventilation installation.

Keywords: industrial ventilation, parameters, fans;

1. Introduction

Designing and building an individual ventilation system should harmonize comfort requirements with the user's ventilation system management, without adversely affecting other system functions. Choosing the most suitable ventilation system for a given situation is largely the key to satisfactory operation. The situations that come into practice are, however, so numerous, complex and varied, the industrial processes in such a rapid evolution, and the need for ever greater comfort, to systematize the different situations that appear and to attach to each category the most suitable ventilation system would be both difficult and impractical.

2. Technological air systems

Industrial air technology includes measures for the indoor environment (general and local), measures to prevent hazardous emissions resulting from industrial processes from evacuation to the outside, such as transport and purification technologies, and measures to prevent or minimize the damage caused by accidents, fires or explosions. Industrial air-conditioning systems can be classified into two categories: industrial ventilation and air-processing technologies. Within this system is part of (Al. Cristea, 1968), (D. Cioclea, 2013):

- **Air conditioning systems that control** air and environmental quality for both human factor and process.
 - **General ventilation systems** where some internal parameters are only partially controlled. Target levels are usually lower than those for air conditioning.
 - **Local ventilation systems** are used for locally controlled areas. These systems are based on local capture of contaminants.
 - **Process ventilation systems** are designed to maintain defined conditions to ensure process performance (eg, paper machine's fume cupboard).

3. Fans

Fans are rotary machines for increasing the air pressure (static pressure) transformed from the mechanical energy received on the motor shaft. The main elements of a fan are the rotor, casing and rotor system (Al. Cristea, 1968).

Following the direction of the airflow in the fans, they are classified into centrifugal or radial fans and axial fans.

Depending on the operating principle, fans may be (Fig. 1) (Al. Cristea, 1968), (I. Matei, 2000), (Băltărețu Raul, 1980):

- axial, where the air enters directly into the fan and is centred on the axis of rotation of the engine. Due to the relatively high rotation speeds compared to centrifugal fans, the axial fans are louder;
- centrifugal, in which the air penetrates axially, makes a right angle and then moves radially outwardly under the action of centrifugal force. The rotor blades may be straight or curved front or rear relative to the direction of rotation;
- bifurcated are usually auxiliary fans that are designed so that the motors operate in fresh air while the rotor is driving vicious air;
- combined (mixed) flow are mainly centrifugal mounted in such a way that they can operate in the same way as the axial ones, the air enters the axial fan and leaves the fan at an angle that may vary from 30 ° to 90 °;

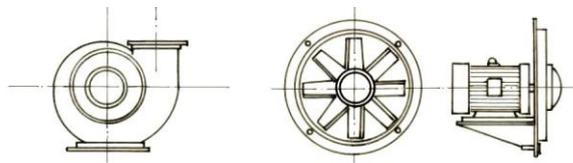

Fig. 1. Centrifugal and axial fans: a) centrifugal fan; b) axial fan

3.1. Axial fans

Axial fans owe their name to the fact that the air movement is along the fan axis. Generally, axial fans are used at high air flows and at low pressures. An axial fan consists of a tubing with a shaft or hub on which a number of blades are fixed. (William A. Burgess, 2004)

Fans with propellers are common ubiquitous air fans for homes, offices and hot work environments (Fig. 2).

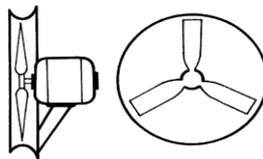

Fig. 2. Fans with propellers

Tubular fan with propellers (Fig. 3) are essentially a more complex version of propeller fans that have been modified so that they can be inserted into a duct (William A. Burgess, 2004).

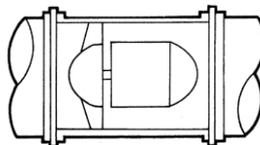

Fig. 3. Tubular fan with propeller

Vane-axial (Fig. 4) are tubular fans that have been modified by adding air-guiding blades to the engine housing behind the fan blades (William A. Burgess, 2004).

Such fans can operate at static pressures of up to 2000 Pa and are therefore suitable for use in local exhaust systems, being used as fresh air intake fans (William A. Burgess, 2004).

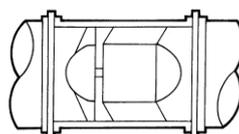

Fig. 4. Tubular fans with control blades

3.2. Centrifugal fans

Centrifugal fans use a rotor to increase the flow of air. As the air moves from the rotor hub to the blade tips, it gains kinetic energy.

A centrifugal fan works on a totally different principle than the axial ones. The centrifugal word means flowing from the centre (Fig. 5), (Al. Cristea, 1968).

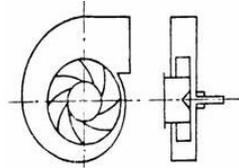

Fig. 5. Typical centrifugal fan (horizontal air suction and vertical discharge)

After the number of suction mouths, the centrifugal fans are single-aspirating and double-aspirating and, after the total developed pressure, they are classified in (Al. Cristea, 1968):

- low pressure fans (up to 100 daPa);
- medium pressure fans (up to 500 daPa);
- high pressure fans (up to 1000 daPa), above this pressure, their construction must to be modified, entering into other categories of machinery;

3.3. Bifurcated ventilators

Bifurcated ventilators are typically auxiliary fans that are designed so that the motors operate in fresh air while the rotor circulated vicious air. To do this, the fan casing is designed to allow the air to pass anywhere as the engine is encapsulated (Fig. 6) (William A. Burgess, 2004).

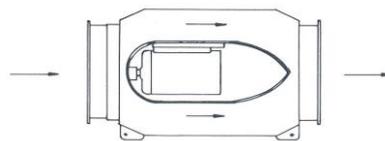

Fig. 6. Bifurcated fans

3.4. Combined flow fans (mixed)

Mixed rotation fans are hybrid fans in the sense that they are typically mainly centrifugal mounted in such a way that they can operate in the same way as the axial ones. With these fans, the air enters the axial fan and leaves the fan at an angle that may vary from 30 ° to 90 °. The flow of air through the rotor thus becomes partially centrifugal (Fig. 7) (William A. Burgess, 2004) .

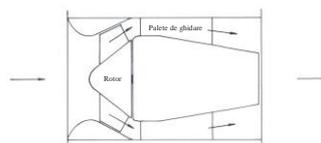

Fig. 7. Mixed air flow fan

4. Functional parameters of industrial ventilation installations

The functional parameters defining the performances of a fan are: airflow, pressure, speed, power and efficiency. In addition to functional parameters, it is also necessary to know the parameters of the air condition (temperature, humidity, absolute pressure, air velocity) and the aerodynamic parameters of the ventilation ducts (the geometric elements of the column, the aerodynamic resistance of the column, the unit coefficient of loss of air) as it mostly determines the operation of a ventilation system.

4.1. Functional parameters of a fan

The functional parameters of a fan are: airflow, pressure, speed, power, output, voltage (Al. Cristea, 1968), (I. Matei, R. Moraru, 2000), (Băltărețu Raul, 1980), (INCD-INSEMEX Study, 2013).

Fan flow - is the number of cubic meters of air trained in the unit of time in the suction mouth, expressed in m^3 / h .

The air flow inside a duct or the suction and discharge port of the fan is determined by the geometrical elements of the pipe (section of the pipe) and the air flow rate therein.

The formula for calculating the air flow is given by the relationship:

$$D = s \cdot v \cdot 3600 \quad [\text{m}^3/\text{h}]$$

Fan pressure - is the actual pressure produced by it and expresses the increase in fan pressure between the suction and discharge ports. The total fan pressure is equal to the sum of the total pressure measured at suction and fan discharge (dynamic pressure and static pressure).

4.1.1. The absorbed power of a fan (Pa)

The total power of a fan is the power absorbed (Pa) from the power source required to provide effective power to the fan shaft and is determined with:

$$Pa = \sqrt{3} \cdot U \cdot I \cdot \cos \varphi \quad (\text{kW})$$

depending on the values obtained from the measurements for the current, the electrical voltage and the power factor.

4.1.2. The useful power specific to the ventilation (Pu)

The useful power of a fan is the useful mechanical work done in the time unit for air circulation and is given by the expression:

$$P_u = (Q \times H) / 102 \quad (\text{kW}) \quad \text{or} \quad P_u = (Q \times H) / 1000 \quad (\text{kW})$$

where: Q - fan flow rate [m^3/s];

H - Fan depression [mm of water] or [Pa]

4.1.3. Fans speed and drive motors

The speed of an engine or fan (n_M, n_V) is the circular motion of the rotor around its axis or from a fixed point made to the point of departure and expressed in rpm.

$$\frac{n_M}{n_V} = \frac{D_V}{D_M}$$

where: n_M, n_V - engine and fan axle rotations (rot / min)

D_M, D_V - pulley diameters on the motor and fan shaft (m)

4.1.4. Fan yield

Fan efficiency - is the ratio between the useful power and the absorbed power received at the fan shaft, determined with:

$$\eta = (N_u / N_a) = [(Q_v P_v) / 1000 N_a] \times 100 \quad [\%]$$

in which:

Q_v - airflow rate developed by the fan, m^3/s ;

P_v - Fan pressure, Pa, total or static to yield total or static efficiency;

N_a - power absorbed at engine spindle, kW.

The rational operating range of a fan can be ensured by observing the stable operating condition ($P_v \leq 0,9 P_{\max}$) and by an economical operation ($\eta_v = 0,85 \eta_{\max}$).

4.2. Air condition parameters

Air condition parameters include: air temperature, air humidity, absolute air pressure and air flow rate in the duct. These parameters are the most important characteristics of the ambient air, having a direct influence on human health and on the effectiveness with which they operate (Al. Cristea, 1968), (I. Matei, 2000), (Florica Băltărețu, 1987):

- **Air temperature** - is measured with an ordinary thermometer, a dry tank or electronic devices.

- **Relative humidity** - the ratio between the mass of water vapour contained in an air volume at a given temperature and the mass of the vapour required to saturate the same volume of air at the same temperature and expressed as a percentage (% RH).

- **Absolute air pressure** - Barometers are devices for measuring absolute static air pressure.

4.2.1. Air flow rate

Air velocity in pipelines is chosen according to the destination of the plant. In systems in social, cultural, administrative, commercial, sanitary, residential and similar buildings, the air velocity in pipelines is limited by noise conditions. Installations in industrial halls, which usually drive large airflows and can operate under less severe silences, are sized on the basis of higher air velocities.

In order to determine the required speeds for the transport of solid particles in pipelines, Dalla-Valle's approximate formulas can be used, namely (D. Cioclea, 2013):

- for horizontal pipelines:

$$v = 9 \frac{\gamma_p}{\gamma_p + 16} d_p^{0,4} \quad (\text{m/s})$$

- for vertical pipelines carrying the particles upside down:

$$v = 20 \frac{\gamma_p}{\gamma_p + 16} d_p^{0,4} \quad (\text{m/s})$$

in which:

γ_p - is the specific weight of the transported material in kg/m³;
 d_p - maximum particle size in mm.

The choice of air velocity in pipelines should always be done with discernment. First, the functional criterion has to be considered.

Also, the value of the velocity of the air flow in the column of tubes can be determined by the relation (I. Matei, 2000), (Florica Băltărețu, 1987):

$$V = \sqrt{\frac{2gh_d}{\rho}} \quad (\text{m/s})$$

in which:

g - gravitational acceleration m/s²
 hd - the final mean dynamic pressure (pressure), Pa;
 ρ - air density, kg /m³

4.3. Aerodynamic parameters of the ventilation ducts

These parameters include: the section of the pipeline, the unitary aerodynamic resistance R_0 and the unit air loss coefficient K_0 (I. Matei, 2000), (Florica Băltărețu, 1987), (D. Cioclea, 2013).

4.3.1. Geometrical elements of pipelines

The shape of the industrial ventilation ducts is chosen depending on the available space, the possibility of incorporating them in the structure of the building, the airborne suspension particles. They are round or square in shape because they have the highest transport capacity (m³/h of air) per square meter of lateral surface of the pipe. Also, the air must be run on the shortest way, with a mini-local resistor, and the pipe should be of an appropriate average length.

Measure the geometrical elements of the pipe (width, height, diameter) depending on the cross-sectional shape, calculate the free surface and their perimeter using the mathematical relations of the pipe shape.

4.3.2. Aerodynamic resistance of the ventilation columns

To determine the aerodynamic resistances specific to the R , R_0 , R_C , aerodynamic columns, the Atkinson laws (Al. Cristea, 1968), (I. Matei, 2000), (Băltărețu Raul, 1980), apply:

$$p = \alpha L \frac{P_e}{A^3} Q^2 \quad [\text{Pa}] \quad \text{or} \quad p = \frac{\alpha L P_e}{A^3} \quad [\text{N s}^2/\text{m}^8 \text{ or } \text{kg}/\text{m}^7]$$

where: α represents an aerodynamic friction coefficient, depending on the density of the air and expressed in density units, kg /m³.

To determine the aerodynamic resistance of an air column, the relationship $p = RQ^2$, which is the square law of the fluid flow, applies.

The unitary aerodynamic resistance R_0 , characteristic of leaky columns, is determined by the relationship:

$$R_0 = (P_1 - P_2) / Q_m^2 \quad [(\text{daPa} \times \text{s}^2/\text{m}^6)/\text{m}]$$

in which:

P_1 - represents the pressure measured at a point of the column, to the fan, daPa;
 P_2 - represents the pressure measured at a point in the column, to the zone of release of harmful gases, daPa;
 Q_m - air flow rate in the air column, between the two measuring points, m³/s;
 L - the length of the column between the measuring points, m.

4.3.3. Unit coefficient of air loss

K_0 - represents the difference between the air flow rate developed by the fan and the air flow rate at the column air intake or clear air exhaust in the the area of the formation of noxes and expressed in m³/s of leakage per one meter of column. Air losses mean either airflows drawn along the column or column airflow outflows along its entire path, and is determined by the relationship (I. Matei, R., 2000), (Florica Băltărețu, 1987), (D. Cioclea, 2013):

$$K_0 = \frac{3(Q_1 - Q_2)(P_1 - P_2)}{2L(P_1^{3/2} - P_2^{3/2})} \quad [\text{m}^3/\text{s}/\text{m} \text{ at the pressure } P_1 - P_2]$$

If at the end of the column opposite to the fan, the pressure is null, ie $P_2 = 0$, there is obtained:

$$K_0 = \frac{3(Q_1 - Q_2)}{2L\sqrt{P_1}} \quad [\text{m}^3/\text{s}/\text{m} \text{ at the pressure } P_1]$$

5. Conclusions

1. Technological air processing systems may be: air conditioning systems that control air and environmental quality for both human factor and process; general ventilation systems where some internal parameters are only partially controlled. These systems are based on local capture of contaminants; Process ventilation systems are designed to maintain defined conditions to ensure process performance (e.g., paper machine fume cupboards).
2. By principle of operation the fans can be axial, centrifugal, bifurcated and combined (mixed);
3. Parameters defining the performances of a fan are: air flow, pressure, speed, useful power, power absorbed, and efficiency. The air condition parameters in a pipe are the temperature, humidity, absolute pressure and air circulation speed, and the aerodynamic parameters of the ventilation ducts are: the geometric elements of the pipe, the unitary aerodynamic resistance R_0 and the unit air loss coefficient K_0 ;
4. The unitary aerodynamic resistance R_0 - determines the characteristic pressure loss for a given air flow rate over a given length and is obtained from measurements of pressure, temperature, absolute pressure and airflow velocity measurements using calculation relations;
5. The unit air loss coefficient K_0 is obtained from measurements of pressure, temperature, absolute pressure and air flow velocity and represents the difference between the air flow rate developed by the fan and the air flow rate at the suction nozzle air in the column or clean air discharge in the area of the formation of emissions and expressed in m^3/s of leakage air per one meter of column.

Abstract

Mining industry is characterised by specific work conditions, imposed by natural particularities and by the characteristics of the production process. They require a series of complex and specific measures, which are intended to create normal work conditions, without bringing any harm to workers, by accidents or occupational diseases.

Due to the fact that methane, entity present in coal mining, represented in time the main factor of hazard and a major concern in researching and gaining higher safety conditions. Worldwide, intensive research aiming to provide knowledge on the elements connected with the occurrence and prevention of methane hazard, demonstrates that no price is too high for rewarding research for managing underground health and safety.

On the other hand, in compliance with the Intergovernmental Panel on Climate Change (IPCC), 17% of the global warming effect is generated by methane. Methane comes from a series of anthropogenic and natural sources,

Both types of sources contribute to the increase of underground methane concentration, the major contribution being of natural ones. Methane is rapidly transformed into less hazardous molecules which enter in other transformation cycles. Methane's contribution to global warming is significant, its' global warming potential being over 20 times higher than the one of carbon dioxide.

Based on the available data presented in Romania's national communication on the manner of applying the provisions of the Framework convention on climate changes, there is a real capacity for using specific measures for applying the provisions of the Kyoto Protocol.

Same data reveal the fact that there can be performed an additional gas emissions decrease of minimum 6%, compared to the official engagement communicated by Romania in the European integration process.

Methane releases into the atmosphere following the exploitation of coal have double ecologic impact, participating in the destruction of the ozone layer and in contributes to the enhancement of the greenhouse effect. At the same time, methane released into the atmosphere in coal mining, may be used by miners as a primary power source for covering the own power requirements of it may be used for commercial purposes.

Keywords: industry, atmosphere, mining, methane;

1.Introduction

The need for degassing must be related to an increase in underground security, as well as to the reduction of ventilation costs due to the movement of the quantities of methane released, respectively the possibility of rational utilization of methane, while reducing the environmental impact and, implicitly, global warming(Ianc N 2015).

The application and valorisation of the local degassing was implemented at the Lupeni and Vulcan mines.

Reducing the impact on the underground environment by degassing.

2. Methods and systems for reducing the impact on the underground environment

2.1. Centrifugal degassing

Establishing the opportunity for mine degassing involves a detailed analysis of the complex of factors influencing methane emissions, a methane emission forecast, a diversified ventilation factor analysis, a clear knowledge of deposit reserves and exploitation dynamics (Băltărețu and Matei, 1987).

The factors determining the necessity of degassing the mass of rocks at the mine, sector, coal bed or mine workings level, are represented by:

- installed ventilation conditioning;
- air flow rates in underground and in the areas with large methane releases;
- additional air reserve determined according to the absolute methane flow at the permitted concentrations of the norms;
- the balance of absolute and relative methane flows and the ratio of these parameters to the installed and additional air capacity of the mine;
- special situations of preparation and exploitation (loose cuts, jomp exploitation, etc.).

The most used process is the capture and drainage of the gases with the help of some pipe sections introduced into the exploited space.

At C.N.H. - Petrosani, central degassing applies to the Lupeni and Livezeni mines.

Centralized degassing installations are located at the mine surface, equipped with 4 groups of vacuum pumps for gas suction, are of Polish origin and have the following characteristics:

- flow: $Q = 25 \text{ m}^3/\text{min}$;
- maximum suction depression: $H = 4.000 \text{ mm H}_2\text{O}$;
- maximum discharge pressure: $P = 3.000 \text{ mm H}_2\text{O}$;
- engine power: $N = 75 \text{ kw}$;
- Speed: $n = 735 \text{ rpm}$.

The degassing of the above-mentioned units was accomplished by capturing methane from wells drilled underground and by capturing methane from old mine workings (the space exploited). The research carried out by INSEMEX Petrosani over the years on the degassing of the rock mass, led to the elaboration of degassing frameworks depending on:

- type of mine workings;
- exploitation method;
- the thickness of the coal layers;
- Tilt of coal strata.

Among the existing degassing methods, the most used are:

- the "C" frame method (Fig.1.a) - which applies when performing preparation mining works which crosses a thick coal layer or a package of layers;
- the "G" type method (Fig .1.b) - which applies to coal layers with a slope of up to 35° , which is operated with frontal stopes, the withdrawal method;
- the H-type frame method (Fig.1.c) - applies to coal-bed layers with tilts up to 35° which are operated with frontal stopes, the advance method.

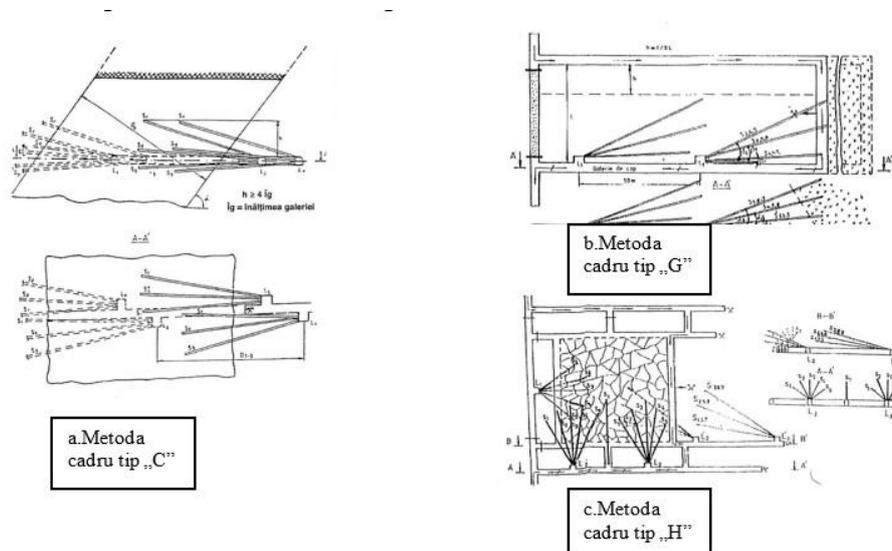

Fig. 1. Fractionation methods applied to mines in the Jiu Valley

The wells for degassing are run based on a program (project). The geometrical characteristics of the well holes in the degassing frame methods are presented in table 1.

Table 1.

Characteristics	Units	Values ranges for degassing frame schemes								
		„A"	„B"	„C"	„D"	„E"	„F"	„G"	„H"	„I"

In Jiu Valley mines, for capturing the methane from the old mine workings (the exploited space), the dams are used to isolate these areas. The results of the capture from the old mine workings (the Livezeni mine) depend essentially on the tightness of the isolation works. (Băbuț. G et al.,2000) The release of methane in the stressed areas drops rapidly behind the stope but never ceases altogether, as long as the methane levels are still present. As a result, variable quantities of gas, which occupy the gaps in the exploited space and which can reach the airflow, are always released in the inactive works (Lupu C.2007; Tomescu C. 2015).

In view of the above, for methane capture under the best conditions it is recommended:

- the closure of the works in which the methane is about to be captured, has to be made with as few as possible dams;
- Depending on the existing possibilities, dams' positions must be chosen before closure, so that they are located in areas with compact rocks and which are not or cannot come under the influence of exploitation;
- The thickness of the dams is slightly influencing their aerodynamic strength. The minimum thickness is given by the mechanical strength the dam must have, depending on the load to which it is subjected by the surrounding rocks.

For the arrangement of the degassing sites (niches), the following steps are taken:

- digging of the degassing niche;
- Drilling and sealing of well holes;
- endowment of degassing locations (niches).

The equipment for a degassing niche must necessarily include the components shown in Fig. 2 (1-capture tube, 2-valve for methane closure, 3-nozzle for injection of cement milk, 4-nozzle for measurement and control 5-pipe connection hose, 6-gas collector and liquid separator, 7-flange, 8- nozzle separation valve, 9 main gas pipe).

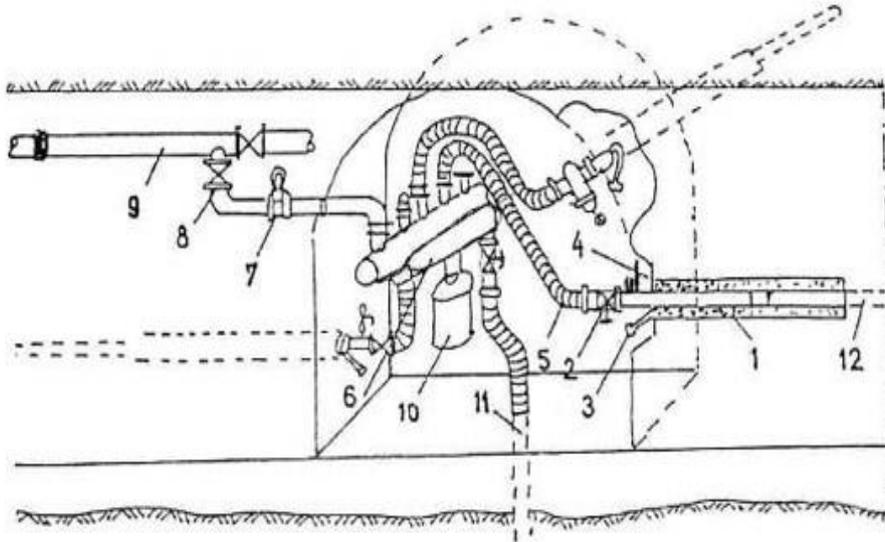

Fig.2. Arrangement and equipping of clearance sites

2.2. Local degassing applied to Jiu Valley mines

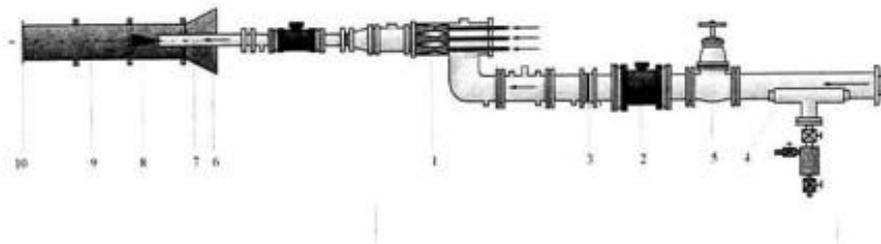

- Local methane capture and drainage can be applied under the following conditions;
- Predicted gas quantities can be drained with ejectors and diluted to the maximum percent methane concentrations permitted in the evacuated air stream;
- it is not possible to ensure the permanent maintenance of methane concentrations above 30% vol.

The forecast of methane emissions as well as the situation of releases of gas from underground works do not justify the desirability of central degassing.

A local degassing plant has the following components (Fig.3.):

- compressed air degassing ejector;
- Devices and devices for measuring, protecting and regulating specific parameters;
- mixing and dilution chamber.

The compressed air degassing ejector is the basic equipment of the plant that develops the energy needed to capture and drain the gas.

1-Ejector degazare	6-Tronson de suplimentare a debitului de aer în camera de diluare
2-Dispozitiv paraflacă	7-Tronson refulare
3-Dispozitiv Royal-Duth	8-Deflector gaze
4-Separator apă-detritus-gaz	9-Camera de diluare a gazelor
5-Robinet cu sertar	10-Plasă de sârmă pentru uniformizarea Curentului de aer

Fig. 3 Local degassing instalation

In the ejector structure, the following components are mainly included:

- funnel with hemispherical biasing (VENTURI type);
- the injection nozzle mounted on the compressed air supply rod;

- mounting case of Venturi funnel, with flange with circular duct and funnel centring disk;
- Rod mounting and guiding housing (buffer chamber) provided with a special flange for coaxial centring of the compressed air supply rods;
- special venting fan mounting bolt;
- the ejector connection to the gas suction side;
- Compressed air distributor for charging the ejector.

The ejectors used in the local degassing facilities at the mining units in the Jiu Valley have the following functional parameters:

- Nominal flow:
 $Q_n = 6 \text{ m}^3/\text{min}$, (3 DIV); $Q_n = 10 \text{ m}^3/\text{min}$, (5 DIV); $Q_n = 18 \text{ m}^3/\text{min}$, (8 DIV)
- Nominal depression:
 $h_n = 250 \text{ mm Hg}$, (3 DIV) $h_n = 300 \text{ mm Hg}$, (5 DIV) $h_n = 350 \text{ mm Hg}$, (8 DIV)
- Compressed air consumption: 4 - 10 m^3/min ;
- Range of action: 2.000 m.

As methane dilution station (mixing chamber), it can be used:

- mine workings, divided by a sealed partition wall;
- ventilation tubes.

Methane dilution in the mixing chambers located in the mining works through a partition wall provides for the execution of the dilution on one side of the mine working, with the closure of the space at the ends with wire mesh. The process provides the conditions for dilution of methane flows ranging from 1 to 4 m^3/min at concentrations up to 1.5% by volume of methane.

3. Conclusions

Analysing the results of the degassing specific parameters according to the type of rocks in the bed and the roof of the coal layers subjected to the degassing process leads to the following findings:

- E.M. Livezeni:
 - the average flow rate of captured gas was $2.95 \text{ m}^3/\text{min}$ and the share of methane flow represented 55% ($1.62 \text{ m}^3/\text{min}$);
 - The average depression size created was 25 mm Hg at the drilling level and 35 mm Hg at the suction pipes in the exploited spaces;
 - the maximum methane concentration was 75% vol., Measured in the networks for the exploited space;
 - the rocks from the coalbed and of layer 3 roof, which was the subject of degassing, are of the type of clay, sandstone, muddy clay, marble sandstone and low greasy clay.
- E.M. Lupeni:
 - the average flow rate of captured gas was $9.6 \text{ m}^3/\text{min}$ and the share of methane flow represented 67 % ($6.05 \text{ m}^3/\text{min}$);
 - The average depression size created was 68 mm Hg;
 - the maximum methane concentration was 100 % vol. in layer 3, bl. II, horiz.400;
 - the rocks from the coalbed and of layer 3 roof constitutes of sandy compact sandstone, limestone marble, claystone, claystone sandstone and quartz sandstone.

Exploitation mining	Average gas flow [m^3/min]	CH ₄ %	Volume CH ₄ degage [m^3/month]	Average flow CH ₄ [m^3/day]
Livezeni	2,15	61	56657	1715,7
Vulcan	1,5	86	55728	1879,5
Lupeni	3,5	66	99792	3397,5
Total central degassing stations Valea Jiului			212177	6994,7

By applying degassing to the Jiu Valley mines, taking into account the amount of methane evacuated through the ventilation system at the main ventilation stations, it resulted that through the degassing process, the total volume of methane evacuated (aeration and degassing) extracted by degassing, from:

- Lupeni Mine: 18,02 %;
- Vulcan Mine: 17,38 %;
- Livezeni Mine: 9,21 %.

Abstract

In recent years, increasing consumption of goods led to the depletion of many shallow ore reserves in the USA and world-wide. Consequently, the underground mines are becoming deeper, hotter, and increasingly mechanized. An underground environment with high temperature and humidity conditions generated by various heat sources such as auto-compression, strata, and mining equipment can affect the thermoregulation processes of the human body. This can lead to a series of heat-related illnesses such as heat rash, heat cramps, heat exhaustion, and heat stroke. There are two methods used to control the climatic conditions in underground mines: (1) Using ventilation and cooling to reduce the thermal stress on the mine workers, and (2) Reducing the heat generated by major heat sources. The latter method could be achieved, for instance, by reducing the fleet size or using battery-powered/electric equipment, to reduce the heat generated by the mining equipment. In addition, understanding the heat transfer processes is also critical for the development of efficient cooling systems to ensure thermal comfort for the underground workforce. This in turn can increase productivity and reduce the risks of heat-related illnesses. To identify what sources generate the greatest amount of heat in the production stopes, efforts have been focused to develop bulk and/or localized cooling systems to provide adequate work conditions in underground mines. This paper aims to identify and analyze all major heat sources and their individual contribution to the overall heat load in underground mines. The effect of heat exposure on health, safety, and productivity of the mine workers will be summarized and discussed. Furthermore, a sensitivity analyses aiming to identify the most cost-effective ventilation strategies and cooling methods and systems based on specific geological and mine operating characteristics are discussed.

Keywords: climatic conditions, heat sources, heat exchange processes, mine ventilation, cooling systems, thermal comfort;

1. Introduction

The human body has certain mechanisms to maintain its core temperature at 37 °C with $\pm 1^\circ\text{C}$. The heat produced in the human body can be classified as: (1) environmental heat load, and (2) metabolic heat. The exchange of heat between the human body and the environment are in the forms of convection, conduction, and radiation. Besides these, heat is produced by internal metabolic processes and depends primarily on the level of activity (e.g. work rate). The muscular efficiency is in the range of 20-25%, at the best (Gravelling, Morris, and Graves, 1988). Consequently, a great proportion of remainder inefficiencies are transferred to the environment as heat.

Depending on the environmental parameters (air temperature, humidity, radiant temperature, barometric pressure), and the skin temperature, heat can be transferred from the environment to the body or vice-versa. In addition, heat is generated by the human body while activities are performed. The heat stored by the human body can be assessed by subtracting the heat losses from the heat gained. If the value is positive, the body's temperature increases and heat-related illnesses may occur. The ability to cope with a hot and humid environment varies from person to person. The individual factors influencing the risk of developing a heat-related illness are: body mass, physical fitness, acclimatization, obesity, and consumption of legal or illegal drugs (Payne & Mitra, 2008).

*Kocsis C. Karoly.

E-mail address: kkocsis@unr.edu.

Experiments showed that if work is continuously performed in a comfortable climate, the core temperature of the human body will increase, and will reach an equilibrium level. The equilibrium level can be reached independent of the environment for air temperatures ranging from 5 to 30°C. However, later findings highlight that this temperature range varies inversely with the work rate. Above the upper limit of the range, the body will face a disequilibrium state, a situation in which heat will be stored in the human body, as its core temperature rapidly increases (Nielsen & Nielsen, 1962). These research findings have been the bases for limiting work in hot environments through the use of heat stress standards (Lind, 1963). From this point, the body utilizes two mechanisms to transfer heat to the environment: (1) increasing blood flow to vital organs, and (2) sweating.

The hotter the underground environment, the more uncomfortable and irritable workers can become and, given a working environment exceeding 42°C can even cause death (Torres, 2011).

2. Cooling Systems for Underground Metal Mines

As the mines are getting deeper and hotter, a greater volume of air is needed to provide adequate work conditions. The approach ventilation-only, is always preferred, and is used for as long as possible in order to postpone the costs of introducing a refrigeration plant (Mackay, Bluhm, & Van Rensburg, 2010). However, at a certain depth, known as critical depth, no effectiveness will be reached just by delivering increased air volumes. At this point, a cooling system should be installed. When a cooling system is installed, the mine's intake air volume should be reduced in order to avoid escalating costs when cooling large volumes of air (Brake D. J., 2001).

There are four major cooling systems, which can be considered for underground metal mines: (1) surface bulk air cooling (BAC), (2) underground BAC, (3) spot cooling and, (4) micro-cooling (e.g. air-conditioned cabins). The cooling power provided by the refrigeration plant may be reduced if some energy efficient systems are implemented such as: (a) the use of an energy recovery system, (b) replacing diesel equipment with battery/electric equipment, and (c) using a ventilation-on-demand (VOD) control systems, which has the ability to provide variable air volumes to the production workings. The bulk air cooling (BAC) system uses chilled water or other refrigerant to exchange heat with the mine air. It can take place in a direct or indirect heat exchanger. The chilled water is provided by either a surface or underground refrigeration plant. A surface BAC system can be a feasible option due to practical aspects. Compared to underground cooling systems, the surface BAC systems are often cheaper and undemanding when it comes to installation, operation, and maintenance (Wilson, Bluhm, Funnel, & Smit, 2003). On the other hand, the surface BAC systems have a low positional efficiency when compared to other methods of cooling since the air is cooled far from the production workings, and as cooler the intake air more heat will be transferred from strata, as the mine air flows along the openings (Mackay, Bluhm, & Van Rensburg, 2010). Consequently, based on surface air temperature, the applied mining method, and other site-specific characteristics, an underground BAC system could be more economical.

An underground cooling system can be introduced by several techniques: (a) as chilled service water, (b) secondary air cooling, (c) tertiary air cooling, and (d) as controlled recirculation within established mine districts (Mackay, Bluhm, & Van Rensburg, 2010). A primary underground BAC system is usually installed not far from the bottom of the intake shaft. If the distance between the underground BAC to the work areas is significant, a secondary stage, or even a tertiary stage cooling system is considered. In respect to secondary air cooling, the components and the methods to cool the mine air are selected according to site-specific characteristics. One option is to use direct-contact spray heat exchangers, while the other option is to use closed-circuit cooling-coil heat exchanger banks. A controlled recirculation system may be used to increase airflow within hot areas. Tertiary or "in-stope" cooling can be achieved by means of tertiary air coolers, where chilled water is used as a coolant (Mackay, Bluhm, & Van Rensburg, 2010).

An ice-based cooling system becomes feasible when the cost of pumping water from underground to surface becomes extremely expensive. Therefore, ice-making plants can be considered to deliver ice to the production workings. Ice is usually mixed with water to form an ice slurry, it is then moved underground by means of gravity. The advantage of this process is that the heat added by auto-compression is used as latent heat to melt the ice, therefore, the slurry arrives underground ready to be used for BAC system or localized spot cooling systems (Bellas & Tassou, 2005).

Spot cooling also known as "decentralized" cooling and is used when heat issues are encountered in areas away from the main airways. The system consists of an evaporator installed inside the auxiliary duct and a condenser installed outside the duct (McPherson, 2012). A high positional efficiency and mobility can be achieved, as the system is close to the production stopes. The main disadvantage includes limited cooling capacity due to size constraints, and the ability of the system to reject heat into the mine's return airways (Brake D. J., 2001).

3. Major Heat Sources and Site-Specific Characteristics Affecting Work Conditions

The total heat load in an underground mine comes from various sources. Depending on the amount of heat generated by each source relative to the mine's total heat load, a particular type of cooling system is preferred. In cases where the surface dry-bulb (T_d) and wet-bulb (T_w) temperatures are high, a surface or an underground BAC cooling system could be used. In this case, it is advised to install the BAC system underground in order to promote heat transfer from the ventilating air to strata, as the intake air downcasts the shaft. On the other hand, if the majority of the heat load comes

from internal sources such as mining equipment, backfill, groundwater, the most cost-effective cooling strategy is to utilize a localized cooling system (e.g. spot cooling).

The refrigeration turndown ratio refers to the usage of the cooling system throughout the year. A high ratio means that the system is only used during summer, while during spring, fall and winter the system is turned off (Brake D. J, 2002). To select an efficient cooling system many site-specific factors as well as operating characteristics need to be taken into account. The site-specific and environmental parameters influencing the decision on the type and location of a cooling system are (Brake D. J, 2002): (1) Auto-compression, (2) Geothermal gradient, (3) Surface climate, (4) Employed mining method, (5) Level of mechanization, (6) Mining depth.

3.1. Auto-compression

Auto-compression is the conversion of the potential energy into enthalpy when a fluid flows from a higher elevation to a lower elevation. For example, the dry-bulb temperature (T_d) lapse rate can be in the range of 9.7 °C per 1,000 meters considering a dry shaft and 101.3 kPa of barometric pressure at the collar of the shaft. However, in the majority of cases, the shaft or the airways are not completely dry. Consequently, the rate of increase in the dry-bulb temperature (T_d) is eroded by the cooling effect of evaporation (McPherson, 2009). In case of wet conditions down an intake shaft and along horizontal airways, the dry-bulb temperature (T_d) will in fact decrease as a result of evaporation (Payne & Mitra, 2008). The wet-bulb temperature (T_w) will increase as the intake air picks up moisture (Whillier & Ramsden, 1975). The variation of the dry-bulb temperature (T_d) with the change in moisture content of the air is shown on Figure 1.

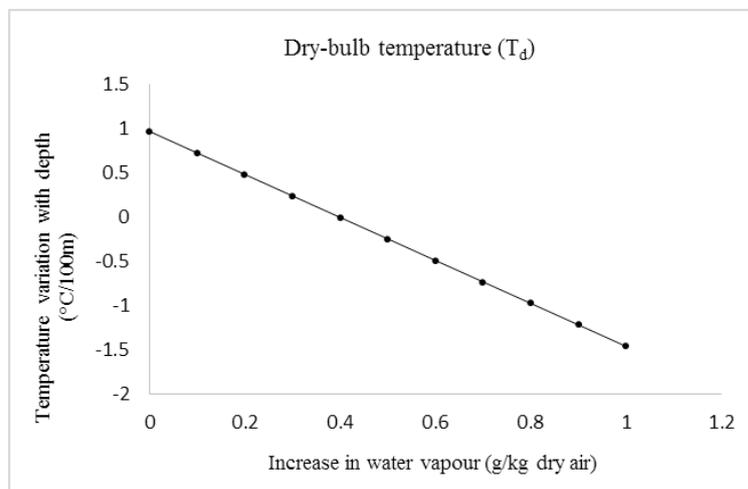

Fig. 1: The effect of moisture content on the dry-bulb temperature (T_d)

For underground mines located in Northern Ontario (Canada) and Australia, auto-compression can account for over 50% of the total heat load. However, at metal mines in western USA its significance can be considered as moderate, thus profoundly impacting the cooling system (Carpenter, Roghanchi, and Kocsis, 2015). Heat added to the mine air also depends on the elevation, gravity, and the specific heat of the air. Fig. 2 shows the effect of auto-compression as well as the effect of average surface air temperatures on the climatic conditions underground. The effect of auto-compression and surface air temperature have been analyzed for 3 different scenarios, which are presented in Table 1. The maximum allowable wet-bulb temperatures in the mine’s return air were assumed as: 28°C, 27°C, and 26°C. The adiabatic lapse rate on the wet-bulb temperature (T_w) was assumed as 4 °C per 1,000 meters.

Table 1: Surface air temperatures for three scenarios

Scenario	Dr-bulbtemperature (°C)	Relative Humidity (RH)	Wet-bulb temperature (°C)
(1) Maximum daily average parameters during summer	32	51%	21
	28	43%	29
(2) Maximum average parameters during summer			
(3) Average parameters during summer	18	43%	11

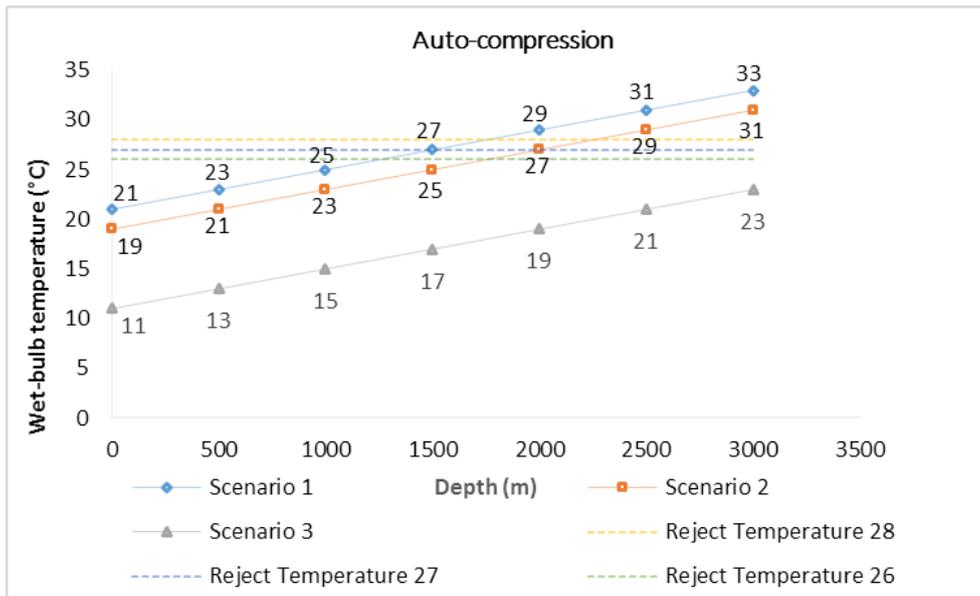

Fig. 2: The effect of auto-compression on the heat load

Figure 2 shows that the critical depth where a cooling system is required assuming that the wet-bulb temperature (T_w) in a mine’s return airways cannot exceed 28°C is 1,700 meters for Scenario 1, 2,250 meters for Scenario 2, and over 3,000 meters for Scenario 3. Furthermore, if the allowed wet-bulb temperature in the mine’s return airways is lowered to 27 °C, the critical depth where a cooling system is required is 1,500 meters for Scenario 1, 2,000 meters for Scenario 2, and over 3,000 meters for Scenario 3. These parameters and values are also provided in Table 2.

Table 2: The critical depth

Allowed wet-bulb temperature (°C)	Surface wet-bulb temperature (°C)		
	Scenario 1	Scenario 2	Scenario 3
26	1,250 m	1,750 m	>3,000 m
27	1,500 m	2,000 m	>3,000 m
28	1,700 m	2,250 m	>3,000 m

3.2. Geothermal gradient

The geothermal gradient is the variation of the virgin rock temperature (VRT) as a function of depth, and it is also a function of the rock thermal properties (McPherson, 2012). The geothermal gradient controls the amount of heat, which is transferred from the surrounding rock formations into the mine air, and vice versa. If the airway is dry, the heat flow is basically proportional to the difference between the virgin rock temperature (VRT) and the air temperature (Payne & Mitra, 2008).

The virgin rock temperature (VRT) is increasing with depth. In general, at approximately 50 meters below surface the rock temperature remains equal to the average surface air temperature. Between 50 meters and 100 meters, the rock temperature changes due to circulating ground water. Below 100 meters, the rock temperature increases according to the geothermal gradient, and also depends on the thermal properties of the surrounding rock formations such as conductivity, diffusivity, as well as tectonic setting (Maurya, Kailash, Vardhan, Aruna, & Raj, 2015).

It is important to predict the virgin rock temperature (VRT) at deeper levels in order to quantify the heat which will be transferred from strata to the ventilating air. For example, a sensitivity analysis was carried out to determine the virgin rock temperature (VRT) as a function of mining depth considering that the surface rock temperature is 18 °C, while the geothermal gradient varies by 10 °C/km, 20 °C/km, 30 °C/km, and 40 °C/km. Based upon the sensitivity analysis, the virgin rock temperature (VRT) trends are presented in Figure 3.

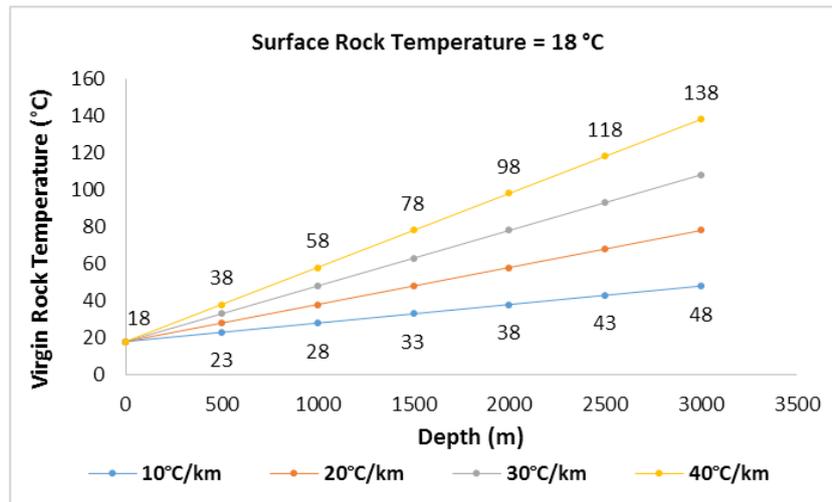

Fig. 3: Virgin rock temperature (VRT) variation as a function of depth

3.3. Surface climate

The surface air temperature has a significant impact in determining the cooling capacity of the refrigeration plant. As the intake air downcasts the shaft, the heat from auto-compression is also added to the ventilating air. At many underground mines, during summer the temperature of the intake air has a higher value than the shaft’s wall. Consequently, the surface temperature needs to be carefully selected when developing a climatic model to determine the type and the cooling capacity of the refrigeration plant. For example, if the selected surface air temperature is 1°C higher than the correct value, the cooling capacity of the refrigeration plant may be over-estimated by 3 to 4 MW, for an intake air volume of 850 m³/s (Karsten & Mackay, 2012). Thus, the added capital and operating costs over the life of the mine can be significant.

In a case study where all major heat sources were assessed and analyzed, the yearly average surface air temperature for an underground mine in Australia and an underground mine in South Africa was determined at 28 °C, and 18 °C, respectively. The difference was basically due to an altitude difference of 1,400 meters between the two mines (Brake D., 2002). For elevated average surface air temperatures such as the mine in Australia, it may be wise to consider installing a high capacity BAC cooling system on surface, as these type of cooling systems are easy to install and to maintain when compared to an underground BAC system. Operational experience has shown that within the development headings and throughout the production workings heat becomes a problem for the mine workers when the average surface wet-bulb temperature (T_w) exceeds 21°C (De Souza, 2002). Figure 4 shows the average surface dry-bulb temperature (T_d) of the air during 2016 in the Elko and Winnemucca areas. Although the yearly average surface air temperature is relatively low for both areas, in July the average dry-bulb temperature has increased to 21.25°C in Elko and 22.5°C in Winnemucca. This means that during the month of July, the maximum dry-bulb temperature on surface can reach temperatures in the range of 40 °C.

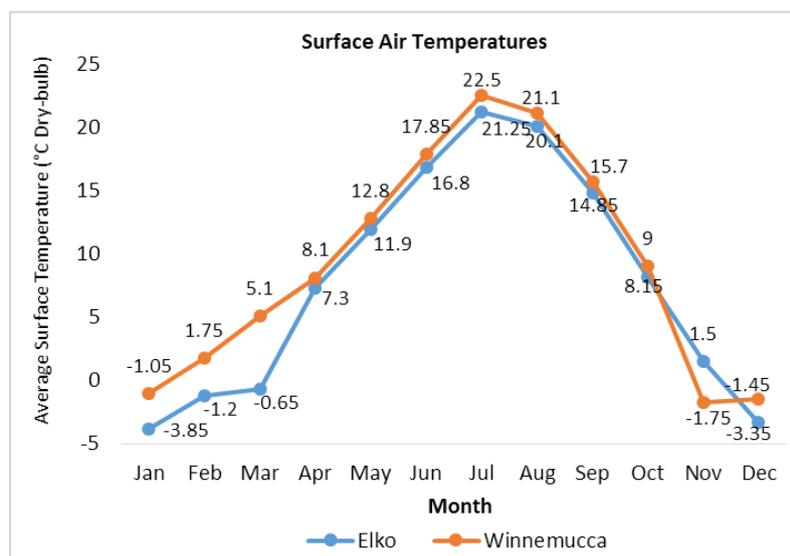

Fig. 4: Average surface air temperature variation in Elko and Winnemucca areas, Nevada.

3.4. Employed mining method

The ventilation system of a mine, as well as its cooling system can largely depend on the mining method employed. For example, when the “sub-level stoping” method is employed, efficient airflow distribution to the work areas and throughout the mine can be a difficult assignment. As the ventilating leaks into the caved areas and voids, the heat removal capacity of the ventilation system can be significantly compromised (Guney & Bell, 1979).

An underground mine’s layout can largely depend on geological factors, geotechnical characteristics, and the geometry of the orebody. For example, vein type deposits are usually mined by means of selective mining methods such as the “cut-and-fill” mining method, and while the mine can be relatively deep, the development and production stopes are not spread laterally. Thus, the residence time of the intake air from the collar of the shaft to the production workings is not significant. Consequently, less heat may be transferred from strata to the ventilating air. Conversely, in case of massive and tabular ore deposits the development and production workings are spread out, thus allowing the ventilating air to pick up a large amount of heat from strata, mining equipment and from other sources (Brake D., 2002). In this case, a spot cooling system is more effective than a surface BAC system. When the “block caving” mining method is employed, a large amount of broken ore is released. Consequently, the heat transferred to the ventilating air from the broken ore and mining equipment can be significant. For example, a study performed at a cooper mine where the “block caving” method was employed highlighted that the heat transferred to the mine air from the broken ore was in the range of 30 MW, which accounted for approximately 21% of the total cooling capacity of the mine (Bluhm, Moreby, von Glehn, & Pascoe, 2014).

The employed mining method can also affect ground water inflow into the mine through fissures, as heat can be transferred to the mine air from this source as well.

3.5. Level of mechanization

The mining equipment utilized in underground metal mines is either diesel and/or electric. The level of mechanization can dictate the heat load in underground mines, and consequently aids in choosing an appropriate cooling method. However, in mechanized metal mines there is low service water usage mainly because in this mines the drilling process is fully mechanized or even automated, and hand-held drills, which are responsible for the majority use of service water usage are no longer used (Brake and Fulker, 2000).

Diesel-powered equipment such as LHDs, haul trucks, and drills generate a large amount of heat and contaminants such as diesel particulate matter (DPM) as well as combustion gases (Roghanchi & Kocsis, 2017). The heat released depend on the duty cycle of the mining equipment and on the engine’s efficiency, which at peak power is considered to be at 33%. Thus, approximately two-thirds of the total input power is released into the mine air as heat (McPherson, 2012). Battery-powered and electrical equipment have a higher efficiency than diesel equipment resulting in less heat released in the production workings and along the haulage drifts. This higher efficiency is achieved because the electric motor requires less input power than diesel engines for the same performance due to torque characteristics of the former (Millar, Trapani, & Romero, 2016). For battery-bowered and electrical equipment the total heat produced is the rate at which power is supplied, less any work done against gravity. Furthermore, the efficiency of the equipment determines the distribution of heat produced. Diesel equipment will produce approximately three times as much heat as battery-powered equipment of the same mechanical output. Another important difference between diesel and battery-powered equipment is that diesels produce part of their heat output in form of latent heat, as each liter of diesel fuel that is consumed produces approximately 1.1 liter of water in the exhaust gases. In situ tests have shown that the factor can actually vary from 3 to 10 liters of water per liter of fuel consumed due to evaporation of water from cooling systems and where water is employed to control dust concentrations (McPherson, 2012). In respect to heat generation, a comparison was performed in an underground mine in Northern Ontario, Canada between a diesel and electric LHD. The results are provided in Table 3 (Millar, Trapani, & Romero, 2016).

Table 3: Heat generation from diesel LHD versus electric LHD

Parameters	Diesel LHD	Electric LHD
Engine output	243	177
Thermal efficiency (%)	37	95
Heat dissipated from the powerhouse (kW)	516	9
Drive train losses (kW)	97.2	97.2
Total heat dissipation (kW)	614	107

4. Discussion

In many instances, simply adjusting or upgrading the auxiliary ventilation system in a problem area of a mine will effectively dilute the pollutants that are generated during production operations and provide adequate climatic conditions for mine workers. Methods to achieve this include (1) extending the auxiliary duct toward the face, (2) installing an additional auxiliary fan to overcome the added pressure losses in the system, (3) changing the size of the fan, (4) switching from an exhausting arrangement to a forcing arrangement, and (5) installing an overlap auxiliary ventilation system. If the required air volumes in the active areas are more than the primary ventilation system can provide, other measures may need to be considered in order to increase airflow delivery. This may include the installation of a ventilation-on-demand (VOD) control system, adding booster fans to improve airflow distribution, and upgrading the surface fans.

Understanding the heat sources and the heat exchange processes in underground mines is critical to design and install effective ventilation and cooling systems in order to provide adequate work conditions in the development and production stopes. To assure appropriate work conditions in underground mines, a “*human comfort model*” was developed at the Mining and Metallurgical Engineering Department of the University of Nevada, Reno (UNR) as part of a 5-year research study. For an underground worker, this comfort model has the ability to determine the following parameters and work conditions: (1) Maximum allowable dry-bulb temperature (T_d), wet-bulb temperature (T_w), and relative humidity (RH) in a production stope and throughout the mine as a function of air volume (Q) and work intensity (e.g. metabolic rate), (2) Continuous work and rest periods in the production areas while minimizing heat stress due to dehydration and adverse work conditions, (3) Optimum airflow velocity in order to assure thermal comfort in the production workings and throughout the mine, (4) Ventilation and climatic parameters for maximum thermal comfort as a function of activity level and clothing. Climatic simulations performed on the “*human comfort model*” showed that the relative humidity (RH) contributes a lot more to deviations from thermal comfort than any other climatic parameters. It is flowered by the level of activity (e.g. metabolic rate) and airflow velocity (v). Quantifying the amount of heat generated from major heat sources such as auto-compression, strata, and mining equipment are critical to design efficient ventilation and cooling systems in order to assure adequate work conditions as a function of mining depth and the level of mechanization.

A number of cooling systems and strategies are available, with varying cooling capability, cost, mobility and efficiency. No one solution is better than the other, as mine specific conditions may require a cooling method that is unique to the particular operation. The majority of the most widespread cooling methods as well as some of the less common ones are basically applicable to the hot and humid underground mines in United States. Cooling systems can be upgraded, and different combinations of cooling systems can be used underground. This is important not only for the safety and health of the mine workers but also for the sustainability of the mining industry world-wide.

Challenges and opportunities of underground coal mining in North-Eastern Hungary

Molnár József^{a*}, Debreczeni Ákosa^a, Tompa Richárd^a

^a*Institution of Mining and Geotechnical Engineering, H-3515 Miskolc-Egyetemváros, Hungary*

Abstract

Several decades of underground coal mines were in operation in the mountainous north-eastern part of Hungary. The main area of utilization of the mined out coal beside power generation was supplying households with fuel mostly for heating. In the beginning of the 1990ies the power plants in question were shut down for economic, environmental and technical reasons. Consequently all the mines were closed no later than 2004 and thousands of miners lost their jobs. A new perspective of coal mining can be enabled by other ways of utilization of coal, e.g. coal chemistry, etc. New opportunities of sustainable underground coal mining in the north-eastern part of Hungary are discussed in the paper. Safe and modern equipment and technology enabling high output, clean coal, furthermore high rate of yield are targeted. Analysis of the properties of coal deposits using three-dimensional (3D) modelling are used for considering opportunities of new mining operations.

Keywords: Underground mining, sustainability, clean coal, coal;

1. Introduction

Underground coal mines of north-eastern Hungary were the major source of fuel for household heating during the past decades until the mid-1990ies in Hungary. Beside household utilization it was used for power generation, industrial heating, chemical raw materials, etc. The highest annual output of the Borsod Coal Mines company estimated 4-5 million tons. Numerous mines of higher and less output could be found throughout the northwest and northern vicinity of the Bükk mountains near Miskolc, Sajószentpéter, Kazincbarcika, Edelény, Putnok, Ózd and Borsodnádásd.

Modernization of underground coal mining resulted mechanization of the work, automation, significant increase of output and consequently decrease of the number of longwalls in the 1960-1980ies. Only 12 longwalls were in operation by the 1980ies (Molnár 2016). As a result of changes in political and economic conditions all the underground operations were shut down by 2004.

2. Cadastre of Hungarian coal reserves

Significant coal reserves remained in Hungary despite mine closures, and these could be taken into account when considering future fuel and raw material demand of the country. So Mining and Geological Survey of Hungary (MBFSZ) contributed a new cadastre of Hungarian coal deposits of greater or less reserves throughout the country which is available in electronic digital form (https://map.mbfisz.gov.hu/coal_cadastre/). Geological information that can be obtained using the database in question is of essential importance in mine design.

3. Demand for new brown coal sources

A special research took place in the past years analyzing possibility of establishing coal chemical industry in the Borsod region in question especially for methanol production. So reserves of brown coal were taken into consideration such as near Kazincbarcika (Tardona), Edelény (Szendrő), and Putnok (Dubicsány and Sajómerce II). Coal demand of chemical utilization should be considered a lucky situation from mining point of view. On the one hand such a plant needs coal of constant quantity and quality as raw material and on the other hand opening a new mine of economic

*Molnár József. Tel.: +03-646-565-111.
E-mail address: bgtmj@uni-miskolc.hu.

output requires one or more major industrial consumers. Chemical industry which has similar remarkable traditions in the region as mining can be the only major buyer as utilization of coal for power generation is not preferred this time.

There are several brown coal deposits in the Borsod region, we focus on the Dubicsány and Sajómercse II ones.

Both coal deposits are close the Sajó river at town of Putnok. Sajómercse II consists of the eastern remains of the former Putnok underground coal mine south of Sajó furthermore some 10 million tons of east of it. The Dubicsány deposit which is north of the river is totally untouched as no production operations were in it in the past.

Main properties of mining point of view of both deposits are described in the paper published by MBFSZ (Debreczeni et al. 2018). Institution of Mining and Geotechnical Engineering was participant in preparing mining plans.

4. The Dubicsány brown coal deposit

262 boreholes were sunk on the 23.58 km² area of the Dubicsány brown coal deposit. Both core sampling and geophysical analysis were done for the vast majority of the holes. Two coal seams (IV and V) are available. Seam IV is thin, not mineable and can be found only on a small part of the deposit. Seam V is mineable and can be found on the whole area.

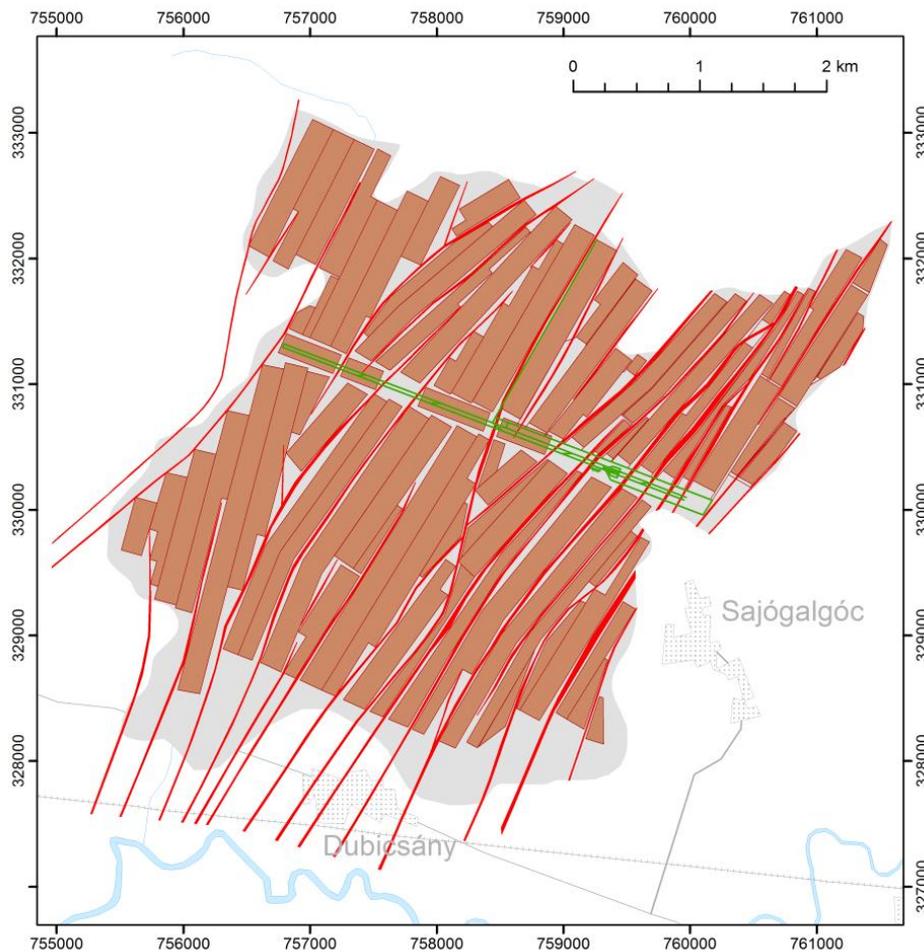

Fig. 1. Development of the Dubicsány coal mine and extraction of the coal reserve. Faults are highlighted by red lines. Püspöki (editor-in-chief), 2018

Total thickness of layers between the two seams (mostly sand) is of 70-72 m at average. Coal reserve of the Dubicsány deposit is concentrated in Seam V. Its thickness is 5-6 m on the vast majority of the deposit except on the south-western part and near the border of the seam. Thinner parts can be observed only on the southwest area as the lower part of the seam is of rather poor quality. Upper part of the seam is of higher sulfur content furthermore of higher calorific value due to lower ash content. The lower layer of the seam is of lower sulfur content and calorific value, this latter one as a result of higher ash content. Lower calorific values can be observed for greater seam thickness.

According to recent technical standards and mining plans, upper part of the coal seam is worth mine out using underground methods. Height of the coal face in the longwalls is 2.5-3.5 m, depth of the seam is 120-230 m on the northern and 200-300 m at the southern part of the deposit, thickness, mineable reserve estimates 49.9 million tons of 12,3 MJ/kg calorific value. The coal can be used as raw material for the chemical industry. Development of a new mine was planned by Borsod Coal Mines company, so two inclined shafts were sunk and more than 2000 m long drifts were made for exploration purposes beside drilling boreholes in the 1980ies. These old drifts should be replaced by new establishments.

The mine should be opened by two inclined shafts at the east side and a pair of main drifts from east to west as it was planned in the 1980ies (Fig. 1). Later a new ventilation shaft or borehole will be necessary to enable proper ventilation. Planned output of the mine amounts 1.54 million tons per year. Mine construction takes 4.5 years. Output will be increased to the total output in 5 years plus time required by design and obtaining licenses. Mine is planned to operate 37 years at the annual 1.54 million tons output level. Number of employees is estimated 900 not including number of personnel of suppliers.

The main mine hazard to be expected is due to water contained in aggregates of the roof layers. Dewatering is planned by wells drilled from the surface and established in the hanging wall of the drifts. Quantity of water can be expected 12-14 m³/min during the mine construction and later 6-9 m³/min. Water can be utilized in water supply of the region and/or industrial water in chemical industry utilizing coal. Mining operation does not risk drinking water reserves.

Environmental impact of an underground mine is much less than of a surface operation. Significant part of the inhabitants of the settlements of the region was employed by coal mining so favorable reception of a new mine can be expected.

5. The Sajómercse II brown coal deposit

The Sajómercse II deposit of 13.6 km² area consist of the remaining eastern part of the former Putnok underground coal mine and the coal reserves east of it. Geological exploration was based both on boreholes, using core sampling and geophysical methods as well and summarizing experiences obtained in the Putnok Mine.

The coal bearing strata contain 6 seams (low and high Borsod strips, seams I, II, III and III/a). Total thickness of these strata estimates 110 m, average depth is 270 m. The coal strips do not belong to the industrial reserve. Similarly Seam III/a under Seam III does not worth for utilization too due to its low quality (8000 kJ/kg calorific value) and irregular spread. Properties of the three main seams can be read in Table 1. The coal from these seams can be used as raw material for the chemical industry.

Table 1. Properties of coal seams of the Sajómercse II brown coal deposit

	seam thickness [m]	height of coal faces of longwalls [m]	coal reserve that can be extracted by longwalls [million tons]	average calorific value of coal that can be extracted by longwalls [kJ/kg]
Seam I	0,8-2,45	1,8-2,2 (average: 2,00)	5,289	12650
Seam II	0,7-5,65	2-2,5 (average: 2,25)	16,366	12000
Seam III	0,8-6,2	2,5-3,5 (average: 3,00)	15,974	13500
total			37,629	12728

Uniaxial strength of Seams I and II is of 12-24 MPa. A little bit lower strength (8-18 MPa) can be observed in Seam III due to clay layers in it. Country rocks are mostly low strength water-bearing layers consisting mostly of sand and clay. Highest strength was observed in the covering rocks of Seam III which is favorable for main drifts. Water hazard furthermore mud intrusion should be expected in all seams from the hanging wall and the foot wall too. Dewatering plans must take it into account.

Development of the Sajómercse II coal mine and extraction of the coal reserve of Seam II are shown on Fig. 2. Development system consist of a pair of inclined shafts on the northern side of the seams, a pair of main drifts in seam III as its country rocks are of higher strength and finally a ventilation shaft or borehole on the south.

Planned output of the mine amounts 1.0 million tons per year. Mine construction takes 3 years. Output will be increased to the total output in 4 years plus time required by design and obtaining licenses. Mine is planned to operate 37 years at the output level. Number of employees is estimated 600 plus number of personnel of suppliers.

The main mine is endangered by water hazard. Dewatering is planned by wells drilled from the surface and established in the hanging wall of the drifts. A detailed hydrogeological exploration is needed before starting mining operations. Quantity of water can be expected 6 m³/min according to experiences from Putnok Mine. Water can be utilized in water supply of the region and/or industrial water in chemical industry utilizing coal. Mining operation does not risk drinking water reserves.

Fig. 2. Development of the Sajómercse II coal mine and extraction of the coal reserve. Faults are highlighted by red lines. Püspöki (editor-in-chief) 2018

The mining area is close to the Lázberc Protected Area, consequently a complex sensitivity analysis is extremely important. Environmental impact of an underground mine is much less than of a surface operation. Significant part of the inhabitants of the settlements of the region was employed by coal mining so favorable reception of a new mine can be expected.

6. Surface facilities and infrastructure of the two mines

[1] Infrastructure required by a new mine is available in the region. There are arterials and main railroad in the valley of Sajó, local roads from the arterial, pipeline of potable water for the supply of the neighboring villages and electric distribution centers.

Former mining facilities do not exist that can be available. So new industrial roads power supply from two independent sources, water supply and sewage and mine water drainage should be built. Furthermore new coal transportation equipment is needed. This will be able to be designed when location and method of the utilization will be known. Proper mine waste disposal site should be established.

New buildings are required by the inclined shafts and the fan furthermore new silos, maintenance facilities, a storage partly covered by shelter, transformers, compressors, boiler, bath, dressing room, lamp house, dispatcher center, office, parking place, internal road and railroad network, public utilities and guarding facilities.

7. 3D modeling of Seam V of the Dubicsány deposit to enable more accurate estimations for mine design

A 3D model was developed to make mining plans more accurate. This model consisted of the following elements.

- Calorific value of the coal was determined as a function of different coal quality parameters (moisture, ash, volatile, fix carbon, sulfur, hydrogen content and higher calorific value). Univariate functions were obtained by regression method. Numbers of points used for the estimations were very high (5648-5989). Estimations proved to be accurate as coefficients of determination were fairly high $0,7670 < R^2 < 0,9948$ and estimated errors of calorific value were low of $0,335 \text{ MJ}\cdot\text{kg}^{-1} < D(\Delta F) < 2,248 \text{ MJ}\cdot\text{kg}^{-1}$.
- Based on the geological data of the deposit a three-dimensional (3D) model was prepared for the numerical computations to determine the quantity and the quality properties of the coal. A picture based on the block model highlights the calorific value of the coal on the upper surface of Seam V (Figure 3). Resolution of the model is shown by the sizes of the blocks that are obvious on the figure.

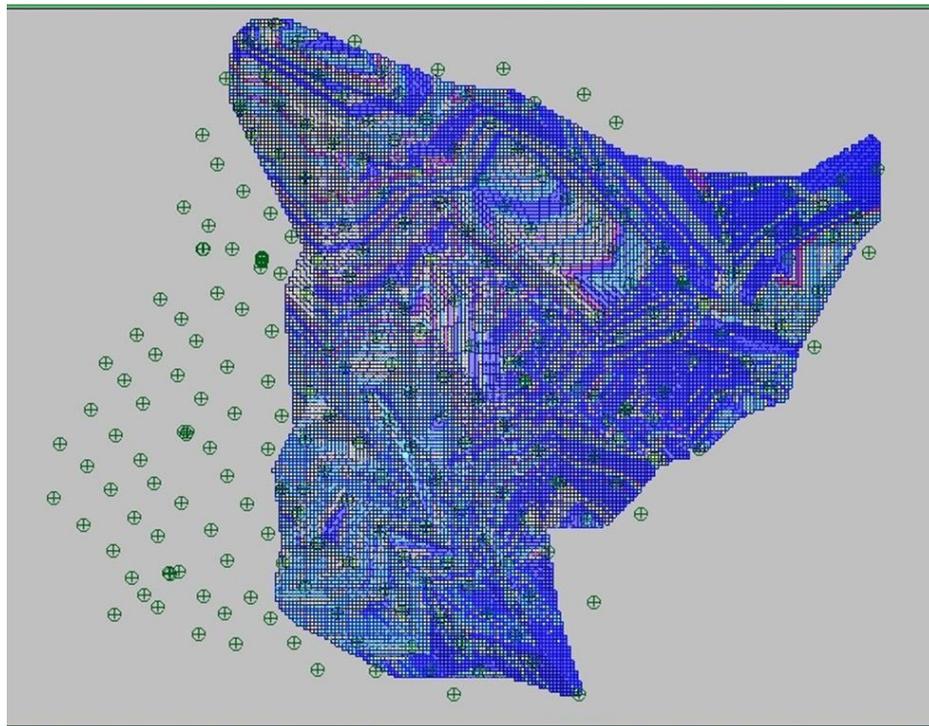

Fig. 3. 3D block model of calorific value of Seam V of the Dubicsány deposit. Drawn by Tompa R., 2018

- Thickness and mean calorific value of Seam V was determined for all boreholes throughout the whole deposit. Valuating thickness and specific heat content enabled more accurate determination of the borders of the parts of the mine (as shown fields North I, North II, South I and South II on Figure 4). Steadier seam thickness and calorific value in a mine field is more advantageous from mining engineering point of view.
- As coal quality changes (deteriorate) obviously from the covering layer of Seam V downwards, it is an extremely important question to determine the proper height of the coal face of the longwalls. This is important for the correct selection of the longwall equipment thus enabling selective cutting. A numerical analysis was done to find the distribution functions of the mass and the heat content furthermore the mean calorific value of the coal as a function of coal face height for the four parts of the mine. Future owners will be able to use these result for proper decisions in mine valuation and mining engineering design.

Abstract

Usually, tunnel final linings are designed according to specific criteria and safety levels required by various codes – Eurocodes for projects located within EU. These codes are mainly applicable in conventional structures, where variability is extremely reduced, and a deterministic approach is largely used.

On the contrary, the loads on the final lining of tunnels result from the interaction of the rockmass, temporary support and the final lining. These loads are subjected to a higher degree of uncertainty due to the high variability of the geomechanical parameters of the rockmass.

On the other hand, materials used for the lining (shotcrete, concrete, steel), present a higher variability than similar materials used in surface construction, due to non-uniformities during the underground construction process. This paper investigates the variation of the final lining loads using Monte Carlo simulations performing a probabilistic analysis using Rocscience’s RS2 Finite Element Software. Selection and validation of the Probability Density Functions (PDFs) for the input parameters is realised using @RISK add-on to Excel program.

Keywords: tunnel desig, probabilistic approach, Monte Carlo simulations, FEM, uncertainty, PDFs;

1. Introduction

The considerable uncertainty of the geomechanical parameters has led to conservative designs of tunnel linings with “hidden” safety factors (i.e. the empirical methods for the estimation of tunnel loads), and the very conservative assumption of complete de-activation of all temporary supports.

When considering the statistical distribution of input parameters, we have to select Probability Density Functions (PDFs) which best describe the population of a specific parameter. In geomechanics, there are difficulties in measuring properties such as rock stresses, rock modulus or rock strength, and we have to select the values for input parameters of PDFs based on the following criteria:

- Intrinsic uncertainty;
- Experimental uncertainty;
- Heterogeneity/ Spatial variation;
- Time variation.

2. RS2 Model to Study Materials Parameter Variability on Lining Behaviour

Considering the given design criteria, the probability of failure is given by the grey areas in Fig. 1. By combining the probability of failure with the consequences of failure, it would result in the risk of the design, and thus, we can evaluate if this risk is acceptable. There is always some residual risk remaining even at the final design stage (the darker grey area on Figure 1), and this risk should be mitigated.

Uncertainties in the estimation of geomechanical parameters arise from the difficulty in measuring these characteristics, and the measurements process is subjected to errors due to the sampling process, sample preparation or sensitivity and calibration of the measuring devices. As a project develops, this uncertainty is reduced by acquiring repeated measurements.

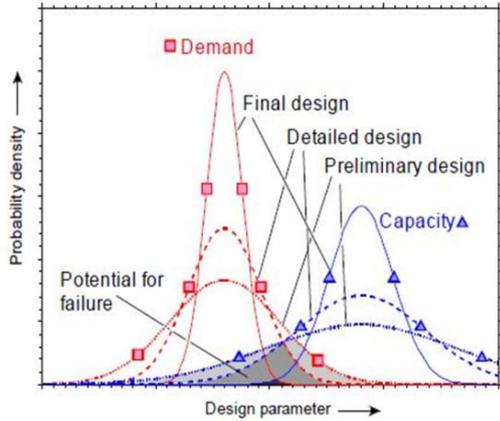

Fig. 1. Demand - capacity PDFs for tunnel lining design;

Normal probability density function, showing standard deviation ranges

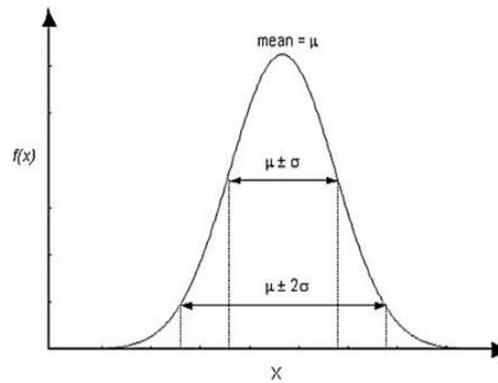

Fig. 2. The normal probability density function

Heterogeneity or spatial variation is an inherent property of the natural materials and rockmass implicitly, and rockmass property will vary within a rock unit. Thus, a failure mechanism will affect more or less severely various locations along the rock unit.

In order to determine the parameters of the Normal Distribution for each considered parameter, the Three Sigma Rule of Thumb has been used, where we estimated the highest conceivable value (HCV) of the random variable, and the lowest conceivable value (LCV). @RISK add-on for Excel has been used to derive the normal distribution for the input parameters. Fig. 3 and Fig. 4 show an example of a graphic representation of the normal distributions for both intact and residual Young's Modulus.

In all RS2 models, a Truncated Normal Distribution has been used – which is considered as the mean +/- 3 standard deviations. Fig. 2 is an example of a truncated distribution, with mean +/- standard deviations.

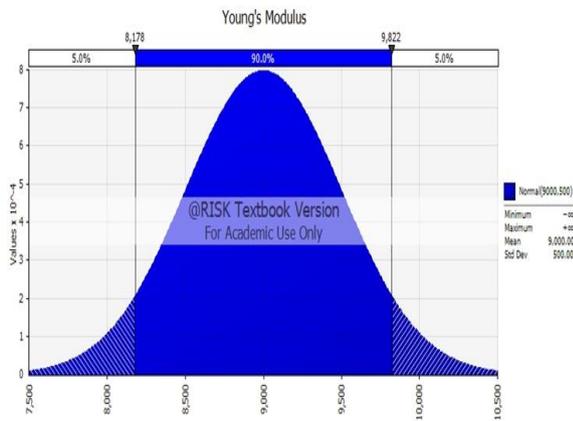

Fig. 3. Young's modulus normal distribution;

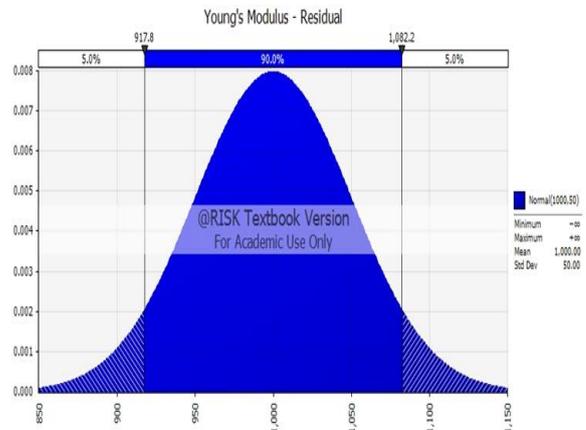

Fig. 4. Young's modulus (residual) normal distribution

2.1. Model Setup and Stress Path

A simple tunnel with an invert has been embedded into the rockmass, and boundary conditions have been specified. An initial stress field of sigma one = 8 MPa, sigma three = 6 MPa, sigma z = 6 MPa has been applied to the model and a plane strain analysis is performed.

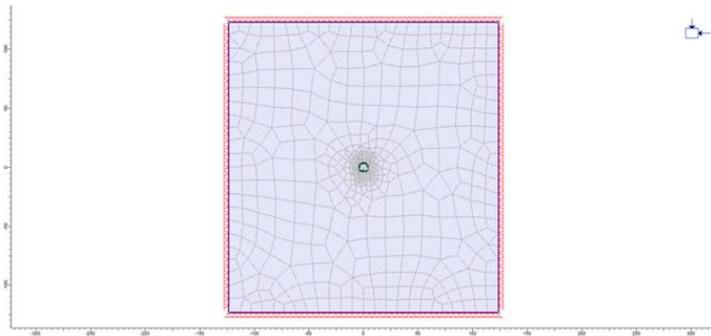

Fig. 5. RS2 model;

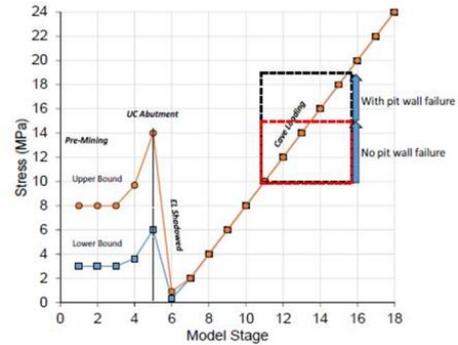

Fig. 6. Applied stress path

The general model used in this probabilistic design is represented in Fig. 5. Subsequently, a number of stress stages are applied to the model, corresponding to the loading-unloading-loading stress path for a tunnel located at Extraction Level within a block caving mining drawbell/ drawpoint – Fig. 6.

A number of 1000 samples of input parameters are generated per run, using Monte Carlo or Latin Hypercubic sampling methods, and then each realisation is run independently. At the end of 1000 runs, results are assembled together as normal distributions.

2.2. Model 1 - Elastic-Perfectly Plastic Behaviour (Hoek-Brown Parameters Peak = Residual) + Dilation – Probabilistic with Monte Carlo Sampling

This analysis considered that the rockmass behaves elastic-perfectly plastic and the failure is given by a Hoek-Brown criterion. Input parameters are presented in Table 1, and a Monte Carlo sampling technique has been used to generate sets of parameters for each realisation from the given normal distribution.

Table 1. Input parameters for model 1

Variable Type	Material/Joint Name	Property Type	Distribution	Mean	Standard Deviation	Min	Max
Material Property	Softzone	Young's Modulus	Normal	9000	500	7500	10500
Material Property	Softzone	Intact Compressive Strength	Normal	14	1.166	10.502	17.498
Material Property	Softzone	Hoek-Brown parameter (peak) mb	Normal	13	1	10	16
Material Property	Softzone	Hoek-Brown parameter (peak) s	Normal	0.95	0.0166	0.9002	0.9998
Material Property	Softzone	Hoek-Brown parameter (peak) a	Normal	0.55	0.0166	0.5002	0.5998
Material Property	Softzone	Dilation Parameter	Normal	10	1.666	5.002	14.998
Material Property	Softzone	Young's Modulus	Normal	9000	500	7500	10500

Table 2 contains equivalent characteristics in the combined liner – steel arches (parameters are given in Table 3) and shotcrete/ concrete (characteristics presented in Table 4).

Table 2. Equivalent parameters for combined liner: concrete + steel arches

Liner Type	Reinforced Concrete
Equivalent Young's modulus	36927.4 MPa
Equivalent thickness	0.407118 m
Poisson ratio	0

Table 3. Reinforcement properties of steel arches

Type	I-beam (HP): HP360 x 152
Spacing	1 m
Section Depth	0.356 m
Area	0.0194 m ²
Moment of inertia	0.000437 m ⁴
Young's modulus	200000 MPa
Poisson ratio	0.25
Compressive strength	400 MPa
Tensile strength	400 MPa

Table 4. Concrete properties

Thickness	0.355 m
Young's modulus	30000 MPa
Poisson ratio	0.15
Compressive strength	40 MPa
Tensile strength	3 MPa

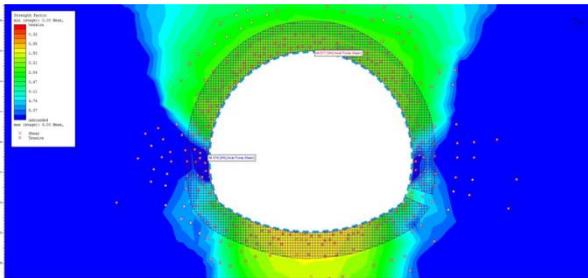

Fig. 7. Axial forces in last stage and strength factor in rockmass;

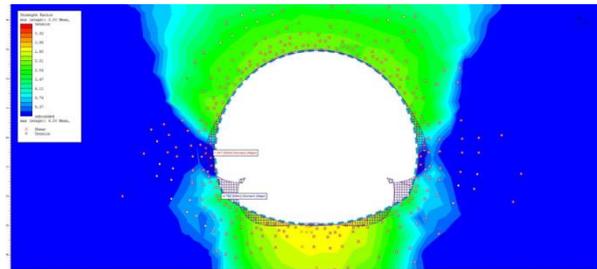

Fig. 8. Bending moments in last stage and strength factor rockmass

Results were calculated for each stage of the stress path – a total number of 18 stages were considered in the analysis.

Axial forces are represented for the last stage (highest load) in Fig. 7, whereas bending, movements acting on the combined liner are shown in Fig. 8.

As mentioned previously, results from the 1000 realisations are compound together into a normal distribution – the user has the option to plot results for each parameter around the mean of the normal distribution.

As an example, the Strength Factor in the rockmass defined as the ratio between applied stresses and rock strength is shown in Fig. 9 and Fig. 10:

Fig. 9 – for the mean +3 standard deviations, corresponding to the Best-Case Scenario; rockmass around the tunnel still present some resistance as the Strength Factor is over unit;

Fig. 10 – for the mean -3 standard deviations, corresponding to the Worst-Case Scenario; rockmass fails around the tunnel, with Strength Factor reaching values of 0.32.

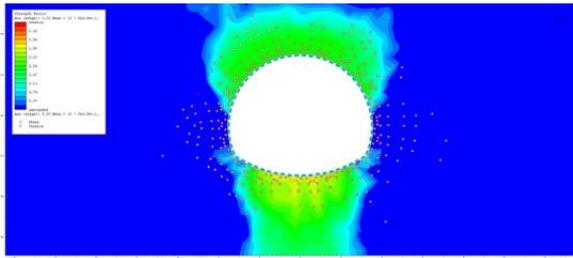

Fig. 9. Strength factor in rockmass for mean + 3 standard deviations;

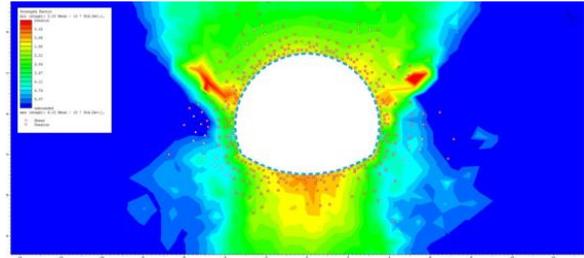

Fig. 10. Strength factor in rockmass for mean - 3 standard deviations

2.3. Model 2 - Model 2 - Elastic-Plastic with Strain Softening Behaviour (Hoek-Brown Parameters Peak \neq Residual) + Dilation - Probabilistic with Latin Hypercube Sampling

This analysis took into account an elasto-plastic rockmass, with a strain softening post-peak behaviour. Table 2 contains input parameters for this model and the sampling technique used is Latin Hypercube.

Axial forces are represented in Fig. 11 along with the Strength Factor in the rockmass and Fig. 12 shows the bending moment applied to the combined liner.

Table 5. Input parameters for model 2

Variable Type	Material/Joint Name	Property Type	Distribution	Mean	Standard Deviation	Min	Max
Material Property	Softzone	Young's Modulus	Normal	9000	500	7500	10500

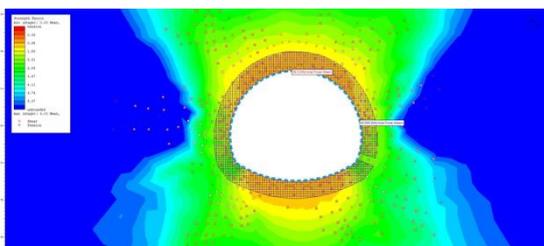

Fig. 11. Axial forces in last stage and strength factor in rockmass;

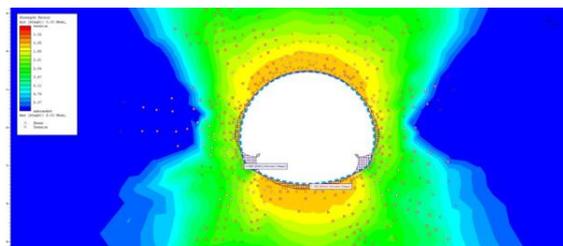

Fig. 12. Bending moments in last stage and strength factor in rockmass

3. Conclusions

Uncertainty in the estimation of input parameters for a tunnel lining design can be overcome by using a probabilistic approach. Using Monte Carlo simulations, implemented in Rocscience's RS2 software, axial forces (mean) and bending moments (mean) could be determined for two models with elastic-perfectly plastic and strain-softening behaviours and characterised by Hoek-Brown failure criterion.

The design engineer has a tool to predict tunnel liner/ support behaviour for various scenarios, from the Base-Case Scenario ($\sigma + 3\mu$) through the Most Probable Scenario (σ), to the Worst-Case Scenario ($\sigma - 3\mu$).

Consideration of uncertain parameters for the liner and the derivation of the reliability index of the system rockmass – liner are the next steps of this analysis.

Loads estimation in block caving mining

Madear Gelu^{a*}, Madear Camelia^b

^a GOLDER, 1, South Parade, Doncaster – DN1 2DY, UK

^b ECO-ROCCA Engineering, 23, Parcului Street, Petrila - 335800, Romania

Abstract

Block caving method of mining requires more development work before the start of ore production than most other mining methods. This mining method implies to have high investment costs and these mining methods are quite inflexible. Initiating and sustaining the cave govern the early productivity and economics of the operation. The paper presents both the theory for loads estimation and results for Monte Carlo simulations for a block caving mine, taking into account the following variables: hydraulic radius of the cave; bulk density; horizontal-to-vertical stress ratio; friction angle at the cave walls.

Keywords: mining, block caving, Monte Carlo simulation, hydraulic radius;

1. Introduction

The stability of the extraction level excavations is critical to the efficient extraction of the ore from caving mines. Several factors have the potential to influence the levels of stress induced in the extraction level excavation, of which significant is the vertical stress due to cave loading.

Estimation of the vertical stresses/ loads acting on the extraction level in block caving mining is paramount for the optimisation of tunnel lining/ support at the Extraction Level (EL). The limit equilibrium solution proposed by Loren Lorig is employed to estimate the average vertical stress at the cave base. Model inputs are derived from experience, theory and the results of numerical and physical experiments.

Monte Carlo simulations are used to obtain stress estimates at the cave base/ extraction level, due to the high level of uncertainty in evaluating input parameters.

In order to derive loadings on tunnels located at the Extraction Level, we should estimate stresses generated during the block cave mining processes at the base of the drawbell/ drawpoint. These loads are used subsequently into the stress path to design the lining/ support of the tunnels located at Extraction Level.

2. Relation Between Caved Column Height and Vertical Stress at the Cave Base

Loren Lorig derived a formula for the quantitative estimation of transmitted vertical stress at the base of a block cave, for the plane strain condition using limit equilibrium analyses.

A fundamental assumption inherent in the analyses is that the caved material is drawn uniformly, resulting in a relatively uniform vertical stress acting on the base.

It is important to note that a uniform draw is seldom achieved in practice. The problem to be analysed is represented in the Fig. 1, and the specific goal was to quantitatively derive the relationship between the base pressure, p , and the geometry of the prism.

Using the limit equilibrium methods for the three-dimensional case, Lorig derived the following formula:

$$\frac{p}{\gamma H} = \frac{1}{\frac{H}{R_H} K_p \tan \phi} \left(1 - e^{-\frac{H}{R_H} K_p \tan \phi} \right) \quad (1)$$

*Madear Gelu. Tel.: +44-7596-076-133.
E-mail address: gmadear@golder.com.

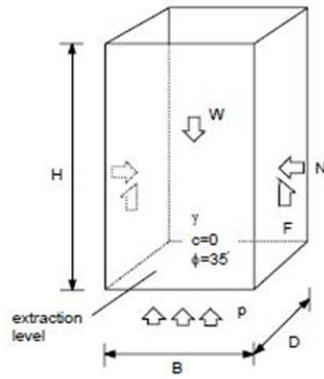

Fig. 1. Lorig representation of the cave

3. Estimation of Vertical Cave Loads on Extraction Level using Pierce’s Model

The limit equilibrium solution adopted by Lorig is based on the bin theory of Janssen (1895), where the vertical stress – at a depth z , below the free surface of a bin is given by:

$$\sigma_v = \frac{R_h * \rho_b * g}{\tan \phi_w * k} \left(1 - e^{-\frac{k * \tan \phi_w * z}{R_h}} \right) \tag{2}$$

where:

- R_h – is the bin hydraulic radius (equal to the area divided by the perimeter);
- ρ_b – is the bulk density;
- g – is the gravitational constant;
- k – is the ratio of horizontal-to-vertical stress;
- ϕ_w – is the friction angle at the bin wall.

The friction angle of caved rock varies within a cave due to variability in bulk porosity, stress UCS of the rock fragments. Barton and Kjaernsly (1981) derived an empirical rockfill shear strength criterion:

$$\phi = \phi_b + R * \log \left(\frac{RBS}{\sigma_n} \right) \tag{3}$$

in which:

- ϕ_b – is the basic friction angle, estimated from shear or tilt tests;
- R – is the equivalent roughness of the caved rock – estimated from porosity and fragment roundedness/smoothness;
- RBS – is the rock block strength;
- σ_n – is the normal stress – in this case, the horizontal stress at the cave perimeter.

The initial formulation of Barton & Kjaernsli shows that Shear Strength (S) was used instead of RBS. Their dependency is presented in (4):

$$\phi' = R * \log \left(\frac{S}{\sigma_n} \right) + \phi_b \tag{4}$$

Relationship between horizontal stress, friction angle and the equivalent roughness is presented in Fig. 2.

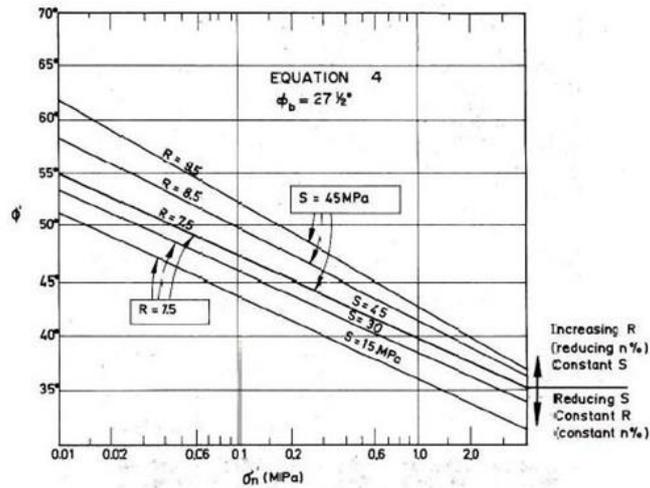

Fig. 2. Horizontal stress as a function of friction angle

4. Actual Modelling using @RISK – Monte Carlo Simulations

In order to perform a probabilistic analysis of the above-presented model of the stresses/ loads at the Excavation Level, Monte Carlo simulations have been performed, using @RISK addon for Excel for Windows.

Input parameters used for simulations are presented in Table 1 – we have used Normal Distributions for the majority of parameters:

Table 1. Parameters and their normal distributions used in simulations

No.	Parameter	Distribution	Variance
1.	Hydraulic Radius, m	RiskNormal (120,10)	120±30
2.	Bulk Density, kg/ m3	RiskNormal (3200,233.3)	3200±700
3.	Gravitational Constant, m/s2	9.81	
4.	Basic Friction Angle, degrees	RiskNormal (30,1.66)	30±5
5.	H-to-V Stress Ratio	RiskNormal (0.5,0.03)	0.5±0.1
6.	Depth from Surface, m	RiskUniform (0,600)	0=600
7.	Draw Factor	RiskUniform (2,3)	2=3
8.	Rock Block Strength, MPa	RiskNormal (35,5)	35±15
9.	Equivalent Roughness	RiskNormal (4,1)	4±3

and input parameters for Uniform Distributions (for Model Rev. 6), are shown in Table 2.

Table 2. Parameters and their uniform distributions used in simulations

No.	Parameter	Distribution
1.	Hydraulic Radius, m	120
2.	Bulk Density, kg/ m3	RiskUniform (2550, 3050, RiskStatic (3200))
3.	Gravitational Constant, m/s2	9.81
4.	Basic Friction Angle, degrees	RiskUniform (20, 35, RiskStatic (30))
5.	H-to-V Stress Ratio	RiskUniform (0.3, 0.6, RiskStatic (0.5))
6.	Depth from Surface, m	RiskUniform (0,600)
7.	Draw Factor	RiskUniform (2,3)
8.	Rock Block Strength, MPa	RiskUniform (20, 100, RiskStatic (35))
9.	Equivalent Roughness	RiskUniform(1, 7, RiskStatic (4))

The following models were run, considering various assumptions as detailed below:

- Rev. 1 – only vertical stresses based on Lorig formula;
- Rev. 2 – Pierce’s approach with R=1 and DF=3;
- Rev. 3 – R – Normal Distribution and DF=3;
- Rev. 4 – DF – Uniform Distribution; Full simulation using parameters as in Table 1;
- Rev. 5 – as per Rev.4 with R=0;
- Rev. 6 - Full simulation using parameters as in Table 2.

Simulation results are contained in each Excel file generated and a summary for Rev.4, Rev.5 and Rev.6 is presented below (Fig. 3 – Fig. 9):

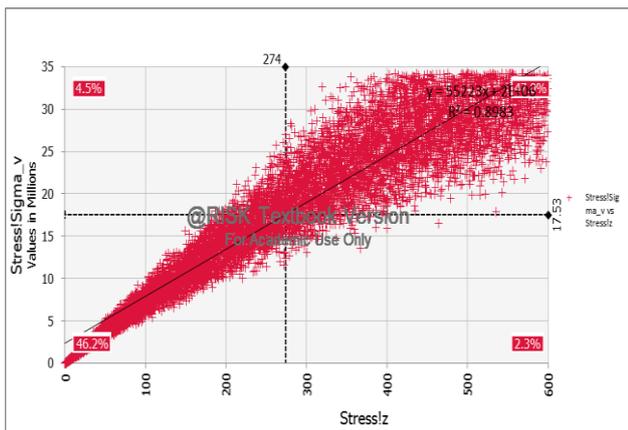

Fig. 3. Realizations for 90% confidence for model rev.4;

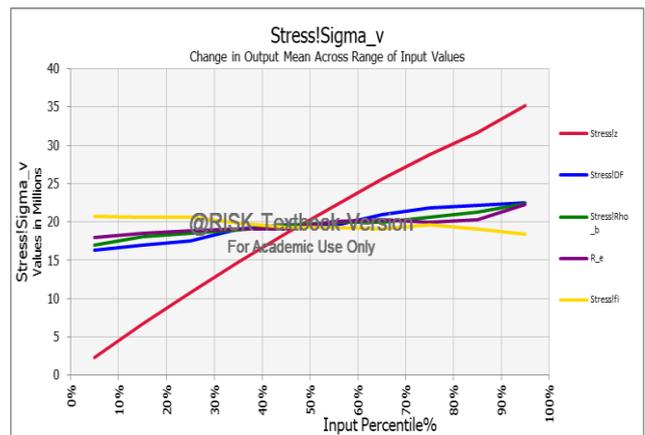

Fig. 4. Spider graph of parameter influence for model rev.4

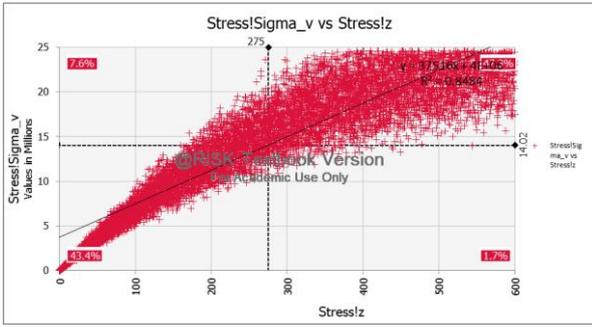

Fig. 6. Realizations for 90% confidence for model rev.5;

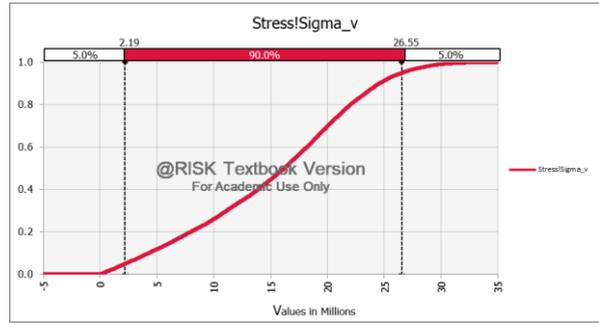

Fig. 7. Cumulative Distribution Function for caving loads (stress) for model rev.5

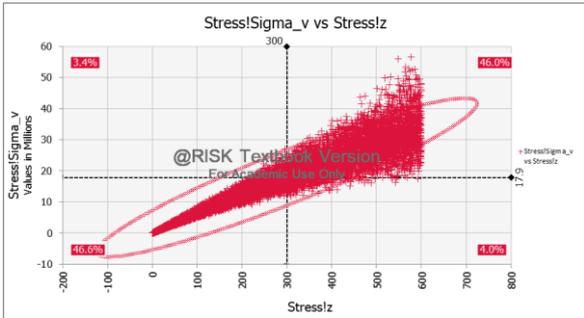

Fig. 8. Realizations within 95% ellipse confidence for caving loads (stress) for model rev.6

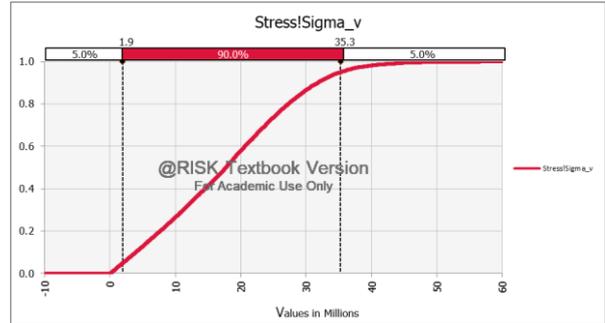

Fig. 9. Cumulative Distribution Function for caving loads (stress) for model rev.6

Fig. 3, Fig. 6 and Fig. 8 show the variation of stresses with depth at the Excavation Level.

5. Conclusions

- The vertical stresses on the extraction level are likely to vary from the average stress estimated by Lorig formula due to the redistributing effects of the draw;
- Physical experiments demonstrated that under less ideal draw conditions, the stress could be as much as 3 times the average vertical load;
- Incorporating a Draw Factor of 2-3 into Monte Carlo simulations, we obtain an estimate of the maximum cave load on the major apexes at various depths;
- If the footprint were consistently drawn over a smaller hydraulic radius (less than the total footprint $H \cdot R_h$), these stresses would be lower due to enhanced arching of stresses into the surrounding stagnant undrawn material.

Planning the development of mining operations under the changing demand for iron ore products

Lutsenko S.A.^{a*}, Zhukov S.A.^b

*State Higher Education Establishment “Kryvoy Rog National University”21/29, Lermontova st., 50002, Kryvoy Rog, Ukraine
State Higher Education Establishment “Kryvoy Rog National University”57, Gorno-zavodskaya st., 50004, Kryvoy Rog, Ukraine*

Abstract

The article reviews the issue of planning the development of mining operations under the changing demand for iron ore products. One of problems concerning development of iron ore deposits at the present-day stage of open mining development has been described. It lies in the fact that mining enterprises operate with a constant production capacity while in the markets of mineral raw materials there is a significant fluctuation in prices and demand for their products. It is almost impossible to envisage these fluctuations in the long term, because they are mainly dependent on the state of the world economy, political situation in the country, etc. In these conditions, it is possible to significantly increase the economic efficiency of development due to implementation of a flexible change in the main parameters of the quarry, which is achieved by justified correction in the development of mining operations by changing the dimensions, parameters and design of the active part of the quarry’s working area. At the same time, due to a change in the working out order for mining operations concentration sites, it is possible to provide quarry operation with a minimum current stripping ratio.

It is proposed to regulate the productivity of the open-pit by changing the wall angle of the working area of the open-pit in the areas of mining operations concentration, as well as the extent and number of these sections.

The planning technique for development of mining operations in a quarry has been developed. It differs from the known techniques due to ability to regulate the main parameters of a quarry under the changing demand for iron ore products, and also takes into account the interrelation of development system parameters that ensure ready for excavation standard ore reserve in a quarry.

Key words: open mining, planning of mining operations development, ore output in a quarry, reserves ready for excavation;

1. The problem and its relationship with scientific and practical tasks

Modern approaches on development of the raw materials base of plants are based on the assumption that all changes in the external environment are predictable [1], while in the markets of mineral raw materials there is a significant fluctuation of prices and demand for their products. It is almost impossible to predict these variations in the longer term, because they mainly depend on global economy condition, political situation in the country, etc. As a result, the goals of domestic mining enterprises have changed. The issues of ensuring competitiveness became paramount. Special requirements are imposed on decisions that determine volume and quality of mined ore, costs and profits of the mining enterprise, which directly depend on the main parameters of the quarries, as well as on the direction of mining operations development.

The practice of quarrying shows that during the crisis periods there is a sharp drop in stripping volumes. This decrease reflects the intention of enterprises to limit the growth of production costs due to the formation of temporary non-operating sides of quarries, as well as operating sides with elevated angles of inclination. This is in large part due to the inability of mining enterprises to ensure a flexible response to changes in domestic and external demand for products without significant growth in development costs, as deposit development projects do not provide for changes in the main quarry parameters over extended periods. Under these conditions, the actual calendar development schedule cannot remain stable for a long period of time and differs markedly from the design one, which additionally leads to a delay in stripping works, untimely transfer of mine openings and, in general, to a general deterioration of mining conditions of development. Therefore, ensuring the operational regulation of quarry main parameters becomes the issue of priority for mining enterprises.

*S.A. Lutsenko.

E-mail address: lutsenkosergeia@ukr.net.

As a result of the analysis of scientific publications, it was established that the existing scientific and methodological base in the field of designing and planning of open-pit mining [2-4] does not allow to provide a flexible response to the fluctuations in demand for extracted raw materials. Modern approaches to the planning of mining development are based on the assumption that the parameters of the external and internal environment will be relatively constant, and therefore, do not provide for changes in the main parameters of the quarry in the long term. This indicates the urgency of developing new and updating the existing methods of determination of quarry main parameters and planning the development of mining operations, especially in the conditions of market economic relations that require reliable optimal design solutions.

2. Highlighting the unsolved problem

From a design perspective, it is important to know not only the possible value of the quarry productivity on ore or rock mass, but also how to plan the development of quarry area.

With increase in the depth of quarries, their working area increases, which leads to increase in the costs for creating and maintaining of mining operations front. To reduce the costs of mining, it is necessary to strive to ensure the size of the quarry working area at any time of its operation to be minimal, yet ensuring the implementation of the production program on ore. This can be achieved by concentrating mining operations at particular sides of the quarry.

The adopted procedure for mining of the quarry field and the entire deposit significantly influences the production capacity of the mining enterprise on crude ore and finished products [5]. At the same time, the effective functioning of mining enterprises depends largely on timely change in quarry productivity in accordance with the change in the demand for iron ore products [6]. And since the production capacity of the quarry is the main indicator that determines the scale of production, its intensity and economic efficiency, then to ensure the reaction of the mining enterprise to changes in the demand for iron ore products, it is necessary to manage the development of the quarry working area by changing the intensity and sequence of mining for its particular sides. For this, it is necessary to have a reliable methodical base of planning the development of mining operations and creation of quarries working area under any changes in the demand for iron ore products.

By management of mining operations development is meant the total sequential operations on assessment of mining operations state, change of size, parameters and design of the active part of the quarry working area, determining the direction of mining operations development and monitoring of specified technological parameters in order to maintain the required mining volume and create conditions for safe and efficient operation of the quarry.

Therefore, selection of a rational method for the development of deposit reserves is one of the main and complex tasks in designing the quarry. This task becomes even more complicated in case of change in the demand for iron ore products and, accordingly, quarry productivity on ore.

3. Task setting

Therefore, was set the goal to develop a procedure for planning the development of mining operations, which will allow for flexible regulation of quarry main parameters under conditions of changing demand for iron ore.

4. Materials statement and results

The procedure for planning of mining operations development is based on the idea of concentrating mining operations at certain sides of the quarry field (active part of the working area), the length of which is determined by optimum values of the working area width and the length of active mining front [7], which provide the normative volume of reserves ready for excavation with regard to defined quarry productivity on ore. It is proposed to regulate the productivity of the open-pit by changing the wall angle of the working area of the open-pit in the areas of mining operations concentration, as well as the extent and number of these sections. At the same time, due to the change in the order of working out the mining areas where works are concentrated, it is possible to provide the open-pit works with a minimum current stripping ratio.

The application of this procedure was studied on the example of a conditional quarry developing a steeply dipping deposit. The opening of the deposit is carried out by means of blind temporary cross-overs (fig.1).

The work flow process is as follows:

1. For the specified (designed) quarry productivity on ore, the optimal values of the width of working area and the length of active mining front, as well as the length and number of mining concentration areas in the working area of the quarry (fig.2) are determined by means of nomogram.

The number of sites involved in the work is determined by the formula (the resulted value shall be rounded up):

$$n_p = \frac{D_a}{100 - D_a}, \quad \text{pcs} \quad (1)$$

where D_a – is the active area of the working part, %.

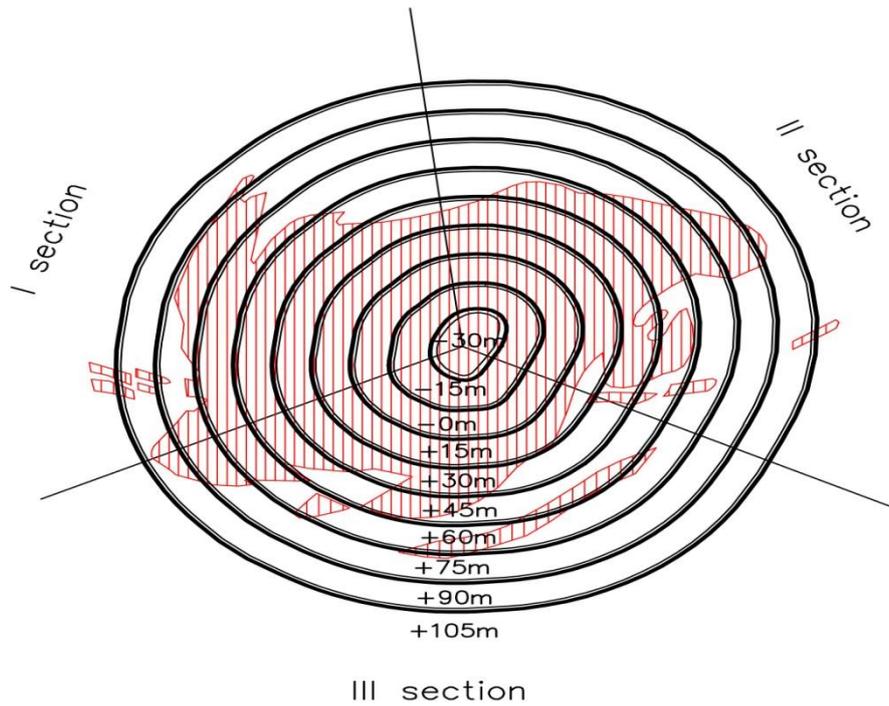

Fig. 1. Mining operations consolidated plan when reaching the mark of quarry bottom lev. -30m

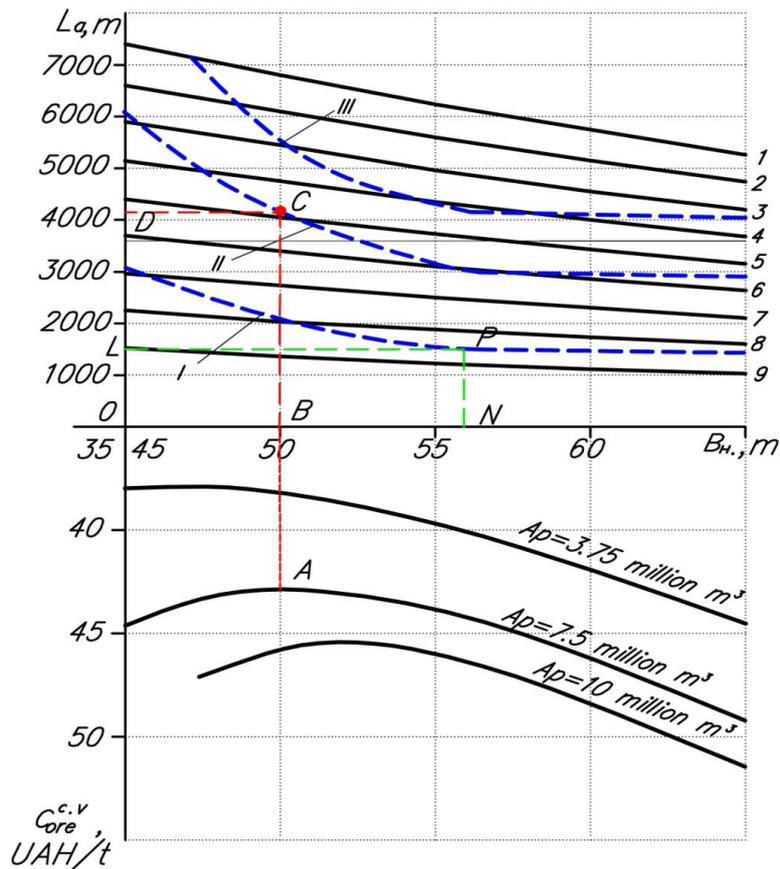

Fig. 2. Change in the length of the front of mining operations, depending on the increase in the specified width of the work site for different ore productivity options

The total number of mining concentration areas is determined by the formula (the resulted value shall be rounded up):

$$N_k = \frac{100}{100 - D_a}, \text{ pcs} \quad (2)$$

Site productivity on ore is determined by the formula:

$$A_p^s = \frac{A_p}{n_p}, \text{ t/year} \tag{3}$$

where A_p – quarry productivity on ore, t/year.

2. The quarry field is divided into equal mining concentration sites, limited with vertical planes (Fig. 1).

3. For each area, based on mining progress in depth, in accordance with the approved direction of quarry bottom sinking (the direction of the quarry bottom deepening shall be determined with consideration of operating sides slope angles, which correspond the operation with maximum possible quarry productivity on ore [8]), the maximum possible productivity and stripping coefficients with regard to their co-relation are determined [9, 10]. We build the graph of stripping current ration based on the progress in depth at each site of the deposit (Fig. 3).

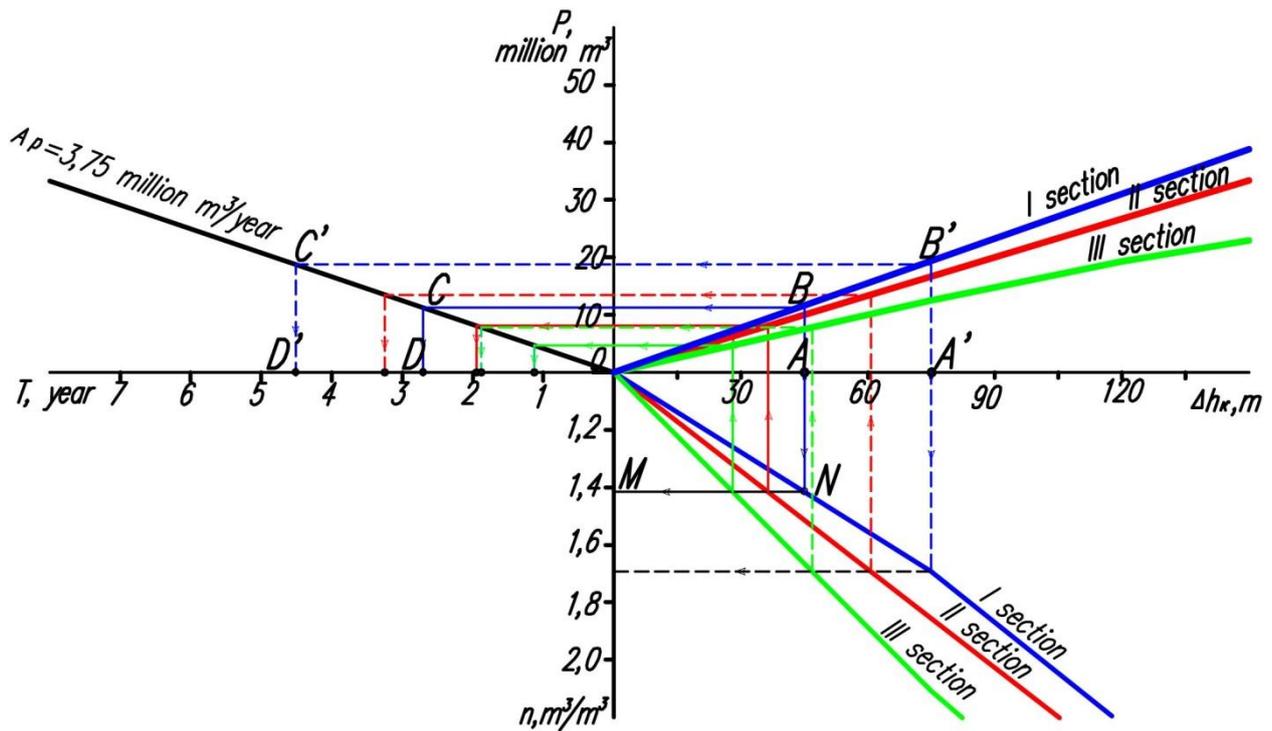

Fig. 3. Nomogram of determining the duration of quarry sites development with their different development intensity

When developing complex-structure deposits of irregular shape, ore bodies are often disturbed by faults, shifts, sometimes are bent, folded. Therefore, it is possible that at some stage of deepening the productivity on ore on the quarry in whole will be equal to the maximum possible with the corresponding width of the working platform, however, at one or more sides of the working area, the productivity will be higher or lower than the specified one. This is due to the fact that the sides of mining concentration picked on the working area do not change their spatial position during quarry sinking operations, in contrast to the ore body, which can change its shape, direction of fall, etc with the depth. Therefore, at some sides the length of active mining front on ore may increase, and decrease at others. At the same time, the length of the ore mining front on the quarry in whole will remain at the designed level.

In this case, on these sites of working area it is necessary to adjust the width of the working platform, by changing the inclination angle of the operating side of the quarry, and, accordingly, the curve of current stripping ratio at the corresponding step of sinking.

4. Determining an efficient order of quarry field development.

As we can see from fig. 3, the depth progress of mining operations at different sites of the deposit is accompanied by different stripping ratio. It is obvious that for operation of the entire quarry with minimum current stripping ratio, it is necessary to start the deepening of mining operations in the site with minimum stripping ratio until stripping ratio is of equal value with the nearest stripping ratio of any other site.

The main condition for the involvement of any section of the open-pit in the development is the equality of the current stripping ratio of this section (n_i) and the current stripping ratio in the whole open-pit (n_k).

Therefore, it can be affirmed that quarry operation with a minimum current stripping ratio will be ensured only if the current stripping ratio is the same in all the sites of the deposit. At the same time, the intensity of sites development will be different.

According to fig. 3, the lowest current stripping ratio and its slowest increase while deepening the quarry is observed in the site I, therefore it is best to begin mining operations from this site.

5. A long-term plan of mining operations development is drawn up.

In this regard, the duration of quarry sites mining is determined (Fig. 3) and a linear calendar plan of mining operations development is drawn up. According to the calendar plan of mining operations development compiled a summary table of increasing volumes of stripping and ore excavation in the course of quarry deepening operations, then the graphs $V = f(P)$ are built. The graphs $V = f(P)$ are averaged and the operating stripping ratio for the periods of quarry operation are determined.

Determination of the state of mining operations at the end of any estimated year is carried out according to the nomogram of determining the duration of quarry sites mining at different rates of sites mining intensity (Fig. 3).

In the fig. 4 showed the comparison of mining operations modes for quarry deepening:

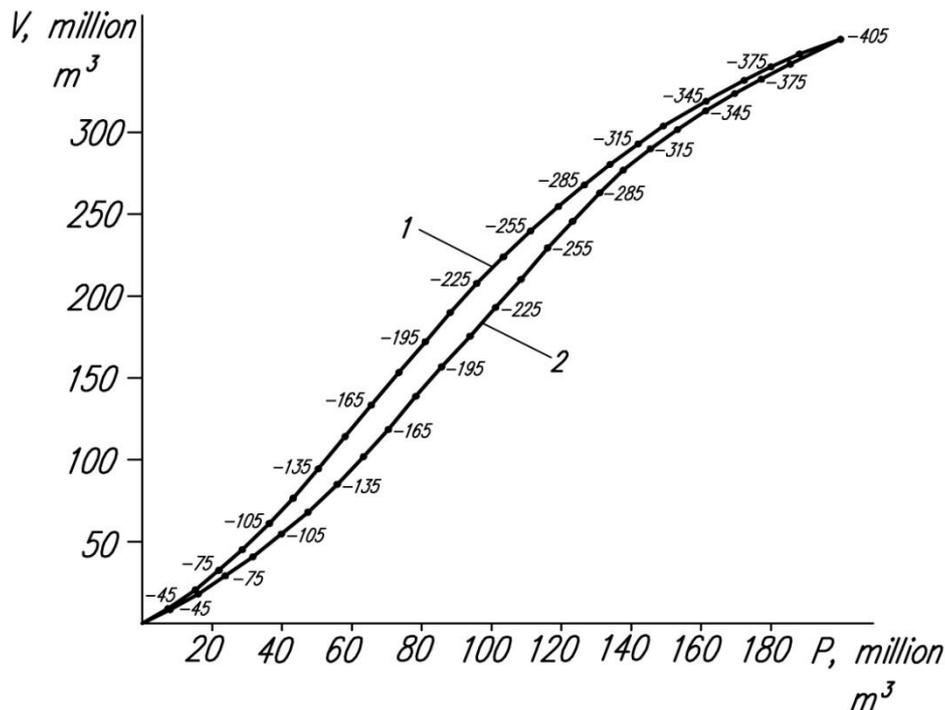

Fig. 4. Change in increasing volume of waste rocks depending on the mined volume of ore

- with a uniform development of the quarry working area (curve 1), when quarry deepening is carried out on all sites simultaneously;
- with uneven development of the quarry area (curve 2), when development of mining operations is carried out according to the developed methodology.

As can be seen from fig. 4, the curve reflecting the planning of mining operations development according to the developed methodology (curve 2) provides a better mode of mining operations than with their uniform development. In case of change in quarry productivity on ore, both upward and downward, the sequence of calculations shall be repeated starting from point 1 of this methodology.

5. Conclusions

As a result of the research has been developed the methodology of planning the development of mining operations in the quarry in conditions of changing demand for iron ore products, which is different from the known methodologies due to ability to regulate the main parameters of the quarry, and also considers the relationship between the width of the working platform and length of the active mining front, that provide the normative volume of reserves in the quarry ready for excavation.

The developed methodology for planning the mining operations development in an open-pit provides:

- the open-pit operation with minimum current stripping ratios at the maximum degree of mining operations concentration;
- work with a specified ore productivity.

Assessment methodology of instantaneous elastic deformation of sedimentary rocks

Toderaş Mihaela^a, Danciu Ciprian^{a*}

^aUniversity of Petrosani, 20, University Street, Petrosani, 332006, Romania

Abstract

A difficult problem that arises in experimental data processing is to establish the value of instantaneous elastic deformation. Based on the analysis of physical theories used in rheology we considered that elucidating the characterisation of rheological behaviour of sedimentary rocks can be realized taking into account the two rheological models, namely Poynting-Thomson and Burgers, through the macro-analytical theories. Regardless of the theory used in the interpretation of experimental results, the requirement to assess more accurately the elastic deformation as a hidden variable occurs. For this purpose, a graphical - analytical - experimental methodology was proposed, which we consider original and that was applied in the case of sedimentary rocks from Jiu Valley. Knowing this deformation facilitates the possibility to establish the rheological parameters and the rheological coefficients included in the nuclei of creep. Such a methodology was found, because otherwise, determining the parameters α , δ , β , γ , χ required a whole series of integral transformations of the experimental functions that is extremely difficult.

Keywords: hidden variable, instantaneous elastic deformation, sedimentary rock, creep, rheological coefficients, nuclei of creep;

1. Introduction

As a result of rheological tests, especially of creep on many types of rocks in the category of low to average strength it was concluded that if maintains long time a rock under a constant load, it will fail, meaning it will break. This is due to the occurrence of the effects of viscous-plasticity, due to creep phenomenon. The literature shows that these effects are actually given by three main mechanisms that occur, namely: movement of dislocations in crystals; developing a microcracking, especially at grain contact; mineral cement's chemical alteration of the solid particles of the rock. Rheology as a science and especially rocks creep, are unfortunately still little known even now, and are still subject of numerous research studies, because all the phenomena that occur in nature and here we refer to the case of rock massifs or earth are carried out in time. Therefore, in this sense there are concerns about the behavior of rocks on the contour of the underground works, which are systems - structures that are working for a long time (whether mining works, tunnels, subways or other underground constructions). When referring to some mining workings, they can be used after the exploitation, as radioactive waste storage cavities and as a special case, a lot of attention should be given to long-term calculations of works, meaning rheological. In areas with water infiltration and where water can accumulate another phenomenon is observed, of pressure rise, leading practically to the same result. This phenomenon is known as the swelling phenomenon and occurs mainly in the presence of certain clays. If the dimensioning was not well done, the damage resulted by increasing the rocks volume can be spectacular and in the end it may even lead to breaking the apron (Toderaş, 2014).

2. Proposed method to assess the instantaneous elastic deformation

A difficult problem that arises in experimental data processing is to establish the value of instantaneous elastic deformation. The difficulty is primarily due to the greater curvature of the creep curve, in the initial stage of loading. To obtain this parameter we proposed a methodology (Toderaş, 2014; 2015) which consists of the following: from the row of values obtained from the creep performance of the tests, we will consider several initial values $\varepsilon(t)$ measured at equal

*Danciu Ciprian. Tel.: +40-726-351-238.
E-mail address: CiprianDanciu@upet.ro.

intervals of time with which differences of first order, second order and so on will be calculated, based on the following relationships:

$$\begin{aligned} \Delta_n \varepsilon &= \varepsilon_{n+1} - \varepsilon_n \\ \Delta_n^2 \varepsilon &= \Delta_{n+1} \varepsilon - \Delta_n \varepsilon \\ &\dots\dots\dots \\ \Delta_n^k \varepsilon &= \Delta_{n+1}^{k-1} \varepsilon - \Delta_n^{k-1} \varepsilon \end{aligned} \tag{1}$$

where: index n represents the number of the considered point, and k – the order of difference.

By replacing the expressions $\Delta_n^k \varepsilon$ in $\Delta_n^{k-1} \varepsilon$, $\Delta_n^{k-1} \varepsilon$ in $\Delta_n^{k-2} \varepsilon$ and so on from the relations $\varepsilon = \varepsilon_0 \cdot e^{\alpha \sigma_c}$, the general equation is obtained:

$$\varepsilon_n = \varepsilon_{n+1} - \Delta_{n+1} \varepsilon + \Delta_{n+1}^2 \varepsilon - \Delta_{n+1}^3 \varepsilon + \dots + (-1)^k \Delta_n^k \varepsilon \tag{2}$$

which will be used to establish the initial deformation $\varepsilon_0 = \varepsilon(0)$ at $t = 0$ according to the measured values $\varepsilon_1, \varepsilon_2, \dots$

All terms of the relation (2) are affected by (n+1) differences, except the last term that is affected by the (n-a) difference. The calculus of the deformations differences stops at the same order, for which, in the limits of calculus, could be written that $\Delta_0^k \varepsilon \cong \text{const}$, for all the n values considered. This, conduct us to the idea that replacing the unknown values is allowed $\Delta_0^k \varepsilon$, for which ε_0 must be known, through $\Delta_1^k \varepsilon$ known, obtaining the relation to determine ε_0 , as being:

$$\varepsilon_0 = \varepsilon_1 - \Delta_1 \varepsilon + \Delta_1^2 \varepsilon - \Delta_1^3 \varepsilon + \dots + (-1)^k \Delta_1^k \varepsilon \tag{3}$$

It is seen that, actually, the problem of determining ε_0 is reduce to summing the data of diagonal row that begins with ε_1 (see Table 1). Appraisalment of the limit value through the deformation goes:

$$\varepsilon_\infty^c = \lim_{t \rightarrow \infty} \varepsilon(t) \tag{4}$$

rising another problem, another question: *which time must we consider?* The logical answer would be "infinite", as in infinite time. If we were to accept the assertions of different researchers, the infinite should be considered as "time to achieve the low rate of deformation". According to the author (Toderas, 2014, 2015), as a criterion, we can consider the notion of infinitely large, which means that this "infinite" is "high time to infinity", meaning the time whose doubling will result in test conditions, to an increased deformation of up to 0.5 %, or a value of 0.005.

Table 1. Differences of deformations to determine ε_0 :

n	t	ε	$\Delta \varepsilon$	$\Delta^2 \varepsilon$	$\Delta^3 \varepsilon$	$\Delta^4 \varepsilon$
0	t_0	ε_0				
1	t_1	ε_1	$\Delta_0 \varepsilon$	$\Delta_0^2 \varepsilon$		
2	t_2	ε_2	$\Delta_1 \varepsilon$	$\Delta_1^2 \varepsilon$	$\Delta_0^3 \varepsilon$	
3	t_3	ε_3	$\Delta_2 \varepsilon$	$\Delta_2^2 \varepsilon$	$\Delta_1^3 \varepsilon$	$\Delta_0^4 \varepsilon$
4	t_4	ε_4	$\Delta_3 \varepsilon$	$\Delta_3^2 \varepsilon$	$\Delta_2^3 \varepsilon$	$\Delta_1^4 \varepsilon$
5	t_5	ε_5	$\Delta_4 \varepsilon$			

Such a procedure gives a superior value for ε_0 , because the curve $\varepsilon(t)$ has the convexity through ε axis, and the first derivative around zero changes convexity clearly. Knowing the value of the instantaneous elastic deformation we can proceed to establish rheological coefficients for which the calculation methodology is based on the considered creep nucleus, meaning for the rocks for which deformation under constant load tends to an horizontal asymptote, the analytical description of creep must be based on the function and so on Abel's nucleus (Rabotnov, 1966, Toderas, 2015, Todorescu, 1986) and when the rock's creep increase unlimited it is recommended the N. Rabotnov's nucleus (Rabotnov, 1966, 1969, 1980). After marking the creep curves for each type of rock analyzed based on experimental data and their analysis, we will proceed to determine the parameters and the rheological coefficients (Toderas, 2015). The original methodology for determining, proposed and presented, was imposed to be diversified in two situations, namely: in the case of using the nucleus of Rabotnov – Rozovski and respectively, for the use of Abel-type nucleus. After the analysis of creep curves, it was found that the relation between deformation and time for some rocks, is of the

first rheological type and for others of the second rheological type. Therefore, to determine the rheological constants it was necessary to consider the integral equation of the hereditary theory of Voltaire type, expressed as:

$$\varepsilon(t) = \frac{1}{E_\infty} \left[\sigma(t) + \lambda \int_0^t L(t, \tau) \sigma(\tau) d\tau \right] \tag{5}$$

in which: $\varepsilon(t)$ and $\sigma(t)$ – deformations and stresses at the time taken into consideration at the beginning of the test; $L(t, \tau)$ – creep nucleus; E_∞ - elasticity modulus in time or rheological modulus.

Therefore, for elucidating the deformation of the rock with respect to time it is necessary to determine the modulus of elasticity and the creep nucleus type of the equation (5). The type - the nature of creep nucleus can be established (Rabotnov, 1966) based on families of rock creep curves obtained experimentally in laboratory. The literature (Reiner, 1958, Tan Tjong Tjong Kie et al., 1989, Tavroghin, 1974, Todorescu, 1986) states that as the creep nucleus for different behaviors and rocks there can be used functions as power, exponential, etc., recommending certain nuclei: Voltaire, Rabotnov, Vialov, Dafting - Abel, Boltzmann, Zaretki, Rjanitân, Rozovski, binomial nucleus, the nucleus with variable parameters etc. Analyzing these nuclei, in the context of experimental data for sedimentary rocks tested to creep, I considered that the most accurate rendering of these values from the laboratory tests can be achieved by using the development of the equation (5) by Rabotnov (Rabotnov, 1966, 1969, 1980) as a fraction - exponential function of the form:

$$L(t-\tau) = \Xi_\alpha(-\beta, t-\tau) = (t-\tau)^{-\alpha} \sum_{n=0}^{\infty} \frac{(-\beta)^n (t-\tau)^{n(1-\alpha)}}{\Gamma[(n+1)(1-\alpha)]} \tag{6}$$

where: Γ is the gamma function; β, α creep parameters of the rock.

Experimental data processing based on such nucleus Ξ_α is complicated (Rabotnov, 1969). This function involves both the properties of several functions, e.g. exponential, and some customizations. For example, the rheological equation of state (5) with linear fractional nucleus type (6) for $\alpha = 0$ is transformed into an integral equation with an exponential nucleus, of the form:

$$\Xi_0(\beta, t-\tau) = e^{-\beta(t-\tau)} \tag{7}$$

Equations of this type are reduced to linear equations with constant coefficients and therefore the hereditary creep theory in this case, can be examined by the elastic - viscous environmental theory. Deciphering the functions time operators can be achieved if for the nucleus the exponential function of fractional order is used, equation (6) and the main properties of integral operators established by N. Rabotnov and M.I. Rozovski, the customizations of this properties and also the appropriate approximations.

For the situation of non linear deformation in time of the material system, N. Rozovski (Rabotnov, 1966, 1969, 1980) gives a more generalized situation, as:

$$\varepsilon(t) = \frac{1}{E} \left[\tau(t) + \int_0^t K(t, \tau) f(\sigma) d\tau \right] \left[\tau(t) + \int_0^t K(t, \tau) f(\sigma) d\tau \right] \tag{8}$$

where: $f(\sigma)$ is a random function of the stress state. As a creep nucleus the exponential function of fractionary order can be used belonging to N. Rozovski (Rozovski, 1958, 1960, 1961, Todorescu, 1986, Toderas, 2015), and in this case can be given:

$$\varepsilon(t) = \varepsilon_0 \left[1 + a \left(1 - e^{-b\gamma t^{1-\alpha}} \right) \right] \tag{9}$$

where: $a = \frac{\chi}{\beta - \chi}$ and $b = \beta - \chi$; β, χ are the creep parameters (with the dimension t^{-1}) and which in case of Rabotnov, respectively Rozovski's nucleus creep, are approximated by the relations:

$$\beta = T_{rel}^{\alpha-1} \quad ; \quad \chi = \frac{E - E_\infty}{E} T_{rel}^{\alpha-1} \tag{10}$$

in which: T_{rel} is the relaxation time; E_0 momentary elasticity module; E_∞ is the rheological elasticity module; ($E_\infty < E$); α, γ are coefficients that characterize the rocks' creep and that can be experimentally determined; they do not have a constant value, no matter the type of rock, as Rabotnov notes (Rabotnov, 1966). We mention that for the case in which $\beta - \chi > 0$, the creep curve that corresponds to Rabotnov, respectively Rozovski's nucleus, is the primary creep curve and is limited by the value of deformation.

If still $\beta < \chi < 0$, without excluding the situations when $\beta < 0$, than the parameters of creep loose their sense given by the relation (10) and it will pass at Abel's nucleus, meaning an unlimited creep in which: $\varepsilon_{(t=\infty)} = \infty$ or:

$$\frac{\varepsilon(t) - \varepsilon_0}{\varepsilon_0} = a \left(1 - e^{-b\gamma t^{1-\alpha}} \right) \tag{11}$$

in which: ε_0 is the relative deformation at the beginning of load ($t = 0$), meaning the instantaneous elastic deformation (Toderas, 2015); a and b are experimental coefficients; α is a non-dimensional coefficient equal according to N. Rabotnov (Rabotnov, 1966) with 0.7 for rocks, affirmation that is still approximate and orientative, reason for which we recommend its experimental determination for each type of rock; γ is a calculated parameter:

$$\gamma = (1 - \alpha)^{1-\alpha} \tag{12}$$

that for the rocks is: $\gamma = 0.6968453 = 0.697$ according to N. Rabotnov (Rabotnov, 1966).

Resolution is to establish the coefficient a of the relation (11) and with the help of creep curves for $t = \infty$, value then replaced in the same expression (11) will obtain a range of values of b for different times t , from which we calculate the value of b as an arithmetic average. Rabotnov's nucleus creep, $K(t - \tau)$ depends of parameters α and β . Experimental data processing based on such a nucleus is complicated (Rabotnov, 1966) because it requires a whole series of integral transformations of the experimental functions and that the values of the parameters do not have sufficient physical clarity. As a result, we can specify the following: the norm of N. Rabotnov's functions depends of the size of β ; the size of β depends of α , including the time at order $-(1+\alpha)$; for all rocks and other materials, sizes and α and β are negative, although analyzing data from the literature shows that in the works of Rabotnov all these parameters appear as positive, while a number of other authors parameters α and β are accompanied by a minus sign. Such a finding leads to a different understanding of the meaning of those parameters; in the expression that describes the flow curve the size is included $(\alpha + 1)$ and a parameter α . It is desirable that in the creep nuclei to enter this size, α , determined directly by experiment. All these findings lead to the idea to propose the following form of the Rabotnov and Abel's nuclei (Ruppenet et al., 1962), expressions in which ξ is always positive, and t_0 has the sense and value of delaying time (T_{int}). In this basis, the connection between parameters α , β , ξ , t_0 can be determined, and also, the connections between the functions of Rabotnov and the proposed one; according this, in the expression of Volter – Boltzmann that we obtained, α_∞ has a physical sense of ratio between stabilized total deformation ε_t and instantaneous elastic deformation ε_{ei} :

$$\alpha_\infty = \frac{\lambda}{-\beta} + 1 \quad \text{or} \quad \alpha_\infty = \frac{\varepsilon_t}{\varepsilon_{ei}} \tag{13}$$

Considering the normal deformation at creep for a constant stress σ_0 (or with a certain sollicitation level Δ_i) and using the expression $\lim_{t \rightarrow \infty} \int_0^t \exists_\alpha(\beta, t - \tau) d\tau = -\frac{1}{\beta}$, it is found that:

$$\lim_{t \rightarrow \infty} \varepsilon(t) = \lim_{t \rightarrow \infty} \int_0^t K(t_0, t - \tau) d\tau = 1 \tag{14}$$

This expression allows to construct standardized graphics for processing the results of creep. Graphics can be built based on tables (Rabotnov, 1966) in which the function values are given:

$$F_2(\alpha, x) = \frac{1}{t^{\alpha-1}} \int_0^\infty \exists_\alpha(-\beta, t) d\tau = \sum_{n=0}^\infty (-1)^n \frac{x^n}{\Gamma[(\alpha + 1)(n + 1) + 1]} \tag{15}$$

where: $x = \chi(t) = \beta t^{\alpha+1}$.

Using the relation between function of Rabotnov and the proposed one and also the obtained relations, it is seen that:

$$\varepsilon(t) = x(t) F_2[\alpha, x(t)] \tag{16}$$

reason for which the ordinates axis will give the value of the right side of the relation (15), and the abscise axis the logarithm of corresponding time:

$$\lg \frac{t}{t_0} = \frac{1}{\alpha + 1} \lg x \tag{17}$$

Such graphics, for $0.1 \leq \xi \leq 0.9$, are given in Figure 1. In this representation, the unit of measurement of time on the x-axis is regarded as the size of t_0 , and for the measurement of deformations on the ordinate axis is considered to be the maximum creep deformation. Analysing such a chart, it is seen the particularity of high practical importance, namely, that all curves intersect near a single point in which the normalization function of creep is 0.50 of its maximum value, size for which the value t/t_0 remains almost the same and can be considered constant, $t^* = 0.640 \cdot t_0$ for any ξ , which enables the determination of the value of t_0 , independent from the value of ξ which is extremely important in experimental data.

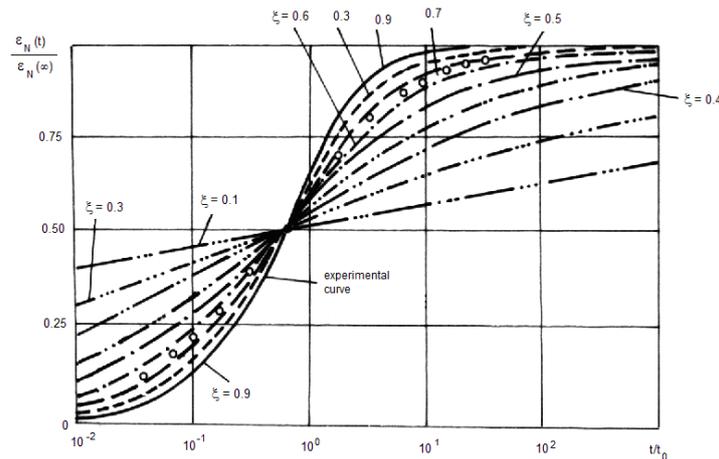

Fig. 1. Normation curves of creep

According to this proposed methodology, the calculus stages are:

1. Rock type, monoaxial compressive strength, loading degree and creep determinations;
2. Establishing the sollicitation interval t_{∞} ;
3. Calculus of the value of deformation $\epsilon_N(t) = \epsilon(t) - \epsilon(0)$;
4. Calculus of normal deformation at creep:
5. Mentioning the time t^* , for which $\epsilon^{NF}(t^*) = 0.5$;
6. Establishing the time $t_0 = t^*/0.64$;
7. Calculus of logarithm $\lg(t/t_0)$ for different values of t ;
8. Constructing the norm graphic of creep in coordinate system $[\lg(t/t_0); \epsilon^{NF}(t)]$;
9. Overlaying the norm graphic over the standard graphic (the nomogram from Figure 1), stage that allows determining the parameter ξ ;
10. Calculus of the parameters $\alpha_{\infty}, \alpha, \beta, \lambda$.

3. Results and discussions

Referring to this methodology, we mention that the time that is taken into account is the one whose doubling leads in terms of experimentation conditions, to an increase of deformation up to 0.5 % meaning 0.005. In Table 2 are shown the values of the instantaneous elastic deformation obtained for the categories of analyzed sedimentary rock (Toderas, 2015).

Table 2. Instantaneous elastic deformation of sedimentary rocks studied in rheological context:

Setting the parameters of creep nucleus was performed by own methodology. For studied rocks, the values of these parameters of creep (α , δ , β , γ , χ), changes in the range: for category of rocks with $\sigma_{rc} < 25$ MPa ($\alpha = 0.579 - 0.9136$; $\beta = 0.00055834 - 0.195243$; $\gamma = 0.695 - 0.80931$; $\delta = 0.136 - 0.6043$; $\chi = 0.0039 - 0.0903$); for category of rocks with $25 < \sigma_{rc} < 55$ MPa ($\alpha = 0.69873 - 0.893$; $\beta = 0.087666 - 0.2547$; $\gamma = 0.696 - 0.782$; $\delta = 0.12493 - 0.655718$; $\chi = 0.017052 - 0.21158$); for category of rocks with $\sigma_{rc} > 55$ MPa ($\alpha = 0.781666 - 0.896477$; $\beta = 0.0275076 - 0.44474$; $\gamma = 0.717312 - 0.79074$; $\delta = 0.457 - 1.217101$; $\chi = 0.06499 - 0.440$). Regardless of the theory used in the interpretation of experimental results, from the beginning it was necessary a proper assessment of the elastic deformation as a hidden variable (Toderas, 2015).

4. Conclusions

We proposed a graphical - analytical – experimental methodology which we consider original. The need to know this deformation was to facilitate as much as possible the determination of rheological parameters and the coefficients included in the creep nuclei. We searched for such a methodology, because otherwise, determining the parameters (α , δ , β , γ , χ) required a whole series of integral transformations of the experimental functions which were extremely difficult. So we resorted to establish a standardization process based on the norming the function of Rabotnov, developing it for the nucleus of Abel and Rozovski (introducing a parameter ξ) precisely because in relation appears $(\alpha + 1)$ and not α . We determined the way of evaluating the normed creep deformation, on which we have built a standardized chart through which is determined the normal function $\varepsilon^{NF}(t)$; we determine the value of the parameter t_* for which $\varepsilon^{NF}(t_*) = 0.5$ resulting the delay time T_{int} noted t_0 and finally, graphics are drawn in coordinates $[\lg(t/T_{int} = t/t_0), \varepsilon/\varepsilon_\infty]$. By overlapping these graphics resulting from experimental measurements over the standardized ones (established for $0.1 < \xi < 0.9$), we determine the appropriate value of ξ . Based on this value, we set the parameters: α , β , γ , δ and χ .

The development of mineral triangulation networks using a simplified calculation process

Filip Ofelia-Larisa^{a*}

^aUniversity of Petrosani, 20, University Street, Petrosani, 332006, Romania

Abstract

The procedure refers to dependent triangulation networks, and consists in the simultaneous utilization of the theory of indirect measurements and conditioned measurements. The use of indirect measurement theory and conditional measurements means a low volume of computation completed by simple matrix relations applied convincingly in practice.

In order to reduce the processing of the measured quantities, there is still a process in which the theory of the indirect measurements and the theory of the conditioned measurements are applied to the dependent triangulation networks, very frequent networks encountered in the mining basins.

Thus, with regard to the mining domain, it follows that triangulation networks play a decisive role in the good development of topographic activity through which multiple mining problems are solved.

The specificity of triangulation networks in support of the overall mining activity is that they develop on surfaces corresponding to mining basins. The form of these mining triangulation networks as well as the density of the points forming them depends on the shape of the mining basin, the number and position of the mining operations within the basin.

Keywords: Mining surveying, topographic underground networks, errors, topographic measurements;

Introduction

It is known that the purpose of triangulation networks is to determine on a certain surface and plurality of points of a certain density.

These fixed points will continue to constitute support and control points for the set of topographic works developed according to the nature of the construction works (industrial, civil, communication, mining, etc.) which it serves to achieve and their tracking over time (Dima, 2005b).

Regarding the way of determining the triangulation points in such networks it is specified that they can result from the accumulation of the order of I, II or III geodetic points, obtaining points of order IV and V or by solving dependent triangulation networks.

The two methods for determining triangulation points have different theories to support the measurement of measured quantities. It is the theory of indirect measurements applied to the determination of points by framing and the theory of conditional measurements applied to the determination of points by independent triangulations (Dima, 1997, 1999).

We consider the dependent triangulation network formed by the old points (whose coordinates are known) A, B, C, D, E, F and new points P1, P2, Q, S (the coordinates of which are to be determined) (fig. 1).

*Filip Larisa. Tel.: +40-764-422-894.
E-mail address: larisafilip@yahoo.com.

Number of equations:

$$r = 20 + 6 = 26$$

The number of unknowns:

$$n = 38 + 4 = 42$$

Or the matrix has the form:

$$av + Ax + \omega = 0 \tag{5}$$

The following is added to the system (5):

$$F = v'v - 2K'(av + Ax + \omega) = \min$$

The minimum condition leads to the system:

$$\frac{\partial F}{\partial v} = 2v - 2A'K = 0$$

$$\frac{\partial F}{\partial x} = 2A'K = 0$$

Where from:

$$v = a'K = 0$$

$$A'K = 0 \tag{6}$$

With relations (6) the system (5) becomes:

$$aa'K + Ax + \omega = 0$$

$$A'K = 0 \tag{7}$$

By solving the system of normal equations (7) it follows:

$$K = -(aa')^{-1}(Ax + \omega)$$

and as a consequence:

$$x = -[A'(aa')^{-1}A]^{-1}A'(aa')^{-1}\omega \tag{8}$$

With the values of the matrix x the correction matrix v is obtained with the equality:

$$v = -a'(aa')^{-1}(Ax + \omega) \tag{9}$$

Note:

The calculation volume is reduced if the expressions of corrections in the equation system (2) are introduced into the equation system (3) (Dima, 2014).

A system is obtained with:

-6 equations
-34 unknown

Conclusion

The work was done on the basis of how to define such mining triangulation networks and their importance in solving the problems of elevation and topographic plotting in a unitary way, for multiple fields of activity, including the exploitation of useful minerals through underground mining works and up-to-date.

The processing of the measured quantities in order to determine the corrections on the directions and the corrections on the coordinates of the points P1 and P2 with the simultaneous use of the theory of the conditional measurements and the theory of the indirect measurements requires a small volume of calculation to obtain a system consisting of 6 equations. The use of matrix calculation methods in defining the theoretical background of the problem has led to easy obtaining simple matrix relations with direct and convenient applicability in the practical processing of measurements.

I mention that the presented analyzes use the matricial calculation with which the form of the error equations systems of the systems of normal equations and the determination of the probable values with the corresponding precisions are adaptable to the computer system.

It is possible to evaluate the clearing afterwards.

Abstract

The purpose of the research is to analyze the patterns of the spatial concentration of explosive energy in a rock massif, which has a complex structure and caused by it the acoustic anisotropy, depending on the design of the borehole charge and the conditions for its blasting; the substantiation of the general approach to the development of technology for the destruction of rock massif under symmetrical effect of the borehole charges. The main factors influencing the impact of the explosion on the quality of the crushing rock under the conditions of application of authored author's decisions regarding the designs of borehole charges, the formation of outcrops, the creation of additional reflective gaps, and vertical ledge of rocks are analyzed in this research. This process of rock destruction with the change of the charge of explosives in the boreholes ranges is considered from the second or third - to the first.

The research methodology includes methods of analytical calculations and geometrical constructions, geomechanical analysis of stressed rock changes in relation to the structural deformities of the ledge of rocks of different heights and lithological composition; substantiation of the simulation model of the propagation of elastic waves in anisotropic crystalline medium and the formation of waveguides in it; static analysis of mine surveyor's observations and mathematical methods for processing the results of experimental and industrial tests. Spatial-mathematical methods of solving problems and comparative assessment of their results are used.

Findings. The peculiarities and conditions of the implementation in iron ore open pit of symmetric blasting of the rock massif with complex regular structure with combined charge of explosives of modern explosives (E) are investigated. The choice of directions` formation in the blast hole network of their location is substantiated. The use of mathematical and simulation modeling, the peculiarities of formation of contours in the rock massif of maximum and minimum stressed zones around borehole charges depending on the physical, mechanical and structural characteristics of rocks as well as relative masses of various types of explosives in the combined charge are determined.

The scientific novelty consists in formulating the author's idea of symmetrical blasting of the rock, differential strain explosion, and analytical substantiation of the parameters of objects and processes for the effective implementation of the developments in the industrial work placement of open pit of ore mining and processing enterprise.

The practical significance of the research is to develop a new effective way of blasting rocks in the open pits of ore mining and processing enterprises and substantiating of the parameters of the technology of the implementation of the method, which reduces the specific costs of explosive materials and increases the profit of the MPE.

Key words: rock massif, explosive destruction, open pit, explosive waves, anisotropy of rocks, symmetrical action of charge of explosives;

1. Formulation of the problem

Despite the extremely numerous and serious scientific research on the effectiveness of Blasting and Explosion Works (BEW) in the open pits, the problem of the unevenness of the granulometric composition of the blasted rock, as well as the excessively high cost and environmental aggressiveness of this process clearly indicates that this problem is not completely solved. Therefore, the task of the search of the ways to avoid the mentioned negative consequences of the explosion is very relevant, as well as the increase in the effectiveness of the BEW, contributes solving the problem of rational subsurface use, resource and energy saving.

As shown by the analysis of recent studies on the theory of explosion and practice of BEW (Fokin, 2008, Bratanek, 1983), one of the least investigated theoretically and unresolved virtually questions is the uneven formation under the action of an explosion of a strained-deformed state of rock masses of a complex regular structure with acoustic anisotropy caused by it, which preferably has a periodic functional dependence (epicycloidal) of

*Zhukov S.A.

E-mail address: lutsenkosergeia@ukr.net.

elastic-mechanical characteristics relative to the spatial orientation of structural dominants of rocks. The increasing effectiveness of blasting can be possible by differentiating the differential strain of the massif, optimizing the interaction between the borehole charges with the massif and between each other, and also improving the BEW technology, in particular - the methods of creating actually working additional reflective elastic waves of slits and structures of charges for this (Skachkov, 2016). In connection with this, the idea was laid for the use of a preliminary reflection slit for the formation of an additional reflective crack in the acoustically anisotropic rock massif of spatially complex forms of surfaces of various stressed states, as well as the intensification of the differential strain of the massif by explosion at the expense of specially designed multi-type charges E. To solve this problem, the research provided justification for the optimal forms of rock destruction zones around charges of explosives and the mutual arrangement of the mentioned one in the explosive network, when the charges of the first series of the boreholes (main relieving charges) are initiated only after passing through them of the direct and reflected of the slopes of the wave tip the explosion of charges of the second row, thus creating the conditions for the symmetrical action of the basic charges between the two reflective surfaces - the vertical slope of the ledge from one, and created with the short-term "back" gap – from the other.

2. Presentation of research material

It is known that the decrease of the rocks crushing quality with the defined structural-regularity (system cracking and blocking effect) is determined by the formation something like a waveguide due to the refraction and reflection of energy rays from the charge of E in a destructive massif on the contacts of the detached rock, as a result of which different zones of the damaged rock between the blast holes have different granulometric composition, that makes the processors to increase the mass of the explosive in the boreholes for a guaranteed reduction to acceptable levels of the "oversized" exit, at the same time inevitably getting the increased output and the redundant mass. This contradiction led the authors to the idea of finding solutions to avoid this effect by coordinating the combination of the trochoid contours of the destruction zones around the borehole charges of adjacent rows in the presence of vertical ledge of rocks and additional reflecting gaps to provide symmetric conditions work of borehole charges, purposefully designed of a combined construction.

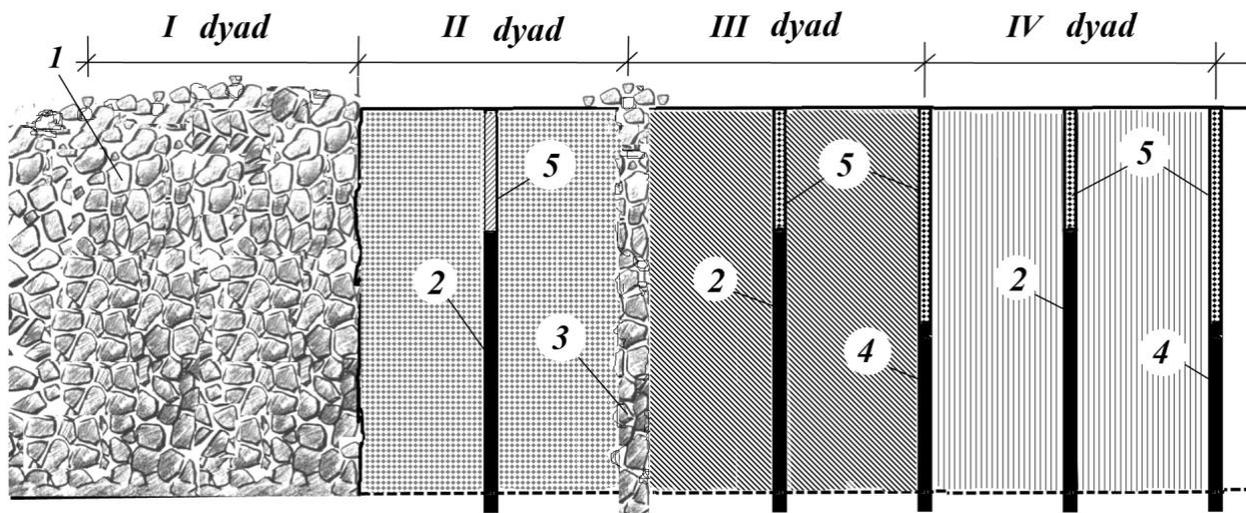

Fig. 1. Scheme of the method of differentiated energy supply of the rock massif with reverse blasting of symmetrically operating borehole charges in the vertical ledge of rocks: 1 - blasted rock; 2 - disintegration charge; 3 - reflecting gaps; 4 - combined charge of incomplete mass for formation of a reflective gap and preliminary softening of the rock

At altitudes of ledges up to 10 m, the boreholes are grouped in 2 and undermined with timing from a pair to an odd, that is, in sequence: 2nd→1st→4th→3rd→6th→5th and so on. The application of vertical slopes in combination with the proposed sequence of charges blasting in grouped pairwise rows ensures the unification of borehole charges, and reduces by 5 ÷ 7% the specific cost of E. Under these conditions, a charge protected by a patent was used as the main one (Shapurin, 2016).

The design of the weakened charge - for the preliminary demolition of the breed and the formation of the reflecting gap - was also developed in various variants for different conditions for the implementation of the BEW (Fig. 2).

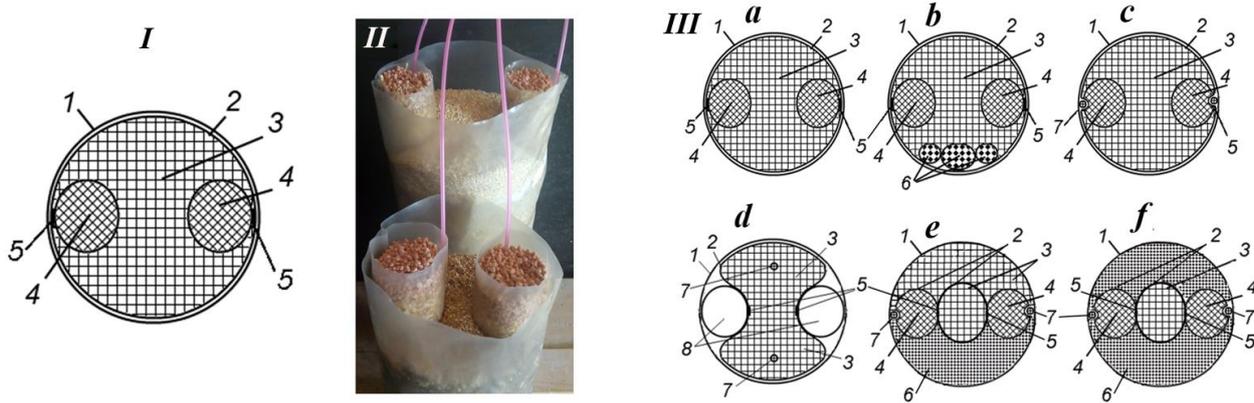

Fig. 2. Cross section of the borehole charges of the paired rows: I - borehole, 2 - polymer shell, 3 - low-brisant charge, 4 - linear high-brisant charges 5 - places of penetration of the sleeve (I); full-scale specimen (II); other variants of charges (III)

The structures and substances of the main and gaps-forming charges are determined depending on the physical-mechanical characteristics of the rocks, the critical diameters of the E, the ratio of the acoustic rigidity of rock with the detonation velocity of the E, as well as the purpose and requirements for the results of the bursting of the massif.

The analysis of the BHD in relation to the open pit "Pivnichniy", where the mentioned above implementation of the differentiated-energy rocks saturation in the conditions of the dry boreholes with the simplest E - Granulite KM was carried out - showed the following. For this E, the measured values of charge density and detonation velocity are 1020 kg/m³ and 3850 m/s respectively, and the estimated heat of explosion is 980 kcal/kg. Calculated for these conditions, the value of the polytropic index (*n*) is 1.8, that is within the limits typical for powdered E (1,5 ÷ 2,0). The mass velocity in the Chapman-Jouguet plane (ω , m/s) is calculated by the formula: $\omega = v / (n + 1) = 3850 / (1,8 + 1) = 1375$ m/s, and the pressure of the detonation wave on the plane $P_2 = v \cdot \omega \cdot \Delta / g = (3850 \cdot 1020) / 9,81 = 5,504 \cdot 10^8$ Pa, $\omega = 1020$ m/s. This pressure is twice the stationary pressure in the borehole: $P_w = 5.504 \cdot 10^8 / 2 = 2,752 \cdot 10^8$ Pa; Since the charge length is 4 m and its diameter is 0.25 m, the area perceived by this pressure is 3.61 m². The total area of the wave from a cylindrical part and two hemispheres from the ends of the charge at the time of its release to the boundary of the crushing funnel is 267.42 m², that is in 74 times larger, than the original (3.61 m²). Taking into account the cost of energy for the rocks destruction (for example, 20%), the pressure is about 3.0 MPa. At the same time, with the approach of the wave to the roof of a ledge, the pressure will be about 0.5 MPa, and near the scarp of a ledge - even less.

At the same time, experimental explosions with the registration of real deformations and stresses in the rock massif around the charges of E revealed somewhat lower indicators than the idealized calculations. Analyzing the stress state and structure of the massif, we established the main cause of this difference - the effect of system macrogaps that divide the rock massif into separate blocks. And after performing a comparative analysis of the values of the above mentioned deviations with the values of the gaps opening, they developed a simplified method of compensating for it in calculations by introducing the corresponding coefficient K_{sb} , which differs from the proposed in (Zhukov) in that, it takes into account not only the level of filling gaps with mineral smalls, but also the kinetics of the explosion and the inertial factor of passing an elastic wave through a macrogap. The physical meaning of this coefficient is in the "stepped" cutting of the amplitude of the elastic wave when it is extended through the blocks or layers of the rock (Fig. 3), in combination with plastic deformations of near-surface zones of macrogaps caused by the movement of rock masses when considering the behavior of the collapses rock massif as a set of elastic rods.

Taking into account these factors, we propose to determine this coefficient within the zones of intense explosive loads as,

$$K_g = \sqrt{f \cdot \rho_g} \left(1 - \frac{r_{f.w} \cdot g_g}{A} \right)^{(1 - \rho_g)} \quad (1)$$

where *f* - strength of the breed; ρ_g - the level of filling of the gap by the small rock, is determined by the ratio of the volume of filler V_3 to the volume of the crack $V_g (\rho_g = V_3 / V_g)$; $r_{f.w}$ - distance from charge to wave front; g_g - the index of specific fracture of the massif, is determined by the ratio of the average width of systemic gaps, normal with respect to the direction of the waves motion ($g_g = \delta_g / l_g$).

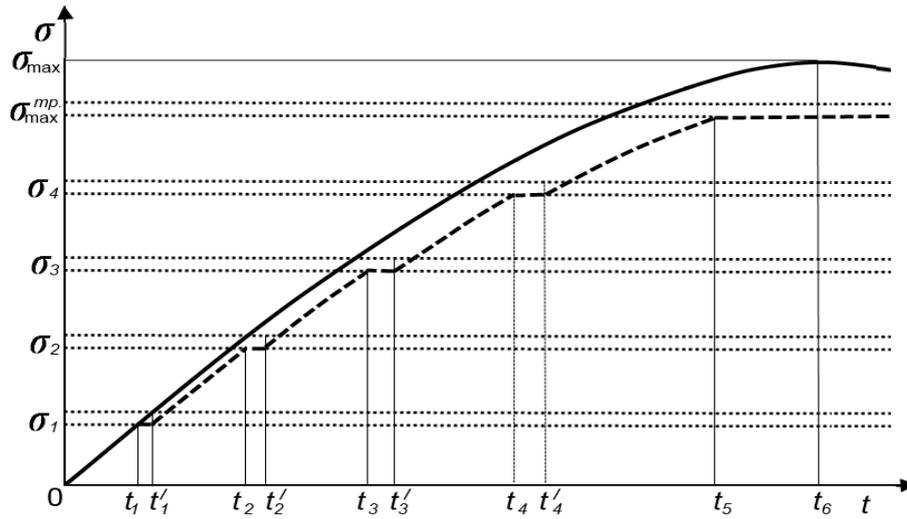

Fig. 3. Modification of the graph of stress (deformation) dependence at the front of an elastic wave under systemic rock jointing of the rock massif

Calculated values of K_g for different breeds and structural characteristics of their massifs are shown in Table 1.

Table 1. Coefficient value K_g

The name of the rock	Average width of cracks, m	Average distance between cracks, m			
		0,5	1	1,5	2
Granite $A_o = 2,5 \cdot 10^{-2}$ M, $\nu = 0,5$	0,001	0,96	0,97	0,98	0,99
	0,005	0,77	0,89	0,93	0,95
	0,01	0,45	0,77	0,87	0,89
	0,02	0,01	0,45	0,69	0,77
Migmatites $A_o = 2,3 \cdot 10^{-2}$ M, $\nu = 0,5$	0,001	0,95	0,97	0,98	0,99
	0,005	0,75	0,88	0,91	0,94
	0,01	0,36	0,75	0,86	0,88
	0,02	0,14	0,36	0,65	0,75
Amphibolitis $A_o = 2,1 \cdot 10^{-2}$ M, $\nu = 0,5$	0,001	0,94	0,96	0,97	0,98
	0,005	0,74	0,87	0,89	0,98
	0,01	0,22	0,72	0,84	0,81
	0,02	0,10	0,22	0,61	0,72

The introduction of this coefficient significantly improves the convergence of theoretical calculations and experimental records for the determination of the interaction of the energy of the explosion with the rock massif. The calculations of the parameters of the approach to contour blasting, to our opinion, are most convenient to perform in accordance with (Matveichuck, 2002), adding in them the spatial-energy indexes by the developed coefficient K_{gr} .

From Fig. 3 it is seen how different theoretical and real, represented by the modified curve, graphs of development of stresses (deformations) at the front of the elastic wave due to the rock jointing system of the rock massif. Accordingly, the boundaries of the zones of minimum and maximum loads of a block rock massif are proposed to be determined not by a theoretical but by a modified trochoid.

As for the experimental registrations of the loading levels of rock massif in parallel (R_{\parallel}) and perpendicular (R_{\perp}) of subthorogonal system rock jointing of rocks, they clearly demonstrated how different stress fields are formed, depending on the degree of cleavage of system cracks and caused this acoustic anisotropy of the massif (Fig. 4): in the cemented by the mineral materials of transverse and incompatible closed longitudinal (a), which are close by the elasticity to the rock, and “fractured cracks” of both systems (b).

The nature of the influence of the structural parameters of the combined charge of E on the relationship between the relative boundaries of the parallel loading zones of the rock massif in parallel (R_{\parallel}) and perpendicular (R_{\perp}) subthorogonal systemic rock jointing from the ratio of masses of high-brisant (M_{hb}) and low-brisant (M_{lb}) charge E (Fig. 6).

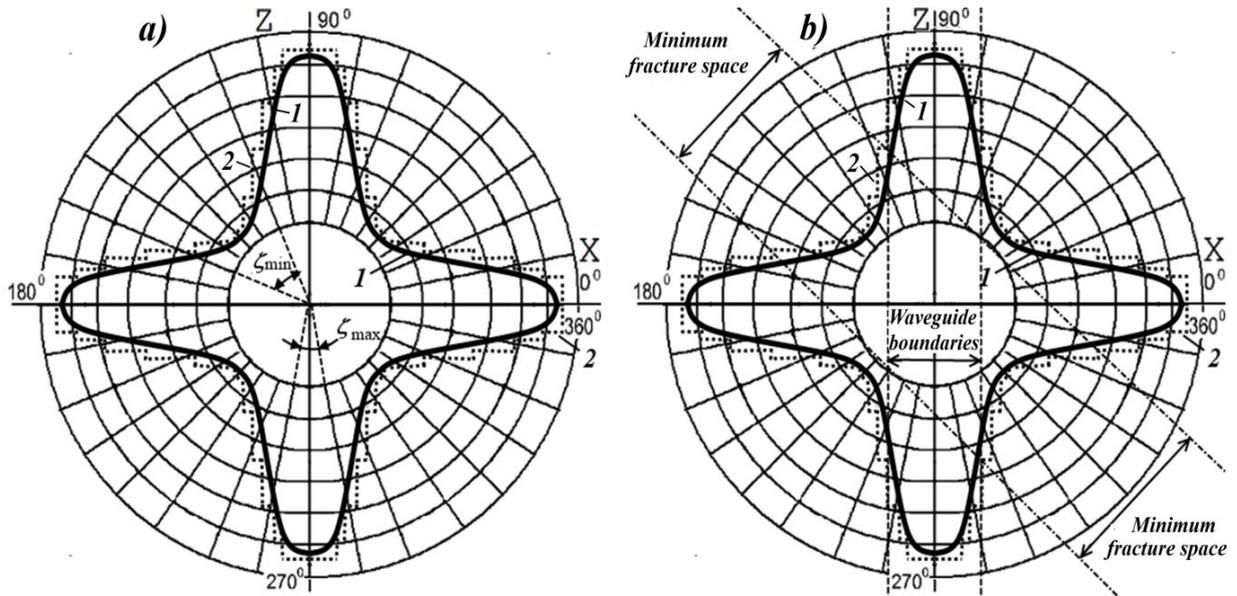

Fig. 4. Limits zones of optimum and maximum loads of a block rock massif by an explosive wave: 1 – theoretical trochoid, 2 – modified trochoid

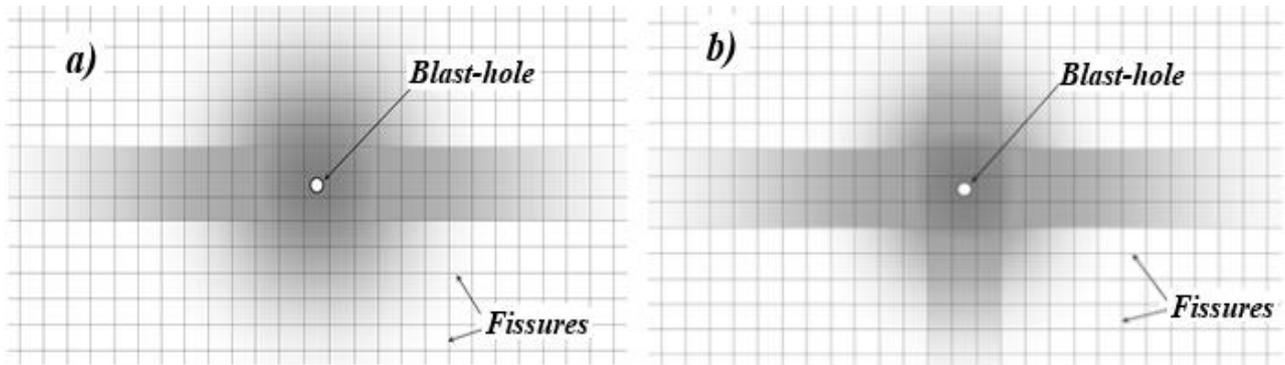

Fig. 5. The difference between the spatial loading of the rock massif around the borehole charge in dependence on the degree of clustering of systemic gaps

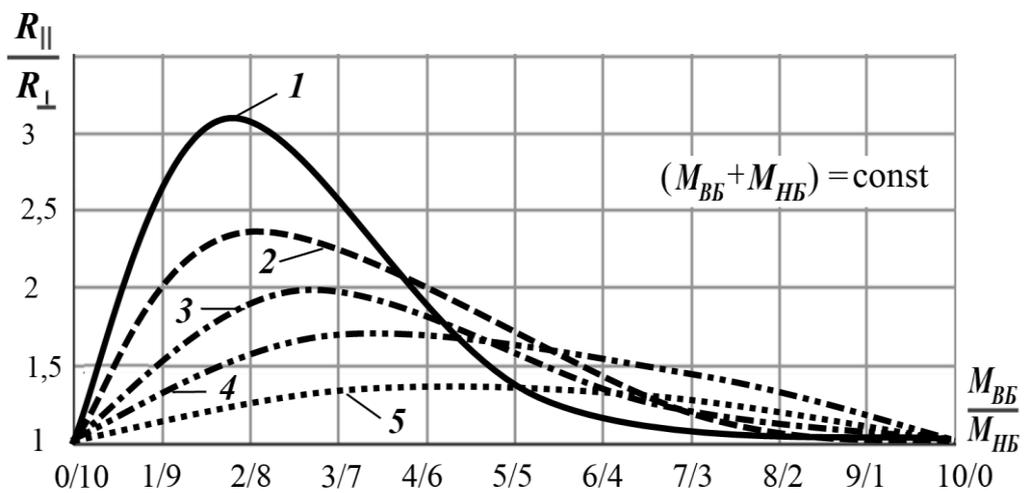

Fig. 6. Relationship between the relative boundaries of the areas of the equal loading of the rock massif in parallel ($R_{||}$) and perpendicular (R_{\perp}) to the subthorogonal systemic rock jointing from the ratio of masses of high-brisant (M_{hb}) and low-brisant (M_{lb}) charge.

3. Conclusions

The described above facts convince that for the ledges up to 11 m, the division of rows into groups, two in each, a significant reduction in the mass of charges in dual rows, the division of charges in the group into separate series and the beginning of the initiation of each series, namely, from the reduced by weight of charges, forcing these reduced charges give all the energy to the formation of a shielding gap, the development of defective rock of microcracks, the formation of reflected waves from free surfaces, overcoming the inertia of the massif, that is together makes easier the work of crushing rocks with the main charges in odd rows, decreasing the overall cost of E and, consequently, increases the effectiveness of E charges.

Characterization and classification of andesites of Criscior and Albini from southern Apuseni Mountains, for capitalization

Danciu Ciprian^{a*}, Toderăș Mihaela^a, Lorinț Csaba^a, Florea Adrian^a

^aUniversity of Petroșani, Universității Street, No.20, Petroșani, Romania

Abstract

The use of rocks in construction is governed by standards that require a series of chemical criteria, mineralogical-petrographic and physical-mechanical that they must meet. The execution of various works is permitted only if they fall within certain quality criteria. In this context, the geo-mechanical properties were determined for Criscior and Albini andesites, which were compared with the conditions of admissibility imposed by current standards, for use in different areas. To get a more detailed view of geo-mechanical properties of the Criscior and Albini andesites it was required a classification based on three criteria: chemical, geological and geo-mechanical. The chemical criterion of intact rock classification considers the content of SiO₂ and alkali-aggregate reaction. From the geological point of view, there were chosen for classification purposes those features that could provide information on strength and deformation behavior. The geo-mechanical classification criterion employed in this paper was in accordance with standards widely used today, trying to characterize the analyzed andesites in terms of physical characteristics, strength and deformation.

Keywords: andesites, aggregate, chemical, geological, strength, classification;

1. Introduction

Rocks were used as building materials since antiquity. Over time, their use in various forms, all over the world, has increased, varying by culture and time (Danciu, 2010; Danciu and Buia 2013, 2016). Raw materials like andesites, from Southern Apuseni Mountains, were used for manufacturing different types of tools since the Early Neolithic (Lorinț and Bărbat, 2014). In Romania, useful rocks are widespread in vorland structures, especially in Carpathian structures. They have multiple uses in constructions, and various other industries. Thus, besides being used as raw stone in constructions, roads and other engineering works, they can be used in ornamental-decorative works, depending on the physical-mechanical and aesthetic properties (Danciu and Buia 2016). This wide range of uses makes very important knowing the places which contain fields which are not exploited so far but whose reserves allow operation in the short run. The construction, rehabilitation and maintenance of road and rail infrastructure sectors implies the use of large amounts of materials, among which the natural aggregates have the largest share. Thus, the rigorous determination of rock qualities where the aggregates, for the above mentioned domains, is absolutely necessary and well-defined periodicity (Danciu and Buia 2013). Using rocks in the execution of various works is allowed only if they meet certain quality criteria. In this context, this study aims to establish the chemistry, mineralogy and geomechanical parameters of andesites from Southern Apuseni Mountains, in order to exploit them for the construction, rehabilitation and maintenance of road and rail infrastructure sectors. The results will be classified and compared to the limit values set by standards.

2. Mineralogical and petrographic study

Andesites from Criscior and Albini were previously analyzed both macroscopically and microscopically to determine the mineralogical-petrographic characteristics (Danciu and Buia 2016).

The mineralogical-petrographic study was based on analysis of thin sections using a polarizing microscope. After the macroscopic and microscopic examinations a detailed description of these rocks was possible.

2.1. Criscior Andesite - sample No.1

Sampling location: Criscior, Hunedoara district. Geologic structure: tardive subsequent magmatism (neogenic), second cycle. Rock type: magmatic, effusive (neovolcanic), neutral. Structure: semi-crystalline (hypocrystalline), porphyry-vitreous. Texture: unoriented (massive), compact. Color: dark gray. Mineralogical composition: neutral plagioclase feldspar, hornblende, microlitic vitreous paste, opaque minerals, secondary minerals (kaolinite, sericite, limonite). Plagioclase feldspar (30.5%) is represented by idiomorphic and hipidiomorphic crystals with incipient alteration stages. The plagioclase feldspar appears mostly zoned, with crystals dimensions varying between 0.3/0.2 mm and 2.0/1.0 mm. Central zones of the plagioclase feldspar, with higher anortite content, appear sometimes transformed into kaolinite and sericite. For most of the cases, the microlitic plagioclase feldspar appears not-altered. Hornblende (4.5%) appears with the rock mass as hipidiomorphic crystals, with dimensions below 1 mm. For most of the cases, the crystals contours are opacitized; sometimes, the amphibole is completely transformed into a secondary product through oxy-hydration. The vitreousmicrolitic paste (55%) in this rock type consists of amorphous volcanic glass, where the feldspars microlites appear nonuniformly distributed. As the feldspars, microlites are predominant, the resulting macroscopic color is dark gray. Reaction to acids: none of the rock components reacts with dilute HCl. Denomination rock: vitreous-porphyry Andesite (Toderas et al., 2017).

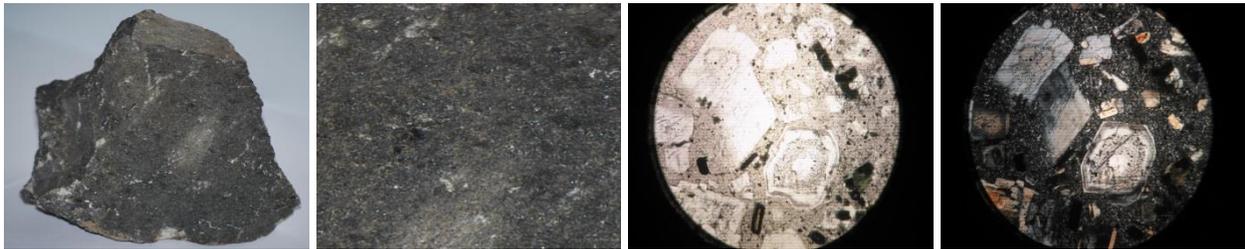

Fig. 1. Criscior Andesite

2.2. Albini Andesite - sample No. 2

Sample location: Albinii-Haneş, Alba District. Geologic structure: neogenic eruptivism of Apuseni Mountains (Metaliferi). Rock type: magmatic, effusive (neovolcanic), intermediary. Structure: hypocrySTALLINE (semicrystalline), porphyry vitreous. Texture: unoriented (massive), compact. Color: grey, slightly dotted. Plagioclase feldspar (23.8%) consists mostly of idiomorphic and hypidiomorphic crystals, rarely zoned. Plagioclase feldspar crystal dimensions vary from 0.01 mm for microlites and 6.2/4.3 mm for phenocryst. For thin sections parallel with crystallographic axis Z and presenting polysynthetic macles (twins), the unidirectional cleavage appears distinctly. Hornblende (12.6%) appears within the rock mass as idiomorphic, hypidiomorphic and xenomorphic crystals with dimensions between 0.2/0.08 mm and 10.3/1 mm.

Fig. 2. Albini Andesite

The sections are either parallel or perpendicular on crystallographic axis Z. Good cleavage appears distinctly, as bidirectional (124°) or basal sections and unidirectional for sections parallel with prismatic faces. Some of the idiomorphic and hypidiomorphic crystals present partial or total opacitization. Microlites (50%) are feldspathic, non-uniformly distributed within the volcanic glass. Opaque minerals (4.5%) are finely crystallized, idiomorphic, hipidiomorphic and xenomorphic, chaotically distributed within the rock paste and consisting of pyrite and oxidic minerals. Secondary minerals, represented by kaolinite, affect partially some plagioclase phenocrysts and microlites. Reaction to acids: none of the rock components reacts with dilute HCl. Denomination rock: Andesite with hornblende (Toderas et al., 2017).

3. Methods and results

The alkali-aggregate reaction reveals the reactivity and potential harmfulness of aggregates containing one or more forms of low crystalline silica (opal, chalcedony, tridimite, cristobalite) and volcanic glass rich in silica (Danciu, 2010;

Danciu and Buia 2013, 2016). By verifying the alkali-aggregate reaction it is established the possibility of using the aggregates together with cements to mitigate or annihilate the reactivity and harmfulness. This determination is required for aggregates used to produce concretes in permanently or alternately contact with water or a wet environment (Toderas et al., 2017). The results obtained from the analysis are presented in Table 1. The chemical analysis for the two types of andesites were aimed at determining the main oxides. The results of chemical analysis are presented in Table 2.

Table 1. Mean values for alkali-aggregate reaction

Recollection place/ Rock type	Silica concentration, Sc [mmol/dm ³]	Sodium hydroxide concentrate reduction, Rc [mmol/dm ³]

Knowing the physical conditions of the rock can help developing a quantitative description and estimating its influence on strength and deformation characteristics. This can only be achieved by determining the physical characteristics. The determination of physical properties was performed in accordance with current standards (STAS, EN, EN), with the recommendations of the International Bureau of Rock Mechanics (BIMR) and the International Society of Rock Mechanics (Simrit). Methods for the determination and calculation relations are found in various specialty papers (Danciu, 2010; Danciu and Buia 2013, 2016). By determining the physical parameters, according to standards and specific procedures, there were obtained the following average values for the analyzed samples (Table 3 - 4). According to the purpose, there were determined the following resistance and deformation characteristics of the rocks: compressive breaking strength, freeze-thaw resistance, static modulus, Poisson's ratio, continuity index, remanent deformation coefficient and coefficient of heterogeneity, in Tables 5-8. The calculation methods and relations used are consistent with existing STAS and with the recommendations of the International Bureau of Rock Mechanics and International Society of Rock Mechanics, some of them are found in the literature (Danciu, 2010; Danciu and Buia 2013, 2016).

According to the purpose, there were determined the following resistance and deformation characteristics of the rocks: compressive breaking strength, freeze-thaw resistance, static modulus, Poisson's ratio, continuity index, remanent deformation coefficient and coefficient of heterogeneity, in Tables 5-8. The calculation methods and relations used are consistent with existing STAS and with the recommendations of the International Bureau of Rock Mechanics and International Society of Rock Mechanics, some of them are found in the literature (Danciu, 2010; Deere and Miller, 1966).

4. Discussion

For the efficiency and success of the classification system used, it must be simple, easy to understand and apply, taking into account only significant and intrinsic parameters of rock that are most relevant in engineering (Deere and Miller, 1966). In this paper we performed a classification of andesites according to the literature (Danciu, 2010; Danciu and Buia 2016; Deere and Miller, 1966; Gercek, 2007; Ramamurthy, 2004; Toderaş, 2008) on the chemical, geological and geomechanical criteria, considering all of them having a significant influence. Depending on the chemical criterion, the rock classification was made based on the chemical composition of rocks and alkali-aggregate reaction, two important criteria in qualitative characterization of the rock.

Table 9. Chemical classification of the rocks

Chemical classification of the rocks	Rock type / Recoltation place	
	Andesite/Criscior	Andesite/Albini
SiO ₂ content	Neutral	Neutral
Alkali-aggregate reaction	Non-reactive	Non-reactive

Table 10. The geomechanical classification of the intact rock

The geomechanical classification of the intact rock			Rock type / Recoltation place			
			Andesites/Criscior		Andesites/Albini	
Characteristics	Property	Classification value	Obtained value	Rock characterization	Obtained value	Rock characterization
Physical	Volumetric density	2,251 - 3,000	2,6397	- heavy	2,6734	- heavy
	Apparent porosity	< 1,0	0,3297	- slightly porous	0,3819	- slightly porous
	Water absorbtion at normal pressure	0,50-3,00	1,4089	- slightly absorbant	1,1652	- slightly absorbant
Resistance	Panet compressive breaking strength (1993)	60-200	143,538	- high resistance	142,404	- high resistance

		< 25	12,715		13,997	
	80 - 100	90,4	- fresh	0	- fresh	
	Static elasticity modulus	20000 - 50000	24036,94	- rigid	24336,23	- rigid
Resistance and deformation	Poisson's ratio	0,2 - 0,3	0,223	- average	0,233	- average
	Deformation behavior	0,001 - 1	0,0038	- elastic behavior	0,0021	- elastic behavior
	Continuity coefficient	0 - 3,125	0,810		0,95	
Resistance and deformation	Deere and Miller Monoaxial compressive breaking strength	50-75	67,352	-average	82,086	- good
		75 - 90				
	E_s/σ_c ratio (Modulus ratio)	< 200	167,460	- low	170,846	- low
	Ramamurthy and Arora Monoaxial compressive breaking strength	110 - 250	143,538	- high resistance	142,404	- high resistance
E_s/σ_c ratio (Modulus ratio)	100 - 200	167,460	- average	170,896	- average	

The geomechanical classification of the andesites was done according to the criteria used today vastly, the rocks being characterized by their physical, resistance and deformation characteristics. Considering the geomechanical criterion, the andesite were classified according to the properties from table 10. Based on the average values of the main physical and mechanical characteristics obtained for the rocks analyzed and compared with the conditions of eligibility, andesites are classified into one of the five admissibility classes (Table 11).

Table 11. Admissibility conditions of the rocks used for rail and road works

Characteristic	Rock class					Rock type / Recoltation place		
	A	B	C	D	E	Andesite/Criscior	Andesite/Albini	
Apparent porosity at normal pressure, %, max.	1	3	5	8	10	0,3297	0,3819	
Compressive strength, dry, N/mm ² , min.	160	140	120	100	80	143,538	142,404	
Wear Los Angeles car type, %, max.	16	18	22	25	30	16,369	11,138	
Crushing compression strength, dry, %, min.	70	67	65	60	50	92,016	92,492	
Freeze-thaw resistance:	3							
- Gel coefficient (μ_{25}), %, max.						0,127	0,113	
- Freeze sensivity (η_{d25}), %, max.						9,565	10,226	

5. Conclusion

Analyzed andesites are compact, having a high density, resulted from the comparisson between the specific and apparent densities. The compressive breaking strength of the analyzed andesites is high, between 140-145 MPa, admissibility class B. The wear resistance has low values, while the dry crushing compressive strength has values above the ones imposed for the admissibility class A, these rocks being recommended for rails and road works. Depending on the values obtained for the gel coefficient and the softening coefficient after freeze-thaw cycles, we consider these rocks to be freeze-thaw resistant. By comparing the obtained results with the admissibility conditions, the analyzed rocks are classified in the admissibility class A. Due to the resistance to bad weather and wear, and because of the high polishing capacity, the analyzed andesites may be used in constructions, as decoration rocks inside and outside, for monuments. For larger projects, the andesite may be used as structure element. The andesite road borders are more lasting and fashionable than the ones from concrete. Also, because of acid rain intensification (due to growing pollution), the andesite replaces marble for monuments, because it lasts more and doesn't reacts with acids. The andesites from

Criscior and Albini used nowadays as aggregates for roads may extend their capitalization domains: for rail works, constructions, ornaments, monuments and for manufacturing andesite prefabricates.

Exploring possible accidents and recommendations for biological waste treatment installations

Nikolay Savov^a, Teodora Hristova^a, Petya Gencheva^a

^aUniversity of Mining and Geology “St. Ivan Rilski”, Sofia, BULGARIA

Abstract

In order to prevent accidents and increase the economic effect, a review of the status of the facilities operating on the territory of a bio-waste treatment plant is made. All facilities have been inspected. On the basis of the registered failures or difficulties in the control of the facilities, critical points of the technological line have been indicated. The possible cases are discussed whose decision would lead to the prevention of accidents and early decommissioning of the available systems. Such analyses are usually made after the occurrence of accidents and the accumulation of data about them; according to the authors, however, a preliminary monitoring will bring about positive economic results. The newly-opened plant has not been in operation for a long time, yet several pre-accident conditions have already been identified. As a result of erosion and corrosion processes, wear of one of the concrete surfaces has been detected in a storage area for bio-waste. Another problem is the disturbed superficial structure and plastic deformation of the front loader buckets. The causes of the erosion and corrosion processes have been analyzed and identified. Measures have been recommended to solve the problems arising from the routine activity of these facilities. Following the implementation of the proposed measures, the lifetime of the inspected facilities is expected to extend.

Keywords: bio-waste; compost; bio-gas; accident; repairs;

1. Introduction

Environmental pollution is one of the major and most topical problems in the modern world. Its prevention depends on each and every resident of this planet. The population growth is also associated with consumption increase that has turned the issue of domestic waste into a global problem. Intelligent waste management is a multi-stage process involving public education in environmental protection, the construction of waste separation, composting, and waste disposal facilities, as well as of facilities for the transformation of wastes into material resources.

The aim of this report is to examine the reasons for the premature repairs in a newly-constructed bio-waste treatment plant. The object of the report are the premises and the adjoining facilities. The analysis of possible problems in such an enterprise will facilitate risk management.

By inspecting the likely locations for the occurrence of breakdowns and preventing them, losses will be reduced. Such an analysis is usually performed after the occurrence of breakdowns and the accumulation of data from them. Since the enterprise has been in operation for a short period of time, the study is constrained by the lack of data. Therefore, inspection is proposed to be carried out through pre-screening.

2. Technological line and problem analysis

The bio-waste processing plant is made up of a production block and a compost storage area that are divided into the following facilities and aggregates: production plant for the processing of food waste; installation for anaerobic decomposition, pasteurization digesters, gas system and co-generator.

2.1. Production facility for the processing of biological (food) waste and compost storage area.

The bio-waste treatment plant processes biodegradable waste from kitchens, catering establishments, commercial enterprises trading in food products with expired shelf life. Initially, the waste enters the waste reception and pre-treatment area (Fig. 1). In accordance with the pre-treatment delivery conditions, waste is shipped 5 days a week, 8 hours per day. The indoor reception areas provide protection against environmental influences. They are equipped with a system of exhaust air biofilters that reduces harmful emissions. The reception areas are equipped with a drainage system for collecting infiltrate released from biological (food) waste. The water is collected in a pumping pit and pumped to a buffer tank.

Fig. 1a). Concrete cell in the biological mass storage area prior to treatment and 1b) Mechanical processing of separately collected biodegradable food waste.

The mechanical processing is performed by a compact system consisting of three efficient components. A front loader loads the organic waste from a temporary storage facility into the hunning system and feeds it into a hammer mill through an auger line (Fig. 1b). This technique ensures a constant size of the organic fraction. The separation of incidental pollutants (e.g. packaging) is carried out by means of a screw conveyor that takes the above to a packing container at a fixed speed.

The shredded waste is fed to a buffer tank through a pump. The organic fine fraction is converted into a biological suspension with a solids content of about 10-15%. Production water is added to it.

2.2. Possible problems in this area

The possible stops due to breakdowns in this area occur during peak load operation and due to the presence of aggressively active components which can be divided into mechanical, electro- and physico-chemical. In the area of mechanical processing, breakdowns of the hammer mill can occur because hard-to-treat packaging falls into it. This stops the facility for hours and a group of workers have to manually remove the cause of the damage. Thus, continuous inspection and repairs are required.

In the bio-waste storage area, the problems encountered are related to the corrosion of the concrete flooring (Gencheva, 2015) and of the metal reinforcement. The destruction of concrete surfaces is caused by physico-mechanical, physico-chemical, and biological factors, as well as by human activity.

The dynamic load by the machines in the storage area and by the heavy loaders has a negative and destructive (corrosion) effect. In the process of excavation the bio-mass out, friction of the load buckets is caused which further damages and wears the concrete out. On the other hand, friction with concrete brings about erosion wear and destruction of the metal of the buckets themselves. Surface destruction of the bottom walls of the storage area is also observed that occurred as a result of friction between the wall and the uncovered front edges of the buckets during the scooping of biological mass (Fig. 2.)

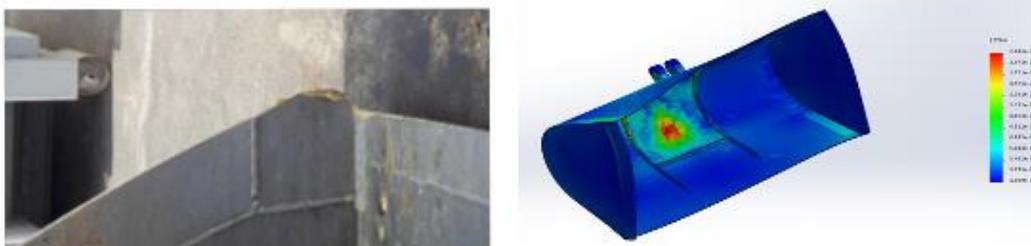

Fig. 2. Damage to the walls by the edges of the buckets and the edge of a bucket and the high tension has analysed by Solid Works programme

The rapid wear of the Liu Gong 842III front loader buckets leads to bursting bottoms and requires excessive replacement of the buckets with new ones. The causes of the plastic deformation and the destruction of metal are

mechanical. Despite the composition of the loaded food waste products, corrosion processes have not been observed so far. An analysis based on the Finite Element Method using the Solid Works Simulation software has established that the cause of the damage is the high tension that the bucket has to overcome. The calculated tension that is acceptable for a bucket with a wall thickness of 8 mm is 120 kN (2017, Minin).

$$P = 3600 \frac{N_{DB} \cdot \eta_T}{v}, N \quad (1)$$

$$P = 3600 \frac{137.0,8}{3,3} = 119563N \approx 120kN \quad (2)$$

It can be concluded that corrosion and erosion processes on the concrete surfaces and rapid wear of the buckets have been established in the storage area. The reasons are the inappropriate type of concrete flooring and the friction of loader buckets. On the basis of inspections and analyses made, the following recommendations are given:

1. A new concrete flooring in the waste storage facility has to be laid. The concrete must withstand the friction and pressure of the load-lifting machinery, as well as the impact of chemical and biologically active substances. The facilities that operate in medium to high corrosive aggressive environments, as in this case, need to be cast from corrosion-resistant concrete. On the basis of the analysis of the strength characteristics and the composition of the concrete, CEM III or CEMI I concrete is recommended with the addition of the required concentration of Pozolite with components of microsilicium dust and treated ash from the Thermal Power Plant. The cement in the composition is recommended to be slag cement or Portland cement. The concrete should not be poured at very low or high temperatures as this will lower the cost of its application and will result in the optimum properties of the floor covering.
2. In order to determine the type of selective corrosion of the concrete flooring and the causes of its generation, it is necessary to monitor the composition and concentration of the aggressive agents present in the waste products within a certain period of time. Another requirement is to measure the highest temperature amplitudes during the seasons since the cells are not equipped with an air conditioning system.
3. It would be advisable for the concrete surfaces to be further treated with wear-resistant, antibacterial and chemically-stable coatings, which will further extend the operation period of the premises and will improve the hygiene in the storage area. Medium and high intensities of weakly aggressive liquid media are observed in the storage area and low intensity of medium and highly aggressive liquid media; therefore, a sheet waterproofing of bituminous or polymeric sheet materials (1-2 layers) is recommended. Epoxy or methyl methacrylate floorings are also suitable.
4. When laying a new concrete floor, it is necessary to work out a 5% slope. The project should provide for the implementation of a levelling layer of fine-grained concrete with an average thickness of 60 mm to form the slope of the floors. The edges between the floor and the walls, columns and foundations under the machines and the apparatus should be rounded to a radius in mm. The foundations under the machines, the apparatus, and the sills around the walls and columns with a height of at least 300 mm are protected with the same insulation as that of the floors.
5. It is necessary to build a drainage system that takes the infiltrate and the released liquids from the bio-waste to a treatment plant. In this way, the waste products will drain and will not stay stagnant and react with the floor surfaces of the storage area.
6. To reduce the friction between bucket and floor, it might be possible for either the whole or just the lower parts of the buckets to be lined with a softer material. Acid-resistant polymer material with a low aging factor and good adhesion to metal is appropriate. Laminated reinforced polymers from the group of the reactoplasts are such materials. As a result of the calculations made, it has been established that the thickness of the walls of the bucket, at its current volume, should be 4 cm to ensure the continuous and fault-free operation of the front loader, without the need for a frequent change of the bucket.

2.3. Anaerobic degradation process

The process of anaerobic degradation takes place in the digesters shown in Fig. 3a.

The buffer tank is used as a mixing and homogenising tank, and also as an offset buffer for those days when no waste material is supplied. The buffer tank is designed for an average stay time downtime of 3 days in order to ensure sufficient storage capacity during non-working days. The start of the process of anaerobic degradation and methane accumulation is suppressed by low temperature, aerobic atmosphere, and short residence time - up to 3 days. The suspension is pumped from the buffer tank to a digester, or bioreactor. There, the anaerobic biochemical process is carried out in several stages. Methane-forming bacteria are strictly anaerobic and sensitive to changes in pH. The suspension is assimilated in the digester, at a mesophilic temperature of about 37°C. The sequence of the processes is hydrolysis, acid formation and methane formation. The roof is designed as a flexible double-membrane roof that is stabilised with air; thus, high operational reliability is ensured.

Fig. 3. (a) Digester for anaerobic degradation and. (b) Combined heat and power station (CHPS).

2.4. Possible problems in this area

The optimum operation of the reactor requires regular monitoring of the environment of bacteria. The bacteria in the reactor are highly sensitive to changes in the pH and in the temperature of the medium. Under unfavourable conditions, anaerobic bacteria cease processing the biomass and emit biogas. If any of the conditions deteriorates, the process of methanogenesis is greatly delayed and stops. In order to optimize the process of operation, we made a lot of experiments at different temperatures ($33 \div 37^{\circ}\text{C}$) and we found out that the productivity grew and the biomass conditions stabilized at a temperature of 34°C . Despite the manufacturer's instructions regarding the specified operating temperature, we found out that each of the reactors had different optimum operating parameters (pH and temperature) depending on the structure and composition of the feed medium. A major problem with this type of reactor is the impossibility of servicing the mixers that homogenize the medium without breaking the airtightness. Service is required every $3000 \div 4000$ hours, which results in process shutdowns, reactor opening, generated gas release, partial loss of biomass, etc. These technological problems lead to mechanical and electrical problems affecting the drive, such as winding or stretching and breaking of power-stirring cables. Due to improper installation, emergency servicing of the agitators had to be carried out by a diver diving into the bioreactor.

2.5. Pasteurisation

After the digester, the processed biomass is heated in the pasteurisation facility in the course of one hour at a temperature of 70°C . Thereby compliance with the relevant hygiene standards (e.g. EG 1069/2009) is guaranteed. The water from the production unit, with a temperature of 85°C , is used as a heat conductor. After pasteurisation, the substrate is transported to a storage tank. The purpose of this tank is to provide storage space for the drainage process. This makes it possible for the digester to be loaded and unloaded repeatedly. The wastes that have undergone pasteurisation are transferred by means of pumps from the storage tank to the drainage stage. At this stage, separation of the substrate into streams of liquid and solid material is carried out by means of a decanter. The solid matter is transported to the maturing area and is mixed with green waste. After draining, the water is poured into a small buffer tank and is then pumped out into a processed water tank.

2.6. Possible problems in this area

The main problems are technological and result from the lack of an averaging tank where the added coagulants have enough time to react with the substrate before the decanter. This will ensure homogeneity of the flow and the decanter will be able to separate the solid phase from the liquid phase with sufficient quality. The requirement is that the humidity of the waste material be up to 30%; currently, humidity exceeds 40-45%, and occasionally amounts to 60%. This causes debalancing of the decanter, leading respectively to mechanical and electrical problems and such associated with control and measuring devices and automation, and CMDA (Control-measuring devices and automation) problems.

2.7. Biogas production

The biogas produced in the digesters amounts to 3,412 t/y. It is stored in the flexible membrane tank above the digester and undergoes a process of dehydration and desulfurization, both of which are additional activities. The wastes should be treated in compliance with Annex VI, Chapter II, C 12 and 13 of the European Regulation EU 1774/2002. The already purified bio-gas is fed to the co-generators, where energy is generated by gas turbines. This energy is supplied to the national electricity grid and the heat produced is employed in pasteurization as well as for everyday and other production needs on the plant.

2.8. Gas Engineering

For security reasons, the necessary safety devices and deflagration equipment are provided along the entire gas route. The biogas produced has a methane content of 50-65 vol. % and a calorific value of 5.0 - 6.5 kWh / Nm³. During anaerobic digestion, sulphate will be reduced to hydrogen sulphide (H₂S) through biochemical reactions. Air dosing is controlled. The products obtained from oxidation, sulfur and sulfuric acid are separated by a fertilising solution. The amount of the waste solution depends on the concentration of hydrogen sulfide in the biogas and on several reaction conditions, such as the pH. The hydrogen sulphide content is highly dependent on the input raw materials. The experience in the treatment of household bio-waste and organic food waste with high concentrations of meat shows that increased concentrations of hydrogen sulphide in biogas can be achieved that reach up to 1000-2500 ppm.

2.9. Possible problems in this area

Hydrogen sulfide is an acidic gas with toxic properties. It may penetrate in the biogas system, thus causing corrosion in the CHPA (combined heat and power aggregate) at high concentrations. The microorganisms that decompose (digest) hydrogen sulphide live in a narrow parameter living environment; therefore, it is necessary to regularly add biomass so that the process could function as a fixed biomass reactor. Currently, there is no established methodology and control system for controlling the concentration of each type of microorganism that carries out desulfurization. The result could be the destruction of the CHPE.

2.10. The co-generators (CHPA)

Two biogas plants in the CHPA are installed with a power of approx. 265 kW and around 600 kW respectively (Fig.3b). The two CHPAs are designed as container units. Prior to cooling, the biogas has a relative humidity of 95-100% and a temperature of 40°C. The heat from the exhaust system is supplied to the digester and to external consumers. If the heat generated by the CHPE plant is not necessary for processing either in the biogas plant or in some of the external consumers, it will be discharged through air-cooled radiators. If, on the other hand, the CHPE facilities do not work and the stored biogas levels reach the permissible limits, the gas is burned on a torch. The facility operates independently from the CHPE and is positioned nearby.

2.11. Possible problems in this area

The following problems can be detected: mechanical malfunctions or failure of the sensors and of the ventilation system. A problem that has occurred in the air monitoring system or an incorrect reporting of methane quantities could bring about a CHPE accident. Biogas that has not been sufficiently enriched with methane might cause malfunction in the plant's electricity production capacities. Employees who have not been well-trained to work with CHPE would cause the decommissioning of the system. Ill-set software of the control system in automatic mode prevents the fully effective operation of the facility.

3. Conclusions and recommendations

After an analysis of the technological line problems encountered by different specialists, we have identified the major factors and reasons for accidents occurring before the expiry of the envisaged warranty for the operation of the facilities on the territory of the biological waste treatment plant. They are:

- technological factors;
- physico-chemical factors;
- electro-mechanical factors;
- problems with control and measuring devices and automation (CMDA problems) and SCADA problems;
- the human factor.

The influence of the individual factors is shown in Fig. 4a.

During operation, it was established that the mechanical, electrical, and CMDA problems were caused by technological errors, unfulfilled planned repairs, and personnel errors while operating the systems. Defects in sensors and executive mechanisms lead to a loss of biogas, i.e. losses by non-produced energy. The identified erosion and corrosion problems were the result of aggressive environment which was higher than the technologically planned.

To prevent the occurrence of further problems, it is necessary to:

- replace components of the machinery and equipment with such made of corrosion-resistant materials;
- install frequency inverters and compile the SCADA system;
- implement an additional sensor system and to replace part of the currently installed sensors;
- implement a flexible automatic control and monitoring system that can be further adjusted if parameter altering is required;
- train and motivate the staff.

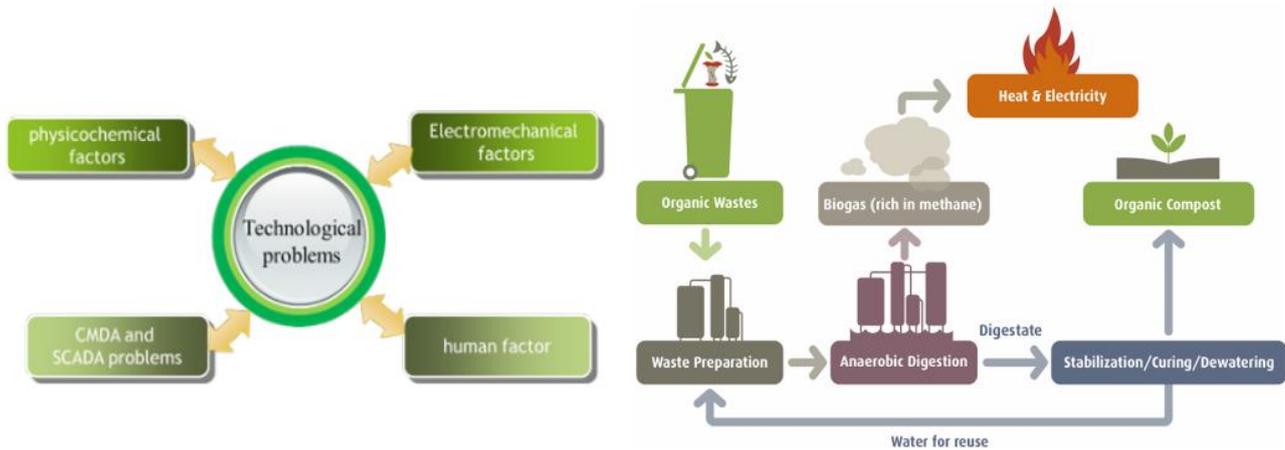

Fig. 4. (a) Factors for the occurrence of accidents and the relationship between them and (b) Technological line for waste processing

4. Conclusion

Based on the analysis made, it can be concluded that the reasons for the accidents are due to an incorrect selection of the installed facilities. The selection should be made in compliance with the nature of the work, as well as with the quantity and the type of waste to be treated. The accidents are associated with the mechanical wear of the equipment, resulting in electro-mechanical damages. The low level of qualification of the staff is another problem that needs to be considered and action should be taken to improve the skills of those employed in the individual sectors. The implementation of the measures recommended will prevent decommissioning of the facilities, which will bring about positive economic results.

Abstract

Personal protective equipment worn or held by a worker to protect him against one or more of the risks that might endanger his safety and health at work, intended for use in explosive atmospheres shall be designed and manufactured in such a way that can't be the source of an arc or an electrical, electrostatic spark or results by a shock that could ignite an explosive mixture. One of the potential ignition sources for explosive mixtures is static electricity, namely electrostatic discharge from personal protective equipment (clothing, footwear, head and hand protection, etc.) and from person. The purpose of the paper is to identify and establish the criteria for the selection of personal protective equipment for use in potentially explosive atmospheres, depending on the risk factors and the classification of hazardous areas, for the purpose of ensuring a level of safety and health at work higher possible.

Keywords: personal protective equipment, static electricity, electrostatic discharges, explosive atmosphere.

1. Introduction

Personal protective equipment worn or held by a worker to protect him against one or more of the risks that might endanger his safety and health at work, intended for use in explosive atmospheres shall be designed and manufactured in such a way that can't be the source of an arc or an electrical, electrostatic spark or results by a shock that could ignite an explosive mixture.

Explosive mixtures may be initiated by a multitude of ignition sources, but if we refer to personal protective equipment, static electricity, more precisely electrostatic discharges, is identified as a source of ignition. Electrostatic discharge as a source of ignition of explosive mixtures may come from individual protective equipment such as clothing, footwear, head and hand protection, face and eyes, and persons.

Static electricity, as a source of electrostatic discharges, may occur in technological processes such as electrostatic painting, printing, sorting of electrostatic materials, etc., or as a random undesirable phenomenon. In general, the occurrence of static electricity or electrostatic discharges may constitute a risk, namely: fires and explosions, unexpected detonation of the electrical detonators and pyrotechnic articles, unexpected operation of sensitive control equipment, electric shock at people.

Of these risks, especially fires and/or explosions due to the initiation of explosive mixtures by electrostatic discharges, requires the application of technical or organizational measures which minimize their effects on the safety and health of workers and other persons.

In this context, it is very important to identify and establish those measures that prevent the risk of fire and / or explosion, in order to ensure the highest level of safety and health at work.

One of the necessary measures is the use of adequate personal protective equipment for the intended use area which meets the essential health and safety requirements specific to environments with risk of explosion so as to avoid the possibility of generating electrical ignition sources, mechanical or other nature. Generally, in industrial spaces where combustible/flammable substances are processed, explosive mixtures of gases, vapors, mists or dust and air may occur under normal working conditions due to processes or accidental leakages.

* Corresponding author. Tel.: +40 254 541 621; fax: +40 254 546 277.
E-mail address: florin.paun@insemex.ro.

Generally in order to reduce the risk of explosions in industrial spaces with potentially explosive atmospheres called "Ex areas", must be used personal protective equipment in special construction for potentially explosive atmospheres which can't produce or constitute sources of energy which could initiate an explosion.

It follows that the personal protective equipment used in such "Ex areas" must meet the essential safety requirements regarding to the explosions hazard by avoiding the ignition sources of explosive atmosphere such as, for example, the sources of electrostatic nature.

2. Safety requirements applicable to the personal protective equipment intended to use in the environments with explosion danger

Personal protective equipment intended for use in potentially explosive atmospheres shall comply with the applicable safety and health requirements depending on the category of equipment and Ex., areas, as laid down in European Parliament Regulation (EU) 2016/425 of 9 March 2016 on personal protective equipment and repealing Council Directive 89/686/EEC.

According to requirement 2.6 of Regulation (EU) 2016/425 "PPE intended for use in potentially explosive atmospheres must be designed and manufactured in such a way that they can't be the source of an arc or spark of electrostatic nature or resulting from a shock, which could ignite an explosive mixture", (Regulation (EU) 2016/425).

Establishing the personal protective equipment compliance with applicable essential health and safety requirements suppose their assessment in relation to the performance of protection against risk factors (explosion, fire, etc.).

Regarding to the assessment of personal protective equipment from the point of view of the performance against static electricity, the requirements are found in equipment specific standards as well as in Regulation (EU) 2016/425.

In this sense, some of the standards referred to can be mentioned, namely: SR EN 1149-5:2008 Protective clothing - Electrostatic properties - Part 5: Material performance and design requirements; SR EN ISO 20344:2012 Personal protective equipment - Test methods for footwear; SR EN 420 + A1:2010 Protective gloves - General requirements and test methods.

Regarding to the requirements for the prevention of dangerous electrostatic discharges from persons, these are given in IEC 60079-32-1/TS/Ed1: Explosive atmospheres - Part 32-1: Electrostatic hazards, Guidance.

Requirements and test methods for static electricity dissipation protective clothing to avoid sparks that may cause ignition according to SR EN 1149-5:2008 are as follows:

2.1 Material requirements

Electrostatic dissipating materials shall meet at least one of the following requirements:

- $t_{50\%} < 4$ s or $S > 0,2$ when the material is tested with the second method (induction charge) specified in SR EN 1149-3, where $t_{50\%}$ represents the charge decay time and S coefficient of protection;
- the surface resistance is $\leq 2,5 \times 10^9 \Omega$ on at least one of the surfaces when the material is tested in accordance with SR EN 11491-1.

For materials which contain conductive wires in the shape of a grid, the distance between them must not be more than 10 mm in any direction (SR EN 1149-5, 2008).

2.2 Design requirements

A static electricity dissipation protective clothing must allow for the permanent covering of all improper materials during normal use (including during bending and moving the body). If such a clothing is made of multiple layers, one of which is for example an insulating material, etc., then the outermost material shall to satisfy the requirements for the material mentioned above.

Also, a static electricity dissipation protective clothing, which follow to be used shall to correspond to the user's body conformation in accordance with SR EN 340 so as to allow the body to move with all the closures provided in accordance with the manufacturer's instructions.

Attachments from non-conductive materials such as labels, reflective tapes, etc., essential from point of view of security are allowed provided these remain permanently fixed in such a way as to avoid important separation between attachments and personal protective equipment.

Conductive parts (zips, fasteners, buttons) are permitted provided that they are adequately covered by the outer material when the clothing is worn in flammable or explosive atmospheres.

3. Selection of personal protective equipment for use in areas with danger of potentially explosive atmosphere

The selection of the personal protective equipment is based on the properties of the constituent materials to provide protection against static hazardous electricity, taking into account the environmental factors, the probability to appear a charging mechanism and the ignition sensitivity of the explosive atmosphere by electrostatic discharges.

When analyzing the risks of electrostatic discharge from personal protective equipment, such as protective clothing and other PPE elements, the relevant parameter is the minimum ignition energy (MIE) of the explosive atmosphere.

The performance requirements for electrostatic dissipative protective clothing provided in SR EN 1149-5 are based on explosive atmospheres with MIE equal to or greater than the most easily flammable mixture of hydrogen in the air.

Table 1 gives some guidance regarding to the electrostatic dissipative protective clothing and other PPE necessary, recommended, or unnecessary based on global risk, which are a combination of the likelihood of an explosive atmosphere, the probability to appear a charging mechanism and sensitivity to ignition of the explosive atmosphere by electrostatic discharges, (FprCEN/TR 16832, 2014).

Where "required" or "recommended" is indicated, it refers to personal protective equipment that have a single level of protection. When "not necessary" is indicated, this means that electrostatic dissipative protective clothing or other personal protective equipment is not necessary, but also that other precautions are still required to prevent electrostatic ignition sources, especially grounding of people and other conductors.

Table 1. Requirements for electrostatic dissipative protective clothing and other PPE

Dangerous areas	Charge probability	0,016 mJ ≤ MIE ≤ 0,2 mJ Explosion groups IIB and IIC		MIE > 0,2 mJ	
				Explosion groups IIA and IIB	Explosion groups IIIA, IIIB and IIIC
Zone 0	high			necessary	
	low		necessary		
Zone 1	high				
	low				
Zone 2	high	recommended		recommended	
	low	unnecessary		unnecessary	
Zones 20, 21 and 22	high				unnecessary
	low				

3.1 Selection of electrostatic dissipative protective clothing

Electrostatic dissipative protective clothing must meet the performance and design requirements specified in SR EN 1149-5 and shall represent the outer layer of clothing when worn in hazardous areas.

Underwear and fully covered by electrostatic dissipative protective clothing are not necessary to be made of electrostatic dissipative materials, as long as it does not interfere with the electrical continuity between the wearer's body and the electrostatic dissipative protective clothing, (Păun et al., 2017).

One of the minimum requirements specified in Annex II of Directive 1992/92/EEC is that "... appropriate measures should be taken to minimize the risks to workers from the physical effects of an explosion." This involves that protective clothing worn in dangerous areas must provide protection against heat and flames. The need to protect against heat and flames shall be based on the results of a risk assessment, (Directive 1999/92/EC).

An explosion produces more physical effects, including explosion waves, throwing of fragments, etc. To protect workers from the thermal effects of a possible explosion, protection against heat and flames should be incorporated into electrostatic dissipative protective clothing, (Părăian et al., 2013)

Alternatively, an ensemble may be worn, that is, the protective clothing against heat and flames is worn together with electrostatic dissipative protective clothing, in which case the electrostatic dissipative protective clothing must be the outermost layer and must cover all insulating clothing. The outer layer must also have flame propagation limiting properties, (FprCEN/TR 16832, 2014).

Although Directive 1999/92/EC may require employers to provide workers adequate protective clothing, the requirements for such clothing are specified in Regulation (EU) 2016/425 and is not necessary to bear the conformity marking for ATEX equipment, unless the clothing contains electrical or electronic components.

3.2 Selection of protective gloves

Wearing gloves in hazardous areas may be necessary to protect the wearer from various hazards, to protect the handled products, or to improve manual handling. If gloves are necessary for any of these reasons, then gloves must also protect against electrostatic dangers if they are worn in hazardous areas as recommended in Table 1, (FprCEN/TR 16832, 2014).

Metallic hand tools and other conductive objects that can be held in the hand and is not earthed are based on hand contact as the primary earthing means. Gloves intended for use in hazardous areas shall provide an electrical connection between the hands of the wearer and any conductive object that is held in the hand so that the resistance to the ground is within acceptable limits, (Păun et al., 2017).

Materials used to carried out palms, fingers and any areas extending over the wrist of the wearer must meet the requirements for electrostatic dissipative protection gloves specified in SR EN 16350.

3.3 Selection of footwear and foot protection

Conductive and antistatic footwear as defined in SR EN ISO 20345, SR EN ISO 20346 and SR EN ISO 20347 are intended primarily to provide earthing means of personnel. In many cases, only the sole of the footwear is made of conductive or antistatic materials.

However, areas of insulating materials which form the upper part of the footwear and which may extend to the bottom of the foot in the case of boots may present an electrostatic risk if they are subjected to massive electrostatic charges. In such cases, the upper part of the footwear should be made of electrostatic dissipative materials as in the case of other elements of electrostatic dissipation clothing, (FprCEN/TR 16832, 2014).

Leg protection in the form of knee pads and tibia protectors usually wear over clothing. If the outer layers are made of textile materials, they must be electrostatic dissipative materials as well as other elements of electrostatic dissipative clothing and can be evaluated according to EN 1149-5, (Părăian et al., 2013).

4. Conclusions

The generation of electrostatic charges and their accumulation on persons and on the personal protective equipment worn by them present a danger in the presence of potentially explosive atmospheres or explosive substances from point of view of their initiation by electrostatic discharges.

The explosion hazard presence of due to the initiation of explosive atmospheres or explosive substances by static electricity discharges implies and requires appropriate protective measures to prevent electrostatic discharges from persons by selection for the use of personal protective equipment, which to meet safety requirements related to the prevention of ignition sources (static electricity), to which is added the provision of ways to dissipate the charges to the ground.

Abstract

Due to the continuous technical and economic development of the human society, a large number of chemical substances and compounds in the form of combustible dusts and powders are increasingly being used in the technological processes present in various industrial branches. These combustible powders, during their production, handling and storage operations, in combination with air, may lead to potentially explosive atmospheres.

The presence of combustible powders and dusts, and possibly the appearance of potentially explosive atmospheres, has led to the need to adopt and enforce protective measures to ensure an acceptable level of protection in accordance with current rules, protective measures materialized mainly through use within locations endangered by the presence of potentially explosive atmospheres of properly protected technical equipment so as to reduce the possibility of ignition of the surrounding explosive atmosphere.

Therefore, in order to be able to establish with certainty the requirements of the technical equipment that can be used in potentially explosive atmospheres generated by the fuel / air mixture, it is necessary to know the type of dust, as well as a series of parameters defining its sensitivity to ignition with different sources and the severity of the explosion it can generate, parameters known as explosive characteristics

The paper highlights the explosive characteristics of combustible powders, the methods and equipment necessary to carry out experimental tests to determine these characteristics.

Keywords: combustible dusts, potentially explosive atmospheres, explosive characteristics, explosion protection.

1. Introduction

Due to the continuous technical and economic development of the human society, a large number of chemical substances and compounds in the form of combustible dusts and powders are increasingly being used in the technological processes present in various industrial branches. These combustible powders, during their production, handling and storage operations, in combination with air, may lead to potentially explosive atmospheres.

In Figure 1 is shown the variety of industrial branches in which there are present combustible dusts from the technological processes specific to each domain (A. Jurca ș.a., 2014).

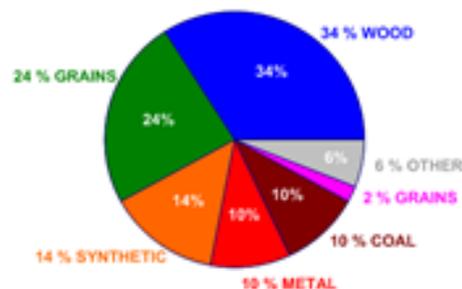

Fig. 1 – Variety of combustible dust in industry

* Corresponding author. Tel.: +40 254 541 621; fax: +40 254 546 277.
E-mail address: mihai.popa@insemex.ro.

For particulate solids (powders, flours, various powders, etc.) to be safely handled, it is absolutely essential to know the characteristics that influence security, including those that define the flammability and explosiveness of the powders. Also, knowing the explosive characteristics of combustible dusts is particularly important for choosing the technical equipment to be used at the work points endangered by the presence of potentially explosive atmospheres generated by these combustible powders, in order to adopt and apply protective measures to ensure an acceptable level of protection in accordance with the rules in force so as to minimize the possibility of ignition of the surrounding explosive atmosphere.

It is well known that an explosion may occur if the dust / fuel powder is present in suspension in admixture with air (with sufficient oxygen) within the explosive limits, corroborated with the existence of a source of initiation with sufficient ignition energy, and the pentagon can be defined the explosion shown in Figure 2.

Fig. 2 – Pentagon of ignition to combustible dusts

The mechanism underlying the explosion of the dust / air mixture can be explained by a chain reaction as follows: the heat of the ignition source comes into contact with the suspended particulate matter, produces its heating which results in the release of some substances chemical gases such as hydrogen, methane, ethane, etc. These combustible gases, in admixture with the air, form at one time an explosive mixture which, in contact with the source of ignition, ignites and creates conditions of heating the neighboring particles, this time, with a higher volume. This reaction is repeated from near to near the entire volume in which the powder is suspended.

The paper, in essence, presents the explosive characteristics of combustible powders, the methods and the equipment necessary to carry out the experimental tests for the determination of these characteristics under laboratory conditions, as well as the interpretation of the results obtained from the laboratory tests.

The current paper is given by the increasing importance of national and international levels to ensure a high level of occupational health and safety at workplaces where dust particles and combustible dust are produced, handled and stored.

2. Characteristics of combustible preparations which may produce an explosive atmosphere

In order to identify the existing explosion hazard in a space where a potentially explosive atmosphere generated by the dust / air mixture is present, the properties of the combustible dusts / powders and their safety characteristics must be known. The security features describing the relevant safety properties of combustible dust / powders are:

- a) LEL lower explosion limit, UEL upper explosion limit;
- b) LOC limiting oxygen concentration;
- c) p_{max} maximum explosion pressure
- d) dp/dt_{max} maximum rate of explosion pressure rise;
- e) MESH maximum experimental safe gap;
- f) MIE minimum ignition energy;
- g) Minimum ignition temperature of an explosive atmosphere;
- h) Minimum ignition temperature of a dust layer;

It is necessary to specify that the limits of explosivity and the limit concentration of oxygen define the combustion properties of combustible dusts / powders, while the maximum explosion pressure, the maximum explosion pressure increase velocity and the maximum experimental experimental gap define the explosion behavior theirs. Also, in order to identify the hazards of ignition, the ignition properties of an explosive atmosphere must be determined, namely: minimum ignition energy, minimum ignition temperature of an explosive atmosphere and minimum ignition temperature of a dust layer.

2.1. Explosion limits

Each dust / fuel powder has a lower explosion limit (LEL) and a higher explosion limit (UEL) and only mixtures within these limits can be initiated by a source of ignition.

In the case of dust and combustible dust, the lower explosion limit is approximately 20 to 60 g/m³ of air, and the upper explosion limit is approximately 2 to 6 kg/m³ of air. Explosion limits for dusts, compared to gas explosion limits, do not have the same meaning, as dust clouds are generally not homogeneous, in which case dust concentration can fluctuate a lot due to dust and dispersion in the atmosphere. Due to this, where there are deposits of fuel dust, it is always necessary to consider the possibility of forming a potentially explosive atmosphere.

2.2. Oxygen Limit Concentration (LOC)

Oxygen Limit Concentration (LOC) is the maximum oxygen concentration in a dust / air / inert gas mixture at which an explosion can not occur under the specified test conditions.

2.3. Maximum Explosion Pressure (p_{max})

Maximum Explosion Pressure (p_{max}) is the maximum value of the pressure occurring during the explosion of a dust / air mixture at the optimum concentration in a closed container determined under the specified test conditions (SR EN 14034-1, 2011).

2.4. Maximum Explosion Pressure Speed ($(dp / dt)_{max}$)

Maximum Explosion Pressure Speed ($(dp / dt)_{max}$) is the maximum increase in pressure per unit time in a closed container during an explosion of an atmosphere determined under the specified test conditions (SR EN 14034-2, 2011).

2.5. Minimum ignition energy MIE or E_{min}

Minimum ignition energy MIE or E_{min} is lowest electrical energy stored in a capacitor which upon discharge is sufficient to effect ignition of the most sensitive dust/air mixture under specified test conditions (SR EN ISO/IEC 80079-20-2, 2016).

2.6. Minimum ignition temperature of a dust cloud

Minimum ignition temperature of a dust cloud is defined as the lowest temperature of the hot surface on which the most ignitable mixture of the dust with air is ignited under specified test conditions (SR EN ISO/IEC 80079-20-2, 2016).

2.7. Minimum ignition temperature of a dust layer

Minimum ignition temperature of a dust layer is the lowest temperature of a hot surface at which ignition occurs in a dust layer under specified test conditions (SR EN ISO/IEC 80079-20-2, 2016).

The specific constriction of dust (k_{st}) is also called the explosion index and represents the independent volume characteristic determined by the use of the following cubic equation:

$$(dp / dt)_{max} \cdot V^{1/3} = \text{const.} = K_{st} = K_{max}. \quad (1)$$

Depending on the determined value, dust can be classified in the following classes.

Table 1. Characterization of dust according to the explosion index value

Dust explosion index	K_{st} [m · bar/s]	Characterization
St 0	0	No explosion
St 1	> 0 ÷ 200	Poor explosion
St 2	> 200 ÷ 300	Strong explosion
St 3	> 300	Extreme explosion

3. Methods for the determination of the combustibility powder explosivity characteristics

In order to determine the explosive characteristics of combustible dusts / dusts, a series of standards have been developed and implemented at European level which present the methods that can be applied and the equipment required for this. These standards were taken over as Romanian standards by INCD INSEMEX Petrosani:

SR EN 14034-1+A1:2011 – Determination of explosion characteristics of dust clouds.

Part 1: Determination of maximum explosion pressure - p_{max} ;

SR EN 14034-2+A1:2011– Determination of explosion characteristics of dust clouds.

Part 2: Determination of the maximum rate of explosion pressure increase – $(dp/dt)_{max}$;

SR EN 14034-3+A1:2011– Determination of explosion characteristics of dust clouds.

Part 3: Determination of lower explosion limit LEL for dust clouds;

SR EN 14034-4+A1:2011– Determination of explosion characteristics of dust clouds.

Part 4: Determination of the CLO oxygen concentration limit of dust clouds;

SR EN 50281-2-1:2003/AC:2013 – Electrical apparatus intended for use in the presence of combustible dust.

Part 2-1: Test methods. Methods for determining the minimum ignition temperature of the dust

SR EN ISO/IEC 80079-20-2:2016 - Explosive atmospheres.

Part 20-2: Product features. Test methods for combustible dusts.

4. Apparatus for determining the explosion characteristics of combustible powder

To determine the explosive parameters for combustible dust / powder, one of the apparatus used is KSEP-20. This apparatus consists of an explosion-proof spherical blast-furnace made of stainless steel with a volume of 20 dm³ - Figure 3. A water jacket has the role of absorbing the heat produced by the explosions. To perform the test, the dust to be analyzed is dispersed within the sphere of the pressure dust receptacle through a quick acting valve and a dispersing nozzle. The quick acting valve is pneumatically opened and closed by an auxiliary piston. The compressed air valves are electrically activated. The ignition source is located in the center of the sphere.

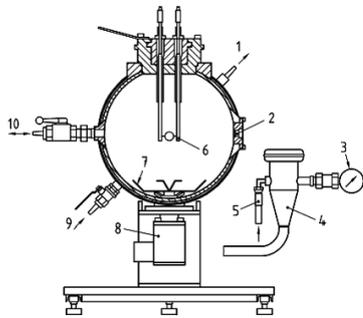

Fig. 3 – The KSEP-20 test facility

The legend:

- | | |
|---|--|
| 1 Water outlet | 6 Ignition source |
| 2 Pressure transducers | 7 Spray nozzle |
| 3 Manometer | 8 Quick-acting valve |
| 4 Dust container (0.6 dm ³) | 9 Inlet for water |
| 5 Air intake opening | 10 Exhaust outlet (air, reaction products) |

Depending on the parameter to be determined, the commands to the test facility are transmitted using an interface and a dedicated software. Two piezoelectric pressure transducers are recorded on the inner wall of the explosion vessel recording variations in the pressure of the explosion produced inside the vessel. After the test, the data obtained using this software is collected, generating based on recorded data the graphs necessary for the evaluation of the explosive parameters (Jurca A. ș.a 2007).

Figure 4 illustrates how the graphs are collected and generated based on data collected through the specialized software for Niacin USP (Nicotinic acid), the chemical formula of which is C₆H₅NO₂.

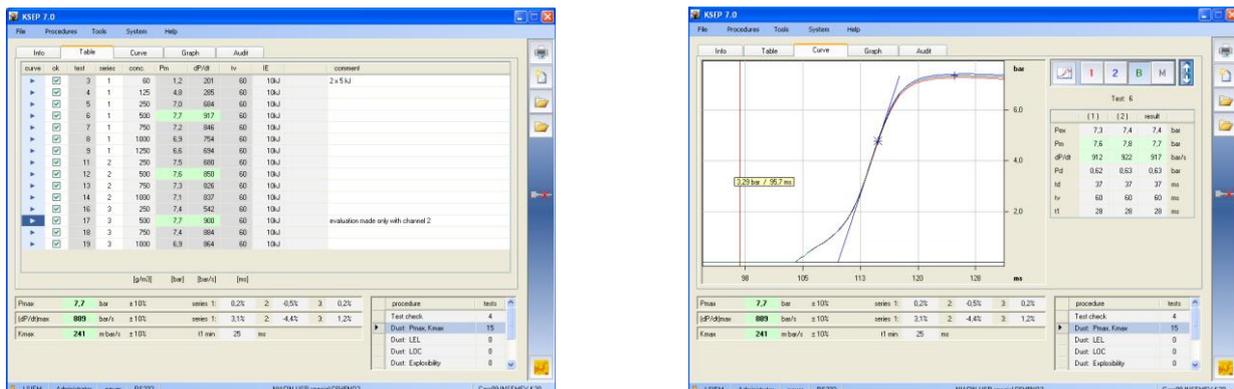

Fig. 4 - Integrated collection system of results

In this case, the following explosive parameters were determined:

- maximum explosion pressure - p_{max} [bar];
- maximum rate of explosion pressure increase - $(dp/dt)_{max}$ [bar/s];

Following the tests, the results presented in table no. 2 for series of dust samples at different concentrations of Niacin fuel USP (Nicotinic acid) – $C_6H_5NO_2$

Table 2. Test results

Test	Serie	Concentration of dust [g/m ³]	p_m [bar]	dp/dt [bar/s]
1	1	60	1.2	201
2	1	125	4.8	285
3	1	250	7.0	684
4	1	500	7.7	917

9	2	500	7.6	850
10	2	750	7.3	826
11	2	1000	7.1	837
12	3	250	7.4	542
13	3	500	7.7	900
14	3	750	7.4	884
15	3	1000	6.9	864

Explosive indexes p_{max} and $(dp/dt)_{max}$ are defined as the average of the maximum values obtained for each series of tests (total 3 series) (SR EN 14034-1, SR EN 14034-2).

Subsequently, the K_{max} explosion index is calculated by $(dp/dt)_{max}$.

$$p_m \text{ [for 3 series]} = \text{the maximum value in each series;} \quad (2)$$

$$p_{max} = (p_m [\text{series 1}] + p_m [\text{series 2}] + p_m [\text{series 3}]) / 3; \quad (3)$$

$$p_{max} = 7,66 \text{ [bar]} \quad (4)$$

$$(dp/dt)_m \text{ [for 3 series]} = \text{the maximum value in each series;} \quad (5)$$

$$(dp/dt)_{max} = (dp/dt [\text{series 1}] + dp/dt [\text{series 2}] + dp/dt [\text{series 3}]) / 3 \quad (6)$$

$$(dp/dt)_{max} = 889 \text{ [bar/s]} \quad (7)$$

Taking into account the cubic law presented as well as the value of the volume in which the tests $V = 0.02m^3$ are obtained, it results :

$$V^{1/3} = 0,02^{1/3} = 0,27144 \quad (8)$$

$$(dp/dt)_{max} \times V^{1/3} = \text{const} = K_{St} \quad (9)$$

$$K_{max} = 0,27144 \times (dp/dt)_{max} = 0,27144 \times 889 = 241,3 \text{ [bar m/s]}. \quad (10)$$

Taking into account the result obtained as well as the classification shown in Table 1, the explosive index for the tested Niacin USP (Nicotinic acid) – $C_6H_5NO_2$ - St 2 (strong explosion).

5. Conclusions

In industrial production processes where combustible powders / dusts are present, it is of great importance to know their explosive characteristics in order to be able to accurately determine whether or not they are explosive and implicitly whether their processing, handling and storage may lead to the emergence of potentially explosive atmospheres.

The determination and interpretation of explosive characteristics of combustible dusts / powders is of paramount importance in the primary phase of the explosion risk assessment as well as the adoption and application of protective measures ensuring an acceptable level of protection in accordance with the rules in force , protective measures materialized primarily in the use of properly protected equipment in locations at risk from the presence of potentially explosive atmospheres so as to reduce the possibility of ignition of the surrounding explosive atmosphere.

Abstract

In order to be used safely, all electrical or non-electrical equipment operating in areas with potentially explosive atmospheres should be provided with enclosures that provide a certain degree of IP protection (International Code). According to the general standard SR EN 60079-0 in hazardous areas Ex it is necessary that an electrical / non-electrical equipment, in addition to the specific type of protection, must provide at least a standard degree of protection IP XX, the test procedures being in accordance with the requirements of SR EN 60529 and in the case of rotating electric machines according to SR EN 60034-5. The normal degree of protection is protection against access to hazardous parts inside the enclosure and protection against penetration of solid bodies and protection against water penetration inside the equipment. Tests for the determination of the first characteristic number - protection against penetration of solid bodies are particularly important for equipment intended for use in hazardous areas of explosive atmospheres generated by combustible dust as this protection is also a requirement for explosion protection. Within the ENExEMEIP laboratory of INCD INSEMEX, laboratory tests have been developed to verify the first characteristic figure by building a high performance dusting chamber, according to the method standardized of European standard, and purchasing a stand for checking the protection against falling water in the form of rain and against water projections, which determines the second characteristic number 3 and 4.

Keywords: potentially explosive atmospheres; normal protection degree; combustible dust.

1. Generality

Many types of dust that are generated, processed, handled and stored, are combustible. When ignited they can burn rapidly and with considerable explosive force if mixed with air in the appropriate proportions. It is often necessary to use electrical apparatus in locations where such combustible materials are present, and suitable precautions must therefore be taken to ensure that all such apparatus is adequately protected so as to reduce the likelihood of ignition of the external explosive atmosphere. In electrical apparatus, potential ignition sources include electrical arcs and sparks, hot surfaces and frictional sparks.

Areas where dust, flyings and fibers in air occur in dangerous quantities are classified as hazardous and are divided into three zones according to the level of risk.

Generally, electrical safety is ensured by the implementation of one of two considerations, i.e. that electrical apparatus be located where reasonably practicable outside hazardous areas, and that electrical apparatus be designed, installed and maintained in accordance with measures recommended for the area in which the apparatus is located. Combustible dust can be ignited by electrical apparatus in several ways:

- by surfaces of the apparatus that are above the minimum ignition temperature of the dust concerned. The temperature at which a type of dust ignites is a function of the properties of the dust, whether the dust is in a cloud or layer, the thickness of the layer and the geometry of the heat source;
- by arcing or sparking of electrical parts such as switches, contacts, commutators, brushes, or the like;
- by discharge of an accumulated electrostatic charge;
- by radiated energy (e.g. electromagnetic radiation);
- by mechanical sparking or frictional sparking associated with the apparatus.

* Corresponding author. Tel.: +40 254 541 621; fax: +40 254 546 277.
E-mail address: niculina.vatavu@insemex.ro.

In order to avoid ignition hazards it is necessary that:

- the temperature of surfaces on which dust can be deposited, or which would be in contact with a dust cloud, is kept below the temperature limitation specified.
- any electrical sparking parts, or parts having a temperature above the temperature limit specified.
- are contained in an enclosure which adequately prevents the ingress of dust, or
- the energy of electrical circuits is limited so as to avoid arcs, sparks or temperatures capable of igniting combustible dust;
- any other ignition sources are avoided.

2. Normal degree of protection provided by the enclosures of the equipment

When choosing, designing and installing electrical equipment intended for use in explosive atmospheres, besides the protective measures required (choice of anti-explosion protection, temperature class and explosion group of liquids, explosives, mists and / or dust suspensions in air or in the form of a layer), electrical installations must be protected by enclosures to ensure:

- Protect people from access to dangerous parts inside the carcass (parts moving or under voltage);
- Protection of equipment inside the enclosure against the penetration of foreign solids;
- Protection of equipment inside the enclosure against harmful effects due to water penetration.

The significance of each characteristic figure is given in Tables 1, 2 and 3 (SR EN 60529:1995 + SR EN 60529:1995/A1:2003).

Table 1. The significance of first characteristic figure

	NAME	EXPLANATIONS
FIRST CHARACTERISTICS	0 Unprotected	<ul style="list-style-type: none"> • Touching the parts moving or under voltage inside the enclosure is not obstructed; • The penetration of foreign solids is not hindered
	1 Protected against penetration of foreign solids larger than 50 mm	<ul style="list-style-type: none"> • Accidental or intentional touching of internal parts under voltage or in motion, with a large surface of the human body, for example the hand, is not possible. 	2 Protected against penetration of foreign solids 12 mm or larger	<ul style="list-style-type: none"> • Touching or wishing with finger or analog objects whose length does not exceed 80 mm, internal parts under voltage or moving is prevented; • Penetration of foreign solid bodies with a diameter of 12 mm or more is prevented
	3 Protected against penetration of foreign solid bodies of 2.5 mm or larger	<ul style="list-style-type: none"> • Touching with tools, wires, etc. with a diameter or thickness of more than 2.5 mm, of the internal parts under voltage or in motion is prevented; • Penetration of foreign solid bodies with a diameter equal to or greater than 2.5 mm is prevented
	4 Protected against penetration of solid bodies foreign than 1 mm or larger	<ul style="list-style-type: none"> • Tapping with wires or bands over 1 mm thick, internal parts under voltage or moving is prevented; • Penetration of foreign solid bodies with a diameter equal to or greater than 1 mm is prevented
	5 Protected partially against dust penetration	<ul style="list-style-type: none"> • Touching in any way the internal parts under voltage or in motion is prevented; • The penetration of the dust is not completely obstructed, it can penetrate only to the extent that it does not impede the proper functioning of the electrotechnical product
	6 Protected completely against dust penetration	<ul style="list-style-type: none"> • Touching in any way the internal parts under voltage or in motion is prevented; • Dust penetration is completely obstructed

Table 2. The significance of second characteristic figure

	NAME	EXPLANATIONS	
THE SECOND CHARACTERISTIC	0	Unprotected	<ul style="list-style-type: none"> Water penetration is not obstructed
	1	Protected against vertical drops of water	<ul style="list-style-type: none"> Water droplets falling vertically should have no harmful effects
	2	Protected against drops of water falling below an angle of max. 15 ° to the vertical	<ul style="list-style-type: none"> Drops of water falling below an angle of max. 15 ° to the vertical should not have harmful effects, ie drops of rain falling vertically do not damage the product inclined at an angle of max. 15 ° to the vertical
	3	Protected against water falling as rain	<ul style="list-style-type: none"> Water falling as rain, at an angle of max. 60 ° to the vertical must not have harmful effects
	4	Protected against splashing with water	<ul style="list-style-type: none"> Water sent from all directions on the housing must be free of harmful effects
	5	Protected against water jets	<ul style="list-style-type: none"> Water sent with a hose in all directions on the housing must be free of harmful effects
	6	Protected against shipboard conditions	<ul style="list-style-type: none"> Water from strong waves or jets must not penetrate the carcass in harmful quantities
	7	Protected against the effects of immersion in water	<ul style="list-style-type: none"> The penetration of harmful water into the enclosure completely immersed in water at a given pressure and time must not be possible (checked according to Table 4, figure 7)
	8	Protected against prolonged immersion in water	<ul style="list-style-type: none"> The product resists prolonged immersion in water under conditions specified by the manufacturer
	9	Protected against high pressure and high water jets	<ul style="list-style-type: none"> High pressure and high-temperature water from any direction on the housing must be free of harmful effects

Enclosures of electrical or non-electrical equipment, whether used in normal environments or potentially explosive atmospheres, must provide a certain degree of IP protection.

In accordance with general standards that set out the basic methods and requirements for the design, construction, testing and marking of electrical and non-electrical equipment for use in potentially explosive atmospheres with gas, vapor, fog and combustible dust: SR EN 60079-0 and SR EN ISO 80079-36 it is necessary for the equipment to be provided with a housing with a specific IP protection degree for a certain type of protection. The specific test procedures are in accordance with the requirements of SR EN 60529-1995 / A1-2003 and SR EN 60529-1995 / A2-2015, and for rotary electric machines according to SR EN 60034-5.

If a characteristic number is not required, it should be replaced by the letter "X" (or "XX" if both digits are omitted), eg: IP6X; IPX7; IPX6 / IPX8).

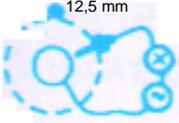

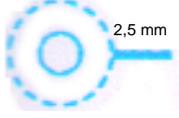

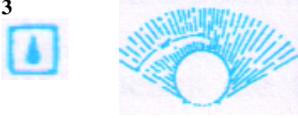

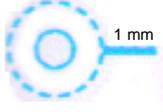

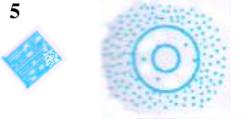

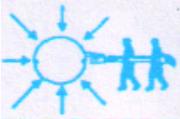

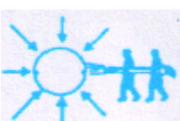

In practice, the following degrees of protection can be achieved, shown in Table 3.

Table 3. Degrees of protection

CODE	The first characteristic figure (solid bodies)	The second characteristic figure (water)										
		0	1	2	3	4	5	6	7	8	9	
IP	0	IP00	-	-	-	-	-	-	-	-	-	-
	1	IP10	IP11	IP12	-	-	-	-	-	-	-	-
	2	IP20	IP21	IP22	IP23	-	-	-	-	-	-	-
	3	IP30	IP31	IP32	IP33	IP34	-	-	-	-	-	-
	4	IP40	IP41	IP42	IP43	IP44	-	-	-	-	-	-
	5	IP50	-	-	-	-	IP54	IP55	-	-	-	-
	6	IP60	-	-	-	-	-	IP65	IP66	IP67	IP68	IP69

The synthesis of the tests for determining the IP code digits is shown in Table 4 (SR EN 60529:1995/A2:2015 + SR EN 60529:1995/AC:2017).

Table 4 - The synthesis of the tests for determining the IP code digits

IP	Test	Description	IP	Test	Description
0		Unprotected	0		unprotected
1	50 mm 	protected against foreign solids with a diameter of 50 mm and above (protected from hand-held access to dangerous parts)	1		protected against drops of water falling vertically
2	12.5 mm 	protected against foreign solids with a diameter of 12 mm or more (protected against finger contact at dangerous parts)	2		protected against vertical droplets of water that can be rotated at 15 °
3	2.5 mm 	protected against solid foreign bodies with a diameter of 2.5 mm and higher (fine tools, wires)	3		protected against spraying water at an angle of up to 60 ° to the vertical
4	1 mm 	protected against solid foreign bodies with a diameter of 1 mm and higher (fine tools, wires)	4		protected against sprayed water on all sides
5		protected against dust (against hazardous deposits)	5		protected against jets of water from all sides
6		Dust-tight	6		heavy water jet, equivalent to sea waves during storm
			7		protected against immersion in water
			8		protected during permanent immersion in water (1000 mm)
			9		protected against strong water jets (high pressure and high temperature)

3. Improvement methods and technical tests for technical equipment

In the framework of the PN - ELTOX project, in the ENExEMEIP Laboratory, the principle diagrams were developed and the tender dossiers for the purchase of two test stands were elaborated:

- A dust chamber designed for large-scale equipment to determine partial or total dust protection (IP 5X and IP 6X);
- An automated stand for water spray testing (IP X3 and IP X4).

According to the basic principles presented in Fig. 1 in which the dust circulation pump can be replaced by other means to keep the suspension of talcum powder in a closed test chamber. The talc powder used must be able to pass through a square mesh fabric at which the nominal yarn diameter is 50 µm and the free space between threads of 75 µm. The talc powder used is 2 kg per cubic meter of the test chamber. The talc should not be used in more than 20 attempts.

Depending on the category established by the manufacturer, the dust-proofing test inside the equipment is carried out using the vacuum pump (for category 1 carcasses) and without the vacuum pump (for category 2 carcasses).

According to SR EN 60529-1995 / A1-2003, the electrical equipment casings are divided into two categories:

- Category 1: enclosures where the normal operating cycle of the equipment causes reductions in internal pressure relative to ambient air due, for example, to the effects of thermal cycles.
- Category 2: housings in which there is no pressure difference with respect to ambient air.

In general, machinery intended for use in potentially explosive atmospheres of fuel-dust atmospheres must have a standard IP 5X or IP 6X protection rating and enclosures when testing for the first characteristic figure: -5- protection partial dustproofing, ie total protection against dust penetration, are considered to be of category 1, which in the normal operating cycle are heated and therefore the test is carried out in the dust chamber using the vacuum pump.

The pump connection must be made through a hole specially designed for this test. Without a different specification from the specific product standard, this hole must be in the vicinity of vulnerable parts. If there are other holes (eg other head inlets or outlet holes), they should be treated as normal.

The purpose of the test is to pass through the housing, with a depression, a volume of air equal to 80 times the volume of the test case without exceeding a 60-hour extraction rate of the carcass volume. Under no circumstances should the depression be greater than 2 kPa (20 mbar) in the manometer shown in Figure 2. If the extraction rate is 40 to 60 volumes per hour, the test takes 2 hours.

For testing the characteristic digit IP 5X or IP 6X for large-dimension equipment, use the dust chamber shown in Fig. 1.

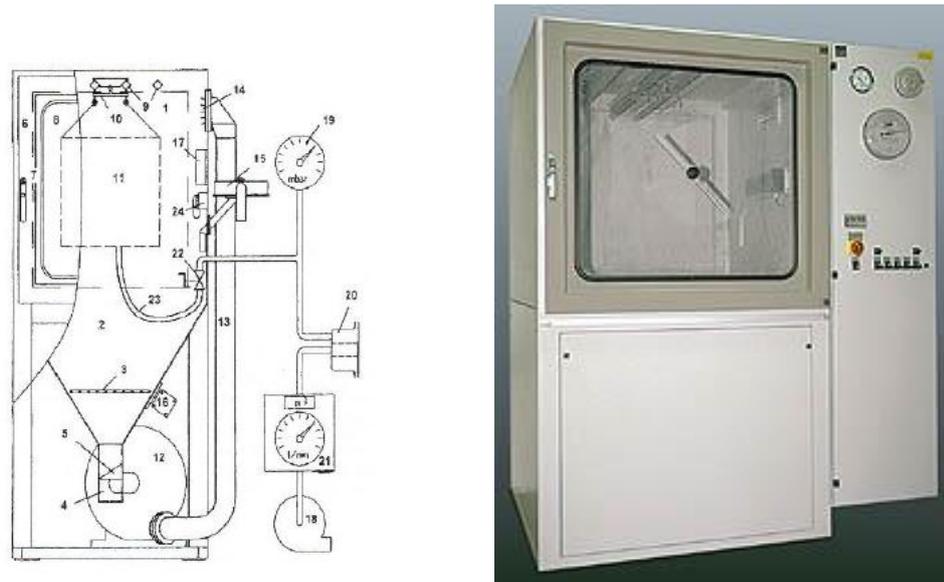

Fig. 1. Dust test Chamber – principal scheme

Enclosures with the degree of protection IP 5X “Dust protected” do not have to prevent ingrees of dust totally. However, dust should not penetrate in an amount sufficient to interfere with the satisfactory operation of the equipment enclosed or to impair safety. In the case of enclosures with degree of protection IP6X “Dust tight” it is necessary to prove that no dust can penetrate into the inside of the enclosure. The test are carried out by means of a dust chamber with a sealed test cabinet, in which talcum powder is kept in suspension by means of an air stream. The talcum powder must be prepared in such a manner that it will pass through a sieve with a mesh size of 0,075 mm. The quantity of talcum given in the regulation is 2 kg per cubic of test cabinet volume.

Attempts to protect against water penetration, indicated by the second characteristic figure, are performed with fresh water. During the tests for IP X1 to IP X6, the water temperature must not differ by more than 5 K from that of the product under test. In the case of tests for determining the IP X9, the equipment protected against strong water jets is subjected to high pressure and high temperature (upon agreement between the beneficiary and the manufacturer).

During the test, moisture inside the housing may partially condense. The condensing water that is deposited should not be considered as the penetration of the outside water.

To test the characteristic figure IP X3 or IP X4 in the case of small size equipment, an automated oscillating tube stand is used, as shown in Fig. 2.

The stand has been designed to provide: an adjustable height of 500 to 1250 mm, the possibility of installing an oscillating spring with a radius between 200 ... 1800 mm; the adjustable speed of the oscillating spring (adjustable); possibility of limiting oscillation angle (oscillations of almost 3600, 1800 on both sides of the vertical); adjustable test duration between 1 and 60 min; adjustable pressure, flow adjustment 30 ... 300 l / h; rotary sample placement with automatic oscillating motion and oscillating speed adjustment.

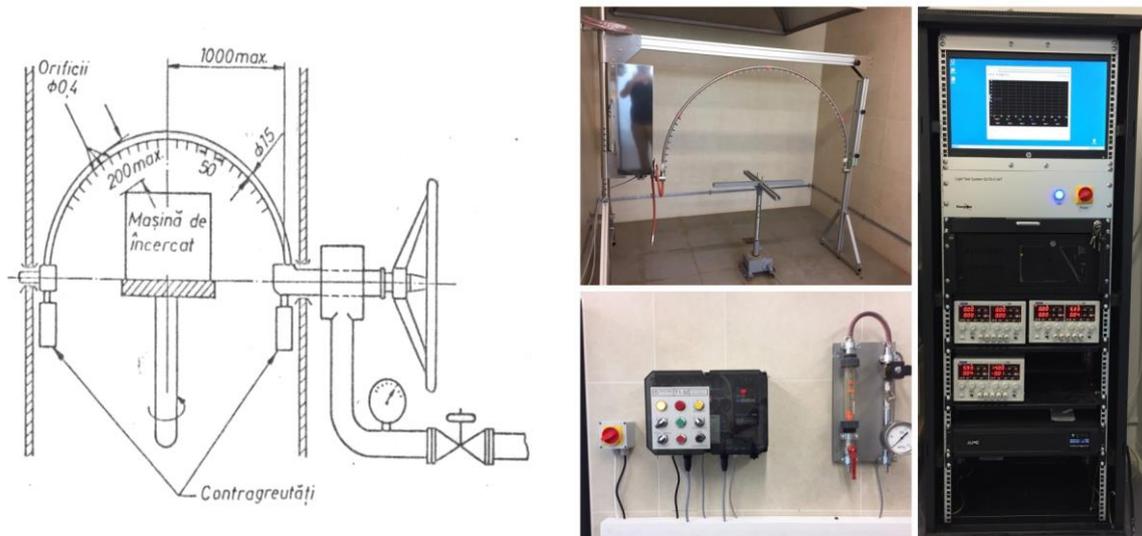

Fig. 2. Apparatus for checking the protection against falling rainwater and water projections; The second characteristic number 3 and 4 (oscillating tube)

5. Conclusions

Dust and water penetration tests inside electrical and non-electrical equipment, ie the determination of the first characteristic number IP 5X and IP 6X, or the determination of the second characteristic digit IP X3 and IP X4 of the normal protection degree with the stands. The above test is particularly important for assessing the compliance of the equipment with the requirements of the harmonized European standards and the explosion protection requirements of the ATEX Directive, taken over in the Romanian legislation by GD 245/2016.

In order to perform these tests, the ENExEMEIP laboratory at INCD-INSEMEX Petroșani designed the technological schemes and elaborated the specifications for the purchase of a large-scale powder testing chamber and an automated water test stand in the form of rain. The stands meet the requirements of SR EN 17025, these tests may be included in the accredited testing field within the GLI laboratory.

By providing these stands, the test conditions are met to meet the demand of various manufacturers / manufacturers, importers, distributors or users for verification / certification of electrical and non-electrical equipment intended for use in potentially explosive atmospheres.

Abstract

Worldwide, there is an increasingly acute crisis of raw materials coming from conventional resources. A way to confute this crisis is the exploitation of waste from different industries, their processing becoming competitive in the conditions of increasing costs of extracting some useful minerals.

This paper aims to establish the chemical composition (macro elements) of raw coal ashes from the Jiu Valley from several mining units and to establish the chemical composition of special products from the Jiu Valley Preparation Plant in order to make an optimal decision in case of possible capitalization.

From research carried out so far on raw coal ashes and special products in Jiu Valley, it has been found that there is a concentration above the average of European Union countries of metal oxides present in the coal ashes. Large amounts of ashes, exploitation efficiency and waste recycling tendency considerably reduce the technical and economic difficulties of extraction from non-bauxitic raw materials. Thus, the existence and composition of these macro elements was studied using the process of dissolving alumina in HNO₃ in a quantity less than the stoichiometric value, when Al(NO₃)₃ • 9H₂O is formed, because the iron remains insoluble in the solution afterwards being extracted from moist and dried concentrates in soft or strong fields.

Keywords: ash; coal; environment, macroelements;

1. Introduction

In the last three decades, the dynamics of global coal production has regressed under the influence and competition of other sources of primary energy, respectively oil and natural gas. Very economic advantageous exploitation conditions of hydrocarbon reservoirs, and in particular those in economically weak countries, has weighted the world balance of primary energy carriers against coal.

Typically, raw coal (as extracted from deposit) does not fully correspond to quality of various uses or technological processes. In order to bring it into the state demanded by consumers and to be used in the most economical way, coal is subjected to physical and physical-chemical processing operations, called preparation operations.

Coal preparation comprises a complex of mechanical operations (grading, grinding, concentrating, draining, etc.) to which raw coal is subjected in order to improve its quality and to adapt it to different processes where it is to be used or recovered. As a result of coal preparation process, a special product is produced in which the structure and chemical composition of coal is not changed.

Ash represents the inorganic mass of coal formed by oxidation at 850°C. A series of elements known as minor elements or trace elements, in quantities between 1 ppm and 1% (Au, Ag, Pt, Co, Ga, In, Mo, Ni, Sn, V, Cu, Pb, Zn, Cd, etc.) and elements known as major elements or macroelements in quantities of more than 1% by weight of ash (SiO₂, Al₂O₃, Fe₂O₃, CaO, MgO, SO₃, Na₂O, K₂O) are present in coal ash (Simion, 2014).

Coal ashes from thermoelectric plants, because of their content in various metallic oxides, are considered as new sources of raw materials. From research carried out on ash recovery, the question was put to use ashes from energetic complexes (CTE) by first extracting metal oxides (Fe₂O₃, Al₂O₃) usable in metallurgical industry followed by the use of by-products resulted for obtaining products (Ghiță et al., 1973), (Simion, 2014).

2. Content of macroelements in coal ashes

Chemical composition of ashes is particularly complex, the content and oxidic nature varying widely, depending on the genesis of coal (Petrescu et al., 1987). From mineralogical observations performed on coal-based minerals, specialists noted that they are made up of 95% loamy minerals and the rest of 5% of associated minerals are: pyrite, marcasite, dolomite, siderite, calcite, sodium and potassium halides, quartz, feldspar, magnetite, topaz, tourmaline, hematite, etc. (Petrescu et al., 1987).

In some countries, such as Poland and France, there are industrial installations for extracting metallic oxides from coal ash. In Romania, because there are no such installations, there is a need to compare ash composition in some European countries (Table 1) with ash composition in our country to check tailings quality.

Table 1. Coal ash composition in some European countries and U.S.A.

The diagram of the macroelements distribution in these ashes is shown in Fig. 1.

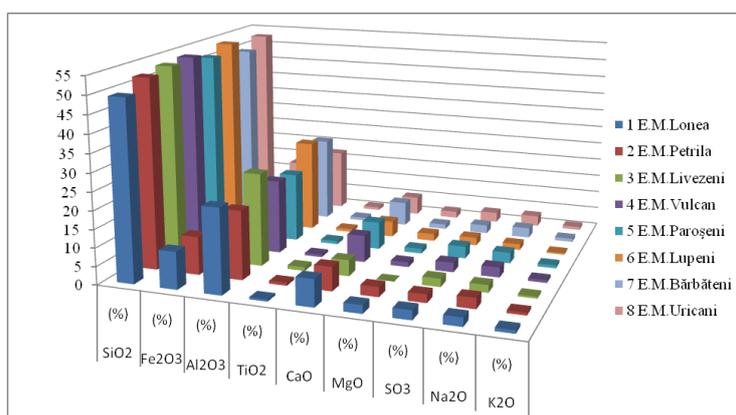

Fig. 1. Diagram of the macroelements distribution

The analysis of macroelements content in Jiu Valley coal ashes, shows that the SiO_2 content is high, classifying the coal ash into a high abrasive class, complicating the extraction process and increasing the production cost of metals obtained, but the content of useful metals and other elements that can be extracted tilts the balance in favour of ashes exploitation, to capitalize the waste resulting from oxidation.

Depending on the chemical composition of ashes, the recovery manner and technology are chosen and the chemical composition of coals actuates its behaviour in the combustion process in the furnaces of steam boilers. Thus, a high content of alkanes acts as a fusing agent, leading to slagging of ashes (Ionescu and Moldovan, 2005). Ashes containing iron oxides are more fusible than those containing aluminium oxide and silicon dioxide. A high content of silicon dioxide may indicate the presence of a significant amount of free quartz in the tailings, which generates a high abrasiveness of ash (Ghiță et al., 1973).

Higher content of sulphur trioxide in the ash composition can lead to corrosion of the boiler, accompanied by pollution of the atmosphere with sulphur oxides, harmful to flora and fauna. Knowledge of the composition of inorganic mass of coals is particularly important, not only in the case of its use for energy, but also in the case of metallurgical coal, which must have an as low as possible ash content, as it runs into coke (Moldovan et al, 2003; Moldovan and Ionescu, 2006).

3. Content of macroelements in special products ashes

In order to establish the chemical composition of ashes, coal was extracted from 4 mining coal mines, coal subjected to the preparation process at Coroiești Coal Preparation Plant. The methods of analysis used are in line with current standards for determining the chemical composition of ash, applicable both in industrial processes and in laboratory (STAS 10274/4-90; STAS 10274/5-75; STAS 10274/5-7).

The ash used in our case is the result of burning special coals in laboratory. The chemical analyses were carried out on three parallel samples, resulting in a final arithmetic mean of results that matched the corresponding values for maximum admissible differences for each determination method (STAS 10274/4-90; STAS 10274/5-75; STAS 10274/6-88).

The chemical composition of the special coal ash resulted from Coroiești Preparation Plant is shown in Table 3.

Table 3. Chemical composition of the special coal ash resulted from Coroiești Preparation Plant

N ^o Preparation plant	Oxides (%)								
	SiO_2	Fe_2O_3	Al_2O_3	TiO_2	CaO	MgO	SO_3	Na_2O	K_2O
1 Petrita	39,89	15,60	25,81	1,33	6,72	1,00	5,93	2,01	0,72
2 Livezeni	39,06	13,51	27,56	1,57	3,50	2,02	4,19	6,52	0,61

4 Lupeni	35,67	13,61	29,25	0,92	6,60	2,18	4,66	5,46	0,85

The diagram of macroelements distribution in the special product ash from Jiu Valley Preparation Plants is shown in Figure 2.

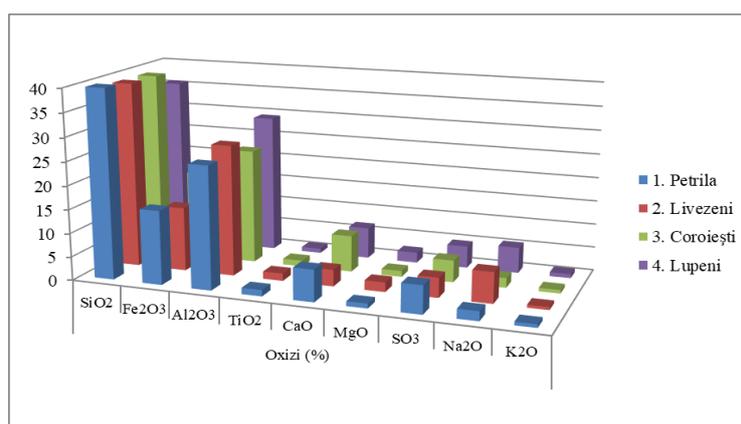

Fig. 2. Macroelements distribution in special product's ashes

Compared to the previous situation, for ash obtained by oxidation of special coals resulting from the preparation process, the metal oxide content has improved, for alumina by up to 52% and for iron oxides by up to 62%.

The distribution of macroelements in the special product ash from Coroiesti Preparation Plant (fig. 2) shows that the useful elements replace the silicon dioxide content, which reduces cost of maintenance for combustion boilers and capitalizes the recovery cost of metallic oxides from coal ashes.

Coal preparation doesn't have only positive effects, as sulphur trioxide (SO₃) content of the coal mass doubles, leading to a much higher level of sulphur oxides emitted into the atmosphere, requiring a gas desulphurisation plant or a modernization of the existing one.

Sulphur trioxide also creates problems in ash dumps or tailings ponds because it reacts very easily with meteoric water forming acidic hydrogen ions and mineral acidity on its path that even in case of pollution, natural receptors become unusable for domestic consumption, riverbeds are covered with precipitate that contaminates the water source and inhibits or eliminates a variety of aquatic organisms, causing severe imbalances in the food chain (Lazar and Dumitrescu, 2006). By extracting these elements from ashes, these impacts can be minimized and we will have an excess of raw material, a much less polluted area with natural landscapes, with no opportunistic species capable of inhibiting the ecosystem restoration capacity (Lazar and Dumitrescu, 2006).

After the extracting these metals, coal ash could be used as: filling material in various road works, raw material in cement production, raw material in clinker blocks production, improvement products in agriculture, anti-skid, fire and frost high resistance material etc.

Onward, we suggest a few technologies for the extraction of iron oxides and alumina from coal ashes.

4. Extraction of iron oxides and alumina from coal ashes

The natural reserves of non-aluminous materials of alumina-silicate type (kaolin, clays, etc.), as well as ashes from C.T.E. regardless of the type of coal, suitable for alumina production, can be considered as inexhaustible. This view is all the more rational as global coal-based energy will record an average growth rate of 2.3% per year by 2020, less than the projected 2.6% increase, but also a real increase of 3.4% per year between 2007 and 2012, according to International Energy Agency (IEA) estimates (International Energy Agency, 2018). Experts approximate that Romania has coal, especially coal and lignite, for another 250 years (International Energy Agency, 2018).

Literature in the filed (Matjie et al., 2005), recommends the use of two different technologies for the production of alumina from non-aluminous raw materials, depending on the removal of iron from nitrate solutions, namely:

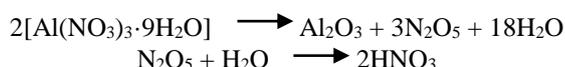

- dissolving in HNO₃ below the stoichiometric value, when Al(NO₃)₃ · 9H₂O is formed in contact with which the iron remains insoluble (Matjie et al., 2005);
- dissolving in HNO₃ over the stoichiometric value, when Al(NO₃)₃ · 9H₂O is formed and the iron passes into a solution where it is subsequently removed (Matjie et al., 2005);

In order to obtain Al₂O₃ from the Jiu Valley coal ash by treatment with HNO₃, dissolution in HNO₃ below the stoichiometric value was used, Al(NO₃)₃ · 9H₂O was formed, which in contact with the iron remained insoluble (fig.3) (Matjie et al., 2005) and for laboratory alumina production ash from Paroşeni thermal plant was used.

Optimal conditions for the leaching phase, reflected by an efficient output of alumina extraction and iron separation are:

- HNO₃ concentration = 40%;
- HNO₃/Al₂O₃ ratio = 0,9;
- Leaching temperature: 220°C
- Leaching time: 2 hours

After filtration of the pulp to separate soluble aluminates from insoluble iron compounds Fe_2O_3 , $\text{Fe}(\text{OH})_3$, the resulting solution was evaporated and crystallized. After leaching and sedimentation, water was liberated at 120°C , while increasing the concentration of Al_2O_3 in solution. It was then treated with a 5% HNO_3 solution at 100°C and exposed to crystallization. The aluminium oxide was crystallized as $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ and the next step consisted of breakdown of this compound into Al_2O_3 and HNO_3 according to the reactions:

In order to make the process more profitable, the issue of nitrate solution deferrization has been raised. The Fe_2O_3 content of the solution after leaching was 0.3g/l (0.4% Fe_2O_3) and 0.3% $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$. The solution obtained from the leaching process was improved by red-sludge treatment from the extraction of alumina from bauxite, resulting in an enriched preconcentrate.

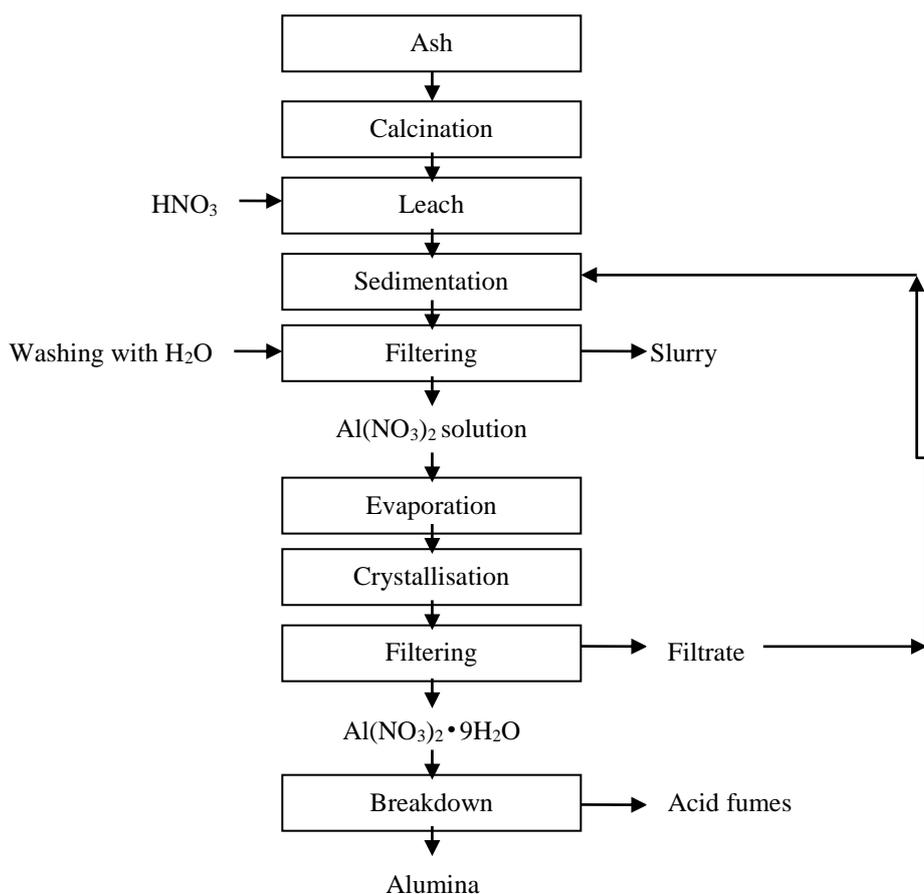

Fig. 3. Flow diagram of alumina production process by treatment with HNO_3 (Matjie et al., 2005)

Concentrations of metallic oxides present in the preconcentrate do not fall within the limit of industrial phase exploitation, and in order to move to the industrial phase two more problems needed to be solved:

- deferrization of aluminium oxide to the limit required by the norms for obtaining aluminium for electrolysis;
- increasing the recovery rate of nitrogen oxides, respectively nitric acid.

Obtaining iron oxide concentrates represents a major concern at the present stage for the complex and integral use of ashes from C.T.E. In order to obtain iron oxide concentrates from the ashes, especially methods based on the principle of magnetic separation were examined (Friedeberg, 1995). The chemical composition of ashes has shown the presence of magnetised oxides (magnetite, hematite) and compounds of manganese, calcium, magnesium, which improve the quality of iron concentrates (Friedeberg, 1995). For iron and steel metallurgy, the absence of copper, silver, arsenic, sulphur, etc. from the ashes represents an advantage because these elements belong to non-ferrous metallurgy and make it difficult to extract iron oxides (Lazar and Dumitrescu, 2006).

The separation of iron oxides from ashes has a double importance and necessity:

- attaining a new source of ferrous metal concentrates usable in steel industry;
- deferrization of ashes from C.T.E. for their use in alumina production.

Magnetite type Iron minerals are of interest for the purposes pursued. Magnetite and hematite have been identified in both the free grains as well as punctiform impregnated in the quartz and silicate masses. The most commonly used methods for obtaining concentrates refer to wet separation in weak magnetic fields and dry separation in strong magnetic fields. Concentration through flotation has an increased output for iron ores or ashes of weak magnetic components (Friedeberg, 1995; Negoiu, 1970).

The technology, consisting of weak field magnetic preconcentration, followed by grinding the preconcentrate to a fineness of less than 0.2 mm followed by a new weak field magnetic separation was verified on a pilot scale.

The preconcentrate obtained by applying a magnetic field of 11900 A / m intensity has the composition of shown in Table 4.

Table 4 Composition of preconcentrate obtained by applying a magnetic field of 11900 A / m intensity

Fe (%)	SiO ₂ (%)	Al ₂ O ₃ (%)	CaO (%)	Mn (%)
35	25.2	10.7	2.0	0.31

5. Conclusions

Centralized data shows significant variations in the chemical composition of ash according its origin. As with coal ashes in other countries, there is a higher content of SiO₂, Al₂O₃ and Fe₂O₃ and lower in other elements (TiO₂, CaO, MgO, SO₃, Na₂O, K₂O). Ashes also have a high SO₃ content, which indicates that a reduction in the sulphur content of their composition is required. With the extraction of iron and aluminium oxides, a magnetic field preconcentration has been obtained which reveals that the reuse of a large amount of ash can alleviate or solve environmental problems. Moreover, besides solving environmental problems, the use of ash is a way to save natural resources and energy.

Abstract

Through smokestacks, combustion plants discharge flue gases into the atmosphere, gases containing significant amounts of polluting substances such as: gaseous noxae (sulphur oxides - SO_x, nitric oxides - NO_x, carbon monoxide and dioxide - CO and CO₂); as well as flue dust (suspended particulate matter - aerosols, precipitate dusts), unburned and soot. At present, methods used to measure ambient air concentrations are continuous methods that are fully automatic (monitoring stations) and discontinuous instrumental methods, using numerical display devices equipped with sampling probes.

There are situations in which the smokestack does not have inspection holes for taking samples or there is no platform located at the appropriate height (recommended by normative acts) or certain situations where the smokestack height is 30-50 m making it impossible to sample burned gases.

Lately, drones have become more and more intelligent, and given the current complexity and performance of hardware and software, we could say that this development will take place swiftly. The current paper explores the possibility of using drones equipped with gas sensors to measure industrial gas emissions from large combustion plants. In this case, account shall be taken of air currents generated by drones and temperature of discharged exhaust gases.

This method has a character of novelty because drones are not currently used in industry.

The results of the research will conclude if drones equipped with sensors will or will not be widely used in this field, given their advantages and disadvantages. Furthermore, this paper will be a starting point for future research regarding gas emissions measurements both by using drones and the standardized measurement method (sampling inside smokestacks). Also, the use of aerospace vehicles (drones) will be a real help for improving services, quick reaction in case of damages, for the safety and security of workers.

Keywords: emissions; combustion gases; drone..

1. Generalities

A drone is an UAV aircraft (Unmanned Aerial Vehicle), able to fly without being piloted by a person, which was originally used only for military purposes for the recognition of targets and bombing of strategic targets.

What differentiate drones from other unmanned aerial vehicles (UAVs) is, firstly, their much-reduced size and weight, then the fact that power supply is provided by a battery or other power source.

Except for military drones, areas of use for civilian drones (figure 1) are multiple, applications being even scientific. They have the following features and benefits:

- Positioning and movement are usually based on GPS system;
- Feature a powerful onboard computer and sensors, or other devices such as high-resolution and infrared video or photo cameras, range finders, radars, etc;
- Data transmission or communication with the checkpoint is done either by radio or via the internet and devices including PCs, tablets and smart phones can be used as control devices;
- Are able to independently come back to where they left;

* Kovacs Marius. Tel.: +400254541621; fax:400254546277.
E-mail address: marius.kovacs@insemex.ro.

- Because power is supplied from a battery, they have a reduced period of operation - the drones autonomy expanding from tens of minutes to several hours;
- Are silent when in use and at high altitudes/ distances they become difficult to see with the naked eye;
- Are able to maintain stable at a fixed altitude or within a certain position;
- Are resistant to shocks and exposure to water or high temperatures.

Components of multirotor drones

The construction of the drone begins with the skeleton or the drone frame. It is made of lightweight materials resistant to static and dynamic stresses such as duralumin or carbon fibre, and can also be made of expanded polypropylene or nylon fiber reinforced high-density plastic (Figure 1). Both trussed beams and tube-type elements are used depending on the size of drones and number of motors. The frame is made by joining the motor port arms with a central connecting piece in a rigid structure. In addition to supporting the engines and the landing gear, the frame must provide the possibility of fastening electronic flight control modules and camera or auxiliary devices. The landing gear is attached to the frame structure by means of shock absorbers and can be rigid or retractable.

Fig. 1. Multirotor drone

Each arm supports an electric motor that will operate a propeller. Brushless motors are used due to increased efficiency by reducing friction compared to brush and collector motors as well as due to very low power losses. For choosing the engines, the total weight of the drones and their accessories must be known.

Multirotor drones use propellers that rotate in opposing directions. The important parameters of the propellers are the length and the pitch. Larger length and higher pitch improve the ascent force.

Of all existing battery types, the lithium-polymer batteries are best suited for charging drones because of their physicochemical properties. They present a number of advantages over both Lithium (Li-ion, Li-Fe) and Nickel-based (NiMh, NiCd) batteries.

2. Aerodynamics of drones and the air currents they form

Through their operation, drone’s propellers move large amounts of air forming whirls. These air currents generated by drone rotors influence any gas sensor placed in their immediate vicinity (Patrick et al 2012).

Aerodynamic forces are modeled to consider the variation of push coefficients with different flight conditions, in order to calculate the aerodynamic effect of traction and traction upon propulsion rotation. This aerodynamic analysis is very useful to predict the dynamic behavior of the system in the presence of wind fields and gives us indications of the type of propeller and characteristics of the engine to be installed on the drones.

Figure 2 shows the classical configuration of a quadrotor. The four rotors are labeled from 1 to 4 and are fitted at the end of each transverse arm. A pair of rotors spins clockwise while the other pair rotates counterclockwise: this way it is possible to avoid the return deviation due to reactive torques and lateral movement without changing the pitch of the blade propeller. Fixed point simplifies rotor mechanics and reduces gyroscopic effects.

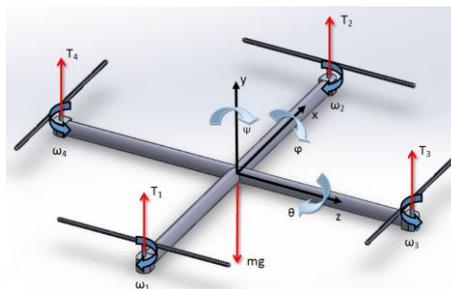

Fig. 2. Quadrotor force and axle system T1 ÷ T4 - Traction force due to rotation, ω1 ÷ ω4 - angular velocity vectors, x, y, z - drone displacement axes

According to figure no. 3 a and b, a series of whirls are formed around the drones which are difficult to evaluate.

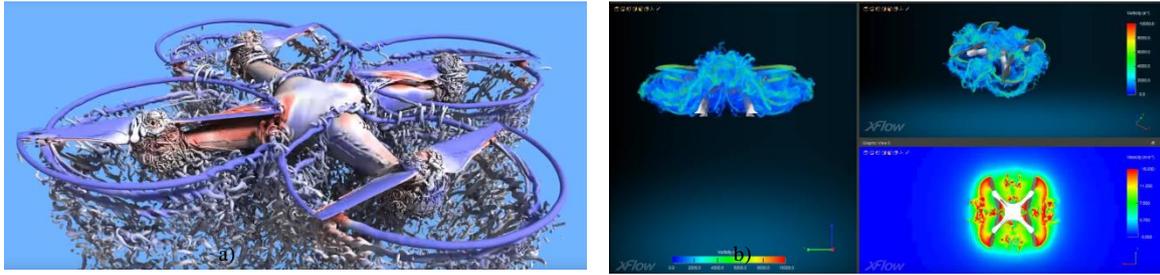

Fig. 3. Exploring drone aerodynamics with computers. a) 3D view, b) analysis using the X Flow program

The simplest theory to estimate the performance of a propeller is the impulse theory. This model uses an ideal fluid, respectively the air is incompressible, not viscous and irrotational, while the propeller is modeled as a disk with the same area described by the propeller rotation. This disc produces an evenly distributed pressure jump when flowing through it (Andres M P G, 2017). Figure 4 shows the model sketch.

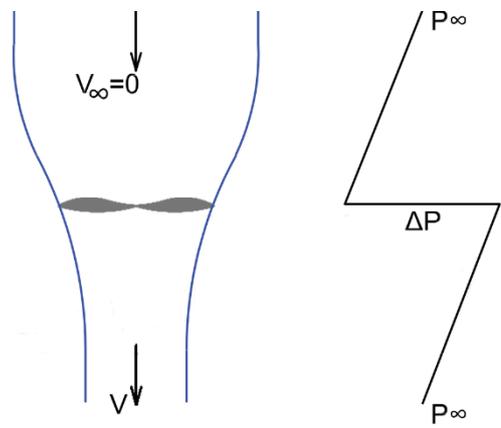

Fig. 4. Simplifying the disk for impulse theory

Applying the Bernoulli equation to fluid before the disk,

$$p_{\infty} = \frac{1}{2} \rho v_i^2 + p_i \tag{1}$$

where ρ is air density, v_i is the disk-induced velocity at the fluid, p_i is the pressure just before the disc, and p_{∞} is the pressure of the uninterrupted liquid. Applying Bernoulli after the disc,

$$\frac{1}{2} \rho v_i^2 + p_i + \Delta p = p_{\infty} + \frac{1}{2} \rho v_{\infty}^2 \tag{2}$$

where v_i is infinite downstream speed, see Fig. 4. from equation 2 and 3.

$$\Delta p = \frac{1}{2} \rho v_{\infty}^2 \tag{3}$$

$$T = \Delta p \cdot A \tag{4}$$

where T is the push, Δp is the increase of the pressure caused by the propeller and A is the disk area according to equation 5:

$$T = \frac{1}{2} \rho A v_{\infty}^2 \tag{5}$$

International research highlighted the whirls created by a propeller spinning at 4500 rpm and the structure of currents indicates that the strongest vortex is created at the tip of the blade, as well as the fact that the peak vortex and the inner vortex descend below the rotor following a helical trajectory (fig. 5.).

Controlling a quadcopter is based on power and torque of the propulsion system; therefore, an adequate estimation of aerodynamic parameters is very important for controlling aerodynamic vehicle parameters.

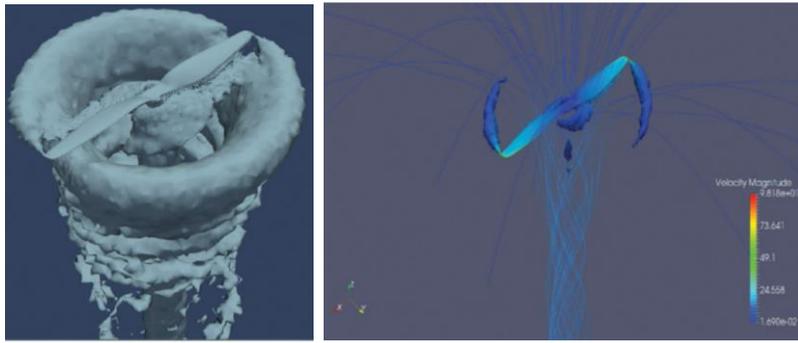

Fig. 5. Swirls created by a single propeller

Computerized simulation of air streams created by 4 rotors indicates the following results (Seokkwan Y, et al, 2016): while the top and bottom left rotors are rotating counter clockwise, the top left and bottom right rotors rotate clockwise. This direction of rotation is typical for quadcopters. Take note of the step-up intake of whirls above the rotors.

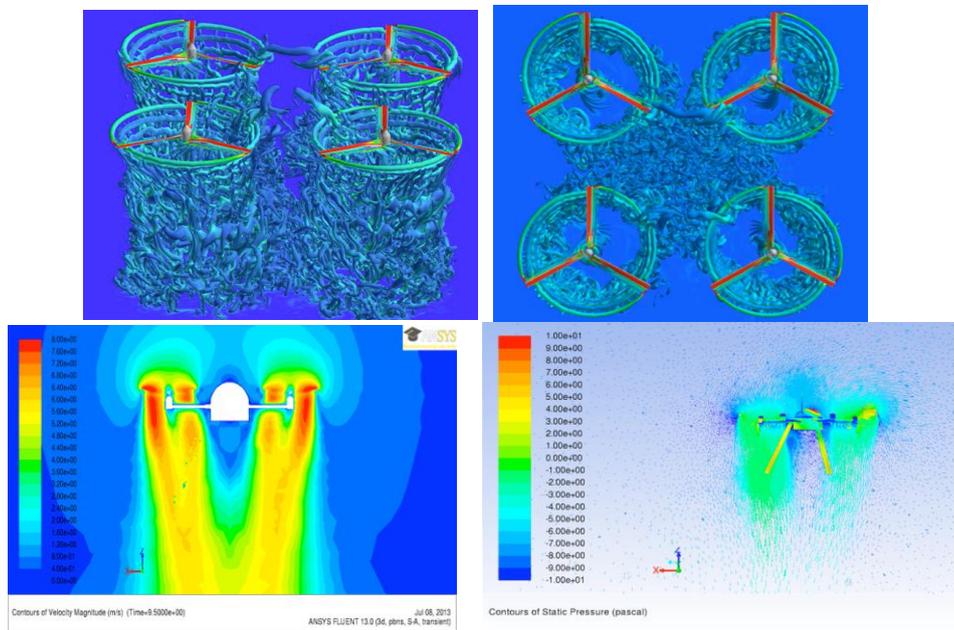

Fig. 6. Simulation of whirls created by drones. a) lateral view b) top view c) simulation performed in ANSYS regarding velocities generated by propellers d) simulation of pressure generated by drones

This phenomenon was not observed in isolated rotors. A top view in fig. 6 b), c) show significant interactions of the turbulent flow between rotors. Streams up between the rotors can be dragged to the centre. (Patrick et al 2014).

A computational study of the interactive aerodynamics of multi-rotor flows revealed that the separation distance rotor has a significant effect on the vertical force of a hover quadrotor. As the separation distance between the rotors becomes smaller, the efficiency of the quadrotor system decreases. While the fuselage creates little force, it seems to have a positive effect on the rotor efficiency by limiting the interaction between the rotor steps.

3. Possibilities of using civil drones to measure atmospheric air emissions

According to environmental law, any human activity that generates a significant environmental impact is subject to assessment of environmental impact procedures. In this sense, for acquiring the environmental permit, competent authority requires a specific environmental study to analyze the impact of project implementation.

Among the specific environmental protection studies, we mention: environmental report (RM), assessment report of environmental impact (RIM), the environmental review (BM), and security report (RS), location report (RA) and adequate assessment (EA).

Within the procedures for environmental impact assessment (RIM, BM and RM) environmental authority also requires measurements for air, water, soil, in order to know their level of pollution (initial state).

Air quality measurements at a polluting unit should focus on stationary / fixed sources of emissions that generate large quantities of hazardous gases to human health and the environment.

Choosing sampling points at a stationary source (chimney, canal, and pipeline) should be performed in a manner that distribution of pollutants (gas, dust) in source section is homogeneous and speed, temperature and pressure are as stable as possible.

In order not to influence the quality of measurements, the effluent flow (air gas) must have, as much as possible, a laminar flow, presence of deviations, fittings, fans being avoided as possible.

For measuring stationary sources, reference standard SR EN 15259/2009 "Air quality - Measurement of stationary source emissions. Requirements for measured sections and sites, measurement plan and report" as well as SR ISO 9096/2005 indicating the number of sampling points depending on the outlet section of the source and placement of these points must be observed.

For sampling exhaust gases from stationary source (chimneys) there must:

- exist a proper visiting (access) hole in the chimney, for the sampling probe;
- the measuring equipment must be power supplied;
- gas flow must be laminar and without turbulences.

There are situations when the chimney doesn't have a sampling orifice or doesn't have a work platform placed at the proper height (recommended by legislation).

There are also situations when the stack is 30-50 m high so that makes sampling flue gases impossible.

To perform gas measurements at large combustion plant chimneys, having high air flow rates and large sections, by using drones, some safely recommendations/conditions must be observed, namely:

- Drone usage must consider the reduced autonomy of equipment (max. 40 min. depending on drone load weight and battery);
- Knowledge of exhaust stacks height so that the vehicle is able to reach in time to mediate gas concentrations;
- Knowledge of exhaust gas speed and temperature, because drones can be used at temperatures up to 600C and a maximum wind speed of 40 km / h;
- Handling equipment should be made so as to avoid its damage or deterioration;
- Areas where there are high voltage wires should be avoided to eliminate risks of dropping the vehicle;
- Wind speed should not exceed 40 km / h to not influence stability of the drone, and to not cause significant turbulence during measurements.

Therefore, undertaking experimental measurements at high stationary sources without working platform or having inaccessible platforms would be useful, so that personnel conducting measurements is not exposed to risk of injury (Figure 7).

Fig. 7. Flying the drones in the area of a flare

Using a drone for emission measurements presents a number of dangers and disadvantages as well:

- The presence of toxic gases, hot, flammable dust and noise;
- Equipment short-circuit or static electricity;
- Flow rate of gas in the chimney should not be too high to not affect the stability of the drone, and to not cause significant turbulence during measurements, etc.

Other possibilities for emissions and immissions measurements with the use of a drone equipped with appropriate equipment can be:

- measurements of fugitive emissions through leaks (doors, windows) around industrial houses;
- measurements of immissions in certain locations within the perimeter of industrial units and at the border of their premises;
- methane detection in landfills;
- odour emission detection;
- leakage detection along gas pipeline lines for technical expertise
- measurements obtained can be used to plot dispersion maps with the AUSTAL software, and so on;
- leakage detection along oil pipeline lines;
- methane from waste disposal;
- odour emission, etc.

4. Conclusions

Performant drones can be equipped with sensors for measuring concentrations of gases from stationary sources or environment, with camera and GPS to overfly polluted areas or to monitor qualitative air parameters in protected areas, but it is necessary to consider the whirls formed by their propellers.

If drones will be used to measure concentrations of toxic combustion gases in the emission chimneys of large combustion plants, they eliminate the danger for personnel who has to monitor such chimneys (inaccessible platforms, high heights).

In view of the institute's experience in the field of environmental studies, it would be advisable, to carry out experiments on the use of drones for emission and immissions assessments in ambient air, within a research project.

The following steps must be taken in order to use drones for measurements of emissions and immissions of gases at stationary sources:

- obtaining the license to carry out drone flight exercises,
- flight experiments to be carried out in an equipped training facility in which sources of gas emissions are created,
- within the experiments to gradually perform exercises at different heights with different objects of different shapes, sizes and weights to test the drone's transporting potential,
- based on these experiments, a device for gas measurement, having a suitable weight and sensitivity shall be found and purchased,
- appropriate measures must be taken to protect the measuring device against whirls formed by drones, gas emissions from funnels and wind speeds,
- gradually carry out flight exercises with the drones equipped with measuring devices close to small, medium and large stationary sources.

Also based on research conducted abroad as well as on the experience of INSEMEX Petroşani in performing expertise in the event of explosions and fires generated by explosive gases, the use of drones can be a great support in the research activity of these events.

Quality of the environment - the result of the interaction between technological progress and education

Lazăr Maria*

University of Petrosani, University street, no. 20, Petrosani, 332006, Romania

Abstract

One of the most acute problems of contemporary society, the quality of the environment and, implicitly, the quality of life, is an intense and sustained concern of specialists from all over the world. After nearly two centuries of accelerated industrial development, the issue of ensuring the quality of the environment and of life on Earth is an essential issue for the whole society. This paper analyzes the main environmental issues at global and regional level, which not only threaten the quality of environmental components but also the safety of the entire planet. Considering that partial solving (unfortunately, many of the phenomena of environmental degradation are already irreversible) of these problems may result from interaction between technological progress and education in the field, the paper focuses on the importance of applying the best technologies available in various sectors of activity and on the role of environmental education. The paper itself is a synthesis that can become a starting point for analyzing and punctually addressing of many and various aspects such as improving the quality of the environment and slowing down of the environment degradation process.

Keywords: environment, quality, life, technology, education

1. Introduction

The major environmental degradation began at the end of the eighteenth century, with the first industrial revolution, and has worsened over the last decades. With the entry into the technological age, mankind began to produce and consume more, to improve production, transport and communication systems. Unfortunately, all these achievements, which were designed to provide a higher level of comfort, had and have a boomerang effect on the environment, affecting (sometimes irreversibly) the ecological balance and extremely fragile and sensitive systems that regulate natural processes at the planetary level. The first air pollution measurements date from the beginning of the 20th century, but only in the last decades of the last century the concerns about global environmental issues were intensified.

International environmental institutions and organizations were set up to initiate debates on changing environmental conditions at high-level conferences and symposiums. As a result, the United Nations is setting up the World Commission on Environment and Development with the stated aim of assessing the level of environmental degradation and establishing solutions for a viable development of society in the future. The Commission produced and published in 1987 one of the most important documents to underpin the major environmental decisions, namely the Brundtland Report entitled "Our common future". The report has brought new approaches to environmental issues and the economic development of society in the public space, recognizing that the scale of human intervention in nature is increasing and the physical effects of these interventions go beyond national borders. Also, the report states that in many regions of the world there are major risks of irreversible environmental degradation (Report of the World Commission on Environment and Development - Our common future, 1987). The report introduces the concept of sustainable development, respectively *„sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs”*.

Taken at the Rio Conference (1992), this concept supported by three pillars (social, environment, economy), would be detailed and implemented through the Agenda 21 document. The main criticisms of this concept relate to its contradictory objectives, respectively economic expansion, environmental protection, poverty eradication and the free market (Fernando, 2003; Hove, 2004), but also relative to the vague manner in which the ways to solve these goals are

E-mail address: MariaLazar@upet.ro.

described. The present paper aims to show that it is essential to pay more attention to the state of the environment, primarily by adding two new pillars for sustainable development, namely technological progress (using best available techniques) and education.

Following the unresolved issues of the Brundtland Commission's main proposal, the United Nations adopted in 2015 the resolution "Transforming our world: the 2030 Agenda for Sustainable Development" setting out a set of 17 objectives and 169 tasks, including deadlines for their achievement. The Declaration states the universal and international character of the implementation of the objectives, but also the fact that "*each state has and exercises free sovereignty over all its wealth, natural resources and economic activity.*" The proposed objectives cover a whole range of global problems faced by mankind, from poverty eradication to ensuring education, health and environment conditions for each person.

2. Relationship between environmental quality and quality of life

Environmental quality can be defined as the state of the main environmental components, which can be expressed at a given moment through a series of quantitative and/or qualitative indicators that relate to different standards. The quality of life is difficult to define, its significance being often reported in two dimensions: a psychological one (the inner psychological mechanism that perceives the satisfaction of life) and an environmental one (triggering the inner psychological mechanism) (Greyson and Young, 1994). As a result, it can be said that, in fact, the quality of the environment is one of the most important components of the quality of life.

Because it significantly influences the quality of life, the quality of the environment is a key factor in assessing the well-being of the population (Holman and Coan, 2008). The characterization of the quality of the environment is quite difficult to achieve because there are a large number of indicators to be analyzed. For this reason, it is necessary to establish a set of indicators that are relevant in the context of the analyzed environmental aspects.

In essence, the indicators with a major importance in determining how life quality is affected by environmental degradation are: the exposure of the population to various forms of pollution, access to resources, access to infrastructure and environmental services, land degradation and other natural resources, loss of biodiversity.

EUROSTAT provides statistics on quality of life in the European Union in the online publication *Quality of Life Indicators*. A set of nine indicators, which can be statistically measured and which relate to a range of facilities to which the population needs to have access to meet their own well-being requirements, is used for this purpose. The used indicators include living conditions, health, education, recreation and social interactions, the natural and anthropic environment. In the context of this paper, two of them will be presented, namely education and the environment.

Education is, in general, an important component of each country's economic growth, the engine of technological innovation and productivity, with a major impact on the quality of life of individuals. Absence of skills and competences limits access to the labor market and economic prosperity, increases the risk of social exclusion and poverty and can prevent full participation in public, economic and civic actions. Education enhances people's understanding of the world they live in, and therefore the perception of their ability to influence its course.

According to EUROSTAT data, although in Romania the percentage of the population with higher education approaches the EU average, paradoxically, the early school leavers rate is very high and exceeds the targets set for 2020. It is quite clear that over the last decade a large part of the Romanian population has migrated and the country's economic problems lead to school leavers not only early, but also in the higher education cycles. As a result, the number of specialists in different fields, including environmental protection and engineering, is declining, which is already reflected in many sectors of activity.

Environmental conditions have a decisive impact on the quality of life, especially as a result of pollution, land, water, landscape degradation etc., causing worsening of the population's health and/or reducing the value of the area or the property in which they live. According to EUROSTAT data, Romania belongs to the category of countries where the population has a high exposure to pollution and other environmental problems, exceeding the European Union average.

It can be seen that the level of exposure of the population to environmental problems is comparable to that of countries such as France and Italy, over Spain, Portugal, Poland, the Czech Republic, Slovakia and well above that of Great Britain and the Scandinavian countries, under the conditions where industrial activities in Romania are much lower. Possible causes for this are: intense pollution from urban agglomerations, as a result of the increase in the number of cars, especially second hand vehicles; small-scale application of agricultural good practice; massive deforestation in recent decades, delay of programs for equipping thermal power plants with facilities for emission reduction.

Given that Romania has committed itself to implement the 2030 Agenda objectives, sustainable development is part of the Romanian public policy, academic and civil society circles. Moreover, the Ministry of Labor and Social Justice has recently recognized a new profession, namely Expert in Sustainable Development, and aims to have a group of experts in the field in all public institutions (Romania's Voluntary National Review, 2018). This forces us to believe that in the future all environmental engineering specialists will be involved by the authorities in solving environmental pressures that will affect the quality of life of the population.

3. Main environmental issues and improvement solutions

The process of degradation of the environment is today indisputable, and the major causes of this degradation include anthropogenic activities. Modern society's efforts to improve its living conditions, particularly intensified during industrialization, paradoxically threaten the safety and quality of life on the planet that hosts us. The negative effects of various human activities are manifested both globally (greenhouse effect, climate change, acid rain, ozone depletion, atmospheric pollution) but also at regional and local levels (water pollution, pollution and degradation of soil, biodiversity loss, degradation of the landscape) (Lazăr and Dumitrescu, 2006).

The main driver of worsening environmental problems can be considered the demographic explosion of the last 50 years. Basically, the world's population has doubled during this period. If in 1967 the planet was inhabited by about 3.55 billion inhabitants, in 2018 the world population exceeds 7.6 billion, and the forecast by UNEP shows a population growth trend towards 10 billion in 2050 (Figure 1).

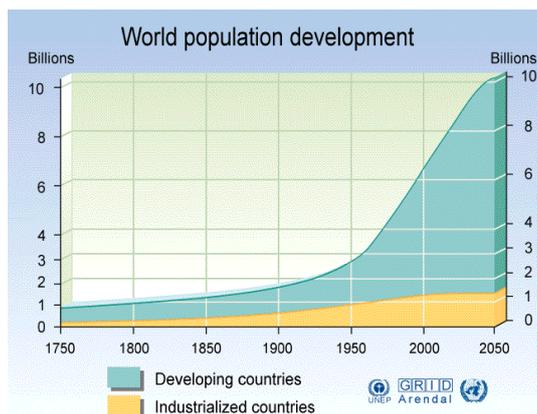

Fig. 1. World population development between 1750 and 2050

Almost 80% of the world's population lives in less developed countries where the environmental pressures are major. Overpopulation is an increasingly prevalent concept, and according to the Global Footprint Network - Advancing the Science of Sustainability, the global ecological footprint is 1.7 planets (Figure 2).

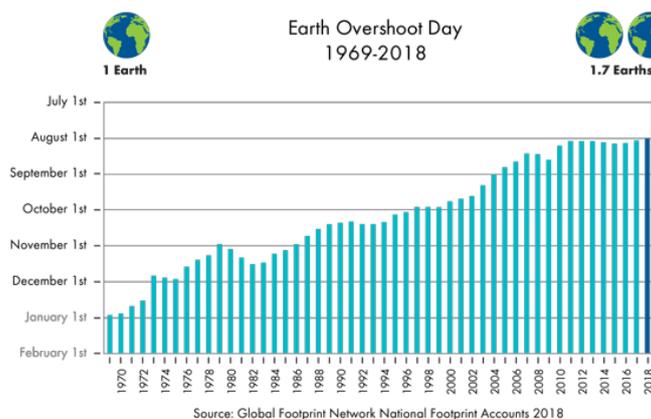

Fig. 2. Overpopulation and resources depletion

Earth Overshoot Day marks the date all of humanity have used more from nature than our planet can renew in the entire year. This date has moved from late September in 2000 to August 1 in 2018.

The exponential growth of the population has as effects increasing demand for land, food and industrial products, mineral resources, increasing transport, increasing the amount of waste to be managed. All these require the intensification of economic activities in different sectors and leading to major pressures on the natural environment. The result of these pressures is represented by different forms of impact at local, regional and global level.

The major challenge of contemporary society is, in particular, to significantly reduce emissions of pollutants into the atmosphere. These emissions generate a global impact such as greenhouse effect, global warming and climate change (carbon dioxide, methane, nitrous oxide, water vapors); destruction of stratospheric ozone (compounds containing chlorine and bromine atoms); acid rain. Such emissions also have natural sources, but they result from most anthropogenic activities. Worldwide, researchers are increasingly concerned with finding effective environmental protection technologies, especially with regard to the atmosphere. Some of the possible solutions for reducing the environmental impact generated by the main sectors of activity are presented in Table 1.

Table 1. Solutions to mitigate environmental impact

Activity sector	Environment friendly technologies
Mining	<p>Using mining simulators to increase productivity</p> <p>Introducing new technologies to replace drilling and explosive operations (surface mining machines)</p> <p>Use of energy from renewable sources and zero emission equipment</p> <p>Innovative waste and water treatment processes from mining</p> <p>Use of methane and carbon dioxide capture and storage technologies</p> <p>Protection of deposits and recycling of mineral resources</p> <p>Ecological rehabilitation of degraded land</p>
Energy production and transformation and other industrial activities	<p>Pond technology - capture of carbon dioxide from fossil fuel combustion processes (valid for all industrial sectors) and pumping into a photobioreactor, where under the influence of LED-generated light result biomass from algae used to produce biofuels, biochemical substances, fertilizers (Applegath, 2016)</p> <p>Use of clean power generation technologies (wind, solar, hydro, geothermal, fusion power plants, etc.)</p> <p>Intelligent energy storage systems</p> <p>Use of fossil fuels with low sulfur content, coal and flue gas desulphurisation</p> <p>Reducing nitrogen oxide emissions by: using burners which combine the fuel with air for a step by step combustion, flue gas recirculation, selective catalytic and non-catalytic post-combustion reduction using ammonia</p> <p>Reducing the use of chemicals that destroy stratospheric ozone</p> <p>Optimizing power generation and supply networks</p> <p>Programs for the reduction, recovery and recycling of waste from all industrial activities</p> <p>Use of the best available technologies in all industrial sectors</p>
Transport	<p>Electric cars with more efficient battery charging technology</p> <p>Intelligent systems to avoid traffic congestion in cities</p> <p>The on-board distillation system, designed and patented by the University of Texas at Austin College of Engineering and Ford Motor Company, which acts as a miniature oil refinery under the hood, not only reduces pollutants generated by hydrocarbon burning but promises to reduce by 80% all exhaust emissions from vehicles.</p> <p>Use of hydrogen fuel cell vehicles</p>
Agriculture	<p>Substantial reduction in the use of fertilizers and pesticides</p> <p>Larger introduction of organic farming</p> <p>The shift to more extensive forms of agriculture, and the application of innovative production methods</p> <p>Use of good agricultural practices, compatible with the requirements of environmental protection and natural resources and landscape</p> <p>Temporary removal of land from agricultural circuit and its use for the purpose of environmental protection</p> <p>Soil conservation and crop rotation</p> <p>Conservation of natural forests and ecological rehabilitation of degraded land through afforestation with endemic species</p> <p>Preventing biodiversity loss by protecting and restoring habitats</p>
Urban development	<p>Use of ecological building materials</p> <p>Implementing the concept of "intelligent city"</p> <p>Ensuring the preponderant energy from renewable resources</p> <p>The orientation of buildings in relation to the cardinal points and dominant winds and the use of vegetation, trees to obtain wind, thermal, noise and air quality protection.</p> <p>Using the best design techniques (the environmental implications should be seen not only in terms of the use of the various available materials, but also of the exploitation and maintenance)</p>

The implementation of environment-friendly technologies can lead to the goals of sustainable development of modern society, so that environmental risk can be reduced to an acceptable level. These solutions are known and applied in many of the developed countries in terms of investing in research and technology. But as long as these countries do not really support countries with a lower level of development, global threats will remain alarming.

4. The role of education in the process of improving the quality of the environment

In the context of worsening environmental quality at all levels (local, regional and global), environmental education is becoming increasingly important and relevant to attempts to protect and improve the state of the environment.

In principle, environmental education is a process of recognizing values and clarifying concepts in order to develop skills and attitudes necessary to understand and appreciate the interrelatedness among man, his culture and his biophysical surroundings (IUCN, 1971). Environmental education also entails practice in decision-making and self-formulating of a code of behavior about issues concerning environmental quality (Martin, 1975).

Today, the environmental education focuses on investigating the conditions and learning processes that enable citizens, young and old, to develop their own capacity to think critically, ethically, and creatively in appraising environmental situations, to make informed decisions about those situations and to develop the capacity and commitment to act individually and collectively in ways that sustain and enhance the environment (Stevenson et al., 2013).

Environmental education involves an interdisciplinary approach to environmental issues, including knowledge from a wide range of fields: mathematics, physics, chemistry, earth sciences, biology, engineering, economics, sociology, etc. Among the main objectives of environmental education are: awareness, knowledge and recognition of environmental issues, training of attitudes and skills in the field, development of assessment and solution skills, participation in the implementation of solutions (Figure 3).

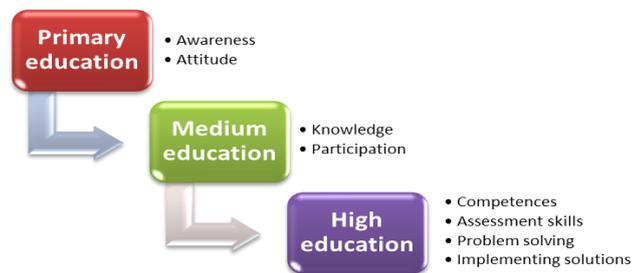

Fig. 3. "Cascade" of environmental expert training

Environmental education is more than just informing the population about environmental issues. If we look at the education system as a whole, namely from the family, the pre-university education up to the three cycles of higher education (bachelor, master, doctorate), a clear distinction can be made between information and specialized education.

Information on environmental issues must lead to knowledge, empowerment and the adoption of appropriate individual behavior to protect the environmental components. This information has to be started in the family and continued in an institutionalized way within the primary cycles. Among other things, it aims at raising students' awareness of environmental issues and determine them participate in volunteer actions of protection (greening, recycling, tree planting, etc.).

Given that some of the population that has already passed school age is little or no knowledgeable in this area, local authorities have a number of mechanisms to empower people of different ages (information actions, flyers, organizing seminars, initiating voluntary activities, etc.).

Environmental education starts from high school and is continued in higher education.

High schools offer a number of specializations in the field of the environment and their graduates are skilled technicians in various types of environmental interventions (technical support for natural resource management, environmental protection, industry, agriculture, forestry and forest management). Graduates can continue their professional training by attending university courses in specializations dedicated to environmental engineering or Earth sciences.

Higher education offers three cycles of environmental engineering training, namely bachelor, master and doctoral degrees. The environmental engineer is a specialist with a complex and multidisciplinary training that uses engineering concepts to manage and improve the environment but also to find innovative solutions for carrying out economic activities with minimal impact on the environment. Among the many abilities acquired by such a specialist are complex understanding and integrated approach to environmental issues, analysis and interpretation of environmental degradation phenomena and processes, identification, estimation and evaluation of the effects of anthropogenic activities on the environment, design and implementation of solutions for improving the quality of environmental factors, the application of communication principles and methods for the promotion of environmental projects.

In Romania, at present there are specializations in the field of environmental engineering in almost all universities, adapted to their specifics. Although the study programs are similar to those in developed countries, the integration of graduates into the labor market and the implementation of acquired knowledge are relatively difficult, given the lack of adequate know-how and a low level of awareness of environmental issues by a large part of the population.

In order for the specialized education to be effective and the graduates to be able to apply their knowledge, it is absolutely necessary to have a correlation between the labor market and the education system and good communication and collaboration between the line ministries, employers and universities.

5. Conclusions

At a time when environmental issues are becoming more and more stringent, mankind is forced to change its current development paradigm. The legislative and organizational framework is established through several international environmental organizations that have set out the directions for action to secure the future of the planet and future generations. Global environmental problems such as global warming and climate change, human health and ecosystem problems, massive pressures on the natural resources of the planet require contemporary societies to find another way to meet their needs and living standards. As we speak of evolution at the economic and social level, the solutions to these problems must be sought by specialists through research, innovation and technology transfer. Implementation of the results may lead at least to an improvement in the environmental conditions and to slowing the natural imbalance processes generated by the accentuated industrialization. To address the major issues relating to the protection of the environment as a whole and its components, education plays an important role in this context. From awareness of environmental issues to assessment and implementation of new technologies, education provides access to information, skills and competences. Thus, it can be argued that improving the quality of the environment and implicitly the quality of life lies at the intersection between education and technological progress.

Equipment for water ozonation in fish breeding lakes

Andrei-Cristian Lupu^a, Marius Petrescu^{b*}

^aUniversity of Agricultural Sciences and Veterinary Medicine, Iași, Aleea Mihail Sadoveanu no. 3, 700490, Romania

^bPetroleum-Gas University of Ploiesti, Bd. București no. 39, 100680, Romania

Abstract

The invention that is presented in the paper refers to the procedure for the ozonation of waters in the fish lakes. It thus combats the phenomenon of eutrophication due to accidental spills of organic substances, overheating of water attributable to climate change, and also the improvement of water quality, which is very necessary for the proper development of fishing activity.

Keywords: ozonization, eutrophication, fish

1. Description

The paper deals with the ozonation of water from fish ponds in order to eliminate the eutrophication phenomenon due to accidental spills of organic substances, excessive water warming attributable to climate change or to improve the quality of water, a very necessary development of fish farming.

Eutrophication is one of the most challenging environmental problems that the surface water bodies are facing in present time (Smith, 2009; Li Kun et al., 2017). Eutrophication is an ecological process, similar to aging, in which a water body is increasingly enriched with essential nutrients of the aquatic plants (Rast, 1996) which results in increase of the primary productivity, i.e. rate of photosynthesis of the aquatic ecosystem (Qin et al., 2013). The most common signs of eutrophication in lakes and rivers involve heavy algal blooms resulting in high turbidity and anoxic conditions in the deeper parts of the waterbody due to the decay of detritus which leads to fish kills (OECD, 1982; Wang, 2009). Eutrophication may lead to severe health hazards to human and animals through various pathways. It is a major health threat if drinking water is collected from eutrophied water body. Eutrophication also results in serious ecological problems as well as have impact on the aesthetic view and economy.

To address the undesired effect of chemotherapeutants in aquaculture, ozone has been suggested as an alternative to improve water quality. To ensure safe and robust treatment, it is vital to define the ozone demand and ozone kinetics of the specific water matrix to avoid ozone overdose (Aikaterini et al., 2018).

Devices for surface water aeration are known by paddle, winding, driven by internal combustion engines mounted on pontoons, boats or rafts.

It is also known an installation which distributes the ozone-enriched air through some pipes provided with holes mounted on some supports entwined in the agglomerate layer.

Still other methods are known, such as the use of motor boats that have the same role of winding by breaking the fat film that forms over the water in organic spills.

These methods and installations have several disadvantages, such as:

- the introduction into the aquatic environment of vibrations in the form of sounds, infrasounds which present discomfort to fish and other aquatic creatures;
- the introduction into the water of hydrocarbons resulting from internal combustion engine cooling systems;
- repeated failure of the aeration ducts due to blocking the holes by detaching them from the supports on which they were mounted in the agglomerate layer;
- level variations due to hydrostatic pressure influence the volume of ozonized air introduced into the water of the lake.

The device for ozonizing water in the fish ponds consists of two unconventional energy sources mounted on the shore of the lake consisting of a vertical wind turbine group and a solar panel with solar panels with known cooling

* Marius Petrescu. Tel. 0725 443 700
E-mail address: marius.petrescu@gmail.com

systems for active surfaces, thus obtained is stored in a space containing a group of accumulators, energy which is then distributed to some modules, a module consists of a device for obtaining the filtered and compressed air passing through a Venturi tube is mixed with the ozone produced by some ultraviolet generators ($\lambda=185\text{ nm}$) by a known method, after which, by means of another special construction module, it is distributed in the water of the basin or the lake, and for the protection of fish against ihtiofage birds, the distribution system also contains permanent magnets mounted on the surface of the rotating distributor due to the reactive effect of the air exhausted in the lake water creating a discomfort to the birds due to the change of the magnetic field, the birds being confused, leave the area where the lake or basin is located, and in order to provide a protection against theft, this water ozonation facility also contains some GPS circuits for signaling site change at installation, audible, luminous, and presence of malicious people especially when the installation is mounted on the shores of the lake.

The paper has the following advantages:

- the occurrence of the phenomenon of eutrophication is excluded;
- improve water quality and the conditions of fish species development;
- achieves the best performance with regard to the distribution of the ozonized air in the water with its winding;
- due to the disturbance of the terrestrial magnetic field by the presence of an artificial magnetic field in the installation area, the fishery activity of the ihtiofage birds;
- it does not depend on the variation of the water level, being always positioned at its surface;
- due to the presence in the water of the oxygen atom (O), part of the parasites and bacteria are destroyed;
- if mounted on the shore, it is equipped with GPS circuits and anti-burglary sensors;

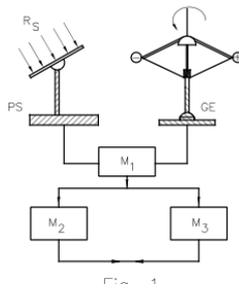

Fig. 1. The overall scheme of the device

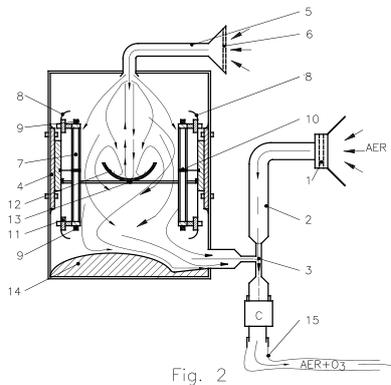

Fig. 2

Fig. 2. Section through the ozone-generating device

The water ozonisation plant consists of an energy module M_1 (Fig. 1) which contains a vertical axis wind group whose active elements for converting the energy of the air currents are aerodynamic cones mounted in such a way that their rotation is in the trigonometric sense (or radial-axial) meaning that coincides with the sense of rotation of the Earth, which is an advantage for increasing the conversion efficiency due to the reduction of friction forces, this phenomenon being little known and applied, and for obtaining energy in cases of meteorological calmness and lack of nebulosity, energy can be obtained using solar cells, the number of which depends on other usage requirements, panels designed to increase the efficiency of cooling systems of the light receiving surface, with cleaning systems for these surfaces and with high-intensity wind protection systems; the ozone system for pools or lakes has a module M_2 containing a compressor C, and if it fails it is replaced by an air turbine TA required to create air intake from the environment that was initially filtered by known means containing the filter group 1 (Fig. 2), after which he enters into a Venturi tube 2, and according to the continuity of flow of fluids through the pipes, a suction of the ozonized air in the narrow pipe is carried out 3 due to the drop in static pressure P_s and increased dynamic pressure P_d , the ozone-mixed air is then compressed into the compressor tank, being sent to a distribution module M_3 to be then discharged into the water

of the lake; in the same module M_2 (Fig. 1) the device for ozone generation from the atmospheric air formed by a closed enclosure is also mounted 4 (Fig. 2) where the air is sucked in due to the pressure drop created by the Venturi 2 through the pipeline 5 after being filtered by the filter 6 and subjected to UV radiation ($\lambda=185\text{ nm}$) issued by two generators 7 mounted in the focus of an ellipsoidal mirror 8, with the sockets 9 and bracelets 10 and reinforced with supports 11, concave chicanery as a crucible 12 caught on a rod 13 has the role of lengthening the aspirated air beam, thus increasing the duration of UV radiation action, of the ozone efficiency (O_3) by decomposition of oxygen molecules (O_2) in oxygen atoms (O) and then combining oxygen (O_2 with an oxygen atom (O) thus forming an ozone molecule (O_3), a reaction similar to those taking place above the stratosphere, a layer that is found after the troposphere; ozone so formed protects us from the other radiation emitted by the Sun; piece of special shape 14 helps with the Coanda effect follow the curve to help the ozone escape into the Venturi tube, and through the flexible pipe 15 (Fig. 2) the air and ozone mixture is driven to a module M_3 (Fig. 1) to be distributed in water.

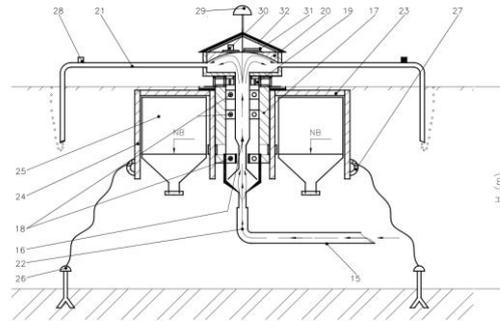

Fig. 3. Section through the ozonization device

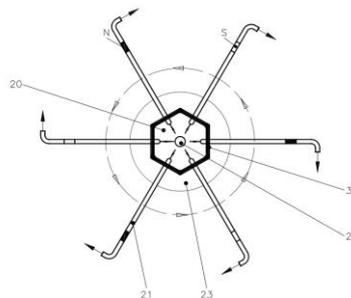

Fig. 4. Above seeing of the distribution device

The module M_3 contains a vertical pipe 16 mounted in a cassette 17 with radial bearings 18 and pressure 19, having another hexagonal shaped box in the upper part 20 having the upper hemispherical wall to ease the air outlet in the pipe 16 to penetrate the water through the pipes 21, which thanks to the construction creates a reaction effect that causes the whole assembly to rotate; the ozone-enriched air enters the pipe 16 through a flexible pipeline 22, and to ensure buoyancy, the whole assembly rests on a circular plastic structure 23 of low density with a circular window in the center in which the box is inserted 17 which contains the bearing system, which allows the distributor to rotate through the reactive effect of the ozonized air at the outlet, the direction of rotation being the trigonometric, identical to Earth rotation, which greatly reduces friction between the water layers during rotation, improving the distribution of ozonized air and water flowing in the installation area, the pipes being curved to allow this; the buoyancy of the device is accomplished by inserting inside the circular structure 23 some niches 24, of some PET containers 25 of different volumes depending on the size of the distribution device and its weight; adjusting the distance to the surface of the water is achieved by introducing a certain volume of water into the PET containers, and to create a pressure inside, a spoon filled with lime powder is placed in each container.

Finally, the device is anchored by the anchors 26 through a plastic thread of the supports 27, and for the protection of fish against birds of different species, on the ozone air distribution pipes 21 some permanent magnets are caught (neodim) 28 which by their presence modifies the distribution of the terrestrial magnetic field in the area of the module location, which creates a discomfort to the birds, leaving the area; the phenomenon is accentuated to most of these things because they are oriented in space by the force lines of the Earth's magnetic field and this change frightens them especially when the disruptive magnetic field is variable due to the rotation of the ensemble, the magnets being mounted with different polarities on the top of the pipes, alternatively.

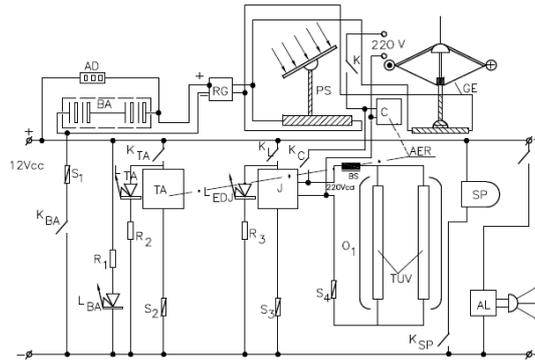

Fig. 5 – Electrical scheme of the ozonozation device

A girofar is used to indicate nighttime operation 29 mounted in the circuit with a battery 30 by means of a twisted electric circuit 31 (connects the girofar in the evening and disconnects it in the morning), these being mounted in the top of the hexagonal cassette 20 on the sides of which are the solar mini-panes 32 to power the battery 30; switch K connects to the network of 220V of the compressor C and the ozone generator when the power of the battery BA falls below projected value due to prolonged weather phenomena (calm and nebulosity).

2. Conclusion

This device for ozonizing water in the lakes is made to avoid the occurrence of eutrophication and to improve the quality of water in which various fish species grow and develop are formed, for example, from two conventional sources of energy known in the art, namely a microcentral baffle solar photovoltaic and a vertical axis wind group, the energy accumulated in batteries with accumulators via a regulating relay, which are part of the M1 module, supplying another M2 module, containing the mini-installations for obtaining the air pressure, a turbine, a compressor and the ozone generation device. The plant also contains another M3 module, which is a special device consisting of a counter-rotating distributor due to the reactive effect of the air outlet through some pipes trapped in a hexagonal enclosure, thus achieving a high efficiency in concerns the penetration of ozone into the water of the lake as well as the flow of water.

^bPetroleum-Gas University of Ploiesti, Bd. București no. 39, 100680, Romania

Abstract

The paper relates to an installation for improving water quality, especially for fish-growing basins of different fish species. Fisheries are required to check for any changes in water quality or fish behavior.

The solution presented in this paper refers to the construction of pools for different fish activities, using materials and constructive forms that ensure good water quality, a clean and healthy environment for the growth and development of different fish species.

Keywords: fish-growing basins, fish, water quality

1. Introduction

The paper relates to a device for improving water quality, especially in juvenile fish breeding pools, existing in fish farms where checks are required to determine possible changes in water quality or fish behavior.

As existing facilities for maintaining the quality of water as a living environment for fish in existing ponds or for other activities, we can mention:

- devices known to refresh water from surface or underground sources using electric pumps;
- winding devices are also known to allow the oxygen to enter the water in pools or where the fish grows;
- there is also known a paddle aerator used in fish cages ponds that helps reduce nonionized ammonia.
- these methods and installations have the following disadvantages:
- noise of aerators or pumps, technological phases that can cause stress on fish with repercussions on the occurrence of diseases;
- are not equipped with recirculating or refreshing water disinfection equipment that may contain bacteria or other micro-organisms that may affect the living environment of the fish;
- consumption of conventional fuels and electricity for the operation of the equipment;
- if the growth ponds are located on the administrative platform in enclosed areas, they are not equipped with earthing sockets, so that the volume of water in the ponds is not connected to the Earth's energy that is beneficial for the fish;
- disinfection equipment with high germicidal ultraviolet radiation and medium flow rates is not used.

2. Objective

The problem solved by the work consists in building pools for different fish activities, from materials and constructive forms that ensure good water quality, a clean and healthy environment for the growth and development of different species of fish.

3. Description

The work to improve the quality of water in the fish ponds is made up of an ellipsoidal basin to allow natural water movement, and to create her pulse, is mounted in the lower part of the ellipsoid, namely in the outlets of the section, some zinc electrodes connected electrically to a closed / open normal contact of a relay powered by an oscillator, which generates in the pool water pulses of electrons coming from the Earth thanks to a socket (Earth is considered a huge electron generator), also for the achievement of good quality water, the device also contains: an ellipsoidal pipe

* Marius Petrescu. Tel. 0725 443 700
E-mail address: marius.petrescu@gmail.com

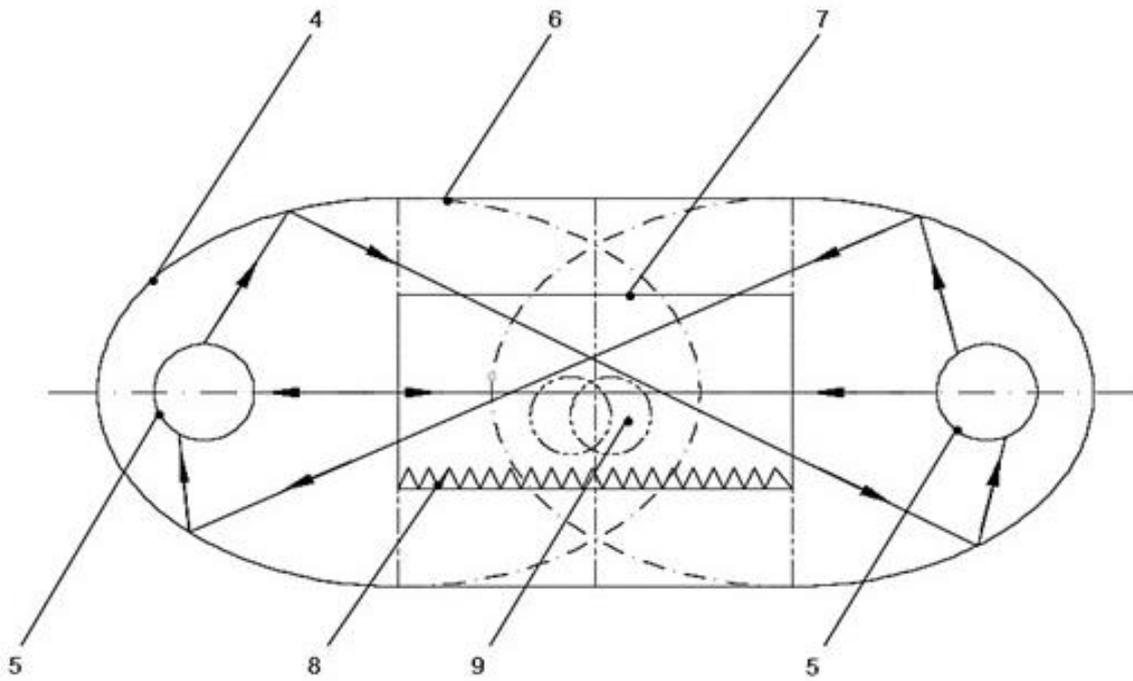

Fig. 2. Section through the disinfection device

At the end of the technological flow when the fish was transferred to the storage and further development basins for fishing or for recovery by transport to the outlets, the basin 1 (Fig. 2) is discharged by opening the valve R_{03} mounted on the drain pipe 9, and after washing and disinfection it is filled with underground water from a drilling 10 by pumps P_{02} , P_{01} , filtered through the filter battery BF, the disinfection being carried out by the disinfection equipment described above, reaching the maximum level is signaled by a sensor SN, after which a new technological stream can begin;

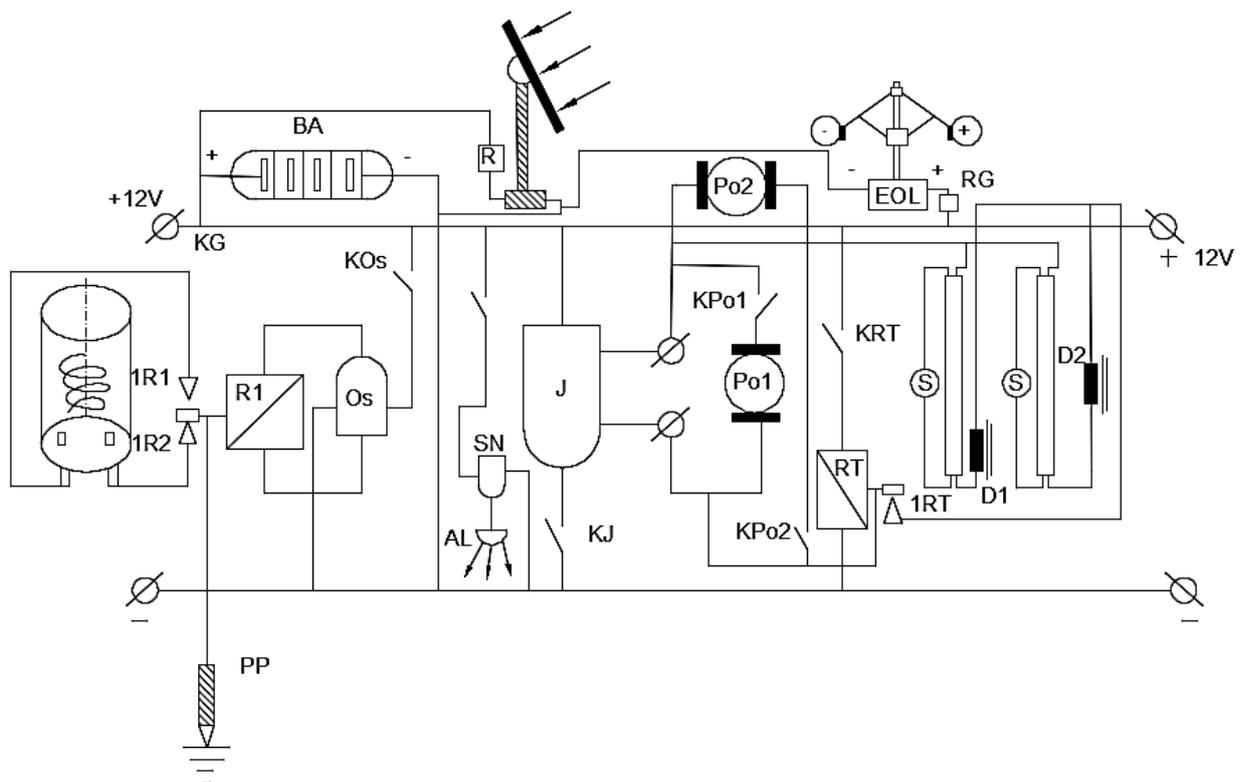

Fig. 3. Electric scheme of the device (tank)

4. Conclusions

The main circuit schematic diagram (Fig. 3) contains the power supply BA charged from a solar panel under the influence of solar radiation RS and the regulator relay RG or from a wind power plant with aerodynamic cones, then the electrical energy thus obtained feeds the following circuits: the circuit for obtaining the water pulse with the relay R₁ through normally open / closed contacts 1R₁, 2R₁ through the oscillator O_s, the warning circuit reaches the maximum level through the sensor SN and the sound alert AL through the switch KO_s, the power supply generated by the inverter I to the voltage of 220 Vca of pumps P₀₁, P₀₂ through the switches K_{P01}, K_{P02}, the supply circuit of the disinfection equipment through the switch K_{PT}, time relay RT with its normally open contact 1RT and wavelength germicidal UV radiation generators $\lambda=153,7\text{nm}$ G₁, G₂ with starters S and drossels D₁, D₂, operation of the entire plant is possible by actuating the general switch K_G.

Mobile autonomous aerator

Andrei-Cristian Lupu^a, Marius Petrescu^{b*}

^aUniversity of Agricultural Sciences and Veterinary Medicine, Iași, Aleea Mihail Sadoveanu no. 3, 700490, Romania

^bPetroleum-Gas University of Ploiesti, Bd. București no. 39, 100680, Romania

Abstract

The paper presents the model of an autonomously mobile aerator usable, especially in fish farms, for operative interventions in the incipient phase of the eutrophication phenomenon. The equipment provides oxygen intake, especially in the summer days when the water temperature is rising. The use of the aerator reduces the losses due to the death of the fish by suffocation. The proposed aerator variant can also be used in polluted waters as a result of the spillage of organic substances.

Keywords: aerator, eutrophication, fish

1. Introduction

The paper refers to an autonomous mobile aerator required especially in fish farms for operative interventions in the event of an early occurrence of the eutrophication phenomenon, in order to ensure oxygen intake of the fish especially during the summer days when the temperature of the water is increasing, avoiding major losses that are caused by the suffocation of fish. This phenomenon of eutrophication can also occur if organic substances are discharged into the lake/pond. Most of the freshwater lakes and wetlands are facing the problem of water quality deterioration and ecological imbalance due to the increasing anthropogenic activities particularly in developing countries (Biswajit, 2018).

Methods for aerating waters, lakes of various uses using motorized boats or rowing are known. A paddle aerator is known to be rotated by internal combustion engines (Sanjib, 2002).

Various equipment is known to introduce ozone in the water used to reduce the microbial flora as well as to enrich the concentration of oxygen in the lake water to survive the fish. There is also known a platform used for recreational tourism and for reducing eutrophication of lakes using ozone-driven air jets.

These methods and equipment have the following disadvantages: - the use of internal combustion engines pollutes with hydrocarbons from engine cooling circuits; - engine noise or other sources determines the stress of the fish; - the use of ozone for aeration is a method that has high costs and therefore its use by aquaculture farmers is avoided; - the oxygen port for motorboats or rowing is negligible; - the use of large platforms requires high pressure air jets not being able to move in areas with shallow water.

2. Objective

The problem solved by the work consists in the realization of a mobile aerator moving remotely on the water of the lake without the use of fossil fuels while at the same time aerating the water which is accomplished by introducing into the water some jets of air simultaneously with the introduction into the air water jets, all at an acceptable price, although this water shift is remote controlled by radio waves.

This mobile aerator has the ability to overcome the above disadvantages in that it contains a floating support which can be a boat, catamaran, etc. of small sizes that are mounted: for example, two photovoltaic panels, and in the back, side and front there are some air turbines and water pumps, which at a programmed time by a microcontroller or remote control on the shore create some jets of air in the lake water and jets of water in the air that provide remote radio scrolling, as shown above from a distance, obstruction of obstacles by infrared sensors, stopping near the shores through a video camera and returning to the starting point performs automatically by using a known remote control by the user.

* Marius Petrescu. Tel. 0725 443 700
E-mail address: marius.petrescu@gmail.com

The device has the following advantages:

- performs rapid intervention in the area where a refreshment of water is required;
- can operate throughout a sunny day or night due to the electricity accumulated by solar panels;
- it does not create noise of thermal motors, which due to vibrations produce a continuous stress to the fish and does not pollute the water of the lake;
- by using water jets, in addition to the oxygen intake, a decrease in the water temperature is also achieved due to the evaporation phenomenon;
- the operation of the aerator takes place in a stand-alone mode without conventional power consumption;
- the mobile autonomous mobile aerator can move into shallow water areas, the preferred location for algae development, and its great mobility results in increased aeration efficiency.

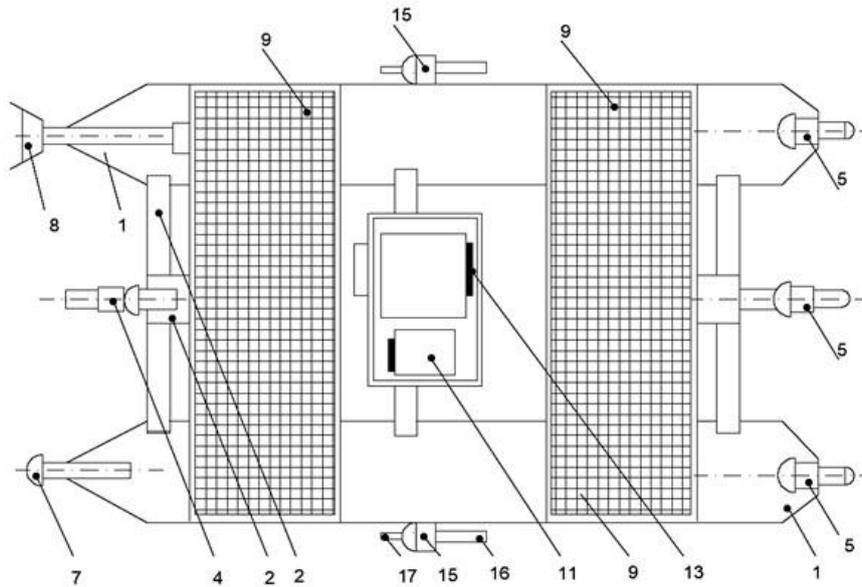

Fig. 1.a. Above seeing of the aerator

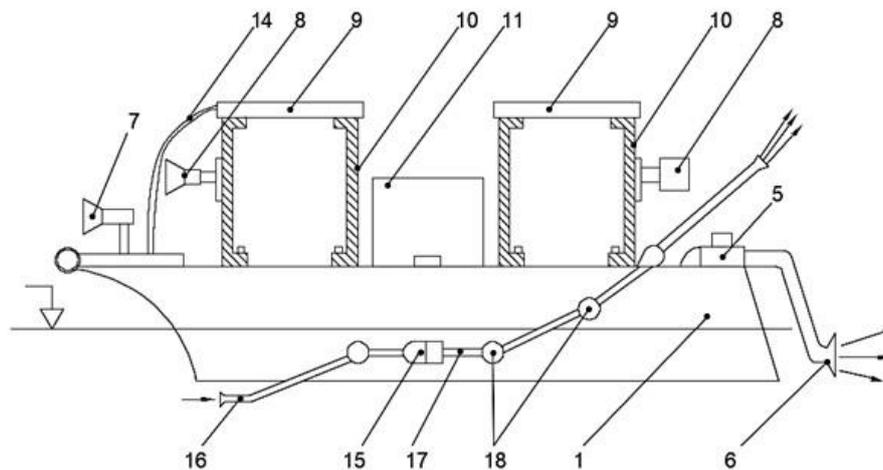

Fig. 1.b. Transversal section of the aerator

3. Description

The autonomous mobile mobile aerator is designed for operative interventions in case of oxygen deficiency in the water of some fish lakes and consists of a miniaturized catamaran with two aluminum floats 1 (Fig. 1.a) connected by transversal aluminum latches 2 and longitudinal latches 3, and at their heads they are tapped: an air turbine 4 for stopping and reversing, and three turbines 5 are used for forward travel, the displacement being possible due to the reaction force of the air jet evacuated in the water through the nozzles 6; to avoid collisions with objects floating in lake

water or shoreline, the aerator also contains an infrared sensor 7 and a video camera 8; for autonomous operation of the aerator, two photovoltaic panels are located above the deck of the catamaran 9 attached to the deck by some aluminum supports 10 between which an enclosure is centrally located 11 of the polycarbonate in which the electronic circuits for controlling the remote operation are located, the photovoltaic panel regulator relays and the emulsion battery 12 (Fig. 1.a) caught firmly with the breech 13, and in order to reduce the drag force due to the air flow, a polycarbonate windscreen 14; to increase aeration efficiency, the self-contained mobile aerator also contains two pumps immersed in water 15 (Fig. 1.b) with the sorb 16 and the evacuation nozzle 17 through known plastic rotors 18 necessary to determine the height of the water jet (max 14 m).

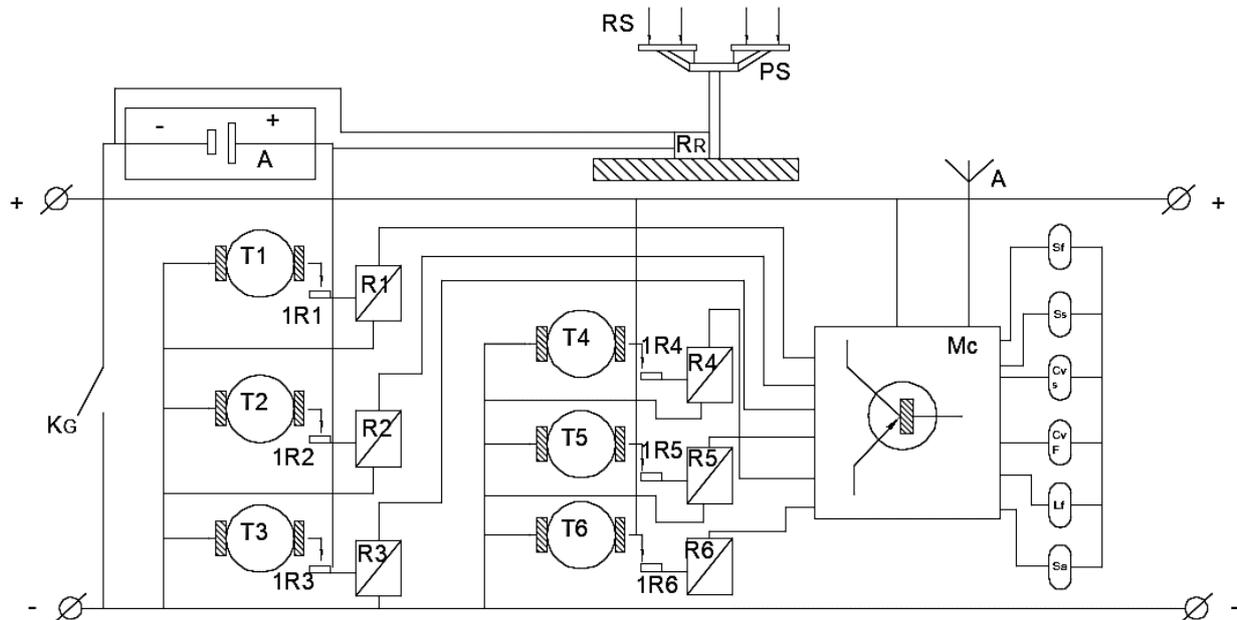

Fig. 2. Electric scheme of the aerator

To increase visibility at night, the aerator is equipped with a headlight 19 which works with a built-in twilight sensor; the electric circuit diagram of the aerator operation contains two photovoltaic panels PS by means of which the solar radiation RS via a regulator relay R_G is converted into continuous electric current stored in an emulsion battery A, current which is used for the operation of the following circuits at the receiver, namely: the air turbine power supply circuit T₁, T₂, T₃, T₄ through normally open contacts 1R₁, 1R₂, 1R₃, 1R₄ of some relays R₁, R₂, R₃, R₄, the supply circuit of the two medium power submersible pumps (throws water up to the height of 14 m) P₁, P₂, through contacts 1R₅, 1R₆ of some relays R₅, R₆, circuits that come into operation when in accordance with commands received by radio from the known remote transmitter, which is located on the lake shore, the microcontroller on board the aerator distributes the on-board power supply for turbines and pumps; because the state of the water glare can change by the appearance of floats and the operator on the shore that has the transmitter does not notice, because of distance or other phenomena that impede visibility, the aerator is equipped with sensors whose circuits coupled to a microcontroller on the aerator are: the sensor circuit S_F (Fig. 2) that senses the front obstruction, S_s – optional rear obstacle, video camera – front view C_{VF}, optional rear view camera C_{VS}, increasing the intensity of the headlight L_F, and if there is a fault in the electrical circuits through the sensor S_A an alarm signal is triggered, to take remedial action, requiring for this purpose the movement to the place where the aerator is located and its recovery.

4. Conclusion

Mobile energy autonomous aerator required especially in farms for operative interventions in case of an early occurrence of the eutrophication phenomenon, using for this purpose a catamaran that uses for its autonomous displacement on the lake surfaces the effect of the reaction of some jets of air emitted in water by some turbines and some jets of water thrown under a certain angle into the air by some submersible pumps, these being operated by radio remote control by a shore operator, the required energy being obtained by two photovoltaic panels and stored in a battery accumulated by decks, air jets in the water, and water jets in the air contributing to the increase of the oxygen concentration in the water, which results in eradication of the eutrophication phenomenon, the whole operation is possible due to programming of the two microcontrollers themselves known, one on broadcast and one on l reception, operation that can last both day and night due to the unconventional energy stored.

Abstract

Nowadays, electronic and electrical equipment for example smartphones, laptops, personal computers, car electronics, etc. represent one of the fastest growing waste (WEEE) stream caused by the accelerated technological development. These devices contain a lot of valuable elements: critical elements (rare earth elements, platinum group metals, In, Ga), precious metals (Ag, Au) and other metals (Cu, Ni, Sn) as well as plastics (polyamide, polyethylene, polypropylene, poly (methyl methacrylate)). The mass ratio of plastics can reach up to even 70% in devices, depending on many parameters, mainly the production year and the application type. Considering mechanical processing methods, sensor-based sorting plays a significant role in waste preparation. The different types of plastics can be separated from each other by applying Near-Infrared (NIR) separators. Present paper gives a literature overview in the field of mechanical processing methods related to WEEE, focusing on NIR separation.

Keywords: WEEE, processing, NIR, separation, recycling

1. Introduction

Processing of electrical waste is a huge problem in most European country. Due to the technological development every year more and more electrical waste have to treat. It is seen in Figure 1, that the volume of collected and treated WEEE in Hungary increase steadily, however the Crisis of 2008 stopped the growing for some year.

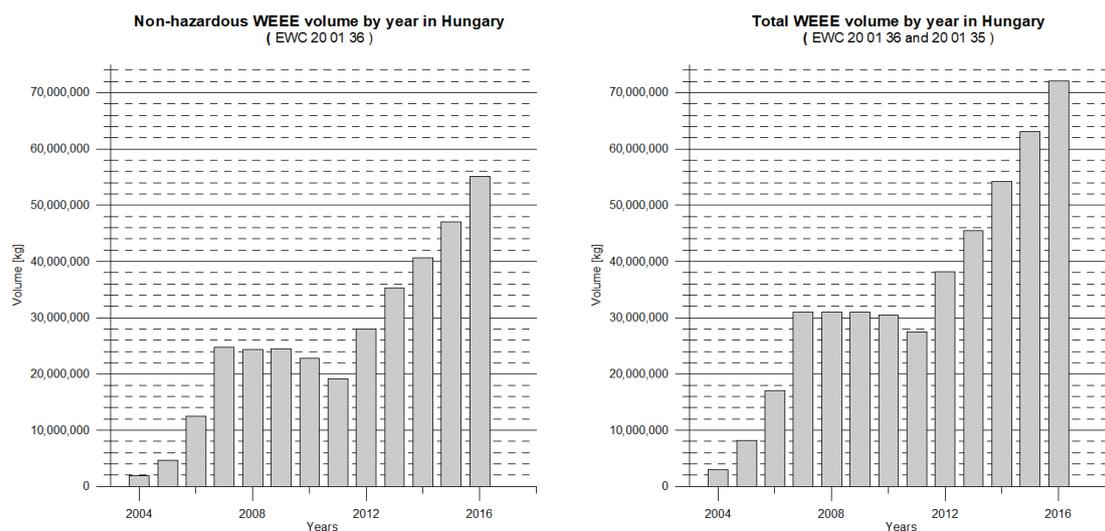

Fig. 1. Non-Hazardous and Total WEEE volume in Hungary (National Environmental Information System, 2018).

* Corresponding author. Tel.: +36-46-565-111/18-08

E-mail address: gtbvir@uni-miskolc.hu

The commonly used method to process the electric waste is disassembling by workers than sell plastic and metal parts for recycling.

2. Typical mechanical preparation technology for WEEE

The flowsheet of typical mechanical preparation technology for WEEE can be seen in Figure 2 (Csóke, 2016). The first step of the mechanical processing is crushing. Shredders are often used as crushers in order to ensure the appropriate liberation by complex forces. The appropriate liberation is determined by the maximum particle size of crushing product. Table 1 summarizes recommended maximum particle size values for some typical WEEE.

Table 1. Recommended maximum particle size values for some typical WEEE related to appropriate liberation

Type of WEEE	Maximum particle size, x_{max} [mm]
Household small appliance	15..20
Telephone	5
Personal computer (PC)	2
Chip	1
Printed circuit board (PCB)	0.5

During mechanical preparation process the particle size becomes finer and finer after each crushing step. According to the mentioned above different machines can be applied to separate the valuable materials (Fe, plastics and non-ferrous metals) considering the particle size. After the first crushing step, belt magnetic separator is suggested for bigger particle sizes, while after the second crushing step drum magnetic separator can be used for smaller particle sizes. Non-ferrous metals can be separated by Eddy current ($x > 3 \dots 4$ mm) or electrostatic separator ($x < 3$ mm) depending on the particle size of feed material.

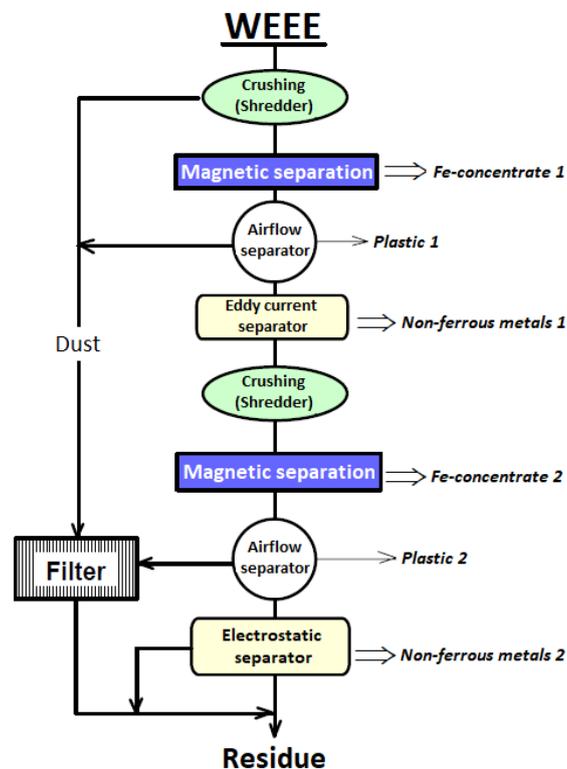

Fig. 2. The flowsheet of typical mechanical preparation technology for WEEE (Csóke, 2016).

3. NIR separation technique for WEEE

The samples are illuminated by a constant light source and either detect a camera reflecting from the sample. The analogue signal captured by the camera placed above the conveyor is proportional to the wavelength of the beam of light. The selection is provided with two air jet nozzles, so there are three products at the same time for the sorting device. In the arrangement shown in Figure 3.

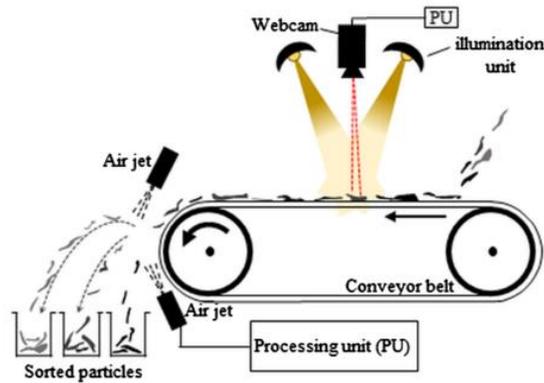

Fig. 3. NIR separator (Gundupalli et al., 2017)

4. Alternative separation techniques for WEEE

4.1. Sorting equipment with eddy current sensors

In this type of separator – like the eddy current separators – eddy current induced in the particles due to a transmitter coil, but this Lorentz force is weaker than the ordinary eddy current separators. In this case, when the transmitter coil induces the eddy current, the electromagnetic sensor (EMS) detects the electrical conductivity of the various non-magnetic metals. After identification, the particles spill out by an air jet from the nozzles. (Figure 4).

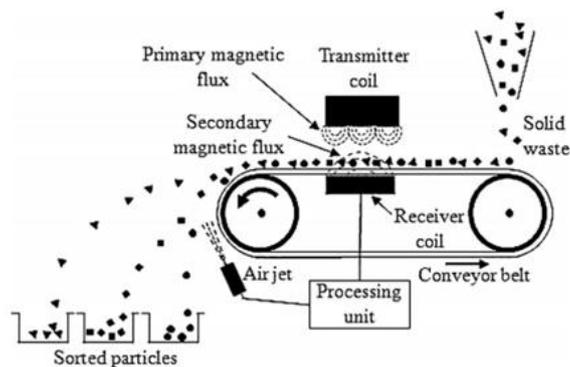

Fig. 4. EMS sensor-based separator (Gundupalli et al., 2017)

4.2. Laser induced plasma spectroscopy

Laser-induced breakdown spectroscopy (LIBS) uses a high-energy laser beam. In 1990, the technology was developed at the Los Alamos National Laboratory, in collaboration with Metallgesellschaft, to identify metal waste. The LIBS system produces a large spectrometry of metal alloys, plastics and treated wood. Advanced atomic spectrometry technique based on optical emission monitoring of a microplasma generated by laser ablation. That is a very short-lived, time-varying temperature and composition source, it is necessary to synchronize with a laser at time with the precision of μs fraction to operate the high-resolution spectrometer that can capture the entire UV and / or visible spectral range simultaneously (Figure 5).

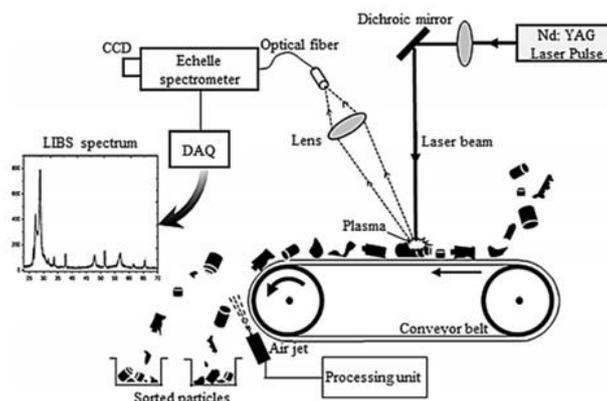

Fig. 5. The LIBS Separator (Gundupalli et al., 2017)

4.3. X-ray separators

Two versions of X-ray separators are known. Thanks to the X-ray transmission system, image processing takes place quickly, in a few milliseconds. During operation, a high-intensity X-ray passes through the material, absorbing some of its energy, while the rest of the weakened X-ray is a tape detector. The atomic density can be determined from the information (Figure 6).

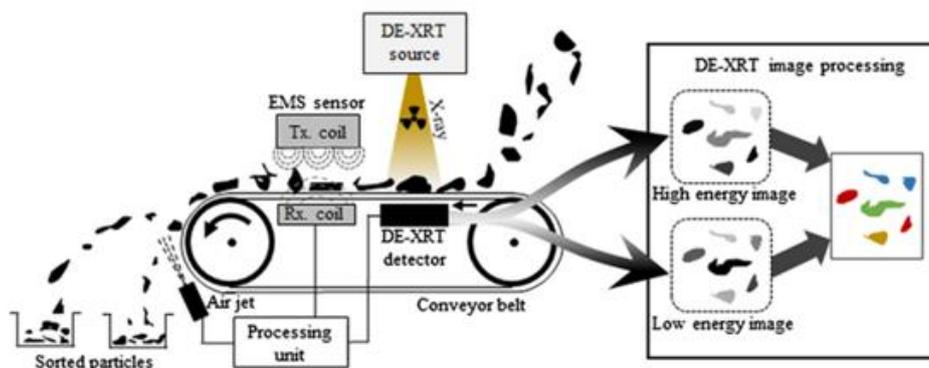

Fig. 6. XRT Sensory X-ray Separator (Gundupalli et al., 2017)

An X-ray fluorescence spectroscopy (XRF - X-ray fluorescence) ionizes the examined sample of electrons on a continuous spectrum X-ray. The kinetic energy of the leaving electron will be the difference between the photon and the electron binding energy.

Nitrite content in the samples collected from in land surface waters in Gradinari village

Petcov Andreea Adriana^{a*}, Camen Dorin^a, Moatăr Mihaela^a, Petolescu Cerasela^a, Turc Alina^a, Sasu Andreia^a

^aBanat's University of Agricultural Sciences and Veterinary Medicine „King Michael I of Romania” from Timișoara, Romania

Abstract

Water is one of the three vital elements needed for humanity by air and food, but we often overlook its importance (Zăvoianu, 2005). Water pollution is a topical issue with an important impact on ecological balances (<http://www.mmediu.ro>). Surface water comes from atmospheric precipitation, snow melting and springs, depending on the incline of the soil and the relief. (www.arin.ro) Normally, the water contains small amounts of nitrates. These result from mineralization of organic matter in water. (NIHWM).

The origin of nitrates can be highly mineralized soil and rich in nitrogen, soil pollution with organic residues. (this is also the most common way of water pollution with nitrites) (<http://www.scientia.ro>)

For the studies done in Gradinari village, Caras - Severin county, were collected water samples at a depth of 9, 10, 12 meters from the well. The harvesting was carried out both in winter and summer (October, December, February, May, July). For the values obtained from the analyzes carried out on the samples taken, the nitrite content in no case exceeded the maximum permitted limit of 0,50 mg/l.

Keywords: water, pollution, nitrite

1. Introduction

The assessment of the surface water quality consists in the measurement of the physico-chemical, biological and bacteriological parameters, on the control sections, establishing the way the standard norms are observed (Josan N, 2002). Surface water differs according to many characteristics: the flow and its variations (to the flowing), the temperature, the concentration and nature of the dissolved or suspended substances, the biological and microbiological content, etc., each mass of liquid water with its bedding and the living creatures being a distinct ecosystem (Alexa E., 2005). Surface waters have many common characters: unlike underground ones, they are typically less mineralized, richer in biological elements, more influenced by other factors (natural and anthropic), more easily polluting, less stable in features, but also have higher capabilities to auto maintain their quality. Comoraste village, has no centralized water supply system.

The water supply of the inhabitants is made from wells, the level of water from the fountains varies from 0.70 m to 14 m, depending on the area (Botoș and Lăzureanu, 2009).

Considering that Ciornovăț river is not a possible source of drinking water, and from deep drilling can not provide drinking water, the water being sandy clay (Luca and Tărău, 2002).

Not any unpolluted human anthropic water is usable for human consumption, and there is no "standard" natural water to treat as natural pollutants, although the anthropocentric conception has made such a term relevant only for water use to man and not to the understanding of water as a whole (Cuc, 2006).

However, in almost all waters there is life that has adapted to those conditions. The same can not be said about waters with human-modified qualities (Vișan et al., 2000).

* Corresponding author. Tel.: +4-0744218842.
E-mail address: andreeazun@yahoo.com

2. Materials and methods

The sampling point studied and noted with Gradinari (Fig.1), is a private property fountain in the Caras - Severin county, located in close proximity (about 150 m) of a zootechnical farm. The working technique is based on legislation that measures the ability of substances to absorb or emit light energy at a characteristic wavelength. From a qualitative point of view, the positions of the absorption or emission lines and streams appearing in the electromagnetic spectrum indicate the presence of a certain substance. From a quantitative point of view, the intensity of the emission or absorption bands or tapes is measured for both standards and samples, then the concentration of the analytes.

An important fact to be mentioned and which underpinned the research at this location is that although there is a water supply network in the Gradinari, 70% of the locals use the water from their own fountains.

The water analyzes consisted in sampling groundwater samples from the fountain of Gradinari locality of Caras - Severin, at depths of 9 m, 10 m and 12 m.

The analyzes performed were those of the nitrite content and the steps taken to obtain the experimental results are as follows:

- Sampling
- Preparation of samples for analysis.
- The proper analysis.
- Calculation and expression of results.

For surface sources, water analysis is carried out by harvesting it 2 - 4 times a year during the most critical periods of pollution, namely at minimum winter and lowest summer temperatures (the highest temperatures) and maximum spring and / or autumn flows (after rain or snow melting). The tests used are SPECTROQUANT NITRIT 14776. (AquaMerck)

Conservation of water samples is another important aspect of the harvesting process, it is a concern to preserve samples for analysis because water analysis is of limited value if the samples have undergone physical, chemical or biological changes during transport or storage.

It is generally advisable to pass a very short time - up to 4 hours - between sampling and analysis of water samples. Preserved samples should be kept at 6 ° - 10 ° C. The water sample vials were transported in isothermal packaging to keep them from being hit.

Fig. 1. Sample collecting point at Gradinari location

3. Results and discussions

For the determination of nitrite content in surface waters, samples from the same water sources were collected at the indicated depths.

The content of nitrites in the surface waters analyzed in Gradinari village ranges from 0.43 mg/l to 0.48 mg/l.

As a result of the analyzes carried out there was no exceedance of the allowed nitrite level below this threshold 0,50 mg/l at Gradinari I, Gradinari II and Gradinari III; but the concentration of nitrite in water is quite high 0.48 mg/l Gradinari I in May month, to the depth of 9 m, respectively 0.48 mg /l Gradinari III in October month, to the depth of 12m, below the maximum admissible limit (Table 1 and Fig. 2)

Table 1. Nitrite content in the samples collected from in land surface waters in Gradinari village

Crt. No.	Village/ depth of harvesting	Month				
		October	December	February	May	July
		mg/l				
1	Grădinari I – 9 m	0.47	0.46	0.45	0.48	0.42
2	Grădinari II – 10 m	0.42	0.39	0.32	0.41	0.43
3	Grădinari III – 12 m	0.48	0.30	0.32	0.39	0.40

*LMA 0.50 mg/l

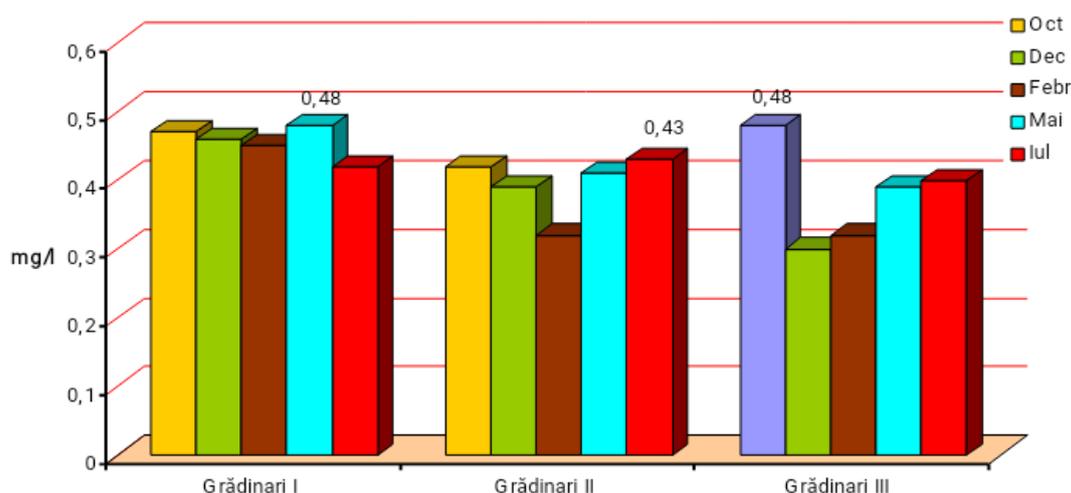

Fig. 2. Representation of nitrite content in the samples collected from inland surface waters in Gradinari village

Nitrite occurs in soils often only in low traces. Forms during nitrification from ammonia or ammonia but is immediately oxidized to nitrate. Microbial degradation processes are formed at different intermediate ammonium stages (ammonification). Water quality does not remain constant over time, but may vary due to many factors, either man-produced (human factors) or natural (which is obviously contributing to human action).

4. Conclusions

Harmful are in fact nitrites that result from nitrates under certain conditions, where nitrates are reduced to nitrite generating secondary nitrate toxicity.

Chemical compounds of nitric oxide - NO_3 - have a very high incidence in nature. They are present in the soil, in standing or flowing water, in the chemical composition of various plant or animal components, and even in meteoric water.

A cause of exceeding the maximum permitted nitrite limit would have been due to intensive farming through the use of significant amounts of nitrogen-based fertilizers over the years, as well as amendments from fertilizer plants. All of this would have contributed to the increase in nitrite content in surface waters.

As a general conclusion it can be stated that, as a result of the researches carried out for 5 months, it is that in the surface water from the analyzed fountain, it is not polluted with nitrites, being in accordance with the European requirements, it does not exceed the maximum admissible limit of 0.50 mg/l.

The use of the analyzed water drill at Gradinari collection point, Caras-Severin, is recommended to be monitored due to the presence of a content close to the maximum admissible limit.

Pollution with nitrites and not only surface waters occurs through the influence of several factors among which we mention a part of them:

- the passage of water through areas of soluble rock - natural sodium chloride, sulphates, sulphites, carbonates, bicarbonates, which makes the shallow surface or groundwater load with higher or lower amounts of such salts, in relation to the concentration of rocks in such salts and the distance traveled by the water in the leaching process
- the passage of surface water through areas with soil erosion processes - this process causes the water, with a meteoric initial source, to pass through the impurities and various materials that enter into suspension in water and which causes the content of these waters to increase in the nitrite compounds.
- the development of hydrophilic and aquatic vegetation - this type of vegetation can create pollution phenomena especially in stagnant or slow-flowing waters. The intensity of water contamination processes is strongly dependent on the length of the vegetation period and on the rhythm of the metabolic processes of the plants.

Challenges and opportunities associated with waste recycling development in Romania

Lucian-Ionel Cioca ^a, Larisa Ivascu ^{b*}, Szilard Szekely ^a

^aLucian Blaga University of Sibiu, Department of Industrial Engineering and Management, Faculty of Engineering, Bd. Victoriei No. 10, 550024 Sibiu, Romania;

^bPolitehnica University of Timisoara, Departament of Management, Faculty of Management in Production and Transportation, Victoria Square No. 2, Timisoara 300006, Romania

Abstract

European Union (EU) policies are regularly targeting a number of actions on reducing municipal waste and increasing its recycling rate. From this perspective, the situation in Romania is not a favorable one and requires measures for improvement. The recycling rate of Romania is well below the EU average. For Romania, in 2017, the recycling rate was 14.5%, and at for the EU it was 46.9%. This paper aims to assess Romania's capacity to increase its recycling rate. It also presents the EU situation. At the end of the evaluation, a conceptual framework of challenges and opportunities is proposed in order to reach the EU objective of recycling policies. Finally, the findings of this study are advancing the specialized literature by the radiography made in this field of waste management. At the end of the paper, the main conclusions of the study and future research directions are presented.

Keywords: waste management; strategy; recycling; reuse; policy.

1. Introduction

The UN's 2030 Agenda for Sustainable Development offers a new global framework that contributes to poverty reduction, combating inequalities and combating climate change. Sustainable development also takes into account occupational hazards (Babut and Moraru, 2018). The agenda includes 17 objectives and their related 169 targets. Since 1990, the EU has introduced policies and targets on waste. These include a series of strategies that pursue the goals of sustainable development. Since 2005, the Thematic Strategy on the Prevention and Recycling of Waste (EC, 2017) and framework legislation such as the Waste Framework Directive (EC, 2017) sets the target for 50% of municipal waste to be prepared for reuse and recycled in EU member states. In 2015, the European Commission publishes the document "Closing the Loop - An EU action plan for the circular economy (EC, 2017) (or Circular Economy Package)". This document sets out a number of new objectives. A first objective is to reach the recycling rate of 55% by 2025. Municipal waste includes household waste and other refuse, which, by nature or composition, are similar to household waste (Ministry of Environment, GD no 349/2005, 2017).

Waste is a major problem in Romania. The country's waste generation rate is on the rise. This increase is due to the degree of urbanization, industrialization and population behavior. Faulty waste management can cause adverse effects on the environment, risk to public health, excessive environmental pollution and other economic and social problems. In EU, waste management shows an improved situation, superior to the situation in Romania. There are a number of regulations and norms that guide EU member states in enhancing waste management (NIS, 2018).

The Environment Committee within the European Parliament approved this year a set of new regulations which oblige EU member states to increase the recycling percentage and encourage producers and consumers to reuse valuable materials imbedded in wastes. This new set of rules establish legally mandatory targets for waste recycling and the reduction of land filling that have fixed deadlines (Antonopoulos et al., 2014).

* Corresponding author. E-mail address: larisa.ivascu@upt.ro

The paper presents an overview of the current state of waste management and recycling management. Starting from the existing situation in Romania and in line with the EU objectives and measures, the paper identifies the challenges and opportunities associated with waste recycling development in Romania. The results of this research can help the competent authorities responsible for urban solid waste management, contracting companies and researchers to develop new opportunities and strategies to improve the situation.

2. Waste management: system quality and new EU rules

In Europe, the amount of municipal waste that is recycled has steadily increased as a result of investment in the collection, proper handling of financial incentives to move away from waste disposal and the banning of landfills in the member states. The performance of EU member states with regard to municipal waste recycling varies, due to multiple factors (economic power, technological innovation capacity, population density and so on). The Circular Economy Package (EC, 2017) contains a number of objectives and measures to be achieved. Among these are:

- Increase the recycling and reuse rate to 65% by 2030 for municipal waste;
- Increase recycling and reuse rate to 75% by 2030 for packaging waste;
- Reduction of landfills up to 10% of municipal waste by 2030;
- Prohibiting the storage of separately collected waste;
- Promoting and implementing economic instruments to deter storage at the level of each country;
- Develop simplified definitions and harmonized calculation methods for recycling rates for all EU member countries;
- Promoting the principles of the circular economy by developing concrete measures to promote the re-use and stimulation of industrial symbiosis - transforming the by-product of an industry into a raw material;
- Launching incentives for producers. Manufacturers should market organic products and support recovery and recycling systems (e.g. packaging, batteries, electrical and electronic equipment and vehicles).

In EU, the targets set by “Closing the loop — An EU action plan for the circular economy” on increasing the recycling rate are being pursued. “Waste recycling is defined as any recovery operation by which the waste is reprocessed in products, materials or substances, either for original purposes or for other purposes. This includes reprocessing of organic materials (e.g. by composting or digestion), but does not include the recovery and recycling of energy in materials to be used as fuels or for filling operations ”(EC, 2017).

The quantity of waste generated in the EU in the period 2012-2017 is presented in Figure 1. The amount of waste is increasing, hence the objectives.

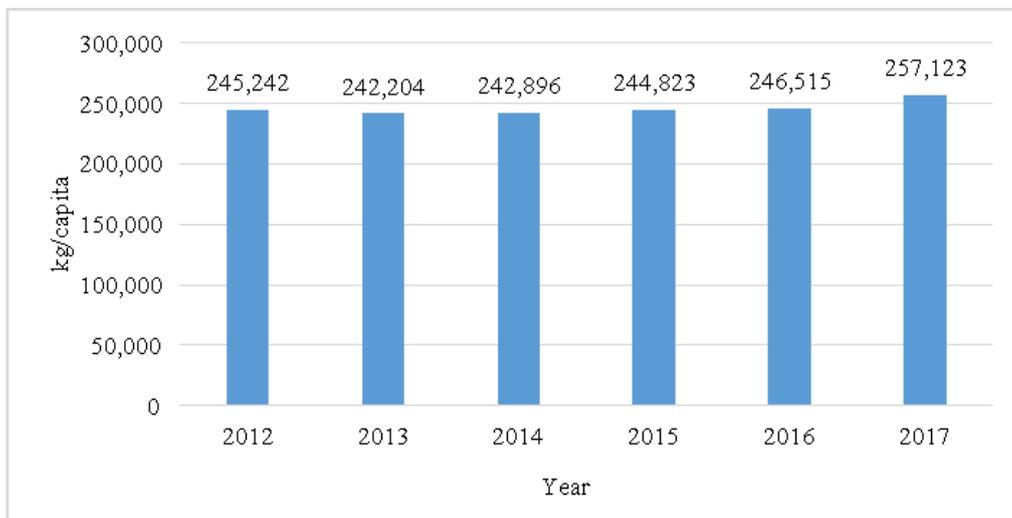

Fig. 1. The amount of waste generated per capita in EU (kilogram/capita) (EC, 2017)

Depending on the method applied to municipal waste, the situation in the EU is presented in Figure 2. It can be noticed that the overall rate of recycling (material recycling, composting and digestion) is increasing, in 2012 it was 41.5%, and in 2017 it was 46.9%. This improvement in recycling rate is a combination of a reduction in the amount of municipal waste generated and the increase in the total recycled, composting and digestive amount (Karak et al., 2014). This growth is considered a success for environmental policy in Europe from 1990 to the present.

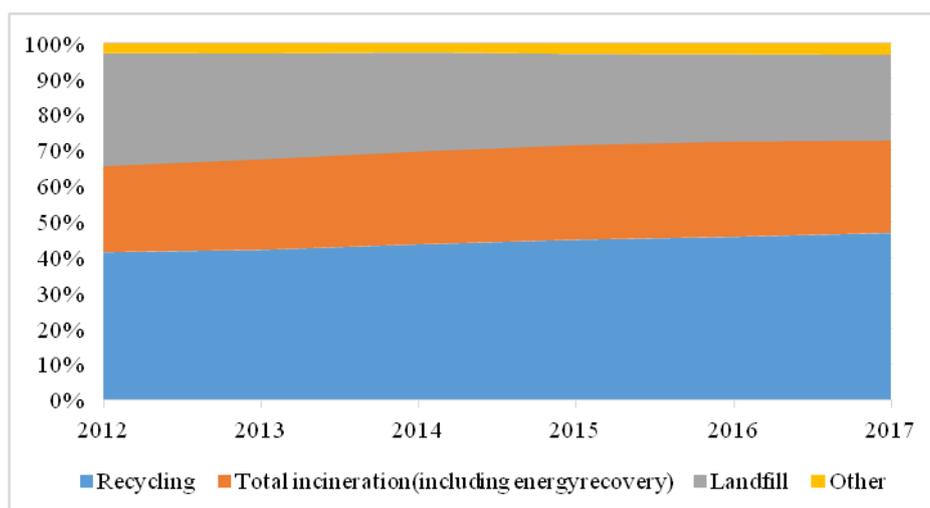

Fig. 2. Share of treatment methods of municipal waste (EC, 2017)

Municipal waste is covered by EU rules and regulations to be reduced (Pires et. al., 2011). Recycling rates for 2012-2017 are shown in Table 1. It can be seen that the recycling rate has increased annually. This recycling rate is expected to increase annually so that in 2025 it will reach 60%. From the perspective of the municipal waste recycling rate, for EU the situation of the rate increase targets is presented in Table 2. It can be seen that the recycling rate is expected to increase by following the objectives of sustainable development (17 Global Goals for Sustainable Development).

Table 1. Municipal waste recycling rate in the period 2012-2017 in the EU

Year	2012	2013	2014	2015	2016	2017
Recycling rate (%)	41.5	42.5	43.6	45	45.8	46.9

Table 2. Recycling targets for municipal waste

Year	By 2025	By 2030	By 2035
Percentage of recycling (%)	60	65	70

2.1. The situation in Romania

In Romania, the competent decision-making and controlling authority in the field of waste management is the Ministry of Environment. Municipal waste includes household waste, industrial and institutional waste, commercial waste, street waste, park and garden waste, waste from urban water purification and construction and demolition waste (Rada et al., 2017). Waste management in Romania includes the following municipal waste management infrastructure (Ministry of Environment, 2017): 51 transfer stations; 101 sorting facilities with a total capacity of approx. 2,431,420 tons / year; 22 composting plants with a total capacity of approx. 180,000 tons / year; 3 mecano-biological treatment plants with a total capacity of 117,000 tons / year; 35 warehouses with a total built-up capacity of 48.1 million tons and 15 non-compliant warehouses with assisted activity in 2016 or 2017. Out of the 101 sorting facilities only 93 are sorting facilities, the remaining 8 having authorized sorting waste from the pile. The 93 screening plants have the following sorting capacity, Table 3:

Table 3. Capacity of sorting facilities in Romania

Capacity of sorting installations	Capacity of installations
93 are sorting equipment installations in Romania	34 plants have a total capacity of about 200,000 tons / year and sort recyclable waste collected separately;
	34 plants have a total capacity of about 700,000 tons / year and sort municipal waste collected in the mix;
	25 plants have a total capacity of about 1,381,420 tons / year and sort separately collected recyclable waste and municipal waste collected in the mix.

More than 45 sorting stations are currently being implemented and their number will be close to 150 nationally. Most are funded through environmental programs. The composting stations are continually developing. New composting facilities are being built and their number is close to 45. New mechanical-biological treatment plants are being developed including an additional 14 (MM, 2018). The total capacity of mechanical and biological treatment facilities is 1,459,000 tons / year. The amount of waste generated per capita is shown in Figure 3. It is noticed that during the period 2012-2015, the amount of waste is decreasing, followed by an increase during the period 2016-2017. This evolution of waste is due to the industrialization and increase of the socio-economic level.

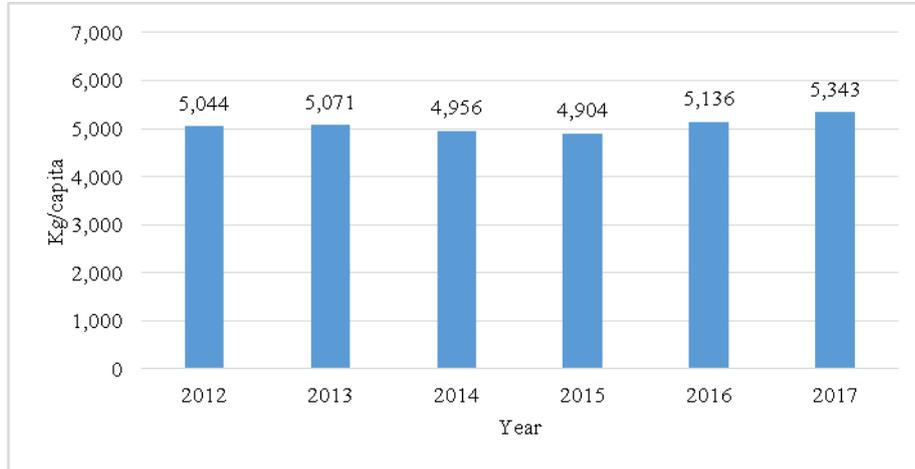

Fig. 3. The amount of waste generated per capita in Romania (kilogram/capita) (NIS, 2017)

In Romania, the recycling rate of municipal waste is well below the average recorded at the EU level. This rate is shown in Table 4. It is noticed that starting with 2012, the recycling rate is on the rise. This growth is slow, succeeding in 2017 to reach the level of 14.5%

Table 4. Recycling rate of municipal waste in the period 2012-2017 in Romania (NIS, 2017)

Year	2012	2013	2014	2015	2016	2017
Recycling rate (%)	12.8	13.2	13.1	13.2	13.3	14.5

Effective municipal waste management at national level is achieved through collection operators and treatment operators.

3. Strategic framework for municipal waste management in Romania

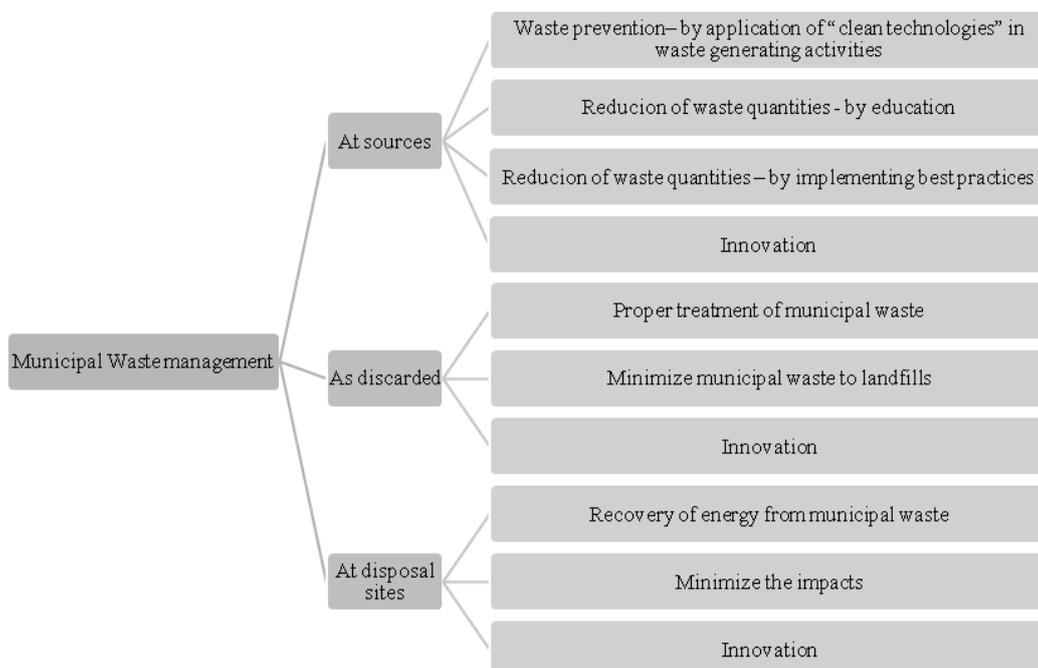

Fig. 4. Strategic framework proposed to improve the current situation in Romania

The situation in Romania needs to be improved to meet the EU's waste management levels. From this perspective, proposing a strategic framework and activities is important. Figure 4 shows a strategic framework taking into account the three directions: at sources, as discarded, and at disposal sites.

The actions to be implemented to increase the quality of the waste management system are related to the existing infrastructure, the human resource involved in waste management activities, and the population. The general strategic objectives for waste management are (Ministry of Environment, 2018):

- Legislative policies and applicable norms - streamlining their application, integrating legislative requirements with economic environmental norms, harmonizing national norms with European norms. Harmonizing and developing national requirements in harmony with European ones.
- Human Resources - Professional training of human resources in accordance with national and European requirements.
- Enhance financial management - reduce costs and apply the "polluter pays"
- Promoting and informing people and agents about the current state of waste management and EU rules and objectives.
- Integrated system - implementation of integrated IT systems for real-time, complete and relevant situations. These situations can be used in future decisions.
- Preventing waste generation - awareness and training of the population on reducing the amount of waste generated.
- Waste recovery - exploring technological and economic opportunities for waste recovery.
- Efficiency of waste collection and transport - the use of innovative and sustainable systems.
- Waste treatment - using waste treatment to ensure rational environmental management.
- Storage - reducing the amount of waste stored to protect the health of the population and the environment.
- Research and development - encouraging and supporting waste management applications to identify the most innovative techniques and methods that are applicable at national level.

4. Summary of findings

Assessing the research, we can conclude on the following aspects regarding Romania's capacity to comply with EU waste recycling requirements:

- Investing in innovation to increase the technology rate of this sector;
- EU objectives and rules follow the 17 sustainable development objectives and related measures;
- EU objectives and norms are moving towards increasing recycling rates;
- The recycling rate in Romania is 14.5% below the EU level of 46.9%;
- Selective collection infrastructure complies with European provisions, but needs to be improved;
- The selection infrastructure must be expanded so that the recycling rate can increase;
- The amount of waste / capita may grow annually as a result of industrialization and socio-economic stability;
- Efforts to reduce environmental pollution should be sustained and implemented at the level of each EU country.

Conclusions

At national level, waste management activities are carried out on the basis of the following principles: the principle of primary resource protection, the precautionary principle related to the use of 'best available techniques not entailing excessive costs – BATNEEC', the prevention of generation, the 'polluter pays' principle correlated with the principle of producer responsibility and user responsibility, the principle of substitution, the principle of proximity correlated with the principle of autonomy and the principle of subsidiarity. Romania's recycling level is well below the EU level, so the current rules and provisions should be revised. The degree of innovation can be improved, and information and education of the population could be solutions for increasing the recycling rate.

Abstract

In the current context of global warming and increased frequency and intensity of severe weather episodes, acute need for sustainable development of the socio-economic environment involving all decision makers is needed. The companies that constitute the pyramid base of the economy must implement policies related to planning, control, assurance and improvement of quality. Air quality is part of total quality management. Monitoring and assessing pollutant emissions are the essential steps for continuously air quality improvement. The purpose of this paper is to analyse emissions of heavy metals (lead, cadmium and mercury) for the period 2003-2016 from the Hunedoara County territory in relation to causes that accentuate or diminish their daily, monthly and annual concentration values. The analysis was based on data provided by the Hunedoara Environmental Protection Agency (APM HD) and the European Environment Agency (EEA). The paper ends with the authors' conclusions based on the monitoring and assessing of heavy metal emissions as part of air quality management.

Keywords: Total Quality Management, emissions, heavy metals, atmosphere, Hunedoara County

1. Introduction

The territory of Hunedoara County is situated in the western part of Romania, being a diverse and harmonious geographic entity, being crossed by the Mureș River and its tributaries in the middle, having the southern upper Jiu River, and the north - the upper basin of Crisul Alb making the link between the western counties of Caraș-Severin, Timiș, Arad and Transylvania in the center of the country (Alba, Sibiu), as well as the counties in the south of the country (Gorj and Vâlcea). The administrative-territorial unit of Hunedoara County comprises 7 municipalities, 7 towns, 55 communes and 457 villages with a population of approximately 460,000 inhabitants.

The problems of environmental quality control have been set after mankind has undergone a brief evolution (on a geological scale) has multiplied (often at small intervals, the population has doubled), occupied in one form or another the whole surface of the planet, profoundly, affected or transformed the natural ecosystems and caused an unknown scare until then: pollution (Căpușneanu et.al., 2015). Industrial pollution addresses the problem of pollution from the workplace to the environmental consequences of the entire earth globe. Industrial pollution of the environment is generally spread by air and water. For the air pollution, both the electricity industry, the gases exhausted by the thermal power plants in the atmosphere, as well as the industrial branches, such as: *the chemical industry and building materials, and especially the ferrous and non-ferrous metallurgy, are to blame*. The most important step in increasing the quality of the environment is the elimination of products that use excess energy and natural products or contain dangerous substances or releases harmful emissions (Constantinescu (Oprea) et. al., 2013).

Thus, there is a need to have a system for monitoring the quality of the environment irrespective of the scale to which it refers or the number of components it encompasses in order to provide an objective image as close as possible to the reality of the environment for adopting correct pollution control and restoration. Being an activity that underpins

^{*} Corresponding author: tel: 0721 277 820
E-mail address: nihilsinedeo_68@yahoo.com

environmental policies and strategies, monitoring environmental quality requires an organization that takes into account both the complexity of the environment as a global system and the institutional structures that are responsible for it.

Data related to the state and the quality of the environment can be provided by country of different types of organizations, but above all by the National Environmental Protection Agency. The issue of air quality is a major concern for many European citizens and the institutions of the European Union.

2. Potential sources of air pollution in Hunedoara County

In Hunedoara County, the potential sources of air pollution are primarily the units for the production of electric and thermal energy, and in a second plan the steel plants, the units for the production of the building materials and the transports etc. The heavy metals emissions in Hunedoara County, according to the inventory of the agency, consist of mercury, cadmium, arsenic, chromium, copper, nickel, selenium, zinc and lead, and attention was paid to mercury, cadmium and lead. In the region, air quality is influenced by the technological processes of the mining industry and the former Hunedoara Steel Plant, currently S.C. ArcelorMittal S.A. Hunedoara, a company that produces tile for pipes, heavy, medium and light profiles, concrete steel, wire and special profiles for mining (<http://www.arcelormittalhunedoara.ro>). The main sources of pollution in Hunedoara County are presented in table 1.

Table 1. Major air pollution sources in Hunedoara County

Crt No	Source of pollution	Activity	The resulting atmospheric pollutants
1	S.C. Termoelectrica S.A. - S.E. Paroşeni S.C. Electrocentrale S.A. Deva S.C. Acvacalor S.A. Brad	Combustion plant with a rated output exceeding 20 MW	SO ₂ , NO _x , powder, CO ₂ , CO
2	S.C. ArcelorMittal S.A. Hunedoara	Installations for the production of steels for continuous casting with a capacity of over 2.5 t / h	SO ₂ , NO _x , powder, CO ₂ , CO
3	S.C. Carpatcement Holding S.A. Sucursala Deva	Installation for the production of cement clinker in rotary kilns with a production capacity exceeding 500 t / day	SO ₂ , NO _x , powder, CO
4	S.C. ArcelorMittal S.A. Hunedoara* * The installation for the production of lime and dolomite was closed on 27.10.2007	Installation for the production of lime and dolomite in rotary kilns with a production capacity exceeding 50 t / day	SO ₂ , NO _x , powder
5	S.C. Carmeuse Holding S.R.L. – Point of work in Chişcădaga	Installation for the production of lime with a capacity of over 50 t / day	powder, CO, CO ₂
6	S.C. Refraceram S.R.L. Baru	Installation for the production of bricks, refractory bricks with a capacity exceeding 4 m ³ and a density of more than 300 kg/m ³	powder, CO, CO ₂
7		Traffic	SO ₂ , NO _x , CO ₂ , CO

Source: own projection

Table 2 shows the major sources of air pollution, units under IPPC legislation, as well as greenhouse gases and pollutants emitted in the atmosphere, specific to them.

In Hunedoara County, industrial activities that have a significant impact on air quality are specific to some economic branches with tradition in the area: mining, iron and power generation (thermal and electrical) (<http://www.anpm.ro>). Mining activities for construction and the cement industry were exploited in quarries located in mining perimeters, on the basis of licenses and exploitation permits. The impact of mining mass activities is manifested by borehole work, sorting activities in sorting facilities, and dumping of tailings on heaps located outside the perimeter with reserves. The steel industry at the level of Hunedoara County was represented during the period 2003 - 2016 by the activities carried out within SC ArceloMittal Hunedoara SA.

The energy industry is represented by S.C. Energy Complex Hunedoara S.A. consisting of: The Mintia Workstation and the Paros Electric Power Plant, resulting in powder (fly ash) having local effects on the environment, through SO₂ and NO_x emissions that contribute to the formation of “acid rain” with regional action and emissions CO₂ that contributes to the “greenhouse effect” increase. Emissions of CO, CO₂, N₂O, NO_x affect the ozone layer.

The pollution of the atmosphere with suspended particles has many sources: first industrial processes, the most important quantity coming from metallurgy and steel, followed by solid fuels, cement factories, road transport, dumps and tailings (Law no. 278/2013). Characteristic for Hunedoara County are mainly tailings dumps and tailings ponds, whose particles are driven by wind over distances of tens of kilometres.

Transport is another factor contributing to air pollution with combustion products: *soot, carbon dioxide, hydrocarbons, lead.*

In order to create an integrative picture of the current environmental conditions, we will present the values of the main indicators related to a month with a high degree of pollution (i.e. August) and the average annual values. These values are compared with the limit values and the alert threshold according to the criteria of Law 104/2011 on ambient air quality (Table 2).

Table 2. The limits for the protection of human health provided by Law no. 104/2011 on ambient air quality

Pollutant	Criterion	Mediation period	Value	Measure Unit	Number of allowed annual exceedances (if any)
Suspended particles, M ₁₀	Limit value	one day	50	µg/m ³	35
	Limit value	calendar year	40	µg/m ³	It's not necessary
Plumb Lead, Pb	Limit value	calendar year	0.5	µg/m ³	It's not necessary
Cadmium, Cd	Limit value	calendar year	5	ng/mc	It's not necessary
Mercury, Hg	Limit value	one day	50	mg/m ³	It's not necessary

Source: own projection

The Hunedoara Environmental Protection Agency is responsible for the annual inventory of emissions of air pollutants - emissions from both fixed sources such as energy burning and transformation industries, non-industrial combustion plants, burning in the processing industry, production processes, extraction and the distribution of fossil fuels and other products, waste treatment and disposal, agriculture, forestry, etc., as well as from mobile sources such as road transport, other mobile sources and machinery. Thus, in Hunedoara County, the Hunedoara Environmental Protection Agency operates five automatic air quality monitoring stations included in the National Air Quality Monitoring Network. They are located in Deva, Hunedoara, Călan, Vulcan.

Consequently, the urban station monitors the indicators: NO_x/NO₂, SO₂, CO, O₃, VOC, PM10, Pb, and the industrial base stations monitor the NO_x/NO₂, SO₂, CO, O₃, PM10, Pb indicators. The values resulting from the measurements corresponded to the tolerance limits established by the Law no. 104/2011

Heavy metals (mercury, lead, cadmium, etc.) are compounds that cannot be degraded naturally with a long retention time in the environment and are dangerous in the long run because they can accumulate in the food chain. These can cause muscular, nerve, digestive disorders, general apathy.

In Hunedoara County, the total area affected by industrial activities is over 10,000 ha. These branches of activity generate waste requiring final disposal and municipal waste disposal is carried out on sites that do not currently meet the environmental protection requirements.

3. The main traits of pollutants - heavy metals: cadmium, lead, and mercury (Cd, Pb, Hg)

There are 35 metals that are present in the workplace as well as in dwellings. Of the 35 metals, 23 metals are considered heavy, such as antimony, arsenic, bismuth, cadmium, cerium, chromium, cobalt, copper, gallium, gold, iron, platinum, silver, tellurium, thallium, tin, uranium, vanadium and zinc. The study has focused on three elements, namely cadmium, mercury and lead.

The main features of **cadmium**: in nature is found as combinations (CdS) in zinc ores; is highly toxic; they are used in alloys to increase the resistance of metals to corrosion agents, especially seawater; the most important source of cadmium contamination is industry, notably the non-ferrous metals industry and the combustion of fuels; is a strong enzyme inhibitor, especially with sulphuric enzymes.

Main features of **mercury (Hg)**: is one of the metals known since antiquity, being known as silver; the classical method for the preparation of mercury consists in roasting the cinnabar in the oven at 600-700 °C, in the presence of air when the metal SO₂ results (since the resultant mercury oxide is thermally unstable):

followed by cooling the mercury vapour in water-cooled sandstone condensers.

Sometimes, especially in the case of small-scale mining, the cinnabar is heated in the oven at 600-700°C, either with lime:

either with iron crunch:

is used in some electrolysis cells as a mercury cathode, in the extraction of gold and silver in various precision instruments and apparatus such as: thermometers, barometers, manometers, densitometers, high vacuum pumps, etc., in

the preparation of medicinal ointments, preparation of mercury fulminate, cinnabar, in AC rectifiers, ultraviolet lamps, amalgam preparation; in pure form, but also in compounds it is very toxic, and ingestion or inhalation can ultimately lead to respiratory arrest and death.

Main features of **lead (Pb)**: it has toxic effects; known and used since ancient times, lead, has constituted and is a major environmental pollutant; its accumulation in large quantities in soil as a result of pollution results in passive absorption in plants; is toxic to the brain, kidney, reproductive system and cardiovascular system; exposure to lead causes disturbances of the intellectual function, which is especially dangerous for children.

Pollution of the atmosphere with suspended particles has many sources: first industrial processes, the most important quantity coming from metallurgy and steel, followed by solid fuels, cement factories, road transport, dumps and tailings. Characteristic of Hunedoara County are mainly tailings dumps and tailings ponds, whose particles are driven by wind over distances of tens of kilometres.

4. Results based on analysis of environmental quality pollution factors with Cd, Hg and Pb

The contribution of energy activity sectors to heavy metal emissions in Hunedoara County for the period 2003 - 2016 is summarized in figure no. 1.

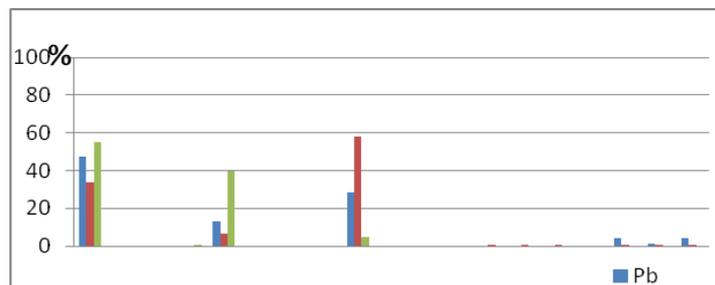

Fig. 1. Contributions of energy activity sectors to heavy metal emissions in Hunedoara County (Source: environmental reports 2003-2016, APM Hunedoara)

From the distribution of heavy metals emissions by sectors of activity it can be noticed that: the largest share of lead emissions comes from the production of electricity and heat (47.29%) and from residential heating (28.53%); the largest share of cadmium emissions comes from residential heating (57.85%), followed by the production of electricity and heat (33.55%); the largest share of mercury emissions comes from the production of electric and thermal energy (55.05%) and from combustion in industry (39.54%).

The contribution of the activity sectors to heavy metal emissions (Pb, Cd and Hg) in Hunedoara County between 2003 and 2016 is summarized in Figure 2.

From the data shown, the highest share of Pb, Cd and Hg comes from the energy sector and the industry sector.

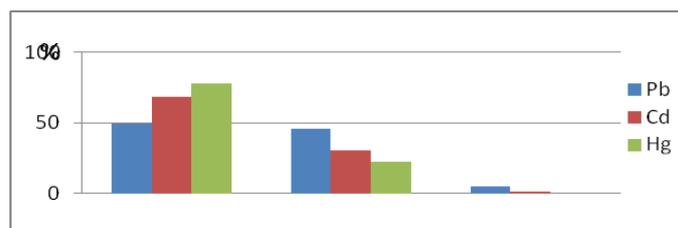

Fig. 2. Contribution of the activity sectors to heavy metal emissions in Hunedoara County (Source: environmental reports 2003-2016, APM Hunedoara)

The contribution of industry subsectors to metal emissions, at the level of Hunedoara County in 2016, is shown in Figure 3:

Fig. 3. Contribution of industry sectors to heavy metal emissions in Hunedoara County (Source: environmental reports 2003-2016, APM Hunedoara)

The share of heavy metal emissions in the industry subsectors, related to Hunedoara County, comes from the production of cast iron and steel. The contribution of transport vehicle types to heavy metal emissions (Pb, Cd), at the Hunedoara County level in the period 2003 - 2016, is presented in figure no. 4.

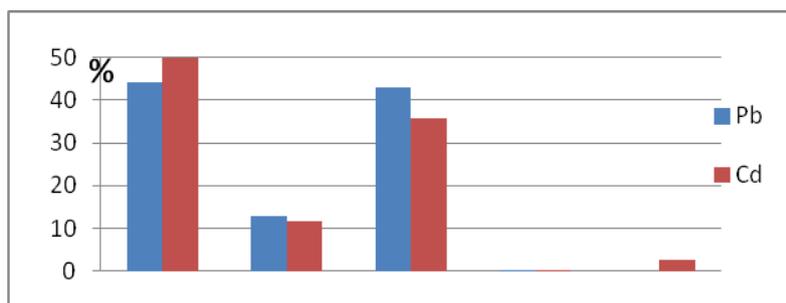

Fig. 4. The contribution of vehicle types to heavy metal emissions in Hunedoara County (Source: Environmental reports 2003-2016, APM Hunedoara)

The transport emissions of Pb come mainly from passenger cars (44.18%) and heavy vehicles (42.88%), the rest being: light vehicles (12.80%) and mopeds (0.14%). In the case of Cd, the highest contribution is given by cars (49.79%), followed by heavy vehicles and buses (35.75%), light vehicles (11.74%), railways (2.55%) and mopeds (0.17%).

Emissions of heavy metals in Hunedoara County, estimated between 2003 and 2016 by the CORINAIR and AP-42 methods, and as of 2009 according to the latest EMEP/EEA Air Pollutant Emission Inventory Guidebook in the table 3:

Table 3. Emissions of heavy metals (kg/year) between 2003 and 2010

Hunedoara County	Year							
	2003	2004	2005	2006	2007	2008	2009	2010
Mercury emissions	2248.92	407.36	180.54	252.59	330.16	300.24	133.47	111.26
Cadmium emissions	213.07	411.22	60.64	62.65	68.07	41.93	86.30	72.74
Emissions of lead	1164.38	7546.49	7035.94	3383.91	2697.17	2122.58	982.49	1841.03
Total emissions	3626.37	8365.07	7277.12	3699.15	3095.40	2464.75	1202.26	2025.03

Source: own projection

The above table shows a decrease in heavy metal emissions since 2009 compared to previous years, as this year was applied the CORINVENT 2009 calculation methodology that provides for different emission factors.

5. Conclusions

Air quality in Hunedoara County continues the general trend of improvement in recent years. Pollutant monitoring is a necessary part of any environmental management system, which is the basis of a fully-informed decision-making process and the development of environmental management strategies.

Since, at the level of Hunedoara County, the energy sector brings a significant contribution to the pollutant emissions, the rehabilitation of the energy blocks will lead to the reduction of atmospheric emissions. Supporting, enforcing and enforcing corrective measures leads to streamlining the control process, but also to the quality of environmental investments, including the performance of efficient management and the achievement of notable financial performance.

The level of emissions of pollutants released into the atmosphere can be significantly reduced through the implementation of environmental policies and strategies as follows: greater use of renewable energy sources (wind, solar, hydro, geothermal, biomass); replacing classic fuels with alternative fuels (biodiesel, ethanol); the use of high energy efficiency installations and equipment (low consumption, high yields); implementing a program for afforestation and creation of green spaces (CO₂ absorption, fine dust retention, oxygen release into the atmosphere). The objectives of the monitoring systems also include aspects related to process optimization, verification and compliance with legislative provisions, such as admissible emission limits. Many pollutants known to have effects on human health gradually fall under regulated control.

Abstract

The main topic of the study is to observe the impact of the quarry on the local climate, particularly on the temperature conditions in the quarry and its influence on a local precipitation in the surroundings. This influence is based on the assumption that the relief of quarry mining area together with thermal circumstances and weather conditions influences the formation of the thermal air currents. The temperatures in the quarry are monitored by temperature loggers. The temperature distribution on the mining quarry wall surface is measured by a thermal imager in various atmospheric conditions. The surface temperature and the wind vector, together with the relief of the quarry and surrounding landscape, are the input parameters for the numerical simulation of airflow, which allows us to visualize thermals.

Keywords: Quarry; local climate; CFD simulation; thermals.

1. Introduction

Every quarry and the impact of mining activities there cause a remarkable impact on the landscape and the surrounding environment. The location of the examined quarry in the landscape is shown in Fig. 1. There are various impacts connected with the mining area, for example blasting, transport of blasted material, development and distribution of dust particles, changes in hydrologic conditions and relief, the impact on fauna and flora in the surroundings, the impact on the local climate conditions etc. Defining and quantifying these impacts is a very complex problem.

The paper is focused on the determination of a possible impact of the quarry on the local climate conditions. The problem includes an analysis of temperature conditions and local precipitations in the given quarry and its surroundings. The presented research covered a continuous measurement of temperatures in the quarry by the temperature loggers. Their location in the quarry is shown by red marks in Fig. 1. The temperature distribution on the quarry surfaces was measured by a thermal imager in various atmospheric conditions.

Local precipitations in the quarry surroundings were measured by 22 rain gauges. Their location is shown by green marks in Fig. 1. One of the goals of the research is to find out if the local precipitations are influenced in various distances from the quarry. This influence is considered as a hypothesis that the relief of mining area of the quarry and the surrounding landscape in combination with temperature and meteorological conditions forms rising thermal columns. A computer simulation of the airflow in the quarry was chosen as a method how to assess the conditions of formation and the influence of these rising thermal columns.

2. Temperature conditions in the quarry

Due to uncovering the rock wall surfaces, the change in the quarry temperature conditions occurs. The change in the character of heat exchange causes the increase in heat transfer of the surfaces' temperature and consequently the increasing of the quarry air temperature in the comparison with the surrounding atmospheric temperature. The consequence of this heat transfer influences the formation of convective rising air currents.

Fig. 1. Distribution of rain gauges and temperature loggers in the quarry and its surroundings

2.1. Air temperatures in the quarry

Air temperature analysis includes the mutual relation between the air temperature in the quarry and the ambient atmospheric temperature. The air temperature in the quarry was monitored continuously from the 2nd June to 12th September 2016 by temperature data loggers GAR 171 in two chosen places, see Fig. 1. One temperature sensor t_1 was situated closely to the uncovered rock surface and the second temperature sensor t_2 was situated in the distance about 20 meters away in a low vegetation.

The results of the air temperature courses measured in the quarry during the month of July are shown graphically in Fig. 2. Together with the given temperatures is plotted the atmospheric temperature course taken from the available data, measured at the near Brno-Tuřany Airport. Here we can observe differences among the mentioned temperatures.

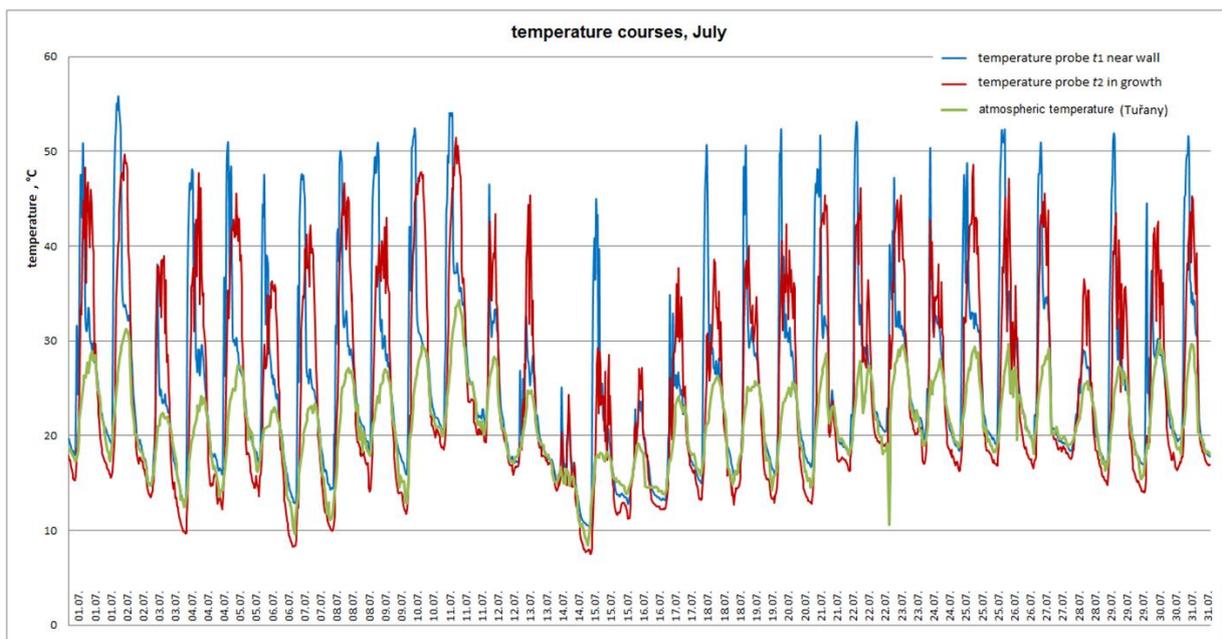

Fig. 2. Air Temperatures in the quarry during July 2016

2.2. Temperature of surfaces in the quarry

Increased temperatures of rock wall surfaces cause a convective air heating in the quarry. The temperature distribution across the mining surface was measured by the thermal imager FLIR T640 under various weather conditions. An example of the measured temperature distribution is given in Fig. 3. The temperature gradient of surface temperature – air temperature – atmospheric temperature causes the convective rising air currents called thermals.

Due to the computer simulation of thermals, we need to know the temperature distribution on the chosen section of the quarry walls along the direction of the wind vector. Software Workswell CorePlayer allows us to analyse accurately the infrared images. A print screen from determination of the temperature distribution along a line in the infrared image is shown in Fig. 3 in the upper part of the figure. In the lower part of the figure, there is plotted the course of temperature along the desired line in pixels. Here, we can observe various phenomena like an influence of incidental angles of solar radiation, shading of spaces, the absorption of solar radiation in forest canopies.

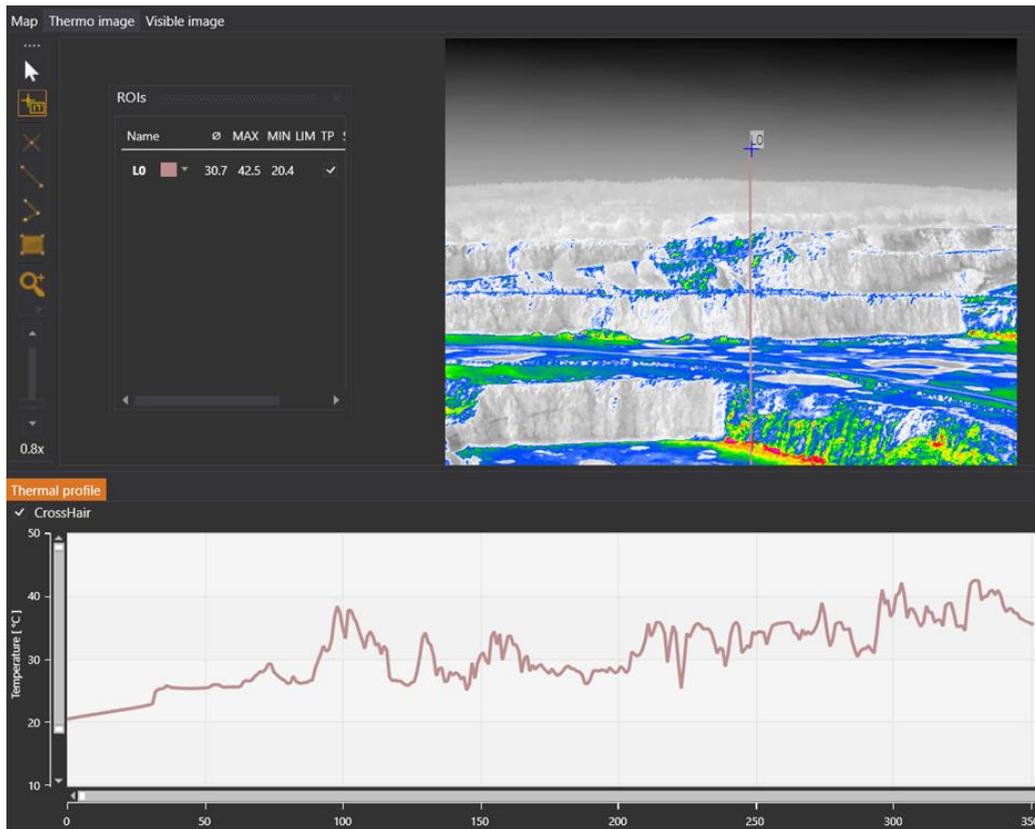

Fig. 3. Workswell CorePlayer software processing of thermal image along the chosen line in the quarry on 27th August 2016 at 1 pm

2.3. CFD simulation of thermals

The CFD (computational fluid dynamics) simulation of thermals was realized by use the ANSYS Fluent, which solves tasks using the finite element method of Reynolds equations derived by averaging the Navier–Stokes equations. Equation solver system was set to mode coupled with discretization of the second order. The key moment for solving these equations was the choice of turbulence model, which was chosen from a variety of models. The k-ε and SST-OMEGA turbulence models were used together with the method of Boussinesq hypothesis.

The following boundary conditions were chosen for the simulation of thermals in the quarry:

- Wind speed: calm and 5 m/s
- The atmospheric air temperature 20 °C
- The average surface temperature of 50 °C and 30 °C in the quarry
- The temperature of the forest cover is equal to the atmospheric temperature
- Material constants are the limestone for quarry area and the wood for forest area

For the purposes of the CFD simulation, the three-dimensional model of the investigated terrain was created by using the SolidWorks software, see Fig. 4. For the chosen direction drawn by the green line in Fig. 4, the two-dimensional profile of the terrain was extracted, as shown in Fig. 5. The airflow simulation was realized for wind directions from south to north and from north to south, see Fig. 5.

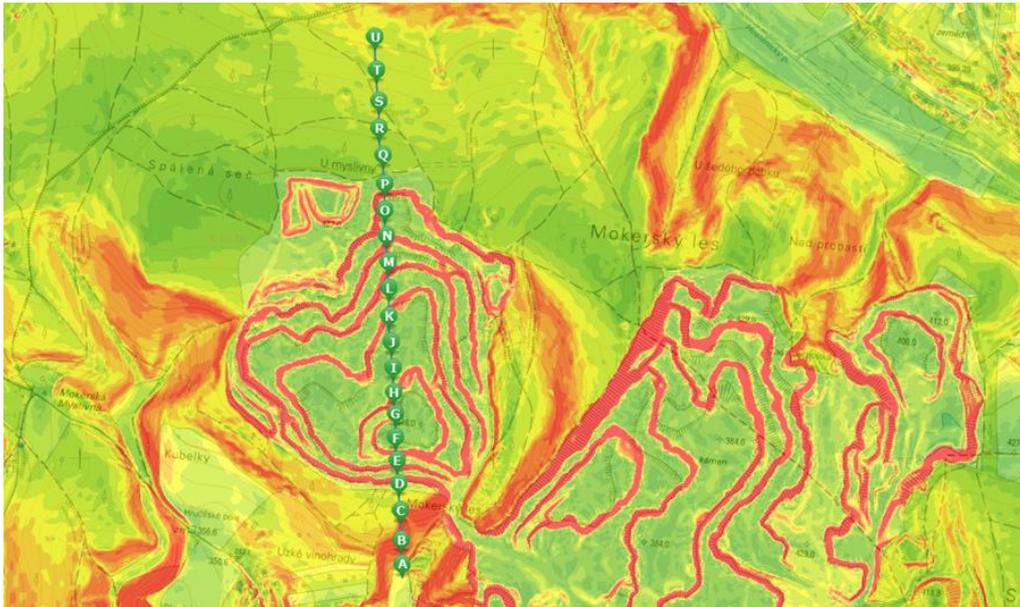

Fig. 4. Investigated terrain with marked line for the CFD simulation

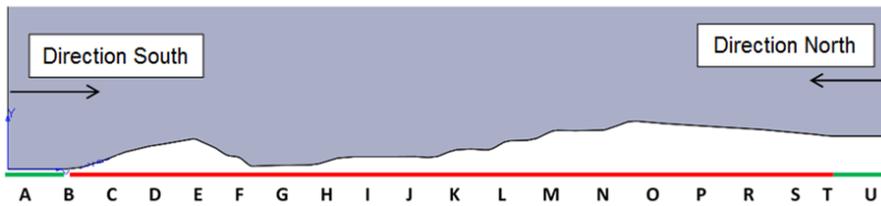

Fig. 5. Altitude relief of the chosen terrain cross-section

Examples of the resulting airflow simulation in the quarry when it is calm are given in Fig. 6 in two modes of display – for the temperature distribution and for the velocity streamlines. In these views, we can observe the typical thermal bubble, which can be understood as the volume of air, resembling the shape of a sphere. From the velocity streamlines, it is clear how this bubble moves upward. When the moist air climbs to a height below the dew point, moisture will begin to condense, the upward movement will stop and cumulus clouds start to form. Therefore, this phenomenon should not decrease rains around the quarry in a calm weather, except the case of an extremely dry air.

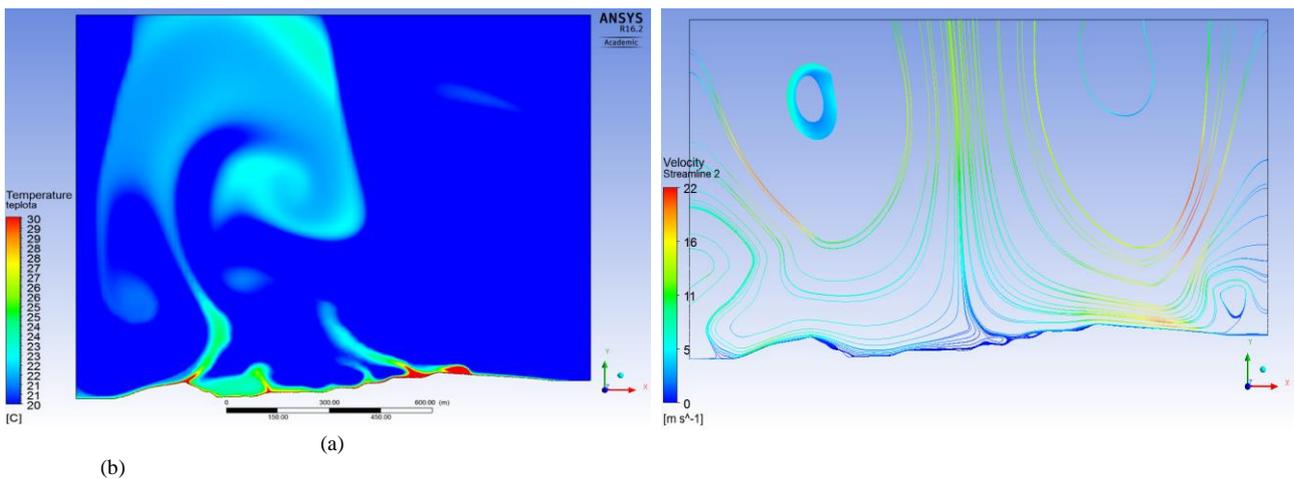

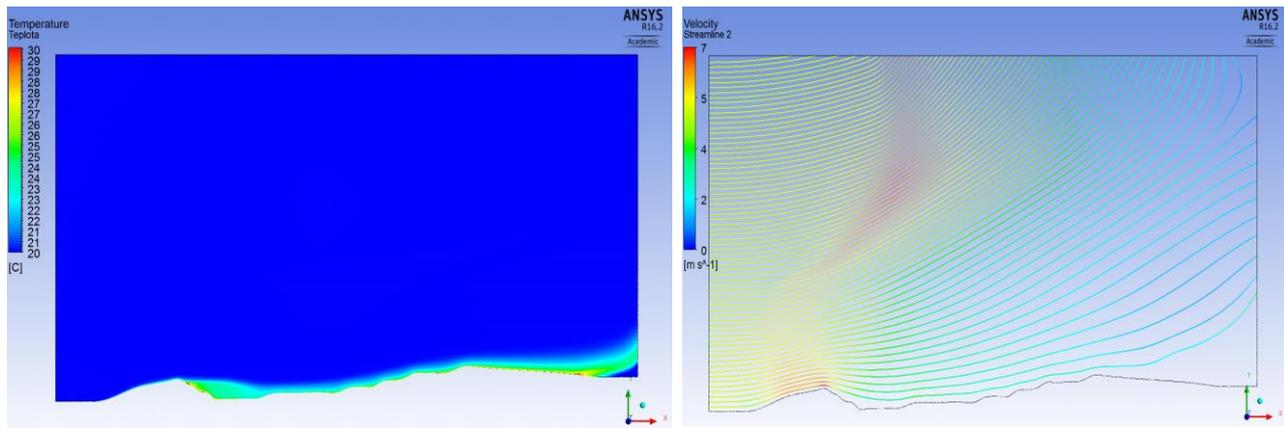

Fig. 6. Simulation of airflow in calm weather: (a) temperature distribution; (b) velocity streamlines

The results of simulation of the airflow in the quarry for the wind speed of 5 m/s are given in Fig. 7, where the temperature distribution and the velocity streamlines are shown. Here, we can observe that in this case of wind speed, rising thermals should not substantially affect the upper atmosphere, where the clouds are forming or where the rain is coming from.

(a) (b)

Fig. 7. Simulation of airflow, wind speed 5 m/s from the south: (a) temperature distribution; (b) velocity streamlines

As the quarry and surrounding landscape are rugged, the formation of precipitation is also affected by a terrain relief. According to the British meteorologist John Sawyer an amount of orographic precipitation depends on three factors:

- Temperature and moisture characteristics of air masses and the nature of the pressure field in the synoptic scale
- Microphysical processes in clouds and evaporation of falling raindrops
- Local vertical motions induced by relief

In our latitudes, the most common types of clouds are as follows: Nimbostratus, Altostratus, Stratocumulus, Cumulus and Cumulonimbus. Since the last three types of clouds are of the cumulus cloud types, they are associated with the occurrence of storms from the heat - i.e. a local phenomenon, we decided to exclude them as they could distort our research. Therefore, we paid attention only to the low clouds (Stratus) and to the middle layer (Nimbostratus and Altostratus). These clouds occur in a range of altitudes 1-3 kilometers above the ground.

3. Precipitation measurement

The precipitation was measured by the standard rain gauges continuously during the summer months of 2016. It should be noted that the summer of 2016 was highly moist for our latitude. The numbered rain gauges were placed around the quarry in three distances, see Fig. 1. The first group of rain gauges (namely numbers: 1-5) was placed on the edge of the quarry. The second group of rain gauges (numbers: 6-16, 20, 22, and 26) was situated in the quarry surrounding at distance about 1-3 km from the quarry border. The last rain gauges (numbers: 11, 18-19, 21, 23, and the Brno-Tuřany Airport) were located at a greater distance about 7-9 km from the quarry.

For the purposes of better illustration, the average precipitation for each month was calculated and compared in different distances from the quarry (the edge of the quarry, the quarry surroundings and a greater distance), see Fig. 8. However, no unambiguous tendency of the quarry influence can be observed here.

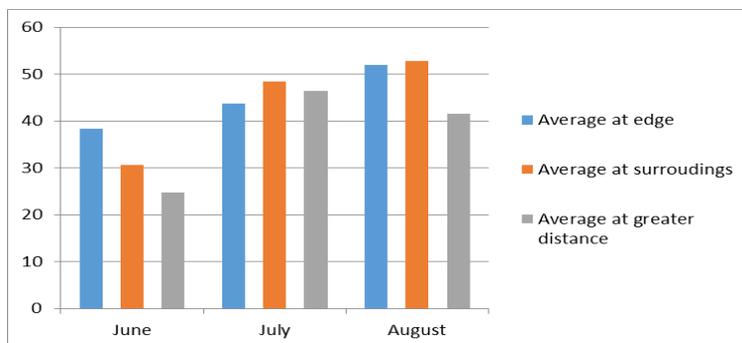

Fig. 8. Comparison of average total precipitation in mm for different distances from the quarry

The more detailed overview is given in Fig. 9, where the daily readings during the summer 2016 are plotted for chosen rain gauges (numbers: 1, 2, 6, 7, 20, and 23). These rain gauges are located on a line from the quarry edge to a distance of 12 km, see Fig. 1. However, not any tendency of quarry influence on precipitation can be found here also.

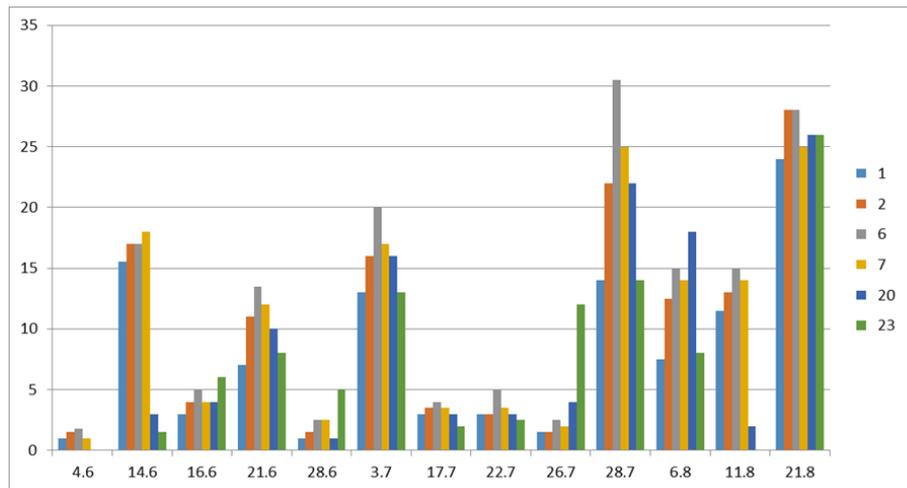

Fig. 9. Daily readings for chosen rain gauges, which are located on a line from the quarry edge to a distance of 12 km

4. Conclusion

The presented project was focused on the study of a possible impact of the Mokrá quarry on the local climate conditions.

There were quantified increased temperature conditions at the quarry area during the summer months 2016. It was found that the air temperatures inside the quarry are substantially higher comparing to the surrounding atmospheric temperature during sunny days. Further, the thermal imaging allowed us to identify the most thermally exposed quarry sites.

The increased temperature conditions cause creation of thermals. The computer simulation was used for the visualization and study of the airflow in the quarry. It was found that thermals could influence the upper atmosphere only in a calm and in very hot weather.

Measuring of precipitation during the summer months 2016 in various distances from the Mokrá quarry did not prove the influence of the quarry on the local precipitation. It should be noted that more generally valid conclusions would require a longer measurement in more consecutive years.

Regarding to the relatively small uncovered area of the Mokrá quarry, its influence on the local precipitation will be minimal. The quarry area is very small in comparison with a large urban agglomeration, such as e.g. the city of Brno located nearby the Mokrá quarry. The landscape around the Mokrá quarry is very different from high mountain massifs, which could cause a rain shadow as well.

A rather limited time for the project caused that some problems are only outlined in the paper. Therefore, some future studies are planned. Namely, it is a comprehensive computer simulation of thermals for various terrain situations and weather conditions.

Acknowledgement

The work presented in this paper has been supported by the specific research project of Faculty of the Military Technology SV18-216, University of Defence in Brno and by the project the Quarry Life Award, Heidelberg Cement.

Substantiating the decision regarding the ecological reconstruction of mining waste dumps – case study for Lupeni dump

Faur Florin^{a*}, Lazăr Maria^a, Nyari (Apostu) Izabela-Maria^a

^aUniversity of Petrosani, University street, no. 20, Petrosani, 332006, Romania

Abstract

According to EC Decision No. C (2018) 1001 final, at the end of this year, productive activity at Lupeni Mining Exploitation will cease, and from the beginning of next year the ecological reconstruction of the site will be started. In this context, the ecological reconstruction of the mining waste dump (branch III), active at the moment, is also under consideration. In the present paper we intend to establish the optimal alternative of ecological reconstruction using a methodology proposed and published in the literature. This methodology makes it possible to identify the optimal alternative of ecological reconstruction (and to eliminate inopportune ones) by following three phases, in a logical sequence, in which a number of factors and indicators characterizing both the site area (the climate of the region, the morphology, the environmental risks etc.) as well as the degraded land (the waste dump), especially in terms of fertility of the stored material. In this way the risk of making an erroneous decision (on the ecological reconstruction option) that does not meet the proposed objective and at the same time may cause unjustified expenses is minimized.

Keywords: ecological reconstruction, methodology, mining, waste dumps

1. Introduction

Ecological restoration and reuse of degraded lands must contribute to the region's sustainable development, therefore, in order to determine the land destination post degradation, a number of opportunities and restrictions should be taken into account. For this reason, a methodology was developed to establish the optimal reuse type, based on scientific principles, without neglecting economic issues and those related to population requirements (Lazăr et al., 2017).

To obtain the desired results, the type of ecological restoration chosen must match local conditions expressed by restrictions related to the geographical position and must take into account a number of principles of ecological planning (McHarg, 1969): 1. The principle of globality or inter-causality; 2. The principle of ambient autonomy; 3. The principle of minimum sizing and reversibility; 4. The principle of economy; 5. The principle of respect for tradition; 6. The principle of transparency and democracy; 7. The principle of respect for the demands of the population.

Having in regard the above and considering the numerous ecological reconstruction projects that failed it was seen as necessary to apply the developed methodology in order to substantiate the decision regarding the ecological reconstruction of Lupeni mining waste dumps.

2. Brief description of the methodology

This methodology follows 3 phases, ordered logically, briefly described below:

Phase I - the initial consultation of the public and decision factors (the current owner of the land, local, county or regional administration, etc.). This first phase takes into account principles no. 5, 6 and 7 and was materialized in the form of public debates (Lazăr et al., 2017). In this phase there were identified the possible types of ecological reconstruction of the waste dump.

* Corresponding author. Tel.: +4-072-446-1601.
E-mail address: faurfloring@yahoo.com.

Phase II - implements into the decision-making process the principles no. 1, 2, 3 and 4. For this purpose a number of characteristics and indicators of major importance in the process of ecological reconstruction of the degraded land must be taken into account (temperature, precipitations, wind regime, inclination of the land, physical stability, accessibility, presence of permanent water sources, flooding, vegetation wildfire and seismicity) (Lazăr et al., 2017).

For each characteristic and indicator there were assigned scores according to the methodology. The total points obtained for each proposed type of ecological restoration being calculated by summing on each row (each indicator must obtain the minimum score required) and then are multiplied for each project with the appropriate economic coefficient, resulting equivalent scores (Lazăr et al., 2017).

By applying the procedure described above, the proposed ecological restoration projects can be grouped into four opportunity classes based on the equivalent scores obtained (Lazăr et al., 2017): 2 - 12 points - inappropriate projects; 13 - 23 points - projects with reduced opportunity; 24 - 34 points - projects with medium opportunity; 35 - 45 points - projects with high opportunity. At this point only the projects within the high opportunity class (or the same class of opportunity) are further considered.

Phase III - the projects that have passed phase II starts from scratch (the scores from phase II are no longer considered). To evaluate and separate the ecological reconstruction projects that passed phase II, a series of fertility indicators and the possible presence of undesirable elements were considered (incompatible with productive restoration, that should also be considered for recreation or leisure restoration): soil structure, soil reaction, nutrients (primary macronutrients - N, P, K; secondary macronutrients - S, Ca, Mg and micronutrients - Fe, Mn, B, Zn, Cu, Mo, Co), humus content, C/N ratio, excess sodium (SAR index), excess of soluble salts, heavy metal content (Lazăr et al., 2017).

By summing the scores attributed to each indicator for each project (while achieving the minimum required score for each indicator) they can be grouped as follows: 0 - 10 points - projects with reduced opportunity; 11 - 20 points - projects with medium opportunity; 21 - 30 points - projects with high opportunity.

After this selection, in terms of opportunity, the projects within the same group can be prioritized in accordance with the individual score and available financial resources (Lazăr et al., 2017).

3. Description of the waste dump and surrounding area

3.1. The waste dump (branch III)

Lupeni mining perimeter is located in the municipality with the same name, in the western part of the Jiu Valley mining basin. The waste dump (formed of three branches) is located 4 km from the main enclosure in a hilly area, with heights ranging from + 780 m, in the Boncii creek area, to + 960 m, on the left side of West Jiul river (HEC, 2015).

Auto access to the dump is limited, with 4x4 vehicles, or pedestrian on steep slopes.

The Lupeni waste dump (branch III) occupied an area of 16.64 ha and a volume of 2,102,620 tons (1,336,827 m³) at the end of 2016, with no foreseen expansion, and its development is in a single step (the designed capacity of the dump was of approximately 2,387,800 m³).

Branch III of the dump consists of two bodies, A and B, that should have been joined in longitudinal section, one of prismatic form located between the pillars P4 and P6 (in conservation for about 11 years and vegetated) and a conical-shaped dumping body in the common area of the three branches, where the sterile material is currently dumped (between the angular station and the P1 pillar). In this paper only the B body is considered.

The waste dump has varying heights depending on the morphology of the terrain and the deposition area.

For the conical-shaped B body (Figure 1), to satisfy the technological and stability aspects of the slopes, a height of 30 - 35 m and a slope angle of 37° - 39° were adopted. These characteristics are obtained by arranging a leveling platform at elevation + 837.5 (access road elevation) by pushing the material with a bulldozer, lateral to the funicular axis towards the common dumping area (HEC, 2015).

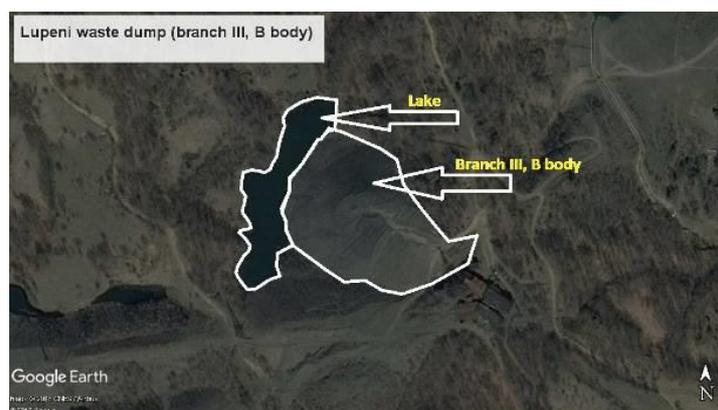

Fig. 1. Lupeni mining waste dump (branch III, B body)

At the contact with the natural terrain, in the longitudinal profile of the funicular axis, a lake is formed (Figure 1). The infiltration of water into the pores of the rocks at the base of the waste dump, leads to a decrease of the resistance characteristics and the risk of landslides (Lazăr et al., 2014).

Moreover, in a study conducted in 2017 it is shown (through the stability analyzes performed with the help of a specialized software) that, practically, in the current geometrical configuration, the slope of the waste dump (being in contact with the lake) is close to the stability (equilibrium) limit. The values of the stability coefficient, determined by Fellenius method, vary between 1.054 and 1.085 (shows a stability reserve between 5.4 and 8.5 %) (Stretenie, 2017).

The deposited material comes from the sorting process that takes place at the surface, in the separation section, respectively from mining works (opening, preparation and exploitation).

It consists of a heterogeneous mixture of soft rocks (clays and marls) and hard rocks (sandstones) with an increased unevenness of granulometry and physico-mechanical properties (Table 1). To these are added coal fragments and alluvial deposits (boulders, gravels and sands) that formed the major bedrock of the West Jiul river.

Table 1. Variation limits for the physical and mechanical proprieties of the deposited rocks

No.	Specification	Measuring unit	Variation limits
1.	Granulometry		
	- clay (under 0,005 mm)	%	2.10÷4.20
	- dust (0,005 – 0,05 mm)	%	2.10÷5.10
	- sand (0,05 – 2,0 mm)	%	13.20÷18.90
	- gravel (2,0 – 20 mm)	%	39.10÷40.90
	- boulder (over 20 mm)	%	44.20÷45.30
2.	Specific weight	kN/m ³	25.30÷26.10
3.	Volumetric weight	kN/m ³	17.60÷18.10
4.	Natural humidity (moisture)	%	13.87÷16.88
5.	Porosity	%	39.83÷41.23
6.	Pore index	-	0.66÷0.70
7.	Cohesion	kN/m ²	32.21÷34.11
8.	Internal friction angle	°	24.00÷28.00
9.	Compressibility coefficient	cm ² /daN	1.50÷1.51
10.	Specific compression	daN/cm ²	6.70÷6.90

The collected samples were also analyzed from the point of view of the chemical composition and the presence of nutrients. These analyzes are necessary to determine the capacity of the waste material to support vegetation and score points in Phase III of the methodology. The results of these analyzes (mean values) are presented in Tables 2 and 3.

Table 2. Chemical composition of the deposited material

Waste dump	Determined parameter								
	pH	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	MgO	CaO	Na ₂ O	K ₂ O	Volatile
Lupeni – branch III		(%)	(%)	(%)	(%)	(%)	(%)	(%)	(%)
	7.32	63.45	10.51	2.23	0.84	0.79	0.96	1.55	19.67

Chemical analyzes show a virtually neutral pH value and do not indicate the presence of elements that could affect human health or would not allow vegetation to develop. The neutral pH value also eliminates the need for additional neutralization works before starting the actual ecosystem restoration.

Table 3. Content of nutrients

Element	Humus	N	P	K	S	Ca	Mg	Fe	Mn	B	Zn	Cu	Mo	Co
	-	Primary macronutrients			Secondary macronutrients			Micronutrients						
Measuring unit		%												
Concentration	2.87	0.35	0.044	1.55	0.21	0.79	0.84	2.23	0.029	-	0.008	0.01	-	0.002

Fertility parameter analyzes indicate low content of macronutrients (primary and secondary) and low to medium micronutrients. From this point of view the land allows the spontaneous installation of species which are present in the areas adjacent to the waste dump and are unpretentious to the soil (especially birch, wild rose and herbaceous species).

3.2. Characteristics of the surrounding area

The evolution of the air temperature during the year is determined by the annual variation of the solar radiation and the air circulation regime, having a maximum in July of 14.5°C and a minimum in January of -5.2°C. In the annual air relative humidity regime, there is a main peak in December (93 %) when the air temperature is low and the minimum is recorded in March-April (77 %). Atmospheric precipitations decrease on average from west to east, they rise with altitude and have an irregular rhythm (Faur, 2009). Table 4 shows the average monthly multiannual temperatures (°C) and monthly and annual quantities of atmospheric precipitation (mm) for Lupeni and Straja.

Table 4. Monthly and annual average temperatures and precipitations

No.	Month Station	I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII	Annual average/total
		Temperatures (°C)												
1.	Lupeni	-4.5	-2.3	2.2	7.1	11.6	15.0	16.7	15.9	12.1	7.4	2.4	-2.0	6.8
2.	Straja	-5.8	-4.8	-2.3	1.9	7.1	10.4	12.4	12.3	9.1	5.1	-0.9	-3.7	3.4
3.	Average	-5.2	-3.5	-0.5	4.5	9.4	12.7	14.5	14.1	10.6	6.2	0.8	-2.8	5.1
Precipitations (mm)														
4.	Lupeni	37.1	14.9	41.8	51.6	80.3	106.4	61.8	61.8	54.7	52.2	44.4	41.3	693.7
5.	Straja	61.9	49.9	58.7	107.0	93.8	124.2	64.6	64.6	66.4	84.1	66.4	55.6	951.5
6.	Average	49.5	42.4	50.2	79.3	87.0	103.0	63.2	63.2	60.6	68.2	55.4	48.5	822.6

The months with the highest rainfall are June and July. Frequency of torrential rains is low. There are no periods of severe drought and the average atmospheric humidity is 4.59 l/mm³.

The wind regime is characterized by a calm period (38 %) and a windy one (62 %). The most frequent winds are from southwest (16.5 %), followed by warm winds from southeast (14 %). Winds from west have the highest intensity, but they are less frequent (4 % of the time) and often cause damages by breaking down or plucking trees from the forests (Faur, 2009). On Beaufort scale, the wind strength ranges from 1 to 4 (over 95 % of the windy period).

The land can be affected by floods only under special conditions (sudden melting of high amounts of snow combined with abundant liquid precipitations).

Vegetation wildfires, caused by natural causes, have not been reported in the region, only small man-made fires that run out of control.

From seismic point of view, according to P100-1 - seismic design code - part I, the peak values of ground acceleration are between 0.10g and 0.15g ($g = 9.81 \text{ m/s}^2$) and the control period is 0.7 (MO, 2013).

4. Applying the methodology

As stated before the methodology involves three phases, allowing in the end to identify the optimal ecological reconstruction type for the degraded land in question.

4.1. Phase I

The identification of possible alternatives for ecological reconstruction of Lupeni dump - branch III, B body was made through questionnaires and discussions with the inhabitants of the municipality. The questionnaires were distributed with the help of the mayoralty, which later facilitated discussions with the inhabitants interested in the project (Corui et al., 2004). Following this approach, four main directions of ecological reconstruction (one with two variants) materialized:

- **Naturalistic recovery** - aiming to recreate the natural landscape, including specific measures for environmental protection;
- **Recreation and sports (practicing mountain biking and motocross)** – to a certain extent is similar to naturalistic recovery, in addition providing specific structures for leisure and sports;
- **Productive restoration** - orchard plantations, namely *Prunus domestica* sp. (plum tree);
- **Productive restoration** - forestry plantations. There were proposed two main species, namely *Pinus sylvestris* (pine tree) or *Fraxinus excelsior* (ash tree).

Further in the text the following abbreviations will be used: naturalistic restoration – NR; recreation and sports – RS; productive for forestry – PF; productive for orchards – PO.

In order to be able to complete the next phases, a brief description of the requirements of each proposed tree and forest species is needed:

Prunus domestica sp. - height up to 10 m. Arbor or shrub with superficial roots. The leaves are elliptic, finely chopped-serrated, white-green flowers (grouped 2 - 5), elongated fruit of different colors from yellow to black-bluish. It blooms in April-May. It requires soils with medium to high fertility, southern exhibition, average temperatures in the blooming months of 6 - 10°C, and those of fruit baking of 15 - 16°C. It is the most common fruit tree in Romania. (Pârvu et al., 1985).

Pinus sylvestris - up to 40 - 50 m in height. It has a pyramidal crown in its youth and irregular in maturity. The bark is brick-reddish, acicular leaves (4 - 6 cm), brown-gray cones (about 7 cm). It blooms in May-June. It is very tolerant to temperature and precipitations, it develops on poor, skeletal soils and on peatlands, with a pH from acid to weakly basic (Pârvu et al., 1985).

Fraxinus excelsior - height up to 40 m. The leaves are composite feathered, serrated. Nude flowers, packsaddle fruits, it blossoms in April, before it's leaves appear. Used for furniture, musical instruments, etc. It develops on plains and hilly areas and requires fertile soils (medium to high), well-structured, moist, rich in calcium, with a weakly to medium basic pH (Pârvu et al., 1985).

4.2. Phase II

In the second phase the proposed projects are evaluated in relationship with the characteristics of the surrounding area and some physical characteristics of the waste dump - branch III, B body: C1 - temperature, C2 - precipitations, C3 - wind regime, C4 - inclination, C5 - stability, C6 - accessibility, C7 - permanent water sources, C8 - flooding, C9 - vegetation wildfires, C10 - seismicity (presented in paragraph 3) and the demands of the tree species (presented in paragraph 4.1). Following this evaluation scores are attributed for each project according to the methodology (Lazăr et al., 2017) and the initial selection matrix (matrix A) for ecological restoration options is completed (Table 5).

Table 5. Matrix A – initial selection of the ecological restoration options

Type of ecological restoration	Indicator										Total points
	C1	C2	C3	C4	C5	C6	C7	C8	C9	C10	
NR	3	3	3	1	1	1	3	2	3	3	23
RS	3	3	3	1	1	1	3	2	3	3	23
PF – Pine tree	3	3	3	1	1	1	3	2	3	3	23
PF – Ash tree	3	3	3	1	1	1	3	2	3	3	23
PO – Plum tree	2	3	3	1	1	1	3	2	3	3	22
Relative importance of the indicator to the ecological restoration project											
Major importance – minimum accepted 2 points											
Medium importance – minimum accepted 1 point											
Low importance (relatively unimportant) – 0 points accepted											

As can be seen from Matrix A, two of the proposed types are eliminated because the minimum score required by the methodology for C5 - stability and C6 - accessibility are not obtained. These are RS and PO - plum orchard (for PO, C1 - the temperature is also at the limit).

By multiplying the total points with the economic coefficients assigned to each type of ecological reconstruction (Lazăr et al., 2017) the following equivalent scores are obtained: NR = 23 x 1 = 23 - **reduced opportunity**; PF – pine tree = 23 x 1.25 = 28.75 - **medium opportunity**; PF – ash tree = 23 x 1.25 = 28.75 - **medium opportunity**.

Following this evaluation, only the two projects, falling in the medium opportunity class, will pass into the third phase.

4.3. Phase III

In order to be evaluated at this stage the two projects, starting from zero, we took into account those presented in paragraphs 3.1 and 4.1 (the characteristics of the waste material and the conditions claimed by the tree species proposed for the ecological reconstruction of the waste dump: I1 – soil structure, I2 – soil reaction, I3 – primary macronutrients, I4 – secondary macronutrients, I5 – micronutrients, I6 – humus content, I7 – C/N ratio, I8 – excess of sodium, I9 – excess of soluble salts, I10 – heavy metals). Thus, by attributing scores according to on the proposed methodology (Lazăr et al., 2017) the B matrix - final selection of the ecological restoration options was constructed (Table 6).

Table 6. Matrix A – initial selection of the ecological restoration options

Type of ecological restoration	Indicator										Total points
	I1	I2	I3	I4	I5	I6	I7	I8	I9	I10	
PF – Pine tree	1	3	3	3	3	1	1	3	3	3	24
PF – Ash tree	1	3	1	1	2	1	1	3	3	3	19
Relative importance of the indicator to the ecological restoration project											
Medium importance – minimum accepted 1 point											

Analyzing the results in Matrix B, we can see that although both projects pass this phase (by obtaining the minimum required scores for each indicator), they fall into different classes of opportunity. Ecological reconstruction using *Pinus sylvestris* (pine tree) falls into the **high opportunity** class, while the variant with *Fraxinus excelsior* (ash tree) in the **medium** one.

This means that the optimal type of ecological reconstruction for Lupeni waste dump - branch III, B body, as determined by applying the proposed methodology (Lazăr et al., 2017), is the one using *Pinus sylvestris* (pine tree).

5. Conclusions

By applying the proposed methodology we were able to eliminate from the second phase three of the initially proposed projects for the ecological reconstruction of Lupeni waste dump – branch III, B body. They were eliminated either because two of them (RS and PO) failed to achieve the minimum required score for two of the mandatory indicators (C5 and C6), while the other (NR) entered into an inferior opportunity class compared to other projects (PF).

In the third phase, the difference between the two analyzed projects was given by the lower requirements in terms of fertility of *Pinus sylvestris* (pine tree) compared to *Fraxinus excelsior* (ash tree). Thus the first species requirements are closer to those offered by the stored sterile material and as a consequence it scores higher, proving to be the optimal alternative for the ecological reconstruction of the mining waste dump.

The methodology can also be adopted to solve different other situations of degraded lands often encountered (eroded lands, lands degraded by industrial processes or unsustainable agricultural practices, etc.)

Clay liner design of a landfill in Jiu Valley based on deterministic & stochastic risk analysis

Camelia Madear^{a*}, Gelu Madear^b

^aECO-ROCCA Engineering SRL, 23, Parcului Street, Petrila - 335800, Romania

^bGOLDER, 1, South Parade, Doncaster – DN1 2DY, UK

Abstract

Coal Mining Industry in Jiu Valley left some abandoned open pits which represent a significant liability to the environment. One solution for the rehabilitation of these sites would be the reuse of the open pits as landfills for Municipal Solid Wastes (MSW). The paper presents the proposed solution for the engineered barrier and leachate management system. Generated volumes of leachate were calculated based on local precipitations data using the most advanced hydrological modelling software for designing landfills and evaluating potential leachate seepage to the groundwater table, used as input parameters in Hydrogeological Risk Assessment (HRA).

Keywords: coal mining; landfill; open pits; environment; risk analysis; HRA.

1. Introduction

To comply with the Landfill Directive (1999/31/EC), Groundwater Directive (80/68/EEC), Water Framework Directive (2000/60/EC), Drinking Water Directive (80/778/EEC), a thorough Hydrogeological Risk Assessment (HRA) should be carried out before applying for permitting to the Environment Agency. To carry out the HRA, a Conceptual Site Model has been developed based on existing information on geology and hydrogeology, as well as mining records.

Clay liner design was based on the impact of existing contaminants in leachate to environmental receptors – the aquifer (Receptor 1) below the site within the bedrock and an imaginary borehole (Receptor 2) outside the landfill area. We have assessed the impacts for List I substances at Receptor 1 and the impacts for List II substances at Receptor 2.

The Source-Pathway-Receptor (SPR) linkages as derived from the Conceptual Site Model (CSM) were used in a multi-tiered Hydrogeological Risk Assessment.

The first phase consists of a Simple Risk Assessment using deterministic approaches. For the worst-case scenario, analytical solutions are solved in a deterministic fashion using conservative input parameters, assumptions, and methods.

The second phase uses a Complex Risk Assessment which is carried out using stochastic techniques to an analytical solution. Monte Carlo simulations are used to evaluate and predict leachate concentrations and elevations during the operational phase of the landfill and to estimate advective fluxes from the landfill. Both advection and diffusion are possible contaminant migration mechanisms throughout the lifecycle of the landfill.

The use of probabilistic distribution functions addresses the uncertainty of the input parameters, and the results are also returned as ranges and defined according to the probability of occurrence. The 95th percentile values are used as outputs from the model, which are representative of the reasonable worst-case performance of the landfill. The Romanian Drinking Water Standard has been used as the Environmental Acceptable Levels (EAL).

2. Background Information and Site Description

Jiu Valley is known to be one of the most important mono-industrial areas in Romania, due to the coal mining industry. In addition to the benefits of this activity, the Jiu Valley is now paying a fairly high tribute to all years of exploitation, namely the acquisition of a large number of degraded land areas. However, the disadvantage of the existence of these surfaces may turn into an advantage if it is taken into account that they can serve as ecological landfills.

An example of degraded space from the mining activities in Jiu Valley, which can be a potential site for the ecological landfill, is Victoria Open Pit (VOP) in Lupeni (Fig. 1 a and b).

Fig. 1. (a) Victoria open pit; (b) Victoria open pit footprint

VOP is located approximately 2 km north-east of Lupeni City Center, in Petrosani Depression, Hunedoara County. The latitude of the centre of VOP, Jiu Valley is $N45.3765^\circ$, and the longitude is $E23.2298^\circ$, with GPS coordinates $45^\circ22'35.4''$ and $23^\circ13'47.28''$. The open pit is delimited at the east by Vulcan Minefield, to the west by the Barbateni Village, having Hateg Mountains to the north and Valcan Mountains to the south. A railway runs approximately 3 km south along DN66A. VOP is within a hilly topography, in the western part being covered by dense forests and meadows to the east. Nearby, at approximately 750 m southeast and 1.5 km southwest, there are few urban areas with buildings and some minor roads serve the area and link to the site. Jiul de Vest river is located approximately 3 km south of the VOP and also two small brooks - Bolosinestilor and Plisabeia - runs nearby.

3. Geology, Hydrogeology and Engineering Geology

Based on the available background information, the following superficial deposits and strata are expected at the site and its environs and are described in Table 1, from the youngest to the oldest:

Table 1. Summary of geology

System – Series - Age	Formation
Neogene – Miocene - Burdigalian	Sandstone, Reddish and Greenish/ Greyish Clays, Carboniferous Schists
Paleogene – Oligocene - Chattian	Sandstones, Marls, Bituminous Marls, Disodilic Schists, Carboniferous Schists and Coals
Paleogene – Oligocene - Rupelian	Clay, Marl, Sandstone, Sandstone Containing Bituminous Clay, Coal

Burdigalian - Hanging Wall Horizon - This horizon is made up of a conglomeratic series in alternation with sandstones, reddish and greenish/ greyish clays, sometimes with plants and carboniferous schists. In Lupeni area there are three distinctive conglomerate layers, which divides towards the east, becoming more like sandstones, with some intercalations of marls, marly limestones, green clays and yellow sands slightly cemented.

Chattian-Aquitainian - Productive Horizon - This geological formation is comprised of a series of micro-conglomerates, sandstones, marls, bituminous marls, disodilic schists, carboniferous schists and coals. Coals are located at various depths within this horizon and are represented by 25 layers of hard coal and brown coal. At the upper part of the horizon, there is an alteration of clays, sands, sandstones, carboniferous schists and coals.

Rupelian - Inferior Conglomeratic Horizon - Conglomerates represent approximately 75% of the total thickness of the formation comprising grey quartzitic rocks, gneiss and pegmatites, which are embedded in a reddish clay layer. On the west side of the Jiu Valley, at Lupeni, Vulcan and Uricani there are green sandstones and white-yellowish limestones distributed randomly. Rupelian deposits are located at the boundary of Petrosani Coal Basin, but there are not found on its north-western side - north of Lupeni, where Burdigalian might overlay them.

Tectonics - Petrosani Coal Basin is embedded into the tectonic ensemble of Southern Carpathians, having in its structure all the three distinct units: Getic Terranes (Nappe); Danubian Terranes (Unit); Neozoic Sedimentary Deposits. The Danubian and Getic Terranes consist of shallow-water marine and non-marine Mesozoic rocks that rest on Paleozoic and Precambrian sedimentary and crystalline rocks. The main tectonic element is represented by the fact that rocks of the Getic Terranes have been thrust eastward over rocks of the Danubian terrace, along the Getic thrust fault, resulting in a synclinal basin.

A geological cross-section and the geological map of the region are presented in Fig. 2 a and b.

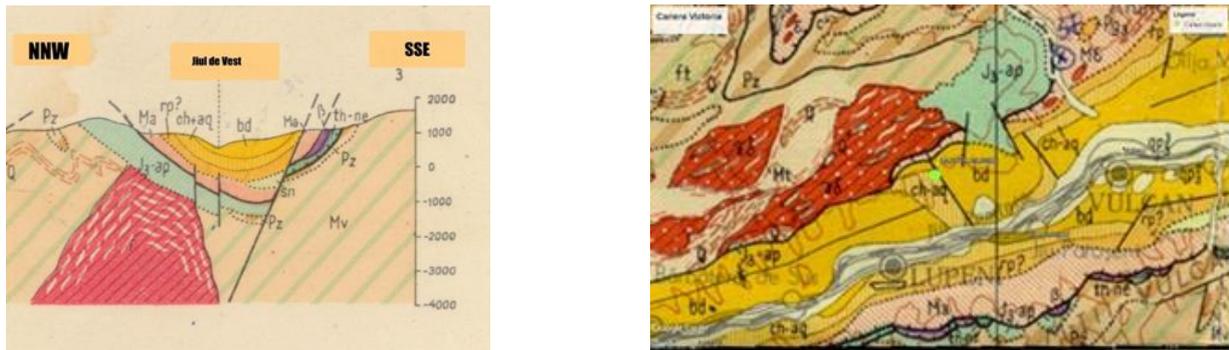

Fig. 2. (a) Geological cross-section; (b) Geological map of the region

4. Quantitative Hydrological Risk Assessment (QHRA)

Victoria Landfill is proposed to be constructed to receive Municipal Solid Waste (MSW) from nearby towns. A former open-pit is now a potential location for a landfill and would be relatively small in size. Environment Agency requires that as part of the waste management licensing process, an assessment is carried out to predict the likely impact on groundwater and compliance against the requirements of the Groundwater Directive.

Separate risk assessments are to be undertaken for other processes including migration of, and exposure to landfill gases, construction and durability of engineered barriers and leachate management systems and impacts on ecological systems. A hydrogeological conceptual model (Fig. 3) has been developed based on historical mining data and groundwater levels, and the outline design of the proposed landfill.

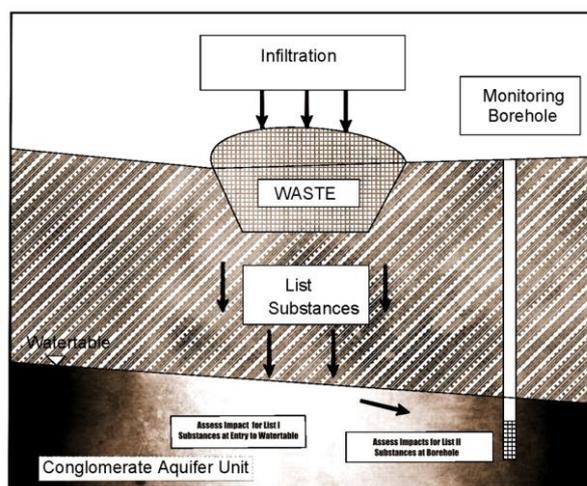

Fig. 3. Hydrogeological conceptual site model

The landfill is underlain by strata that are classified as Minor Aquifer by the Romanian Environment Agency and consists of inter-bedded clays, silts and sands. Hydraulic continuity is assumed between the sandstone horizons and is assumed to have a saturated aquifer hydraulic conductivity between 1.0×10^{-5} m/s and 3.4×10^{-6} m/s. The regional hydraulic gradient is 0.05 towards the SSE, to Jiul de Vest river.

The winter watertable lies at an average of 5 m below the site, and effective rainfall is estimated at approximately 692.8 mm/ year based on Meteo Parang Weather Station.

The potential source of pollution is contaminants within landfill leachate. The concentration of contaminants within leachate is dependent upon the waste type and will decline over time due to degradation of compounds, dilution by infiltrating water and losses to the vapour phase; therefore, existing leachate chemistry from other landfills was considered for this exercise. The environmental receptors considered are the groundwater body below the site within the bedrock and sand and silts for the List I substances, and an imaginary borehole immediately down-gradient of the site for the List II substances and non-listed substances.

Contaminants could reach the receptors via several pathways which comprise some different media components, transport mechanisms and attenuation processes:

Table 2. Pathways, transport and attenuation mechanisms

Media Component	Pollutant Transport Method	Attenuation Processes
HDPE Liner	Direct leakage through damage or defects or as a result of degradation of the liner	Declining source term. Dilution of leachate by rainwater infiltrating waste. Degradation of contaminants within leachate.
Mineral Liner (vertical pathway)	Advection and/ or Diffusion	Retardation, Dispersion
Inter-bedded clays, silts and sands (vertical pathway)	Advection and/ or Diffusion	Retardation, Dispersion
Aquifer Unit (Horizontal pathway/ saturated zone)	Advection and/ or Diffusion	Retardation, Dispersion

A QHRA has been undertaken using the following approaches:

- Analytical Solutions based on Domenico & Schwartz equation;
- A probabilistic method using Monte Carlo Simulations (LandSim);

Both advection and diffusion are possible contaminant migration mechanisms throughout the lifecycle of the landfill. The dominant mechanisms depend on the relationship between leachate levels and external hydraulic heads within the in situ inter-bedded clays, silts and sands and the underlying aquifer unit.

Domenico & Schwartz analytical solution has been used to predict concentrations of the priority contaminants (List I – Trichloroethene) at their respective compliance points, through the process of diffusion when leachate heads are below groundwater levels (winter watertable) in the surrounding subsoils – Scenario 1. A Conceptual Site Model and the landfill layout is presented in Fig. 4.

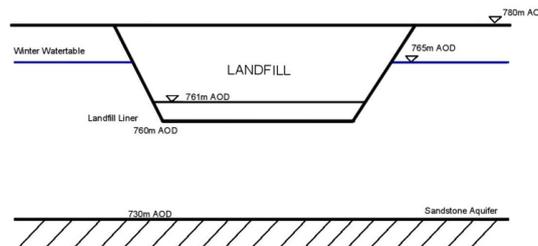

Fig. 4. Conceptual site model for Scenario 1 – winter watertable above leachate level

The input parameters used for the model are based on site-specific data when available and had been selected to be conservative. Domenico & Schwartz equation was used for the Scenario 1, and the solutions are derived in the Laplace Transform and was implemented into an Excel spreadsheet.

LandSim is used to predict leachate concentrations and elevations during the operational phase of the site and to estimate advective fluxes from the landfill when leachate heads exceed groundwater level (summer) in the surrounding inter-bedded subsoils and the potentiometric surface in the aquifer unit – Scenario 2 (engineered barrier without HDPE) and Scenario 3 (engineered barrier with HDPE) - Fig. 9.

Uncertainty within the selection of input parameters is addressed by the use of a probabilistic approach which allows the input parameters to be entered as ranges. The results are also returned as ranges and defined according to the probability of occurrence. The 95th percentile values are used as outputs from the model, which are representative of the reasonable worst-case performance of the landfill. The LandSim assessment models the performance of the landfill under normal conditions, i.e. it assumes that the engineering performance as designed throughout the operational life of the site.

5. Risk Assessment Results

The models predict the concentration of the priority contaminants at both the List I (TCE – trichloroethene) and List II (Ammonium) compliance points as appropriate.

The compliance point for List I substances is at the base of the vertical pathway.

The compliance point for List II substances is 100 m downgradient of the edge of the waste within the application boundary.

The 95th percentile (worst case) concentrations are reported for each of the modelled Scenarios. Scenario 2 & 3 and have been compared to the Guideline Concentrations.

The results for both analytical and probabilistic approaches are presented separately below:

5.1. Analytical Solutions - Scenario 1

For Trichloroethene (TCE), which is a List I organic contaminant, we have used an Excel spreadsheet which solves Domenico & Schwartz equation. The engineered barriers liner consisted of a 1 m of compacted clay and HDPE geomembrane.

Based on the chemical analysis of similar leachate, an initial concentration of TCE was considered in this analysis. The compliance point for the risk assessment is set at entry to watertable, which is, in this case, the external edge of the liner. Using EU/ Romanian Drinking Water Standards (Groundwater Directive), a target concentration for TCE should be set, which is $10 \mu\text{g/l} = 1 \times 10^{-4} \text{mg/l}$. Therefore, TCE concentration at any time should not exceed target values.

Evaluation of mass of TCE leaving the landfill is shown in Fig. 5a and concentration of TCE at compliance point in Fig. 5b – maximum concentration is $2.46424 \times 10^{-5} \text{mg/l}$ which is lower than the target concentration of $1 \times 10^{-4} \text{mg/l}$. Therefore there is an acceptable risk.

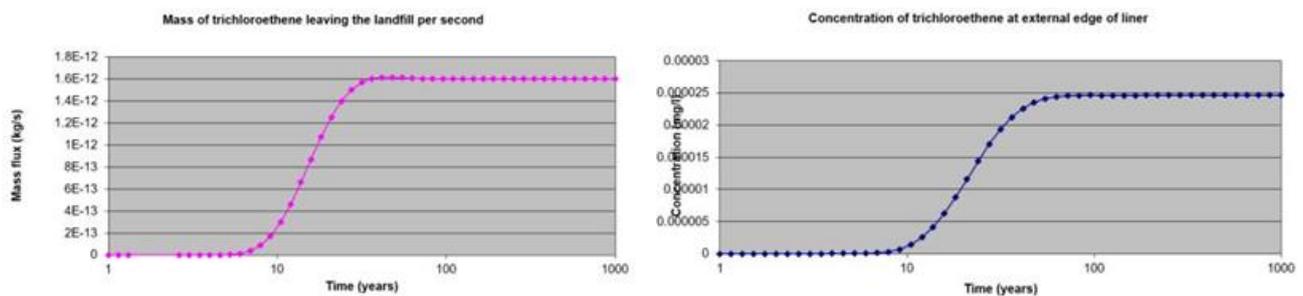

Fig. 5. (a) Scenario 1 – Mass of TCE leaving the landfill per second; (b) Scenario 1 – Concentration of TCE at the compliance point

5.2. Probabilistic Modelling - Scenario 2 & 3

To perform a probabilistic HRA, we have used LandSim software, a tool developed for UK Environment Agency by Golder. Both, Scenario 2 & 3 were modelled simultaneously in LandSim as Phase 1, respective Phase 2.

A graphic representation of the setup is presented in Fig. 6a. The results from the LandSim model are summarized in Fig. 6b – 7, for an ammonium concentration (List II substances) of 723 mg/l (LogTriangular distribution (4.37, 723, 3640) for which the trigger level is 0.5 mg/l.

From Fig. 6b – Scenario 2 for an engineered barrier without HDPE, it results that concentration at the external edge of the liner is higher than the trigger level and this value is halved at the compliance point but still higher than 0.5 mg/l.

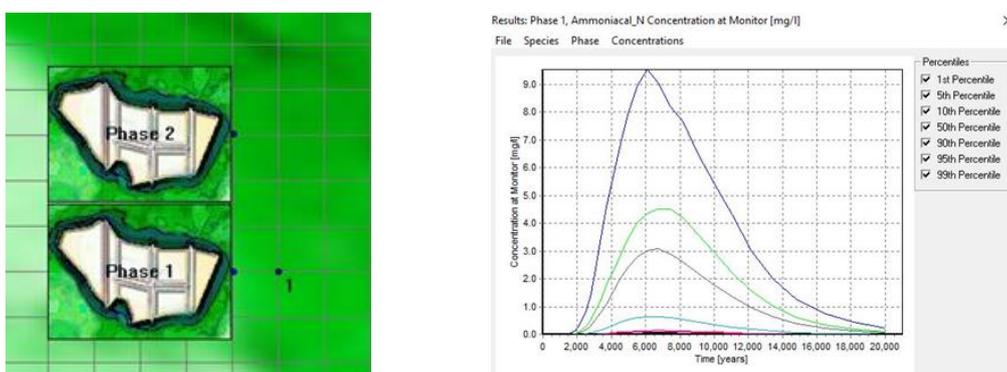

Fig. 6. (a) Scenario 2 (Phase 1) and Scenario 3 (Phase 2) for probabilistic risk assessment in LandSim; (b) Scenario 2 – Ammoniacal concentration at the external edge of the liner 95th percentile (light green curve)

On the other hand, Scenario 3 for an engineered barrier with HDOE, shows a value of 0.6 mg/l of Ammoniacal_N which is slightly higher than the trigger value.

At the compliance point, the Ammoniacal_N concentration should be lower than the EAL (Environmental Assessment Limit) due to retardation, biodegradation, diffusion, and dispersion.

As a conclusion, only an experienced barrier with HDPE will be compliant with Groundwater Directive requirements for the proposed landfill.

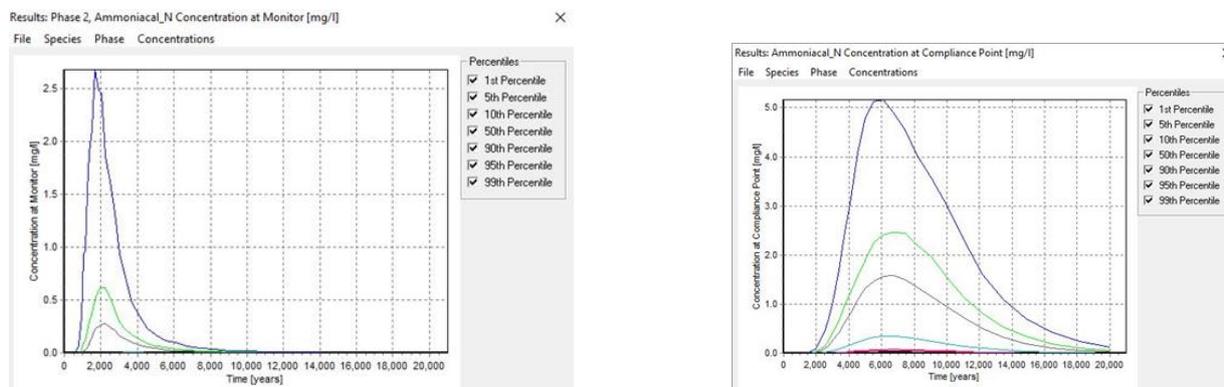

Fig. 7. (a) Scenario 3 – Ammoniacal concentration at the external edge of the liner 95th percentile (light green curve); (b) Scenario 2 & 3 – Ammoniacal concentration at compliance point 95th percentile (light green curve)

6. Conclusions

Due to the likely presence of substances from List I and II in the leachate, the VOC landfill has been engineered to include a leachate drainage and collection system as required by the Landfill Directive for non-hazardous landfills.

The results of the Risk Assessments show that List I substances in leachate are prevented from discharging directly to groundwater beneath the site. The results of the risk assessment for List II substances in leachate have shown that the landfill design prevents pollution of groundwater beneath the site from these substances for Scenario 3: Engineered Barrier with HDPE. Requisite surveillance in the form of risk-based leachate and groundwater monitoring will be carried out at the site, as part of Romanian Environmental Monitoring Plan.

Both conservative (analytical) and probabilistic risk assessments have shown that the landfill will not present a risk to groundwater and does not contravene the requirements of the Landfill/ Groundwater Directive.

Risk-based remedial targets for contaminated land

Camelia Madear^{a*}, Gelu Madear^b

^aECO-ROCCA Engineering SRL, 23, Parcului Street, Petrila - 335800, Romania

^bGOLDER, 1, South Parade, Doncaster – DN1 2DY, UK

Abstract

Land contamination describes a general spectrum of site and soil conditions and contains areas of high levels of chemical substances which occur naturally or in brownfield sites of industrial/ agricultural use. Also, land contamination may occur as a result of accidents, spillages, depositions, migrations or any other similar direct or indirect actions.

The paper presents a consistent methodology to derive remedial targets based on a human health risk assessment approach incorporating a source-pathway-receptor analysis. The methodology is based on RBCA – Risk-Based Corrective Action Procedure developed in the USA and adopted in UK/ EU and leads to the derivation of onsite remediation criteria, which is based on an assessment of the potential impact at the identified receptors.

Keywords: land contamination; soil condition; brownfield; human health; ecology; remedial targets, RBCA, CLEA.

1. Introduction

Whether there is new contamination which falls under Integrated Pollution, Prevention and Control Directive (Industrial Emission Directive 2010/75/EU) or past contamination exists, for any site owner, a series of questions must be answered:

- If the level of land contamination poses a threat to the environment (human health, ecology)?
- If yes, which are the actions that should be taken to remediate the land to an acceptable condition?

To decide if a certain level of contamination matters, the concentration and spatial distribution of any contaminants should be determined, and the risk posed to the environment evaluated.

The basic risk management process in dealing with the contaminated land has three main components:

1. Risk Assessment – if unacceptable risks exist, which actions should be taken;
2. Option Appraisal – evaluating feasible remediation strategies;
3. Implementation of the Remediation.

The overall risk assessment - RBCA methodology, is based on a tiered approach to determine risk-based remedial targets for soil and groundwater and includes initial site evaluation (conceptual site model), a detailed description of receptors, risk assessment for each considered receptor and appropriate overall remedial objective for the site.

Included is an example of developing a Conceptual Site Model for a Combined Sewer Overflow in the UK for a confidential client, during the investigation phase, to be used in the site characterisation process, and the corresponding human health risk assessment.

2. Project Description

Combined sewer overflow (CSO) chambers reduce the overcapacity at the treatment works. In this case, a new CSO chamber including screens and a small shaft tank was proposed to be constructed. It has been proposed to undertake the feasibility for an Unsatisfactory Intermittent Discharge (UID) Project in the West Midlands area, UK.

The works include the construction of a 7.6 m long CSO chamber with a depth of 2.36 m and a small 5 m diameter shaft tank, with a depth of 5 m and associated pipework and other structures. It is expected that the UID would act as a temporary storage facility for sewage, this being currently accommodated by an existing network of combined gravity sewers and manholes.

3. Environmental Settings

3.1. Site Location and General Description

The site is situated approximately 8 km southwest of Birmingham City Centre. Approximately 600 m south of the site there is A45 Road, and the A4040 Road is mapped about 1.8 km northwest of the site. A few other minor roads serve the area and link to the site. The site is within a residential area.

3.2. Hydrology

The River Cole runs about 3 km northwest of the site and Westley Brook, one of the River Cole's tributary, flows approximately 150 m south of the site area. A few other smaller brooks are mapped near the site. The Grand Union Canal is approximately 2 km southwest of the site, and a few small ponds can be found nearby the site.

3.3. Site Walkover

A site walkover for the proposed scheme was carried out, and it showed that the site itself is in Sheldon – Birmingham, and the proposed works will be constructed on the road and pedestrian footpath. The access to the area is via urban roads from A45 – Coventry Road, including Barrows Lane, Church Road and Sheaf Lane. The site is covered by tarmac and is suitable for access by large vehicles. The site is adjacent to residential properties and is located on the relatively flat ground with the minimal ground slope. Also, services have been identified on site.

4. Geology and Hydrogeology

4.1. Geology

Topsoil - is expected to be encountered in areas of undisturbed ground. According to BGS Borehole Records, the Topsoil thickness in the area ranges between 0.15 m and 0.65 m and mainly consists of loose brown clayey sand with frequent rootlets, loose dark brown clayey sand with a little gravel and many rootlets and black sandy clay with frequent rootlets.

Made Ground - No areas of Made Ground are shown on the geological map. However, it is likely to be encountered due to the historical activities at the site. Made Ground is expected to be associated with road construction and site preparation for nearby structures and buildings. Composition and thickness are likely to be varied, and contaminated materials may be present. The studied historical boreholes provided by BGS do not show any Made Ground.

Alluvium - identified on the map about 100 m southwest and about 200 m northwest of the site. In the urban areas, the Alluvium is largely obscured by Made Ground commonly associated with the construction of flood defences, landscaping and the diversion of the rivers and streams into man-made culverts. Consequently, the natural boundaries of the Alluvium in much of the urban area cannot be traced. The Alluvium typically comprises an upper layer of brown clay or silt, up to about 3 m thick, underlain by several metres of pebbly sand and gravel. Thin lenses of peat may be present.

First River Terrace Deposits - are identified on the map approximately 100 m north, east and south of the site. It is commonly 1 to 2 m thick, though exceptionally it reaches 7.8 m thick in some areas. The lithology is predominantly composed of massive-bedded, and cross-bedded gravel and pebbly sand with well-rounded pebbles of Triassic-derived quartz and quartzite.

Glaciofluvial Deposits - are present, at the surface, in the vicinity of the site. These deposits commonly consist of poorly sorted, red, orange and yellow sand, clayey sand, pebbly sand and gravel. Sand and Gravel is generally orange-red, red-brown or yellow, and ranges from poorly to well graded.

Mercia Mudstone Group - represents the solid geology and is likely to be present below the Glaciofluvial Deposits at the site. The Group consists predominantly of red to reddish brown mudstone with sparse grey-green beds. The upper part of the Mudstone is likely to be weathered to clay. The studied historical boreholes provided by BGS do not show any Mercia Mudstone.

4.2. Hydrogeology

Surface Waters - The site is near several brooks, which may contribute to water levels on site.

Groundwater - The Glaciofluvial Deposits are classified as a Minor Aquifer (variable permeability), and these can be fractured or potentially fractured rocks, which do not have high primary permeability or other formations of variable permeability including unconsolidated deposits. Although not producing large quantities of water abstraction, they are essential for local supplies and in supplying base flow to rivers. Regarding the soil classification in the area, soils of high leaching potential are likely to be encountered. The underlying Mercia Mudstone is classified as a "Non-Aquifer". According to the Environment Agency website, the site is not within a Groundwater Source Protection Zone.

5. Historical Land Use

Table 1. Evidence of the historical land use

Map Year of First Occurrence	Notable Features	Potential Contamination Sources
1888 - 1905	The maps show that the area around the site is predominantly rural with some settlements here and there, including farms and cottages. Approximately 250 m northeast of the site there is a Smithy. A Fish Pond and a Gravel Pit can be seen about 850 m west of the site. Another Fish Pond is mapped next to Sewage Pump, which is located about 1.5 km northwest of the site.	On-site: The Road Off-site: Smithy, Gravel Pit, Sewage Pump, Brick Works, Tank, Old Marl Pits
1916 - 1938	Housing and roads development can be observed around the site since 1905. A few new features have sprung up around the site area. Approximately 600 m northeast of the site there are mapped and Old Sand Pit and a Sewage Pump. A Spring is mapped about 250 m northwest of the site.	On-site: The Road Off-site: Smithy, Gravel Pit, Sewage Pump, Brick Works, Tank, Old Marl Pits, Old Sand Pits, Gravel Pit
1954 - 1969	More housing and roads expansions can be noticed around the site area. Approximately 150 m northwest of the site there is mapped a Spring, a Well and Sinks. A Timber Yard is present approximately 300 m northeast of the site and these later become works. Also, the Smithy, the Sewage Pump and the Tanks are no longer mentioned on these recent maps.	On-site: The Road Off-site: Smithy, Gravel Pit, Sewage Pump, Brick Works, Tank, Old Marl Pits, Old Sand Pits, Gravel Pit, Model Railway Ground, Timber Yard (later Works)
1970 - 1978	Westley Brook, which runs southwest to northeast direction, is mapped about 150 m south of the site. Areas around the site have seen rapid infrastructural developments such as new houses, roads and other community amenities.	On-site: The Road Off-site: Smithy, Gravel Pit, Sewage Pump, Brick Works, Tank, Old Marl Pits, Old Sand Pits, Gravel Pit, Model Railway Ground, Timber Yard (later Works)
1980 - 1999	No significant changes are noticed from the previous maps. The Works had been redeveloped as housing by this date.	On-site: The Road Off-site: Smithy, Gravel Pit, Sewage Pump, Brick Works, Tank, Old Marl Pits, Old Sand Pits, Gravel Pit, Model Railway Ground, Timber Yard (later Works)

6. Conceptual Site Model and Hazard Assessment

The primary regulatory regime under which contaminated land is managed in the UK is Part IIA of the Environmental Protection Act (EPA) 1995. The strategy for the assessment of potential land contamination is based on current guidance documents related to Part IIA of the EPA with particular reference to DEFRA's Contaminated Land Reports CLR11, CIRIA Reports C552 and BS10175:2011. As stated in CLR11, a key element of the Preliminary Risk Assessment is the development of a conceptual site model CSM, which may be refined or revised as more information and understanding is obtained through the risk assessment process.

The CSM is described regarding the contaminant Source, transport Pathways and possible Receptors that may be present, and the potential Pollutant Linkages between them, as defined in the relevant legislation and guidance.

6.1. Potential Source of Contamination

Some potential on-site and off-site sources of contamination have been identified and are summarised below:

On-site: Source 1 (S1) - Road & Associated Made Ground: The Road is located on site and is a potential source of contamination of fuel and oil spillage, and the Made Ground is associated with the construction of the road.

Off-site: Source 2 (S2) - Timber Yard: While having the potential to give rise to contaminants and located on the Terrace Deposits it is a sufficient distance and therefore unlikely to have a significant impact on the proposed works. The ground investigation should include appropriate tests.

Off-site: Source 3 (S3) - Cleaning Services: Close to the site and localised on Glaciofluvial Deposits to the north of a former stream, has the potential to have given rise to contamination such as solvents in the groundwater. The ground investigation should include appropriate tests on groundwater.

As a result of characterising the potential sources identified that could reasonably be linked to the site, the Road, the Timber Yard and the Cleaning Services are considered to be potential sources that can affect the site.

6.2. Potential Pathways

The potential pathways by which receptors might be exposed to contaminants (sources) at the site can vary depending on the proposed or current land use as follows:

For humans, the three possible routes of exposure to contaminants are: inhalation of dusts or gas – Pathway 1 (P1); ingestion of dusts or soil either by hand-to-mouth activity or by eating plants grown in contaminated soils - Pathway 2 (P2); dermal (skin) contact with contaminated soils and waters and transfer of contaminants through the skin into the body - Pathway 3 (P3);

For plants and landscaped areas, the main pathway for exposure involves either direct contact with contaminated soils, ground gas or groundwater or uptake of contaminants into the plant leading to adverse impact - Pathway 4 (P4) & Pathway 9 (P9);

For buildings, property and services, the main pathways by which buildings can be affected are through soil gas pooling within the structures, by contact with aggressive or acidic soils or service trenches acting as preferential migration pathways - Pathway 7 (P7);

For controlled waters, the primary routes by which these can be affected are: run-off from the site surface entering surface watercourses near the site - Pathway 5 (P5); leaching of contaminants from the soil migrating vertically or laterally to groundwater beneath the site - Pathway 6 (P6); movement of dissolved contaminants in soil pore water - Pathway 6 (P6); movement of contaminants via groundwater to surface water bodies - Pathway 6 (P6).

6.3. Potential Receptors

Potential receptors at this site, related to the development proposals, the current use of the site, its location relative to sensitive environmental receptors and the ground and groundwater conditions are as follows:

Human Receptors associated with the proposed development are the occupants of adjacent properties, construction workers, public during construction, maintenance workers – Receptor 1 (R1).

The property receptors associated with the proposed development are adjacent buildings and on-site services – Receptor 2 (R2).

Ecological receptors reflect that the area is within a Countryside Stewardship Scheme Target Area and also, the following ecological features are mapped around the site of interest: Green Belt is mapped about 150 m south of the site; National Forest is mapped about 600 m southwest of the site and Woodland Grant Schemes are mapped about 450 m southwest of the site - Receptor 3 (R3).

The controlled waters receptors associated with the proposed development are: surface waters adjacent to the site and groundwaters - Receptor 4 (R4) and reflect in leaching or dissolution of contaminants in soil and subsequent migration of contaminants in groundwater, lateral migration of contaminated groundwater and lateral migration of dissolved phase contaminants via preferential pathways such as drains, pipes, boreholes and trenches.

Based upon the potentially active Sources/ Hazards, Pathways and Receptors, a Conceptual Site Model has been derived (Fig. 1), including the potential pollutant linkages (Fig. 2).

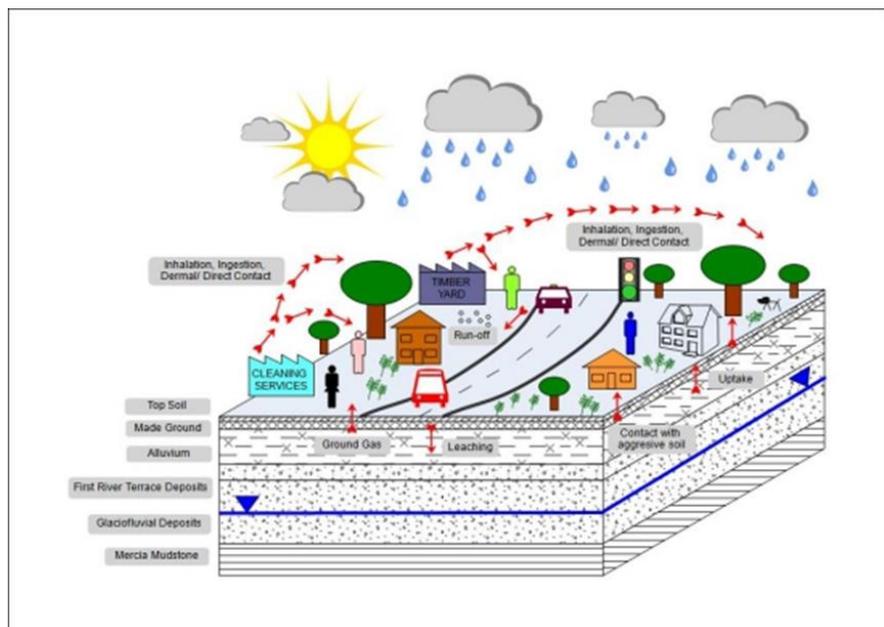

Fig. 1. Conceptual site model

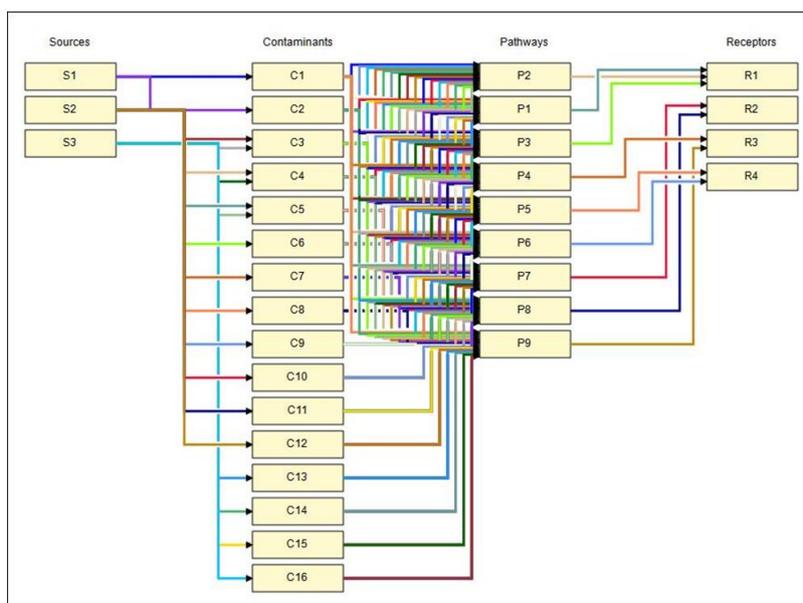

Fig. 2. Network representing S-P-R linkages

7. Human Health Risk Assessment Based on RBCA/ CLEA

Environmental remediation of contaminated sites is based on a risk-based approach for the definition of remedial targets, where the actual pollution of the site is evaluated depending on the effective risk posed to the human health of exposed receptors. The most used technical and scientifically references for this approach are the ASTM Risk-Based Corrective Action (RBCA) standards for evaluating petroleum and chemical release at sites. Both standards provide guidance for the development of a Risk-Based Corrective Action program that integrates the sciences of ecological and human-health risk-based decision making into the corrective action process. More details are found in ASTM E1739-95 (ASTM, 1995) and E2081-00 (ASTM, 2000) standards, which have been issued by ASTM Committee E50 on Environmental Assessment.

The RBCA processes use a tiered approach which incorporates site assessment and response actions with human health and ecological risk assessment, in order to determine the need for remedial actions and to tailor corrective action activities to site-specific conditions and risks. In order to use this tiered approach, an intrusive site investigation is required, which will provide information for the evaluation of the potential effects on the human health receptors; therefore assessing if the site requires remedial action. Based on the derived CSM, an intrusive geo-environmental site investigation plan has been devised, and a sampling & laboratory analysis schedule has been sent to site investigation contractor.

For this paper, we present only the relevant chemical tests required for the Soil Tests – Human Health and Ecology:

Suite B: Soil Tests: Arsenic, Cadmium, Chromium-Total, Lead, Mercury, Zinc, Copper, Nickel, Sulphur-total, Cyanide-total, Sulphide, Sulphate-total, Nitrate – Nitrogen, Ammoniacal Nitrogen, pH, Asbestos (screening & identification MDHS 77), Semi-Volatile Organic compounds (USEPA 8270 including Phenol and Polycyclic Aromatic Hydrocarbons), Volatile Organic Compounds (USEPA 8260), Total Petroleum Hydrocarbons (C10-C40), Petroleum Range Organics (C3 – C8), PCBs (7 congeners).

The RBCA tiered approach has been adopted in the UK by the Environment Agency and transposed in Contaminated Land Report 11 - Model Procedures for the Management of Land Contamination [Environment Agency, 2004]

UK Environment Agency developed a tool for Contaminated Land Exposure Assessment which is used in the UK for Human Health Risk Assessment and the derivation of the risk-based remedial targets for contaminated land (EA, 2009a, EA 2009b). The CLEA model uses generic assumptions about the fate and transport of chemicals in the environment, and a generic conceptual model for site conditions and human behaviour, to estimate child and adult exposure to soil contaminants for those living, working, and/ or playing on contaminated sites over long time periods.

Soil Guideline Values (SGVs) are derived using the CLEA model by comparing the estimated exposure with Health Criteria Values (HCVs) that represent a tolerable or minimal risk to health from chronic exposure. The derivation of HCVs is performed using toxicological data. Soil Guidance Value is a screening tool for the Generic Quantitative Risk Assessment of Land Contamination and represents “trigger values” – above this level, soil concentrations may pose a possibility of significant harm to human health.

We have used CLEA Model running in backward mode, to derive Risk-Based Remedial Targets or Assessment Criteria for our site, starting with a prescribed level of exposure (equal to HCV), and determining the soil concentration that might give rise to that level of exposure.

The following contaminants were taken into consideration, for which laboratory analysis are available: Arsenic: 13 mg/ kg and Mercury: 0.25 mg/ kg. Using the generic residential land use scenario for semi-detached houses and a generic female receptor for all age classes (1 – 18) and an exposure duration of 75 years, we have obtained the following values for SGVs or Remedial Targets: Arsenic: oral: 166 mg/ kg & inhalation: 363 mg/ kg and Mercury: inhalation: 4.97 mg/ kg.

8. Conclusions

Considering few exposure pathways: direct soil and dust ingestion, dermal contact with indoor dust, dermal contact with soil, inhalation of indoor dust, inhalation of soil dust, inhalation of indoor vapor, inhalation of outdoor vapor, and taking into account that measured media concentration for Arsenic and Mercury are lower than Target Values, no remedial actions are required.

Compared to “trigger values” for Romanian Contaminated Land Standards according to OMAPP Nr. 756/ 1997: Arsenic = 15 mg/ kg for “sensible land” and Arsenic = 25 mg/ kg for “less sensible land”; Mercury = 1 mg/ kg for “sensible land” and Mercury = 4 mg/ kg for “less sensible land”, we note that Target Values for Arsenic are much higher (166 mg/ kg > 15 mg/ kg), whereas for Mercury are comparable (4.97 mg/ kg > 1 mg/ kg)

Abstract

In order to achieve the required quality parameters for the impermeable barrier of a Municipal Solid Waste Landfill, the construction process should follow proper procedures. There are two main areas of Quality Assurance and Quality Control (QA/QC) process which should be performed during the construction phase of the MSW Landfill: Construction of compacted clay liners & Geosynthetic material procurement and installation. The paper presents the international approach in the QA/QC process for MSW Landfills comparative with Romanian Legislation and Practice. The importance of the Construction Quality Assurance (CQA) process at the installation of the geomembrane for an imaginary landfill is emphasized by a comparison study on the performance of the landfill with and without CQA.

Keywords: landfills; quality assurance; quality control.

1. Introduction

Construction Quality Assurance (CQA) and Construction Quality Control (CQC) are significant factors in the overall landfill quality management, and the Manufacturing Quality Assurance (MQA) and Manufacturing Quality Control (MQC) of the geosynthetic materials (i.e. geomembranes, geotextiles, geonets, geogrids, geosynthetic clay liners etc.) are equally important.

It is imperative to understand which is the difference between MQC and MQA, and between CQC and CQA.

Construction Quality Assurance (CQA) is a planned system of activities that provide the owner and the regulatory body the assurance that the landfill was constructed as specified in the design. Several activities are included in the CQA: inspections, verifications, audits, evaluations of materials and execution, which are necessary to determine and document the quality of a landfill.

Construction Quality Control (CQC) is a planned system of inspections that are used to monitor and control the quality of a landfill. CQC is performed even by the installer (in case of geosynthetics installation), or by the contractor (in case of natural soil materials), and is necessary to achieve quality in the constructed or installed system. CQC refers to all the measures taken by the installer/ contractor to determine compliance with the requirements for materials and execution as stated in the plans and specifications for the project.

Manufacturing Quality Control (MQC) is a planned system of inspections that are used to monitor and control directly the material which was factory manufactured and is usually performed by the manufacturer of materials. MQC also refers to all the measures that were taken by the manufacturer to determine compliance with the requirements for materials and execution.

Manufacturing Quality Assurance (MQA) is a planned system of activities that assure that all the materials were constructed as stated in the certification documents. Several activities are included in the MQA: inspections, verifications, audits and evaluation of the raw materials and geosynthetic products in order to assess the quality of the manufactured materials. MQA also refers to all the measures that were taken by the Manufacturing Quality Assurance organisation to determine if the manufacturer complies with the product certification.

Manufacturing Quality Assurance and Construction Quality Assurance are performed independently from Manufacturing Quality Control and Construction Quality Control. Even though MQA/ CQA and MQC/ CQC are distinct activities, they have similar objectives, and the processes will complement one another.

* Corresponding author. Tel.: +40 744 60 77 38
E-mail address: camelia.madear@eco-rocca.ro

On the other hand, an effective MQA/CQA program can lead to the identification of deficiencies in the MQC/ CQC process, but the Manufacturing Quality Assurance and Construction Quality Assurance program by itself (in the complete absence of MQC/ CQC program) would lead to an unacceptable level of quality.

Having an effective MQC/ CQC and MQA/ CQA plans in place would provide the required quality management for landfills.

2. QA/QC Process for Compacted Clay Liner Construction

Adequate QA/QC process directly impacts the permeability of compacted clay liners. In this process there are several stages which control the final quality of the compacted clay liner:

- QA/QC before and during clay liner construction;
- Presence of qualified QA/QC personnel on site;
- Preparation and filing of a documentation report.

The construction quality assurance and quality control processes for soil liners have to fulfil three main goals:

1. Sustainability of clay liner materials;
2. Adequate placement and compaction of liner materials;
3. Protection of compacted clay liner.

The steps required to accomplish these three objectives are summarised as follows:

- Adequate preparation of the subgrade;
- Clay liner materials should be suitable and conform to CQA plan and specifications;
- Clay liner material should be prepared, if required, by controlling the moisture content or granulometry;
- Clay should be placed in layers of specific thickness and adequately compacted;
- Protection from damages caused by desiccation/ freezing of the compacted clay liner;
- Preparation of the final surface to install the geomembrane.

A typical testing program in the USA for construction quality control would comprise the followings (as presented by Qian et al.):

Table 1. Testing program for construction of compacted clay liners

Facility Component	Factor	Test Method
Clay Borrow Source	Unified Soil Classification	ASTM D2487
	Moisture-Density Curve	ASTM D1557
	Moisture/ Density/ Permeability Relationship	ASTM D1557
		ASTM D5084
Compacted Subgrade	Moisture/ Density (Nuclear)	ASTM D2922
Clay Liners	Moisture/ Density (Nuclear)	ASTM D2922
	In-situ Permeability Testing	ASTM D5084
	Thickness	Surveying or direct measure
	Slope	Surveying

A typical CQA testing program in the UK during the construction phase of a liner is presented in Environment Agency, and it is based on Eurocode 7, British Standard BS1377 and BS5930.

Romanian legislation regarding the quality control in construction, which also applies to landfills, consists of Law 10/ 1995 and a series of Regulations. Also, there are some Technical Guides and Standards to be used for testing and controlling the compacted clay liners: Technical Guide for Landfilling GT 067-2014, GE-026-97, P 134-95, GP 129-2014.

The Technical Guide for Landfilling requires explicitly at paragraph 3.1.6.2 that a field trial of the compacted clay liner should take place, before the landfill construction. Annexe 1 of the same guide specifies precisely how the field trial should be performed and it is represented in Fig. 1.

Proper documentation of all construction items is essential. The location of any test must be clearly indicated. The drawings and narrative should be clear and concise, and a daily log of construction activities and quality assurance and quality control tests should be maintained.

Finally, a detailed construction certification report should be prepared by both the design and quality assurance firms for submission to Environment Agency.

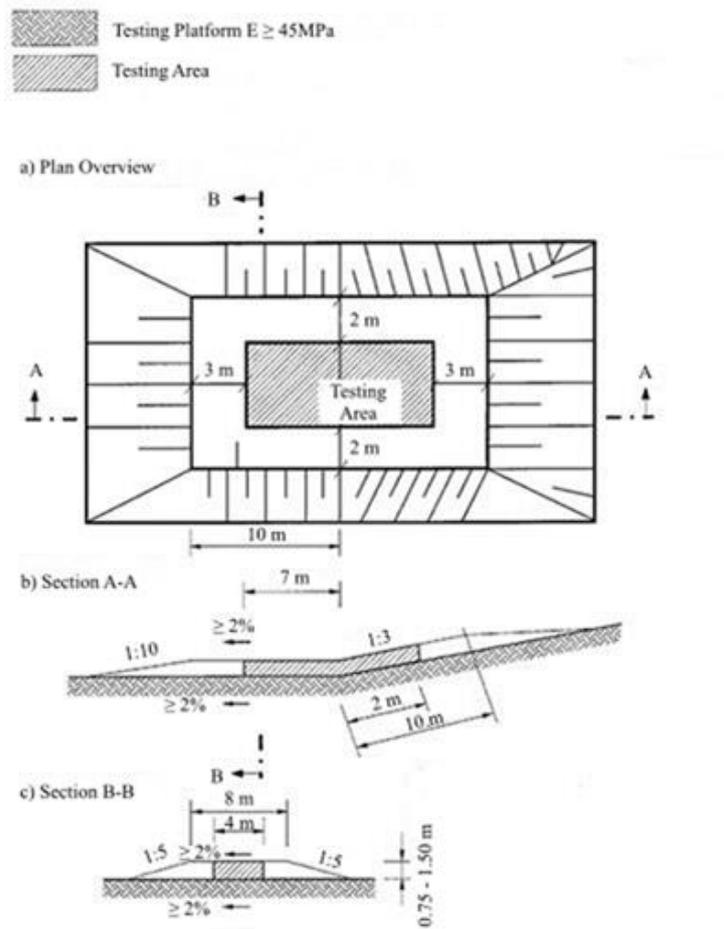

Fig. 1. Compacted clay liner field trials according to Romanian regulations

3. QA/QC Process for Geomembranes Installation

Geosynthetic material installation includes the placement and attachment of the following components into an MSW Landfill: geomembranes, geonets, geotextiles, geocomposites, geosynthetic clay liners, and occasionally, geogrids.

Proper QA/QC must be provided during geosynthetic material installation. QA is provided by an organisation separate from production and installation, whereas QC is provided by the manufacturers and installers of the various components of the geosynthetic system.

In this regard, geosynthetic materials have four levels of quality management associated with them:

- Manufacturing Quality Control – MQC;
- Manufacturing Quality Assurance – MQA;
- Construction Quality Control – CQC;
- Construction Quality Assurance – CQA.

It is important to highlight that a Construction Quality Assurance (CQA) representative should be present on site for material delivery and unload and ensure that conformance test samples are obtained and sent to a laboratory for testing.

For geomembranes, the following conformance tests should be conducted:

- Thickness: ASTM D5199;
- Tensile strength and elongation: ASTM D638, ASTM D882, ASTM D751;
- Puncture: D4833;
- Tear resistance: ASTM D1004;
- Ply adhesion: ASTM D413;
- Density: ASTM D1505 or ASTM D792.

Romanian guidelines on testing and installation of geomembranes are presented in NP 075/ 2002 and GP 107-04, and in the following standards:

- SR EN 13265: 2003;
- SR EN 13257: 2001;
- SR EN 13252: 2001;
- SR EN 13253: 2001;
- SR EN 13251: 2001.

The CQA engineers should review all conformance test results from laboratory conformance testing and report any non-conformance, and ensure that test results meet or exceed the values listed in the CQA plan.

Installation of geomembrane is relatively complicated, and the field seaming is an essential step of the successful functioning of the geomembrane as a barrier to liquid flow.

The CQA inspector/ monitor must ensure that the personnel performing field seaming is fully qualified. Welding technicians should conduct trial welds, and seam test performed accordingly. As each panel is deployed, the geomembrane surface should be observed by CQA monitor for any defects, any holes, blisters, undispersed raw materials, and any sign of contamination. Each location suspected of having defects must be non destructively tested in the presence of the CQA monitor.

The CQA monitor should record daily documentation of all non-destructive and destructive tests.

Romanian Guidelines for the installation of geomembranes at landfills is presented in Chapter 10 of GB 107-04, and the seam testing should be performed in accordance with paragraph 4.5 of NP 075/ 2002.

In order to emphasise the importance of having a CQA plan and QA/QC personnel on site – CQA engineer/ inspector/ monitor, we performed a LandSim analysis for an imaginary landfill, with and without CQA monitoring (liner installed under CQA or NOT installed under CQA).

Table 2 presents the representative input data for LandSim analysis, with the difference of defects between the two runs.

Table 2. LandSim input parameters for liner installed under CQA (with CQA) and liner NOT installed under CQA (without CQA)

Parameter of liner	With CQA	Without CQA
Design thickness of clay (m)	SINGLE (1)	SINGLE (1)
Pathway moisture content (fraction)	UNIFORM (0.35, 0.4)	UNIFORM (0.35, 0.4)
Onset of FML* degradation (years since filling commenced)	150	150
Pathway longitudinal dispersivity (m)	SINGLE (0.1)	SINGLE (0.1)
Time for area of defects to double (years)	100	100
Membrane defects** (number/ ha)		
Pin holes	Min. 0, Max. 25	Min. 0, Max. 750
Holes	Min. 0, Max. 5	Min. 0, Max 150
Tears	Min. 0, Most likely 0.1, Max. 2	Min. 0, Most likely 0.5, Max 10
Hydraulic conductivity of mineral lower liner (m/s)	LOGTRIANGULAR (1e-11, 5e-11, 5e-10)	LOGTRIANGULAR (1e-11, 5e-11, 5e-10)

*Flexible Membrane Liner

**The most likely value for the PDFs which represents the density of pin holes and holes will move from the minimum value selected above to the maximum value selected above over the time period before FML degradation commences.

A comparison of the two runs is presented in Fig. 2 – 5. On the left, we have a concentration of the Ammoniacal _N for the installed liner under CQA, at the base of the clay liner, at the monitoring point, and finally at the compliance point, whereas on the right side, we have the same results for the liner to install under CQA.

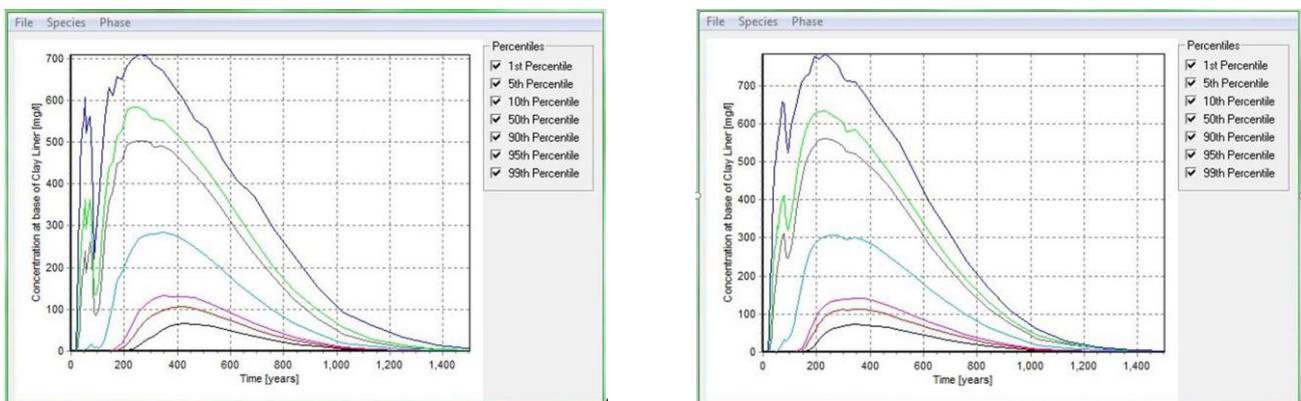

Fig. 2. (a) Concentration at base of clay liner (mg/l) – with CQA; (b) Concentration at base of clay liner (mg/l) – without CQA

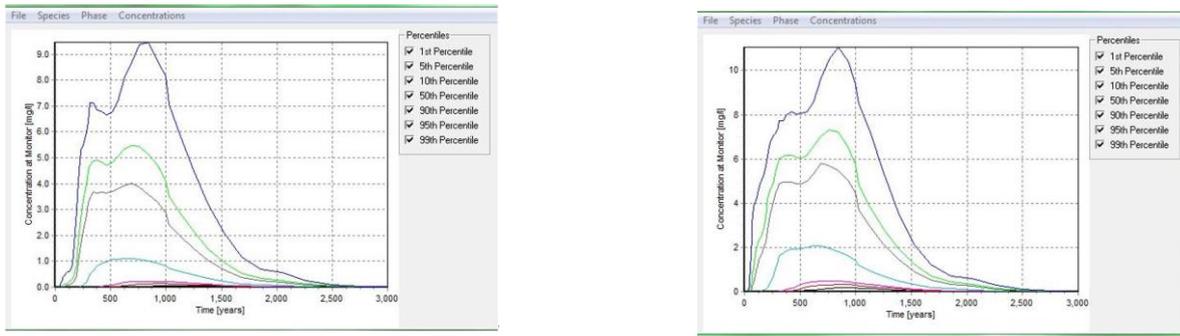

Fig. 3. (a) Concentration at monitor (mg/l) – with CQA; (b) Concentration at monitor (mg/l) – without CQA

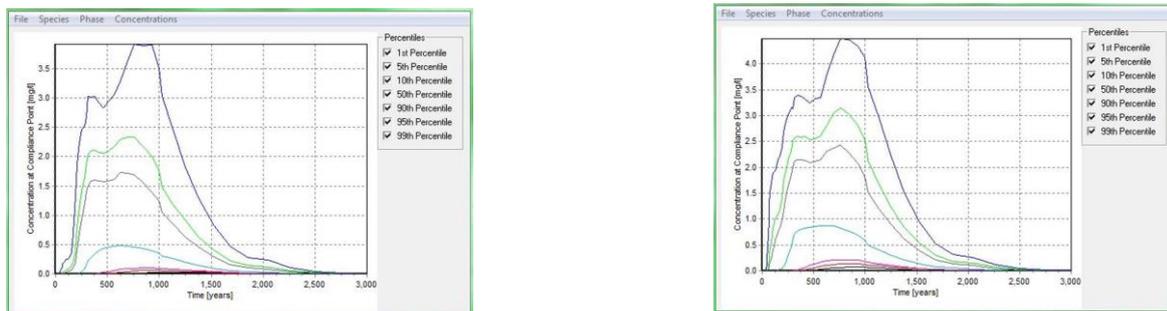

Fig. 4. (a) Concentration at compliance point (mg/l) – with CQA; (b) Concentration at compliance point (mg/l) – without CQA

Statistics at the compliance point is summarised in Fig. 5 (a) and Fig. 5 (b). Comparing the mean value of the concentration of Ammoniacal_N for the first 300 years, it results that without a CQA plan in place, the concentration mentioned above, doubles at the compliance point, making the engineered barrier being unsuitable for the protection of groundwaters in accordance with Romanian Drinking Water Standards.

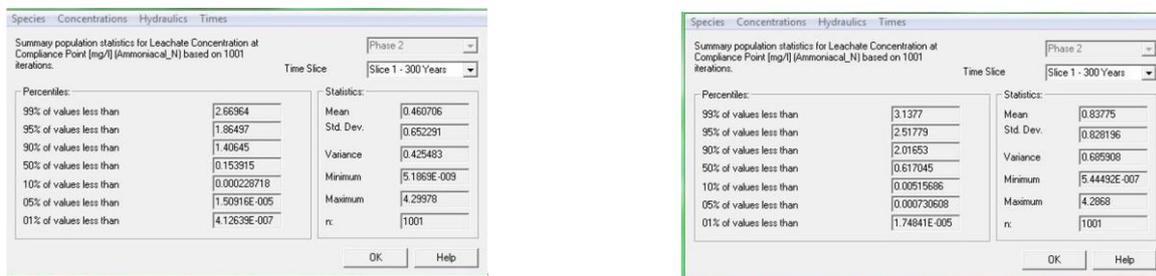

Fig. 5. (a) Summary Statistics at compliance point (mg/l) – with CQA; (b) Summary Statistics at compliance point (mg/l) – without CQA

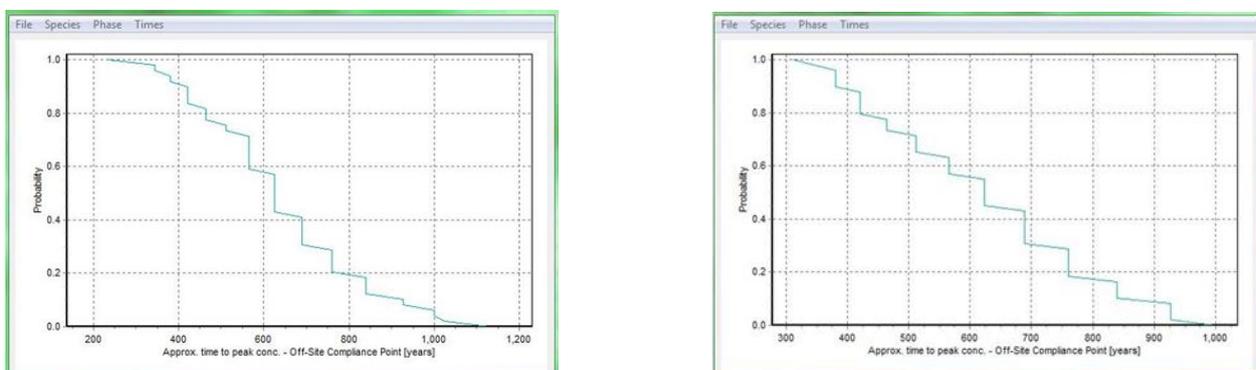

Fig. 6. (a) Time to peak concentration at compliance point with CQA; (b) Time to peak concentration at compliance point without CQA

Fig. 6 (a) represents the time to peak concentration for Ammoniacal_N for the case with Construction Quality Assurance (CQA) at an off-site compliance point with its maximum probability after approximative 200 years, whereas Fig. 6 (b) represents the time to peak concentration for Ammoniacal_N for the case without Construction Quality Assurance (CQA) at an off-site compliance point with its maximum probability after approximative 300 years.

This comparison shows the importance of the implementation of the CQA plan - although we might have a good design of the engineered barrier.

4. Conclusions

Due to the fact that landfills contain massive amounts of organic materials and hold a huge potential to pollute the groundwater and also because the landfill baseliners are by nature buried once these are constructed, and the opportunity to do repairs is extremely limited, a proper Construction Quality Assurance and Construction Quality Control is paramount for the sake of any landfill. Therefore, construction QA/QC at landfills is an essential process in order to achieve the required parameters for the engineered barrier of a landfill. Each construction phase of the impermeable barrier, namely the compacted clay liner and the installation of the geomembrane has its own specific QA/QC procedures.

The importance of the CQA plan is emphasized in this paper and thus the existence of the qualified quality assurance firms (Third-Party Inspectors) which implement the CQA plan and certify to the regulatory bodies (i.e. Environment Agency) that everything is in accordance with the required standards, is paramount for meeting the CQA objectives.

Design of leachate collection system using Monte Carlo simulation

Camelia Madear^{a*}, Gelu Madear^b

^aECO-ROCCA Engineering SRL, 23, Parcului Street, Petrila - 335800, Romania

^bGOLDER, 1, South Parade, Doncaster – DN1 2DY, UK

Abstract

All landfills must have at their base a leachate drainage layer consisting of sands and gravels and/ or geosynthetic drainage material. The most important requirement for a Municipal Solid Waste (MSW) Landfill is that the leachate collection system has adequate drainage capacity to handle the maximum leachate flow produced during landfill operations. The authors present in the paper a comparison of few calculation methods for the design of leachate collection systems using a probabilistic approach, so these systems are compliant with the current legislation.

Keywords: leachate, landfills; drainage layer; probabilistic approach; Monte Carlo simulation.

1. Introduction

The leachate drainage layer has a minimum thickness of 0.5 m as the Landfill Directive stipulates it (1999/31/EC); moreover, the leachate head builds up must be less than this thickness. To properly design a leachate drainage system for a landfill liner, we must be able to estimate the maximum saturated depth over the barrier for any proposed configuration. Landfill Directive, as well as National Regulations, limit the maximum leachate head over the liner to 0.5 m for MSW Landfills.

Factors affecting this maximum saturated depth include the inflow rate into the drainage layer, the hydraulic conductivity of the leachate drainage layer, the leachate flow distance from the upstream boundary to the leachate collection pipe, the slope of the landfill bottom liner, and the hydraulic condition at the downstream end of the drainage layer. Calculation of the liquid head over the barriers is based on the maximum inflow rate using a steady-state assumption, making the design conservative.

Few methods are currently used to calculate the maximum leachate head over the landfill liner, two of them proposed by Moore and two by Giroud et al. and McEnroe, respectively. To take into account the variability of inflow rate, hydraulic conductivity and horizontal drainage distance between the drainage pipes, to the maximum liquid head over the barrier, we have used Monte Carlo simulations using @RISK software. Input parameters are described by Probability Density Functions (PDFs) instead of unique values – as used in a deterministic design.

2. Probability Distribution Functions for Input Parameters

Parameters which affect the maximum leachate head present in the drainage layer are:

- Horizontal drainage distance, L;
- Leachate inflow rate, r;
- Hydraulic conductivity of the drainage layer, k;
- Slope angle of the drainage layer, alpha.

To run a stochastic analysis, first, we have to define these parameters as distribution functions.

Based on international practice, experience and regulations, the following distributions were used for the Monte Carlo simulation:

- L – uniform distribution: Fig. 1a;
- r – normal distribution: Fig. 2b;
- k – uniform distribution: Fig. 2a;
- alpha – triangular distribution: Fig. 2b

* Corresponding author. Tel.: +40 744 60 77 38
E-mail address: camelia.madear@eco-rocca.ro

For the consistency of the units, we have used mm, sec, and mm/ sec.

To run Monte Carlo simulations, we have used @RISK software from Palisade – an add-in to Excel.

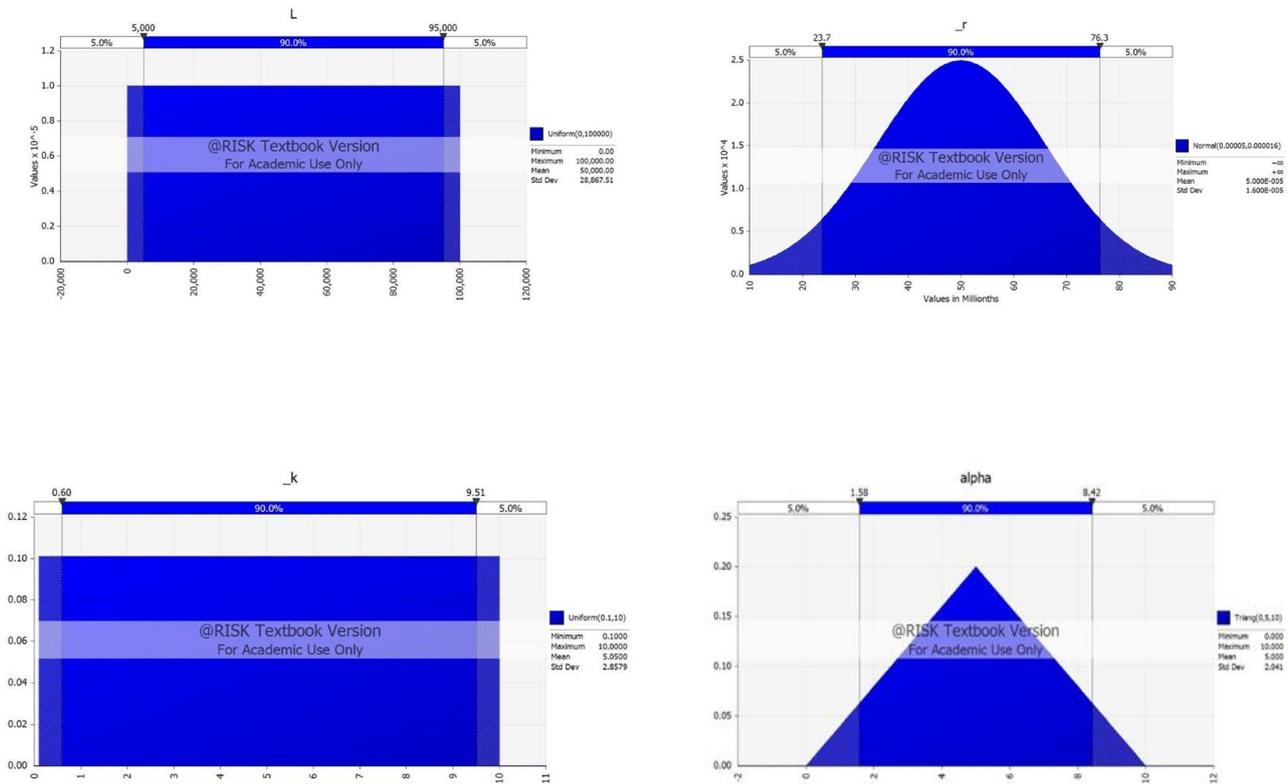

Fig. 1. (a) Uniform distribution for horizontal drainage system; (b) Normal distribution for inflow rate

Fig. 2. (a) Uniform distribution of hydraulic conductivity; (b) Triangular distribution for slope angle

3. Maximum Leachate Head by Monte Carlo Simulations

During the landfill design, there are specific requirements regarding the estimation of the maximum liquid head over a barrier, which must always be assessed in two different locations. One of the requirements is to calculate the maximum leachate head over the base of the landfill, and this should not exceed 500 mm. Another requirement refers to the calculation of the maximum saturated depth in the cover system above the barrier and is essential to mention that this is one of the most important parameters which affects the stability of the final cover directly.

The following factors are known that affect the maximum saturated leachate drainage layer: the inflow rate into the drainage layer, the leachate flow distance from the upstream boundary to the leachate collection pipe, the slope of the landfill bottom liner and the hydraulic condition at the downstream and of the drainage layer.

In this paper, we will determine the maximum leachate head over the base of a landfill which is located in Jiu Valley and in order to simplify the calculation and still have relevant results, we will assume that the flow in the drainage layers of the leachate collection system is in a steady flow rate. In this case, the inflow rate will be constant and is assumed to be equal to the maximum inflow rate.

There are several methods to determine the maximum leachate head over a landfill liner; however, we will use for our particular case Moore’s 1980 Method, Moore’s 1983 Method and Giroud’s 1992 Method.

3.1. Moore’s 1980 Method

The maximum leachate head can be determined by the formula (1):

$$y_{max} = L \cdot \left(\frac{r}{k}\right)^{\frac{1}{2}} \left[\left(k \cdot \frac{S^2}{r}\right) + 1 - \left(k \cdot \frac{S}{r}\right) \left(S^2 + \frac{r}{k}\right)^{\frac{1}{2}} \right] \tag{1}$$

where:

y_{max} – maximum liquid head on the landfill barrier;

L – horizontal drainage distance, mm;

r – inflow rate (i.e. rate of vertical inflow to the drainage layer per unit horizontal area), mm/ sec

k – hydraulic conductivity of the drainage layer, mm/ sec;
 S – slope of the drainage layer, $S = \tan\alpha$;
 α – slope angle of drainage layer, measured from horizontal, degrees.

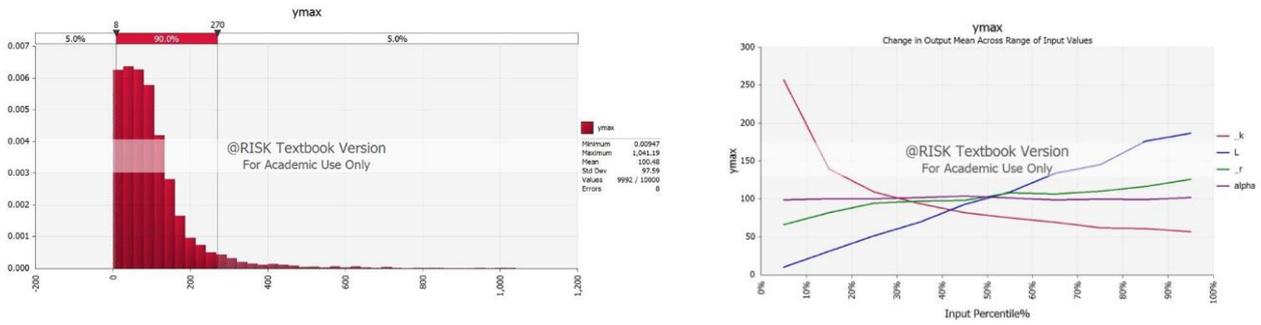

Fig. 3. (a) PDF Model Moore 80; (b) Spider graph Model Moore 80

For Model Moore 80 we ran a Monte Carlo simulation with 10000 realisations.

The resulting Probability Distribution Function is represented in Fig. 5, whereas Fig. 6 shows the influence of each input parameter to the final PDF.

3.2. Moore’s 1983 Method

Moore presented formula (2) for estimating the maximum leachate head over a sloping barrier in 1983 and is a simpler version of the formula (1) presented in 1980.

$$y_{max} = L \cdot \left[\left(\frac{r}{k} + S^2 \right)^{1/2} - S \right] \tag{2}$$

where:

- y_{max} – maximum liquid head on the landfill liner, mm;
- L – horizontal drainage distance, mm;
- r – inflow rate, mm/ sec;
- k – hydraulic conductivity of the drainage layer, mm/ sec;
- S – slope of the drainage layer, $S = \tan\alpha$;
- α – slope angle of drainage layer, measured from horizontal, degrees.

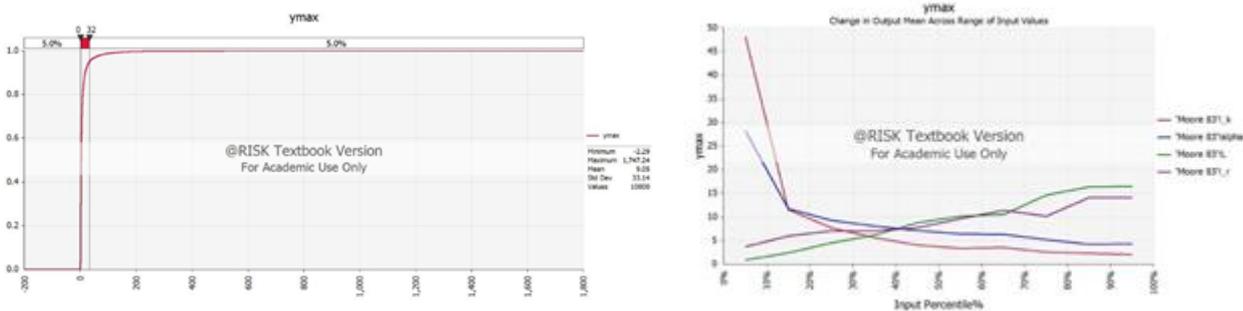

Fig. 4. (a) CDF Model Moore 83; (b) Spider graph Model Moore 83

The same number of realisations has been run for the Model Moore 83, and the Cumulative Distribution Function is shown in Fig. 4a.

The same spider graph – but for Model Moore 83 is presented in Fig. 4b.

This method is less conservative than its previous model.

3.3. Giroud’s 1992 Method

A different formula (3) was presented by Giroud et al. for estimating the maximum leachate head over a sloping liner.

$$y_{max} = j \cdot L \cdot \frac{\left[\left(4 \cdot \frac{r}{k} + S^2 \right)^{\frac{1}{2}} - S \right]}{(2 \cdot \cos \alpha)} \tag{3}$$

The parameter j in the (3) can be calculated as:

$$j = 1 - 0.12 \cdot \exp\left\{-\left[\log\left(1.6 \cdot \frac{r}{k} \cdot \frac{5}{8}\right)\right]^2\right\} \quad (4)$$

where:

- y_{\max} – maximum liquid head on the landfill liner, mm;
- L – horizontal drainage distance, mm;
- r – inflow rate, mm/ sec;
- k – hydraulic conductivity of the drainage layer, mm/ sec;
- S – slope of the drainage layer, $S = \tan\alpha$;
- α – slope angle of drainage layer, measured from horizontal, degrees.

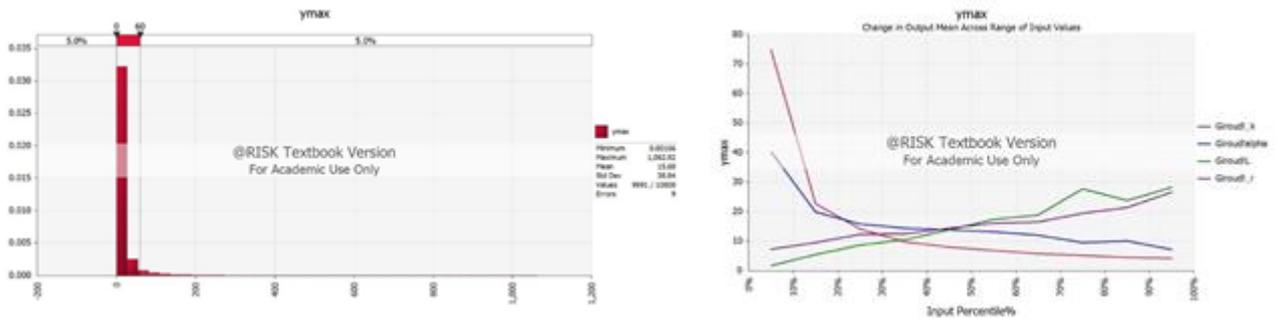

Fig. 5. (a) PDF Model Giroud; (b) Spider graph Model Giroud

Again, we ran a Monte Carlo simulation with 10000 realisations and results are similar to Model Moore 83.

Fig. 5a represents the resulting Probability Distribution Function, whereas Fig. 5b shows the change in output mean across a range of input values.

4. Conclusions

Simple Monte Carlo simulation – each of 10000 realisations, has been run for Moore 80, Moore 83 and Giroud models. The purpose for running a probabilistic analysis was to combine the input parameters – given as ranges and not as deterministic, unique values, and to see how each input parameter influences the final result, maximum leachate head within the drainage layer.

Input parameters are characterised by distribution functions which were derived based on international practice and their influence on the maximum leachate head is shown in spider graphs.

Simulation results are presented either as a Probability Distribution Function (PDF) or Cumulative Distribution Function (CDF), which can be used in the decision making process of the design of the leachate drainage system.

A proposed inventory of sustainable development indicators for the manufacturing process assessment

Corina Dufour^{a*}, Larisa Ivascu^a, Adrian Mateescu^a, Anca Draghici^a

^a Politehnica University of Timisoara, Pta Victorie 2, 300222 Timisoara, Romania

Abstract

Today, new challenges in developing sustainable management models, particularly for manufacturing processes, have emerged because of the new demands imposed internationally for various industrial processes as: resource management (reduce waste and resource efficiency), cleaner production and technologies, recycling and reuse, improving social conditions, better working conditions etc. Operation management models such as Lean Manufacturing and Value Stream Mapping (VSM) have contributed to the development of manufacturing processes by reducing waste in the production flow. This paper aims to propose a conceptual method to integrate a new group of sustainable development indicators into the VSM model to better support the sustainability perspective to the manufacturing process assessment process. Furthermore, the paper discusses how the inventory of the sustainable development indicators was designed (has been considered and selected) based on the literature review in this field. The proposed method will be described together with some considerations for its practical exploitation in different manufacturing processes. The research results have an important contribution to the literature in the field, because of the proposition of new sustainability indicators related to the manufacturing process.

Key words: Sustainability indicators; Lean Manufacturing; Value Stream Mapping; Manufacturing process

1. Introduction

Operation management approaches have evolved over a period to adapt to the new challenges of sustainable development and competitiveness. In this context, Value Stream Mapping (VSM) has been recognized as an excellent tool for process mapping (Braglia et al, 2011) and is used for the of “leaning” industries to make them both more responsive and more competitive (Dinesh and Vaibhav, 2007). Historically, in manufacturing process, responsiveness and competitiveness were measured through indicators such as production costs, time to market or stock costs. Increasing customer interest and awareness of environmental and social impact have steered manufacturing companies to follow-up new indicators related not only to the traditional economic dimension, but also to environmental and social dimensions, giving birth to sustainable manufacturing.

In the context of the present article, there will be considered the integration of VSM approach (and model), sustainable development (with respect to the dimensions given by the Triple Bottom Line model) in the case of manufacturing systems with the purpose of proposing a new method for the integration of environmental, social and economic indicators in the VSM model. Thus, the sustainable development assessment process in the case of manufacturing will be more accurate.

The article starts with a first section presenting a two-parts literature review on sustainable development and the VSM approach, followed by a debate on sustainable development in the manufacturing context. Follows a proposed conceptual method for including (integrating) in the VSM approach, an aggregated indicator that mirrors the influence of environmental and social indicators on the value added (as per calculated in the VSM). In the end, some final conclusions and future research fields are presented.

2. Literature review

2.1. Sustainable development and manufacturing

Manufacturing is critical from the standpoint of sustainable development as it has important environmental and social impacts and is, in the meantime, crucial to economy (Lucato and al, 2017). This has been strained even more as the United States Department of Commerce embedded sustainable development into manufacturing by defining sustainable manufacturing: “the creation of a manufactured product with processes that have minimal negative impact on the environment, conserve energy and natural resources, are safe for employees and communities, and are economically sound” (Faulkner and Badurdeen, 2014; Joung et al, 2013; Feng and Joung, 2009, OECD, 2011). It is inferred from this definition that both the final product and the manufacturing process must be sustainable (Faulkner and Badurdeen, 2014).

Enhancement of manufacturing processes is a challenging field as the manufacturing process is characterized by the existence of several sub-processes, the assessment of which can be complex or incomplete (Kluckek, 2017). Although considerable work has been undertaken in advancing the understanding of sustainable development indicators, literature stresses the need for a clear measurement system, as well as implementation methods (Mani et al, 2014; Veleva & Ellenbecker 2001; Brown and al, 2014; Azapagic and Perdan, 2000). More so, many initiatives are intended for external communication rather than adapted for internal steering (Feng and Joung, 2009).

The bulk of literature was selected by including works that address at least three sustainable development dimensions with the purpose of categorizing the type(s) of metric(s) used: aggregated or non-aggregated. Although, Joung et al (2013, p. 150) distinguish indexes and indicators (“aggregating several indicators through weight-based mathematical methods” vs “a measure or an aggregation of measures from which conclusions on the phenomenon of interest can be inferred”), the authors shall use the term “aggregated indicator” for all measures obtained by a mathematical method and the term “non-aggregated indicator” for all measures obtained through observation, measurement or appreciation.

After reviewing public frameworks, repositories, methodologies and/or indicator sets, many authors point to the need of more clarity regarding the harmonization of indicators (Joung et al, 2013; Veleva & Ellenbecker, 2001; Azapagic and Perdan, 2000; Feng and Joung, 2009). They emphasize the absence of one or several dimensions (Joung et al, 2013; Veleva & Ellenbecker, 2001; Kluckek, 2017; Eseoglu and al, 2014), the number of indicators to be assessed (Veleva & Ellenbecker, 2001) or the limited instructions for implementation (Veleva & Ellenbecker, 2001). As most publicly available indicator sets have already been reviewed extensively in research literature, the selected articles refer to manufacturing industry as a whole, a specific sector of the manufacturing industry or across industries.

It was concluded that on a general basis, and regardless of the type of indicator (aggregated or non-aggregated) ultimately assessed, the implementation of sustainability in the manufacturing industry requires choice of appropriate indicators and measurement procedure (measurement method and acquiring of data) and finally data analysis, decision-making and impact evaluation (Joung et al, 2013, Azapagic and Perdan, 2000). If Azapagic and Perdan (2000) favor a given-basis assessment for defining progress, Joung et al (2013) point to the necessity of setting goals next to which progress can be compared. The poor applicability of the indicators sets at the operational levels is also pointed often (Veleva & Ellenbecker, 2001; Zackrisson et al, 2017; Lucato and al, 2017), as the necessity for less time-consuming approaches is stressed. A noteworthy approach is suggested by Azapagic and Perdan (2000) through their indicator categorization approach which proposes that training and health and safety belong to the economic sphere rather than the more traditional social sphere and should be interpreted in correlation with the indicators of the environmental dimension of sustainability on which they have a direct impact. This goes in the direction of the finding of Zackrisson et al (2017) regarding sustainability indicator interconnection.

In the case of aggregated measurements, supplementary safeguards must be implemented. Lucato et al. (2017) define the sustainability level as the area of the triangle obtained in an orthogonal system, where the axes are defined by the three sustainability dimensions and thus special considerations need to be given to the measurement unit and to the same direction influence of indicators on performance.

Table 1 summarizes the literature review according to the type of sustainability measurement, main sources for indicator selection, the specificity to an industry and, in the case of aggregated indicators, the aggregation method.

Following the literature review, we have concluded that the assessment of sustainable development for manufacturing processes is characterized by the absence of a plebiscite framework, assessment method or indicator set; this derives from the numerous initiatives and wide definition of sustainable development.

Table 1. Categories of sustainability measurement in manufacturing literature

Reference	Type of Sustainability Measurement	Industry Specific	Main Source	Aggregation Method
Azapagic and Perdan (2000)	Non-Aggregated (35 indicators)	Cross-industry	Life Cycle Approach	NA

2.2. Sustainable development and Value Stream Mapping

Value Stream Mapping (VSM) can be defined as “the process of mapping the primary raw material and information flows in converting raw material to finished product or creating a service of value that a customer is willing to pay for.” (Martin, 2013). VSM is intensely used in lean approaches as the easy-to-understand mapping (Faulkner and Badurdeen, 2014) allows rapid identification of waste. VSM is also an important tool for decision makers as it gives a holistic perspective with a clear representation of the flow of information (Martin, 2013) and thus can fill the void of a more hands-on-deck approach. Its main strength resides in being easily comprehensible and highly visual, and as such literature points out, to the danger of overcrowding the VSM by integrating supplementary social and environmental indicators (Faulkner and Badurdeen, 2014; Brown and al, 2014). On the other hand, such integration can induce important gains in terms of cost, image, quality and lead time (Yusof et al, 2013). The difficulty related to the adding of sustainable development metrics to the VSM resides in the aspects of the metrics themselves, which, despite several initiatives from industry, research and regulatory bodies are neither standardized, nor do they capture accurately the risks to which employees are exposed to (Faulkner and Badurdeen, 2014; Brown and al, 2014). These findings are coherent with those of the previous chapter of the article.

Faulkner and Badurdeen (2014) are among the pioneers proposing an approach for the visualization of the sustainability of manufacturing processes by combining Value Stream Mapping and sustainable development in the approach “Sustainability-VSM” (Sus-VSM). They add supplementary indicators regarding environmental and social

dimensions as well as the necessary graphic representations, to the traditional VSM method and time-based metrics. Their proposal for the selected indicators for the environmental dimension of manufacturing included three metrics (process water consumption, material usage, energy consumption) and the social dimension by two metrics pertinent to the most impacted stakeholder, which are the employees (physical work and the work environment).

Brown and al (2014) have approached Sus-VSM by developing the works of Faulkner and Badurdeen (2014) and applying the Sus-VSM to different configurations of the manufacturing environment (job shop, flow shop, cellular). Thus, the conventional VSM approach was implemented by adding economic indicators; questionnaires were added for the assessment of the two social indicators (job hazard and ergonomics) and technical data for the environmental indicators (energy and water consumption). The difficulties in implementing the Sus-VSM model are similar to those for the traditional VSM with regards to the configuration of the manufacturing process, but the collection of data related to the environmental and social dimensions is far more an endeavor as opposed to the economic dimension.

Yusof et al (2013) has later modified the conventional VSM by calculating, for each dimension of sustainability, the sustainable score (ratio of the value adding metric over the non-value adding metric) and by aggregating it into a general sustainability score for the entire process. The non-value-added activities will then be improved through the implementation of the 6R method (reduce, reuse, recycle, recover, redesign and remanufacture).

Finally, it was concluded that the difficulties regarding the implementation of sustainable VSM are less related to the structure or methodology of the VSM for which Faulkner and Badurdeen (2014) proposed an extension, but to the definition and measurement of the sustainability indicators themselves and by defining the methodology for their joint assessment rather than individual. Table 2 presents a categorization of the literature review on sustainable VSM of manufacturing processes by the type of sustainability measure. Furthermore, based on the literature review it was concluded that issues related to the selection of indicators and application of a designed framework are common limitations of assessing sustainable manufacturing in general, and through VSM particularly. The few approaches that include an aggregated indicator for the influence of economic, social and environmental dimensions, are time-consuming and difficult in floor-shop implementation. As such, in the context of the present research there will be proposed, in the next section, an approach for the assessment of sustainability performance in association with the VSM model, independently of the selection and choice of indicators and inducing a diminishment of the value added for social and environmental draw-backs.

Table 2. Categorization of sustainability measure regarding the Sus-VSM approach in the literature (alphabetical order)

Reference	Type of Sustainability Measure
Brown et al. (2014)	Non-Aggregated
Faulkner and Badurdeen (2014)	Non-Aggregated
Yusof et al. (2013)	Aggregated

3. The Proposed Conceptual Model

The literature review pointed out that only intertwining social, economic and environmental indicators can lead to a real measure of sustainability (Joung et al, 2013). In the present research it has been considered that an aggregated approach for the measure of sustainability is more appropriate than a non-aggregated approach as it can give a global, holistic vision and can allow much easier steering and benchmarking. As a pillar economic indicator in value stream mapping, value added, is the object of considerable Lean effort. What is more, value added is also an aspect of manufacturing that appeals to the end customer, as it is a concept within his grasp. In accordance with Azapagic and Perdan (2000) research, in the present approach it has been considered that regardless of the methodology of calculation of value added, in collaboration with other indicators it can give a pertinent measure of sustainable development.

The proposed model enriches the field of aggregated measures for sustainability within manufacturing. The novelty of this model resides in the fact that it can be used for any social and environmental indicators of the manufacturing process through the introduction of a new concept Sustainable Value Added (Sus-VA). Thus, this conceptual framework is compatible with the indicators for which data is available through stable and repeatable measurements, and for which analysis is possible. According to our preliminary development, it was considered that any environmental and social indicator has an influence on the value added of the final product and that by computing the influence of social and environmental indicators on the value added, a new measure of sustainability can be obtained: Sustainable Value Added (Sus-VA). It is defined as the value added of the final product which is the result of a manufacturing process and which considers the environmental, social and economic impacts of the manufacturing process. Sus-VA can be calculated according to equation (1), where VA is the value added according to the calculation in the traditional VSM approach and $EnSolx$ is the Environmental and Social Index.

$$SusVA = VA \times EnSolx \quad (1)$$

In the context of the proposed approach, the Environmental and Social Index (EnSoIx) is defined as the aggregated index of environmental and social indicators evaluated for every process (as per manufacturing unit VSM) on a scale between 0, as the lowest graduation and the target of the organization (as per company strategy). For each manufacturing process, there will be considered the social indicators defined by equation (2) and the environmental indicators defined by equation (3):

$$s_i^j, i \in (1, m) \quad \text{and} \quad j \in (1, n), \quad (2)$$

$$e_i^j, i \in (1, p) \quad \text{and} \quad j \in (1, n), \quad (3)$$

In equation (2) and (3), “m” is the number of social indicators for the manufacturing process “j” and “p” is the number of environmental indicators for the manufacturing process “j”. In this conceptual framework, each indicator is determined within the minimum and the target goal and is then transformed into a percentage of achievement for being included in the model final report. The percentage of achievement in the case of social indicators ($\%s_i^j$) and of environmental indicators ($\%e_i^j$) are calculated using equations (4) and (5):

$$\%s_i^j = \frac{s_i^j}{\text{target}(s_i^j)}, \quad \text{with} \%s_i^j \in [0,1] \quad (4)$$

$$\%e_i^j = \frac{e_i^j}{\text{target}(e_i^j)}, \quad \text{with} \%e_i^j \in [0,1] \quad (5)$$

As through its fundamental definition sustainability is achieved through the balance of its three dimensions: economic, social and environment. Thus, there have been considered that there is no need to propose a hierarchy of indicators. This would also avoid introducing subjective bias in the evaluation. With these assumptions, the average social and environment indicators for a given process are then computed based on the mean of the indicators, as shown by the equations (6) and (7) respectively.

$$\bar{s}^j = \frac{\sum_{i=1}^m s_i^j}{m} \quad (6)$$

$$\bar{e}^j = \frac{\sum_{i=1}^p e_i^j}{p} \quad (7)$$

Finally, the EnIx is the environmental index for the manufacturing unit and is computed as the average of the mean environmental indicator for each process, according to equation (8). Similarly, the SoIx is computed as the average of the mean social indicator for each process, according to equation (9).

$$EnIx = \frac{\sum_{j=1}^n \bar{e}^j}{n} \quad (8)$$

$$SoIx = \frac{\sum_{j=1}^n \bar{s}^j}{n} \quad (9)$$

The EnSoIx of the manufacturing unit, will be the average of the EnIx and the SoIx of the unit, as shown by the equation (10).

$$EnSoIx = \frac{EnIx + SoIx}{2} \quad (10)$$

4. Conclusions

The literature review has pointed out that the measurement for sustainability needs a more integrated approach of the environmental, social and economic dimensions. Such approaches remain scarce in the field of sustainable manufacturing and even more so for a compound usage with other Lean techniques such as Value Stream Mapping. One of the most commonly assessed indicators through VSM is value added, which is limited to the economic sphere, but could be used, in conjunction with social and environmental indicators, as a measure of sustainability in manufacturing.

The proposed conceptual framework introduces a novel concept: Sustainable Value Added. Sus-VA is calculated as an aggregated indicator for sustainable manufacturing, based on the value added as computed through the conventional VSM weighted by the Environmental and Social Index (EnIx and SoIx). Sus-VA delivers a unique measurement of sustainability for manufacturing processes regardless of the advancement of a company on the sustainability path (it could monitor the level of development). In addition, this approach includes social and environmental indicators that the company chooses to consider in the value stream, with the limitation that the value stream is impacted by the subjective choice of indicators (according to company strategy). In order to avoid this aspect, stakeholders and shareholders should be involved in the final analysis and decision.

The main advantage of the proposed conceptual framework is that it induces a social and environmental weighing of the conventional value added; it can be used as a tool for internal steering, benchmarking and external communication. Another advantage is that the framework can include upstream and downstream impacts on the final product if the VSM was drawn up to include these elements and if the traditional value added was computed for the entire chain.

Further research should include an application of the conceptual model for empiric validation (establish the set of indicators for a specific industrial field and/or a particular manufacturing unit), consideration of inclusion of the life cycle approach within the model and understanding of how the Sus-VA can be improved through Lean techniques.

Quality assessment of Petroșani urban landscape

Grigore Buia^a, Ciprian Nimară^{a*}

^aUniversity of Petroșani, University Street, no.20, Petroșani, 332006, Romania

Abstract

The landscape is the world around us, including everything we see or feel wherever we are. It is continuously in space and time: in space as a series of physical and social events, and over time as a continuity of these events that constantly change the space. Through this paper we wanted to make a quality assessment of the urban landscape of Petroșani town to highlight certain characteristics specific to the mono-industrial towns, which identity was lost along with the territorial, urban and socio-economic evolution

Keywords: landscape, quality assessment, urbanism, visual impact, Petroșani;

1. Introduction

The landscape is an important resource, being a remarkable natural and cultural heritage that is appreciated for its beauty and aesthetics, but also its contribution to the identity of a region. Beyond the way the landscape highlights some ways to look at the world, it also puts us face to face with the issues of nature and the way we relate to it. On the other hand, urban and industrial development requires us to talk about urban landscape, industrial landscape, or technological landscape (Bold O., Nimară C., 2016).

Numerous definitions of "landscape" and "geographic landscape" have been imposed over time. Most of them refer to the "landscape view", to the concrete elements of the landscape and the relationships between them, avoiding its subjective reality. Even if the emphasis is on the objective reality of the landscape, that is what is measurable, palpable, concrete, it becomes at one point a subjective reality (consequence of the human perception process). Hence, the landscape is a dual, objective and subjective reality to the same extent (Baciu N., 2014).

The landscape designates a part of a territory perceived as such by the population, the character of which is the result of the action and interaction of natural and/or human factors. The perception of the landscape by the community is a process of cognitive nature that implies the recognition by community members of common values of patrimony with great significance to the community. The principle of community participation aims to provide the public with the opportunity to express their views on the identified landscapes and to participate in landscape identification (Armaș I., 2006). Petroșani town, which corresponds to the geographical coordinates 45°24'44 " latitude N and 23°22'24" longitude E, with an area of over 20,000 ha and a population of 37,160 inhabitants is the largest locality in the Jiu Valley (Petroșani Depression).

By the number of inhabitants, it occupies the third position in the area and at the same time is the most important center of the mining industry in the country. It is located in the southern Carpathians, at a height of 500 m, well connected with the peaks of the Parâng Mountains in the East, Șureanu Mountains in the North-East, the Vâlcan Mountains in the South and the Retezat Mountains in the North and North-West.

2. Urban landscape of Petroșani town

The urban landscape of Petroșani town is part of the category of landscapes belonging to mono-industrial towns which territorial development has led, especially during the industrialization, to the loss of some patrimony buildings or, if they have escaped being demolished, in the post-communist period, with the restitution of former owners or their heirs to staying in various stages of degradation (For example Ianza Castle and colony).

* Corresponding author. Tel.: +0040 762 115 633
E-mail address: ciprian.nimara@yahoo.com

The architectural style of the buildings differs, depending on the period in which they were built, being present in the landscape buildings that were built at the end of the 19th century (the Evangelical Church, the Roman Catholic Church), the beginning of the twentieth century (Ianza Castle, the Worker's Casino, the No. 1 Comprehensive School, Orthodox Church, Unitarian Church etc.) as well as buildings built after 1980, these being mostly blocks of flats and various cultural or administrative buildings (Figure 1).

Fig. 1. Landscape view of Petrosani town

Soil degradation due to underground exploitation may occur within the mining area located on the territory of Petrosani. Industrial waste resulting from technological processes and industrial activities carried out by economic agents consists of: sterile dumps, metal waste, sludge, wood wastes and other types of waste.

The sterile dumps located on the territory of Petroșani town come from E.M. Dâlja, E.M. Livezeni, U.P. Livezeni and E.M. Petrila South. The sterile dumps, as well as the access roads to them are arranged on expropriated land. The sterile dump is the result of investment works following the sorting of coal.

3. Visual impact analysis

The landscape is an instrument of territorial design and development, with changes in the national economy accelerating the transformation of the landscape. Defining elements that condition the landscape are *form* and *history*, and landscape analysis and reading requires knowledge of the structure and materials that make up the landscape.

In the definition and perception of the landscape, different approaches were taken, the best known being:

- approaching the *objective landscape* characteristic of the Soviet school. This approach focuses on the correlations between physico-chemical factors, soil and biotic support. Objective landscape analyzes cast out man and anthropic construction and refer to pure natural terrain, difficult to trace in reality.
- approaching the *subjective landscape* characteristic of the French school, which falls in the extreme of the subjectivism of perception, of the links with art, philosophy and the history of the landscape. However, it is worth noting that the French school has made significant contributions to the holistic landscape and has accentuated the areas of perceived landscape, lived landscape, landscapes created (parks and gardens).

Basically, the landscape can not exist without a man, the latter interfering with the landscape and modifying it according to its needs (Eg. changing the landscape to increase the tourist value of some sites).

The objective bases of analysis (Table 1 and Table 2) of the urban landscape of Petroșani town are:

- the relief, represented by the slightly elongated intra-mountain depression, with the hilly foundation, the neighboring scenery being visible the piedmonts (Dâlja Piedmont and Maleia Piedmont) as well as the Parâng and Vâlcan mountains;
- natural elements more or less compete with visual harmony through diversity;
- the built elements are testimonies of the presence of man and reveal an obscure value, not negligible to an observer and constitute an important element of the landscape.

Table 1. Analyze point of urban landscape by major structures

Territorial system framing	Mountain framing	Structural framing	Administrative framing	Geomorphological framing
Large area (1-10 km ²)	Mountain landscape	Terrestrial landscape	Urban area	Depression landscape

Table 2. Analyze point of urban landscape by natural and anthropic indicators

Biography and soil	Climate	Culture and history	Social-economic framing	Dynamic state of operation
Coniferous and mixed forest, brown soils, grey woods soil and clay soils	Mountain climate with temperature inversions	Modern and contemporary architectural values	Mining activities, commercial activities, residential areas, tourist or recreation areas	Modified structures, degraded structures, irreparable structures

The cultural landscape of the urban peripheries is a distinct type of urban landscape, as a result of an environment in the same destiny with the city, in the prolongation of which it is established, undermining its existence on the one hand, on the one hand, and on the other hand, an alternative.

The cultural landscape of the urban outskirts is a landscape in transition, a contradictory resource, corresponding to a process of changing the reference systems across the entire urban system, including indeterminacy, disorder, vague, incoherence, absence. Despite its often desirable, aesthetically pleasing appearance, the landscape's cultural landscape is one of authenticity and potential, giving urban culture a consistent regeneration field.

The criteria for identifying the landscape are part of the methodology elaborated on the basis of 451/2002 Law for the ratification of the European Landscape Convention. The Convention takes into account international legal sources in the field of protection and management of natural and cultural heritage, land-use planning, local autonomy and cross-border cooperation.

4. Quality assessment of Petroșani urban landscape

From a qualitative point of view, an evaluation was made taking into account 13 indicators, as can be seen in the following table (Table 3):

Table 3. Quality assessment of urban landscape

Name of indicator	Value		
	Low	Medium	High
Buildings and historical monuments	19 th century	X	
	20 th century	X	
Buildings and constructions of new architectural value after 1989	X		
Buildings built between 1950 and 1989			X
Green areas, parks and recreation areas		X	
Pedestrian assemblies, public squares	X		
Homogeneity of architectural style	X		
Visible homogeneity in height	X		
Visual homogeneity as shape and structure		X	
Aesthetic contrast between buildings (shape, structure, color)		X	
Detached, demolished or demolished buildings	X		
Contrast on residential areas		X	
Accessibility between functional areas			X
Industrial zones in operation	X		
Decommissioned industrial zones	X		
The visual and qualitative aspect of the transport infrastructure		X	

5. Conclusions

Through this paper we wanted to make a quality assessment of the urban landscape of Petroșani town to highlight certain characteristics specific to the mono-industrial cities, which identity was lost along with the territorial, urban and socio-economic evolution.

Most of the time, the focus is on the objective reality of the landscape, which is measurable, palpable, concrete, but it becomes at one point a subjective reality, being a consequence of the process of human perception. Hence, the landscape is a dual, objective and subjective reality to the same extent.

The quality assessment of landscape is a process that is aesthetically related to a subjective value scale that is often the cultural, educational, understanding, and style of each subject or respondent. It refers to the natural, cultural or urban landscapes that it has been seen or analyzed previously. Most of the time, the quality assessments of the landscape or the environment have been countered by the assessment scale used in the form of qualitative values: high, medium or low.

The underground space, a solution for the protection of the environment

Daniela Ionela Ciolea^{a*}, Emilia Cornelia Dunca^a

^a University of Petrosani, Universitatii Street, no. 20, 332006 Petrosani, Romania

Abstract

The research, concerning the development of underground facilities worldwide, it indicates that both a favourable environment for the use of the underground space (or space location understood as great) and a boost to the adoption of the method are required to achieve the underground construction of major underground facilities. A major incentive for the use of underground space is growing international concern on the environment, which led to rethinking future urban construction and industrial. It is clear that increased pressure on the use of terrestrial lead to two trends already present in many countries, or the construction of high-rise buildings or use scale growing facilities of underground space, variant seems however, it is the most advantageous. In this context it is important to plan new type of underground facilities wisely. Planning must be effectively controlled and used to maintain the natural surface and side effects involved in the development of underground projects are anticipated.

Keywords: underground space, the environment, the use of underground space, construction

1. Introduction

The increasing world population and rapid development of modern society will have a significant impact on the livelihoods of people in the future, leading to higher living standards, increasing consumption of food, energy and minerals. Due to population growth, urbanization and economic growth this earth must now support transport systems extensive industrial development and trade and growing demand for housing, so that the area under agriculture decreases gradually since the seats flat and generally fertile they initial development was places historically.

A major incentive for the use of underground space is growing international concern on the environment, which led to rethinking future urban construction and industrial.

The largest underground city in Cappadocia, Derinkuyu was discovered only in 1965, when one of the region's residents cleans up in a room of his house.

Finally, archaeologists and speleologists have discovered that behind the wall hiding a real underground city, which stretched at least 18 stories underground to a depth of about 85 meters, and can accommodate about 30 000 people.

In fact, experts have not fully explored even today underground city of Derinkuyu.

2. The current state of the underground space

Environmental damage caused in the last century has significantly reduced quality. In this respect good knowledge of damage caused to the environment in developed countries use obsolete technologies affecting the environment in poor countries with environmental pressure due to overpopulation and increasing needs, promotes better understanding of the phenomenon of environmental pollution and enables us to take appropriate action to protect it.

But environmental damage is done not only because of human error or technical accidents but also due to cultural approaches inadequate or blind economic policies.

Accumulation of quantities in recent years increasingly more waste owing to increased human activities, process reported worldwide, raises very important economically and environmentally.

* Ciolea DI. Tel.: 0751081047.

E-mail address: cdipentrucdi@yahoo.com.

Thus, it is estimated that between growth rate and the volume of waste there is a proportional relation, which contributes to the worsening conflict in the modern age of technology, on the one hand and ecology on the other. The massive increase discharges of waste and toxicity of a good part of their content jeopardizing the ability of the environment to assimilate them.

The emission and waste discharge into the environment of the initial stage of the process is pollution, followed by reaching the ambient concentrations in the quality of the biological environment.

Therefore a fundamental objective of any policy and strategies for environmental protection is to reduce the amount of waste from production and consumption patterns as a result.

Such an objective can be achieved by way of recycling, reconditioning or recovery of waste and deposit them in appropriate conditions to eliminate any possibility of environmental pollution. But desirable as better integration of environmental concerns into consumption and production schemes.

According to statistics and international studies, the quantities of waste generated in each country and the average per capita was related to the degree of development and urbanization, the type of technology applied in the production of specific and consumption patterns, income levels and lifestyle population.

However, the level of development and civilization leaves its mark on the business of environmental protection waste pollution.

Effective waste management in the context of sustainable development refer the following dilemma: waste disposal or recovery of the amount remaining under the restrictions of cost and the environment.

The aim in waste management is to maximize the preservation of non-renewable resources and neutralizing negative effects on the environment.

So the concept of the cultural sector can be characterized by including waste issues within the general actions for environmental protection, given that any waste which is not used or neutralized, pollute the environment.

Currently in developed countries of the total expenditure on environmental protection:

- 20 ÷ 25 % of which are intended to be recovered by recycling useful minerals and the costs incurred are recovered;
- 75 ÷ 80 % are for the collection, neutralization, elimination and / or economically non-recoverable waste disposal.

In Romania, the costs for the collection, transportation, disposal and storage of waste solids is about 27 % of the total expenditure for environment protection, reflecting a relatively small and insufficient concern.

The ratio of investments for the recycling of waste and waste pollution protection is negligible, less than 1 % of the total investment. Meanwhile developed countries spend for this area, between 5 and 15 % of total investments.

Reported per capita total annual waste in Romania is about 12 tons compared to about 10 tons as the media representatives on all countries in Western Europe.

The differences between the two levels can be explained by: character structure of the economy and lack of funds; outdated technology; lack of continuing concerns for the environment.

The highest weights are held in our country waste resulting from underground mining and quarrying - over two fifths. In terms of the amount of waste dumps and tailing ponds is the most important source of environmental pollution. Evaluate all over the country, about 360 million tons, which make up the waste deposits and tailings ponds current production resulting from the activity occupies an area of 11.600 hectares, which is equivalent to about 0.08 % of the total agricultural area of Romania 0.12 % of total arable land.

Of the total area occupied by waste dumps and tailing ponds have been provided up to now, about 9 %. If they are supplemented ash, slag and waste ore metallurgical processing, shows that over 70% of solid waste pollution due to industrial activities freely. In Romania of over 2 million tons of waste annually, representing about 95 % of industrial waste. (Wegner, 1993) Although difficult and costly removal and disposal remains the central issue of environmental strategy.

Methods of waste disposal, the most used is deposition on land or burial ground (especially for municipal waste, in Romania there are currently only two landfills and no ecological waste incinerator). So costs are low, this presents a high risk of pollution by high potential for groundwater contamination, soil and explosion through gas accumulation.

In these circumstances the main objective of sustainable management of waste is to eliminate as far as possible the risk of pollution by pretreatment of waste deposited or depositing them in complete safety or in underground facilities, specially built for this, but that society contemporary Romania can not allow, particularly in economically, either by use of underground spaces resulting from the mining activities of various useful minerals.

Today suggested the need to calculate economic benefits by assessing the feasibility of all actions that can change the environment. Thus, a proper economic analysis can only be one that will take into account the environment.

This is a problem for both people and industry, and acceptable solution must be based on acquiring the already serious problems affecting quality of life and future can endanger life itself.

Using underground space it has been recognized as one of the most important ways of solving difficult problems of waste management.

In the face of immense pressure acting on the environment, using underground is a safe and most often only economically, given a correct design, safeguard the environment.

It must however be borne in mind that the underground facility may affect the environment both positively and negatively, so the role of design and studies to be carried out is precisely to maximize the positive effects and to eliminate or minimize the negative ones.

3. The direct benefits on the underground space

Using underground space, in compliance with its copy of the surface results in a large number of direct benefits, most important being (Stefan, 2006):

- First point
- temperature is approximately constant in the ground which is an advantage for storage of certain products;
- moisture is easily controlled, and the quality of groundwater can be kept without difficulty;
- safety is excellent in terms of fire, flood, hurricane, big rain and snow;
- proliferation of insects and bacteria is better controlled than in the conventional storage of goods;
- damage and loss of production are considerably reduced material;
- land area is protected from pollution of the gas, liquid and solid. It also avoids aggression and destruction of forest land, flora and fauna.

Because of these advantages, today reported a large number of uses of underground spaces for storing: various documents, fuel oil, compressed air and other sources of energy, water, food and agricultural products, weapons and weapons sludge from waste treatment plants, spent fuel from nuclear power plants and atomic other radioactive waste, and municipal waste.

Also the underground space can be arranged to house museums, swimming halls, vaults of banks, research centres, oil refineries and various waste recycling centres, hydroelectric and atomic power plants. If atomic nuclear plant at Chernobyl was built underground as the vast majority of the damage caused by the explosion in April 1986 could have been avoided. Due to environmental constraints rising that are currently imposed on the various laws in most developed countries, they have been made in recent years, a large number of projects underground, while many others are under construction or stage conception.

There is now a general attention to these types of engineering solutions and many countries have begun to consider the underground space as a "resource" that must be treated and managed with care. Some developed countries have decided to evaluate this important resource in their territory by measuring underground spaces natural of abandoned mines or other excavation underground to develop large-scale projects in order to seek and implement new solutions for utilization of these resources.

Underground environment is not only an object of potential impact but also an element of moderation, which becomes clear when hosted arrangement aimed at protecting the environment such as water treatment plants or landfills.

Changes in the type and geographical distribution of the industry could lead to conflicts of land use: Also, changes in the environment, energy and operating costs in the industry may require new strategies and industrial policies.

Underground space can resolve some of these conflicts, and change long-term industrial strategy should consider the underground option. Underground disposal and storage projects are feasible, economically viable and can be clearly provides environmental benefits.

It therefore appears objectively as a detailed analysis, the environmental benefits related to the use of underground spaces are considered in economic terms, can often allow a change of perspective that compensates very high costs for the execution ground.

Practice environmental impact assessment must become an essential component in the design of all facilities to help address these enormous fears of humanity.

Benefits resulting from the achievement of underground facilities not only environmental benefits, but applies to:

- anyone directly involved in the work (client, user, company building);
- economic-social and people directly or indirectly involved due to the effects caused by construction work.

If achieving underground facilities between itself and the environment can be distinguished both positive interaction and negative, but it is important that the design work specific to succeed in harnessing all those positive interaction, to control and moderate the intensity of the negative in order to successfully use such arrangements and to eliminate the possibility of undesirable uncontrolled further, that through their action could cause damage to the environment.

Industrial activities could become technically, economically and legally feasible and environmentally advantageous placing them underground would be: deposits of oil, petroleum products and natural gas; deposits of industrial and consumer goods; cold storage of food; waste disposal mining, metallurgical, construction, household and radioactive; wastewater treatment systems.

Also the underground space could be used for recreational facilities such as museums and different places, but also for security deposit and religious facilities, while identifying appropriate sites and assessments correct.

4. Examples of the use of underground space

4.1. For residential use

Uses the underground space as living space is probably the oldest of its use by people. Archaeological and anthropological research found many fossils in caves that serve as shelter in various parts of the world. Thus two of the remotest discoveries of cave dwellings are Qafzeh in Israel, dating back 92 000 years ago and Klasies River Mouth in South Africa where he was born the theory of anatomy, that people lived from 60 000 ÷ 120 000 years ago.

In many countries and regions of the world can give examples of historical settlements underground. The main reasons for the use of underground space for residential seem climate, there is a geologist and suitable topography, the need for protection against intruders and the existence of previous examples.

Settlements included significant underground dwellings carved in stone in Cappadocia in Turkey, which reached its peak in sec. X - XI of the Byzantine period. Two of the most famous underground cities are Kaymakli and Derinkuyu Anatolian which included civil engineering, ventilation shafts and tunnels connecting several kilometers excavated existing volcanic tuff.

In 1963, British archaeologist James Mellaart discovered a fresco now considered the oldest ever discovered landscaping work. Dating back 8000 ÷ 9000 years ago, the painting is also the oldest work of art made on a built area of people - a wall made of bricks plastered with mud. Fresca measuring 2.5 meters by two cones depicts a volcano erupts while being placed on a structure composed of multiple packs apparent. Soft volcanic tuff enough to allow a man to dig through it with a spoon. When exposed to air, however, the material is solidified. Historical evidence shows that around 700 before Christ people armed with iron tools digging into the ribs of Cappadocia to build their homes. Nobody knows how many underground cities in Cappadocia hide. Have so far been discovered eight cities and many smaller villages, but certainly there are others hiding underground. (***)

4.2. Derinkuyu - the largest and most mysterious underground city discovered

One of the characteristics of the underground cities Cappadocia is set. It is known that in this region there are over one hundred underground settlements, many of which are open to the general public, however. Derinkuyu underground city is located in the eponymous town at a distance of 40 km of Goreme, Turkey. Originally built in soft volcanic rock in Cappadocia by Phrygians in the eighth and seventh century BC, the underground city Derinkuyu was expanded and developed in the Byzantine period. The city was connected with other underground cities through long tunnels of several kilometers.

To accommodate between 3000 and 50000 inhabitants. The complex has 11 levels. There are approximately 600 outlets by the city, hidden courtyards or under buildings. The city is about 85 m deep underground. It comprises the usual rooms found in underground cities, (churches, winery, living rooms and food storage, etc.). In addition, a large room that presents an arch, located in the 2nd, was a Christian missionary school rooms left were used for the study.

Derinkuyu city contains about 15 000 channels supplied fresh air ventilation in the depths of subterranean city. Vents that have a depth of 55 m were used as fountains.

The extensive network of passages, tunnels, corridors inclined linking family rooms and common areas where people puteu meet, work and pray. Level 3 and 4 are vertical scale. This passage leads to a cruciform church, which is the lowest.

Derinkuyu underground city was where the early Christians hid from the region, who escaped from persecution carried out in the Roman Empire.

One of the tunnels discovered by cavers is wide enough to allow simultaneous passage of three. Going along it, the scientists found that the tunnel connects to another underground city located at 10 kilometers away. Moreover, several findings suggest that at some point, all Cappadocia was linked to a hidden network of underground tunnels. Today, many people in the region use these tunnels to post cellars.

Archaeologist discovered that cities were lit with torches or oil lamps in, producing enough heat to maintain the temperature at a pleasant level. Moreover, it is likely that these underground cities have been used first as a winter shelter. In time, however, as the Hittites, Assyrians, Romans, Persians, Byzantines, Seljuk Turks and Christians found through these caves, each of these civilizations has deepened and extended them for another purpose: the defense. Moreover, scientists have concluded that the Seljuk Turks and Christians extended the original rooms, dug in prehistory, so as to allow the creation of underground stables for horses.

These civilizations were not the only ones considered cities as a good shelter underground war. In 1990, when the Gulf War was in full swing, the Turkish authorities have considered using underground shelter against bombs cities where conflict would be expanded regionally.

The underground city of Derinkuyu, underground stables housed below the floor feed. Below are found the communal kitchen equipped with furnaces earth below a ceiling of 3 meters with holes for ventilation. These bore holes specially drilled smoke tunnels, so that it reaches up to 2 kilometers away, to fool the opponents.

In Australia many mining towns have placed a number of housing and community buildings underground to escape the severe heat outside. These examples include Coober Pedy mining towns of White Cliffs and Andamooka.

In France and Spain sec. Twentieth use of underground spaces residential caves link to use as holiday homes, many of which are furnished to the highest contemporary standards.

The energy crisis of the 70^s of the XX century generated a strong public interest in developed countries about the benefits of energy conservation in underground structures, so there have been some developments in the US multifamily along highway in Minneapolis.

4.3. Recreational use

Perhaps the most famous and widespread use of underground spaces for recreation is linked to the exploitation of caves for tourism, and the inclusion of tourism of the old me. Underground recreational facilities include sport facilities and community centers in many parts of the world. Types of facilities used include swimming pools, gyms, hockey halls and sports facilities with multiple purposes. Norway Gjøvik swimming pool and gym Kannusillanmaki sports center in Helsinki, Finland are examples of potential underground recreational facilities.

Georgetown University, Washington, a facility for sport has been extended under existing football field. In China, Hanzhou city has bars, a ballroom and multiple rooms designed for the amusement of children in the underground space and underground city of Hangzhou has a theater with 1800 seats, used and defensive end. Retretti concert hall in Finland is known around the world for acoustic performance achieved. In Japan, the underground space of the former limestone mines Ohya is a place often used for art exhibitions and numerous shows. In Poland mine in Wieliczka is famous for its use as a museum and concert hall. But the examples are many and countries in Central and Western Europe. In Romania are known recreational and health centers for curative value, Slanic Prahova salt mines and mine. These uses are specific underground voids created from solid salt extraction methods. Thus formed underground spaces are large and very large, they have constant temperature (12 °C) and humidity of approx. 50%.

4.4. Use for urban development

The most significant examples are present in Montreal and Toronto, consisting of large parking lots and underground pedestrian interconnected systems that allow movement in much of the area under the city without exposure to inclement weather or road traffic. They also contain shopping areas with the most fashionable stores.

Another example of an integrated urban development is complex underground Les Halles in Paris. The complex covers 100 000 m² and extends on four levels below ground, keeping the area a park surrounded by old and beautiful historical sites and architectural and includes subway, streets, parking lots, a great area for shopping, recreational facilities and a pool swimming. Japan has also a long history of development of underground shopping centers. Today more than 20 Japanese cities have shopping complexes and underground infrastructure services.

There is: using the library, offices, educational institutions, use for industrial facilities, use for military and civil defense facilities, religious use and the use of storage, see in (Georgescu and Ciolea, 2017).

5. The future underground

In the XXI century, a growing group of visionary engineers and architects for increasingly more often to underground. But this time, why not escape religious persecution - their goal is to escape the crowds. (***)

2018 will start construction of 9 billion a city underground, just below the famous canals of Amsterdam, which will include places for shopping, relaxing spaces and parking. Singapore, Toronto and Frankfurt plan also major underground development.

Not only will shop around underground, but Mexicans will live soon there.

A "sky-ground" on 65 levels proposed for Mexico City will descend about 300 meters below the main square. Inverted pyramid created by Bunker Arquitectura, will have a core of ten levels of glass that will send light to the 10 levels of housing, stores 10 levels and 35 levels of offices. Although not necessary to worry about miscreants Romans, living under the earth's surface has some distinct advantages.

"If you take into account phenomena such as natural disasters, where would you rather be: the 50th floor of a tall building or underground?", says Professor Samuel Ariaratnam engineer at the University of Arizona, one of the authors of a report by the National Academy of Sciences of the United States about the future of urban development underground, and if the surface climate change will create catastrophic conditions, then a shield of earth and stones, several meters thick, would be more desirable than a balcony with a view.

As recognizes Ariaratnam, down construction cost is higher than building up: "I think I see skyscrapers reverse in my lifetime," he says. But long term, the benefits begin to appear, and underground becomes a desirable place to live. "Look at hot and wet climates or the very cold. Who would want to hang out? "

One day, you could find and parks in the depths underground. There are proposals in the New York park "Lowline" in a huge area remained without use after scrapping a system of trams in 1948. The name is inspired by the High Line park, which was built on an abandoned rail system in western Manhattan. Mirrors and optical fibre cables will bring daylight into these caverns. Tubes reflectors will play a key role in this project by focusing sunlight above. These innovations will allow grass, bushes and even trees to grow on the surface of the Earth.

Existing underground developments have shown how the phenomena that we associate with the surface can be brought under the ground. Sanford Underground Research Centre - a complex of laboratories in South Dakota, which has levels from 90 metres depth to almost 2500 meters - the architects have worked with psychologists to try to make the environment as pleasant as possible. The screens show images of blue sky and ventilation systems create air flows to mimic the surface breezes. The designs are intended to prevent psychological problems.

But PhD. Raymond Sterling, a professor at Louisiana Tech and an expert in underground spaces, suggests that life at this level should be no problem. "Most people have no problem in using the London Underground or be in a room without windows during a concert", he says. "If people find a reason for this or if there are physical benefits to be underground, they can accept it."

6. Conclusions

Underground space is an important resource whose use land began long before the birth of self-consciousness of man. Underground space in modern times began to be used widely overseas in the US first, then this type of use has grown in Western Europe and Japan. Spaces are underground link to geo-mechanical parameters identification, mining, favourable economic and political, which then serve to assess the feasibility of the proposed comparative technical schemes.

In Romania the lack of use of underground space facilities, consciously or using it enough, can be caused by: geology incorrect perception that the country is poor; absence of a strategic planning of the use of the subsurface; the insufficient funds allocated to this area; absence or insufficient knowledge of the advantages of the underground space; the absence of the necessary technology; tracking failure to respect the environment. The research in Romania in this direction should include the following objectives: presentation of the key points of technical considerations, geological and economic acceptance or rejection of the use of underground spaces; assessment of geological conditions, market and legislative framework and administrative process related to the use of underground space across the country.

In Romania analysis, particularly the following areas with direct implications in economic, social and environmental development should be prioritized: storage of natural gas and oil products; industrial warehouses and consumer goods; food warehouses; waste deposit; systems and storage elements and operation of wastewater treatment plants give industry and the household; storage of agricultural products; storage of raw materials and different materials.

In this regard should be given to re-use mines or excavations developed specially for this purpose, there is a large worldwide experience in the use of underground space even weak and intensely fractured rocks.

Underground space is recommended for residential, religious, recreational, urban development, library, offices, educational institutions, storage for industrial facilities, military facilities and civil defense.

In the process of using underground space must analyze many factors geological, geo-mechanics, mining and economic and solely by test results complexes on their decisions can be location undergrounds various social functions or industrial normally locates the surface.

Visual analysis of deformations from the quarry and inner dump steps from North Pesteana mining perimeter

Apostu Izabela-Maria^{a*}, Lazar Maria^a, Faur Florin^a

^aUniversity of Petroșani, Universitatii Street, no. 20, Petroșani 332006, Romania

Abstract

Deformations and changes occurring in a rock mass, whether natural or anthropic, result from the geotechnical characteristics of the rocks and the influence of various external or internal factors. Under the influence of external factors, such as vibrations, overloads, the presence of groundwater or surface water, there results deformations and changes such as cracks, fissures, erosion and suffosion phenomenon, compaction, superficial or deep landslides etc. These types of deformations and changes signal the possibility of occurrence of negative geotechnical phenomena, such as landslides, which endanger the safety of people and objectives in the zones of influence. Also, these changes can influence the stability of the individual steps and even of the systems of steps, which is why it is necessary to constantly monitor and evaluate the stability in order to carry out the safety of the working operations.

In this paper, a visual analysis is performed in order to identify deformations occurring in the North Pesteana mining perimeter and to highlight the possible problems that may arise in terms of stability of the quarries and the safety of the employees and objectives of the areas of influence.

Keywords: visual analysis, deformations, landslide, quarry, inner dump, stability;

1. Introduction. The importance of visual analysis in slopes stability

The visual analysis of the deformations and changes occurring in a rock mass/rock deposit is an important step in the land stability assessment activity. Based on this, areas with potential risk are identified deformations, changes, possible causes and other related effects are highlighted.

The presence of discontinuities, such as fissure, cracks, fissures, stratification, etc., and changes resulting from surface erosion, suffosion or sliding phenomena, affect the strength characteristics of rocks and, implicitly, massifs of rocks (Rotunjanu, 2005).

Unlike faults that are large-scale tectonic discontinuities, cracks and fissures are small-scale discontinuities. As an extension they may vary from a few centimeters to tens of meters and may have an opening up to a few tens of centimeters. Cracks and fissures can cause the massive fragmentation of the masses and reduce the resistance of rocks and rock massifs (Rotunjanu, 2005).

Deformations and changes occurring in a massive of rocks are the result of alteration of the rocks understood as worsening of geotechnical characteristics under the influence of external or internal factors.

There are two types of alterations: superficial and deep. This paper focuses on the physical alteration of rock or its disintegration over time under the influence of various external or internal factors.

Surface alteration affects the rocks that constitute the superficial layer of rocks and is manifested by the permanent influence of external and internal factors: water, air, climate, organisms and gravity. Unlike this, the deep alteration is manifested under the action of the tectonic forces. The tectonics and micro tectonics of rock massifs are one of the main causes of landslides as a result of the reduction of the strength of the rock massive (Rotunjanu, 2005).

Erosion is the dislocation and entrainment of material on land surfaces. Erosion can be pluvial or windy and manifest, as the name says, under the action of waters or wind, plus the influence of gravity. Rainwater erosion is the main form of erosion that is emphasized in the present case, since surface water leakage, depending on local conditions (rainfall, infiltration capacity, slope angle, water flow speed etc.) can determine the appearance of gullies (up to 30 cm deep) and small to large ravines (with depths of up to several meters) (Lazăr, 2010). The appearance of gullies and ravines are considered as being the primary processes of the landslides (Lazăr et al., 2012).

Landslides are superficial or depth displacements of the rocks on the slopes of rocks massifs. Landslides are the most frequent and dangerous forms of degradation of rock massifs and, most of the time, are signaled by the deformations and changes described in this paper.

Therefore, the first part of the paper shows the importance of performing visual analyzes, which is why a case study for the mining perimeter of North Pesteana quarry was carried out.

2. Location of the objective

The perimeter of North Pesteana quarry is administratively owned by Gorj County, being located within the Urdari and Balteni communes. The North Pesteana quarry was opened in the area where the Jiu River bedside existed prior to its regularization, and includes the Jiu meadow about 2 km wide, with odds of +137 m ÷ +155 m, inclined to the east, towards the Jiu river bed and to the south.

In the mining perimeter of North Pesteana quarry, both excavation and sterile dumping are carried out in 4 steps.

Taking into account that the mining perimeter is still in operation (for the next 6 years), this indicates that with the advancement of the working front and extension of the inner dump, there will always be new deformations and changes within the perimeter that may favor the occurrence of negative geotechnical phenomena.

3. Research and site observations

In order to be able to characterize the technical state of the internal dump and the in situ steps of the North Pesteana quarry, several field visits were carried out between April 2017 and June 2018. At the same time, these visits were aimed at collecting data and information on the geometrical and geotechnical characteristics of the rocks in the perimeter, the eventual sliding (superficial or profound) phenomena that occurred over time and their causes. (Apostu, 2018)

As a result of the visual analyzes carried out, and also on the basis of the information received, regarding the technical state of the quarry and of the inner dump, we will continue to list a number of observed aspects.

As a result of periods of excessive precipitation and of the periods of snow melting, there were some superficial landslides both on the in-situ slopes (Fig. 1.a) and on the inner dump slopes. The reason for these slides is the increase of the humidity of the rocks and, implicitly, of the volumetric weight, which leads to a decrease of the stability reserve.

Numerous erosion zones have been highlighted - generally, gullies (Fig. 1.b), so small ditches - formed as a result of the superficial water flow.

Fig. 1. (a) Superficial landslide on in-situ slope; (b) Gullies on inner dump slope;

As a result of the fact that the dewatering of the aquifer formations is realized naturally through the slopes of the quarry, the suffosion phenomenon was manifested, which led to the occurrence of suffosion zones on the slopes of the steps I (Fig. 2.a) and II. In the case of natural drainage of groundwater, there is continuous entrainment of the fine particles of rocks, which leads to the occurrence of these suffosion zones, basically underground gaps, of different dimensions and at different depths.

As a result of erosion by suffosion, depending on the depth at which the underground gap is formed and its size, can cause collapse of the rocks as a result of loss of rock stability from the roof of the gap.

Recently (at the beginning of 2018), on the eastern slope of the quarry there was a landslide, which affected the structure of the road that serves the mining perimeter (Fig. 2.b). The causes of this landslide were the abundant precipitation and the major infiltrations from the Jiu River.

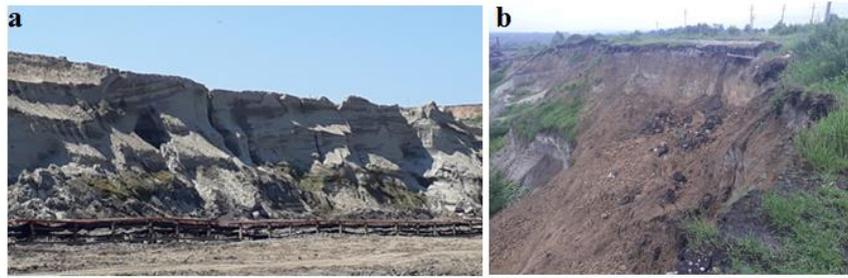

Fig. 2. (a) Sufosis zones on the first step of the quarry; (b) Landslide on the eastern slope of the quarry;

On the berms of the inner dump steps there were fissures and tension cracks (Fig. 3). Although these changes can be attributed to longer periods without rainfall, they generally signal the possibility of occurrence of the landslides, so it is recommended to follow these types of changes.

Fig. 3. Cracks on the berm of second step of the inner dump

Analyzing the situation plans, it has been observed that there are some differences between the projected geometry and the existing one, both in the steps of the inner dump and in the steps of the quarry. These differences generally occur at the slope angles and less at the height of the steps.

The values of the slope angles exceed the maximum values established in the project of $18 - 27^\circ$ for the individual slopes of the dump, respectively 4° for the individual slopes of the quarry. It has been observed that sterile material is deposited in the dump on a natural slope angle, the value of which varies depending on the nature of the rock, reaching in many cases up to $45 - 50^\circ$ (Fig. 4.a). As a result of the applied methods of exploitation and of the used equipment, the slope angle for the pitches reaches values of up to $60 - 75^\circ$ or even higher (Fig. 4.b). It was found from one visit to another that the practice of reducing the inclination of the slopes is not applied, most probably on the fact that the working front, respectively the inner dump, is advancing continuously, so the steps with this geometry have short service life.

Fig. 4. Inclination of the slopes of the quarry and inner dump during the exploitation period; (a) Inner dump; (b) Quarry

It has been noticed that with the advancement of work fronts and the expansion of the inner dump, these deformations are remedied, but new changes arise that signal the reduction of the stability reserve and the possibility of occurrence of negative geotechnical phenomena under the continuous influence of external and internal factors.

4. Measures to reduce the risk of landslide

Generally, these deformations and changes can't be prevented. As these cause the worsening of geotechnical characteristics of the rocks and signal the possibility of occurrence of negative geotechnical phenomena such as landslides, it is recommended to apply local measures to increase the resistance of rocks after their occurrence. Some of the measures that can be recommended for the North Pestean quarry are:

- removal of gullies, ravines, fissures and cracks by material filling, leveling and compacting;
- proper management of groundwater and surface water;

- applying measures to reduce the amount of infiltrated water from the Jiu River to North Pesteana quarry by reducing the permeability of the right bank of the Jiu River;
- reducing the amount of water that drains naturally through the slopes of the quarry or reducing the rate of infiltration by increasing the flow of dewatering in order to prevent the phenomenon of suffosion;
- respecting the projected values of the geometrical elements of the quarry and inner dump steps. Failure to comply with the projected values may favor the occurrence of negative geotechnical phenomena.
- performing visual and geotechnical analyzes, where appropriate, and intervening as quickly as possible to prevent these phenomena from occurring on a larger scale.

According to the literature, the determination of the contours of the working slopes and of the final slopes must take into account a number of criteria, such as the economic and social importance of the objective and the time of their stagnation. Thus, for small service times, such as for working slopes in a mining perimeter, lower stability factors are acceptable, on the grounds that they are remedied as work advances, but for very long service life times, for the definitive slopes, the value of the stability reserve must be high. (Fodor, 1980; Rotunjanu, 2005)

5. Conclusions

The visual analysis allows the highlighting of the deformations and changes that may indicate the possibility of occurrence of negative geotechnical phenomena. Based on the visual analysis, in the perimeter of the North Pesteana quarry, there were identified erosion and suffosion zones, fissures and cracks, superficial landslides that did not affect the overall stability, these modifications being corrected as the work front advanced, but also a larger sliding in early 2018 on the eastern slope of the quarry that affected the structure of the road that serves the mining perimeter.

So far, the deformations and changes occurring on the steps of the quarry and the inner dump of North Pesteana mining perimeter did not affect the overall stability of the quarry or the inner dump, except for the landslide from the eastern slope of the quarry, but they may endanger the stability of the individual steps.

Generally, signs of erosion are the gullies, ditches of small dimensions. Also, the suffosion areas were of small and medium sizes, and did not affect the mining works or the stability of the career steps, but they could seriously jeopardize the safety of employees as a result of rock falls. Fortunately, during the observation period, no such event were recorded. Given the short service life time of the quarry steps, these types of changes are remedied as the exploitation works advance. Given the fact that with the advancement of the work fronts new deformations and changes occur, it is recommended to continuously perform visual and geotechnical analyzes, where appropriate, and to intervene as quickly as possible to prevent these phenomena from occurring on a larger scale.

Considering the behavior of the rocks from the quarry and inner dump steps within the North Pesteana mining perimeter under the influence of the external or internal factors, it is recommended to pay close attention and adequate intervention for the case of definitive slopes of the quarry, that have a much longer service life time than working steps, for decades, to increase the stability reserve and the degree of safety of the objectives in the areas of influence.

Quality improvement of switching parameters at switching with DC hybrid breaker

Titu Niculescu^{a*}, Dragos Pasculescu^a

^aUniversity of Petrosani, 20 Universitatii street, Petroșani, Romania

Abstract

The paper presents a modern method of improving the switching quality with hybrid DC switches by using a method for extinguishing the electric arc that emerges among the contacts of a direct current breaker. The method consists in using a LC type extinguishing circuit, which must be optimally dimensioned. From this point of view, a theoretical analysis of the phenomena that appear immediately after disconnecting the charge is presented, specific diagrams being presented. With their help, the elements of the extinguishing group can be dimensioned. In the second part of the paper, an analysis of the circuit commutation process is made by decomposing the process in particular processes that take place at different time sequences. For each interval it is conceived a model of numerical simulation in MATLAB-SIMULINK environment, which integrate the characteristic differential equations and draws the variation curves of the voltage on the condenser and of the oscillating current from the circuit.

Keywords: differential equation; electric arc; hybrid breaker; simulation; switching quality; zero current.

1. Introduction

In the hybrid breakers of direct current that don't have natural zero current, the situation of charge disconnection which is accompanied by the emergence of an electric arc inside the switcher and in time it can destroy its contacts, appears as a high problem (Atmaji, 2000), (Far and Jovicic, 2018). In these cases the commutation necessitates additional circuits that are parallel connected over the main breaker. The basic idea is to produce an injection of counter current which opposes the current of arc, therefore being produced a null resulting current through the main breaker (Bartosik, 1997), (Robbins, 1995). The effect of this zero current is the extinguishing of the arc among the contacts of the breaker.

The electric scheme of the basic circuit for the commutation of the charge in direct current is presented in Fig.1:

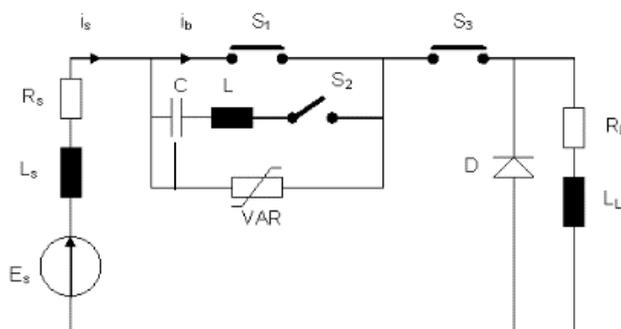

Fig.1 The electric scheme of the commutation circuit

The source of continuous voltage E_s that has the internal parameters R_s and L_s is connected in series with the main breaker S_1 , with the electrical separator S_3 and with the electric charge of parameters R_L and L_L . In parallel with the main breaker an auxiliary circuit is connected, consisting of a condenser C , a coil L and an auxiliary switch S_2 , which usually

* Corresponding author. Tel. +4-072-392-2072.
E-mail address: niculescu_titu@yahoo.com.

is a semiconductor (thyristor). The varistor VAR limits the overvoltages from the terminals of the breaker and the suppressor diode D takes the current when its slope is negative.

For extinguishing the arc in the main breaker S_1 , the auxiliary switch S_2 is immediately closed after the disconnection.

The energy stored in the condenser C taken from the source E_s , is released and generates a current that opposes the source current, resulting a zero current through the contacts of the main breaker.

The condenser C together with the coil L form an oscillating circuit that will produce a second zero current through the main breaker, in case the arc didn't extinguish itself on the first zero current. After the extinguishment of the arc (Pasculescu et al. 2017a), (Pasculescu et al., 2017b), the condenser C is charged again from the source E_s being prepared for a new commutation manoeuvre of the circuit (Benouar, 1994), (Das, 1997).

2. Analysis of the arc extinguishing process

If we mark U_{1c} the equivalent continuous voltage of the extinguishing circuit and its equivalent resistance R, the differential equation of the voltages is given by the relation (1):

$$LC \frac{d^2 u_c(t)}{dt^2} + RC \frac{du_c(t)}{dt} + u_c(t) = U_{1c} \quad (1)$$

From where the capacitive current:

$$i_c(t) = C \frac{du_c(t)}{dt} \quad (2)$$

Based on the equations (1) and (2), the numerical simulation scheme was conceived in MATLAB-SIMULINK (Ghinea and Firteanu, 2000), (Yang et al., 2017), (Zhang et al., 2017), which draws the arc current through the main breaker S_1 (Fig.2).

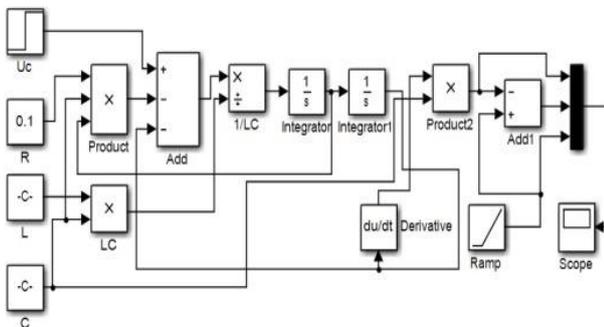

Fig.2 The numerical simulation scheme of the arc current

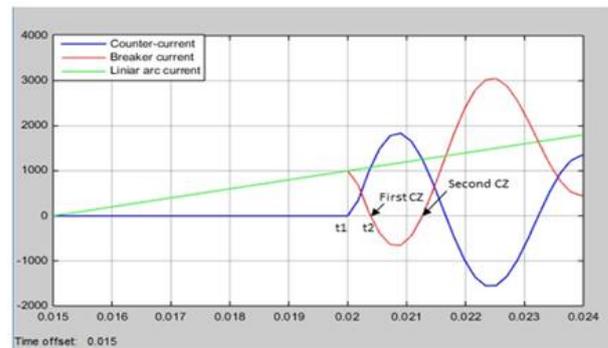

Fig.3 The diagram of the currents through the main breaker

The simulation scheme from Fig.2 generates the MATLAB diagram of the currents that appear in the commutation system (Fig.3). As it can be seen from the scheme, at the moment t_1 , (related to the disconnection moment), the current reaches the value i_{t1} when the voltage on the condenser C has the value U_{C0} .

On this moment t_1 , an injection of counter current emerges in opposition with i_s , so that the current through the contacts of the main breaker begins to decrease (Franck, 2011), (Shan et al., 2017). At the moment t_2 it becomes zero and the voltage drop on the condenser decreases to the value U_{C2} .

3. The analysis of the commutation processes

For the study of the commutation process, the circuit from Fig.4 was used.

The process of interrupting the current can be divided in three time intervals, where each interval is described by a differential equation.

These differential equations can be integrated in the MATLAB-SIMULINK environment, which allows the drawing of the current variation curves and of the voltage on the condenser.

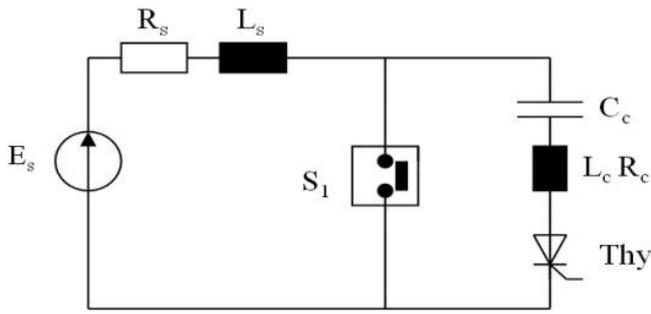

Fig.4 The electric scheme of the commuted circuit

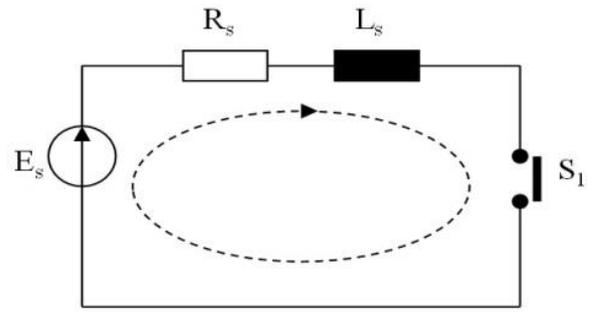

Fig. 5 The flow of the current in the interval [0-t1]

The following moments of time were taken into account.

- t_1 – the time after which S_2 closes and the oscillating process begins;
- t_2 – the time after which the first zero current appears through the main breaker S_1 ;
- t_3 – the time after which the source current becomes zero and the condenser C is maximum charged.

3.1 The time interval $[0 - t_1]$

In this time interval the current of the source goes through a loop E_s like Fig.5, and it is described by the differential equation (3):

$$L_s \frac{di_s}{dt} + R_s i_s = E_s \tag{3}$$

If the initial conditions for this interval are taken into account, the current through the circuit has the expression:

$$i_s(t) = \frac{E_s}{R_s} (1 - e^{-\frac{t}{T}}) \tag{4}$$

where $T = L_s/R_s$ is the time constant of the circuit. Its variation is an exponential function.

3.2 The time interval $[t_1 - t_2]$

At the moment t_1 the oscillation in the extinguishing circuit begins and the countercurrent appears through the main breaker.

The voltage on the condenser that belongs to the extinguishing circuit is described by a differential equation of second order:

$$LC \frac{d^2 u_c}{dt^2} + RC \frac{du_c}{dt} + u_c = U_{c1} \tag{5}$$

where U_{c1} is the voltage on the condenser C_c at the moment t_1

The differential equation (5) is integrated in the MATLAB-SIMULINK environment. The scheme of numerical simulation which draws the voltage variation (Koldby and Hyttinen, 2009), (Vincens et al. 2017) on the condenser and the current through the extinguishing circuit is presented in Fig.7.

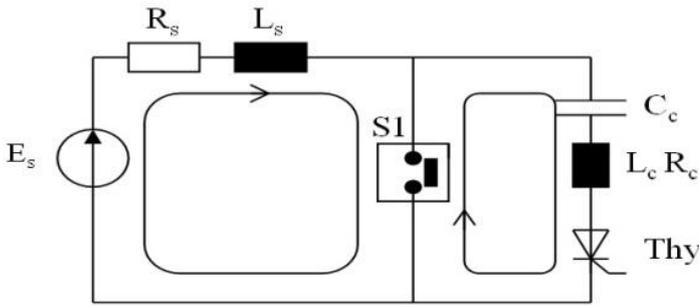

Fig.6 The flow of the current in the interval $[t_1-t_2]$

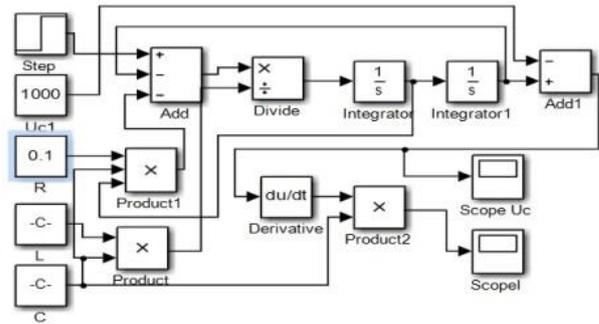

Fig.7 SIMULINK model of the oscillating and of the current through the condenser in the interval $[t_1-t_2]$

This model generates the following diagrams: (Fig.8 and Fig.9):

At the moment t_2 the current through the main breaker S_1 becomes zero and the voltage at the terminals of the condenser reaches the value U_{c2} .

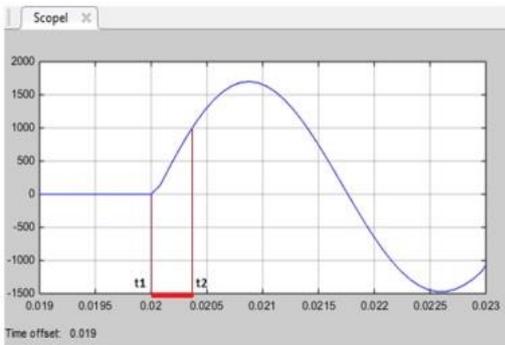

Fig.8 The variation of the current in the interval $[t_1-t_2]$

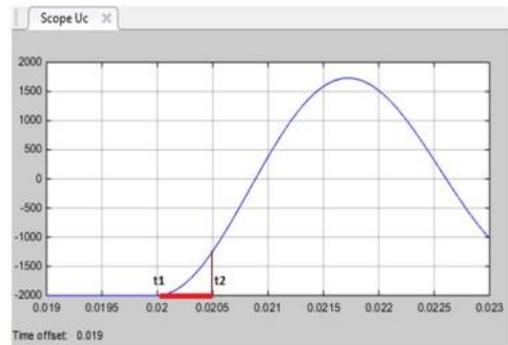

Fig.9 The variation of the voltage on the condenser in the interval $[t_1-t_2]$

3.3 The time interval $[t_2 - t_3]$

In this interval, the current of the source becomes equal with the current through the condenser. The voltage on the condenser at the initial moment is U_{c2} and the current I_{t2} . After switching on the main breaker, the circulation of the current takes place as it is shown in Fig.10:

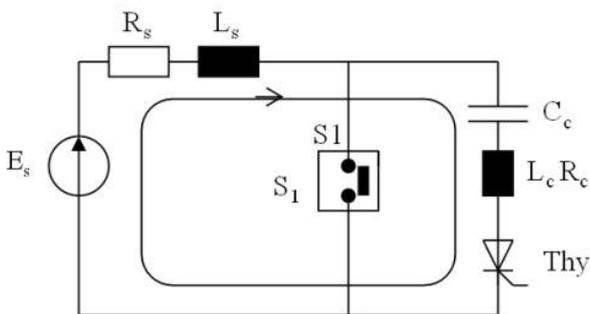

Fig.10 The circulation of the current in the interval $[t_2-t_3]$

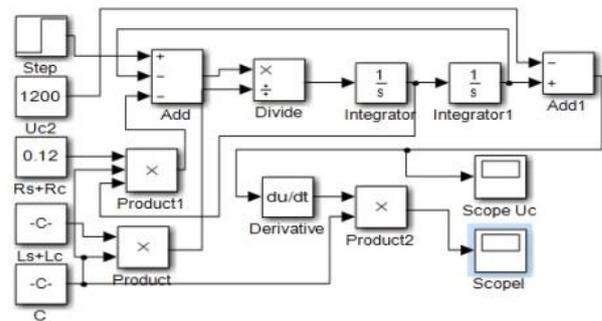

Fig.11 The SIMULINK model of the oscillating voltage and of the current through the condenser in the interval $[t_2-t_3]$

The voltage on the condenser of the extinguishing circuit is described by a differential equation of second order:

$$C_c(L_s + L_c) \frac{d^2 u_c}{dt^2} + C_c(R_s + R_c) \frac{du_c}{dt} + u_c = U_{c2}$$

(6)

The differential equation (6) is integrated using the same environment of numerical simulation. The simulation model (Pasulescu et al., 2014) that generates the variation of the voltage on the condenser and the variation of the current through the extinguishing circuit is presented in Fig.11.

The SIMULLINK model previously presented leads to obtaining the following diagrams:

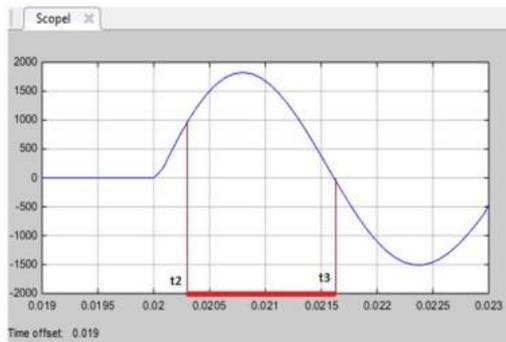

Fig.12 The variation of the current in the interval $[t_2-t_3]$

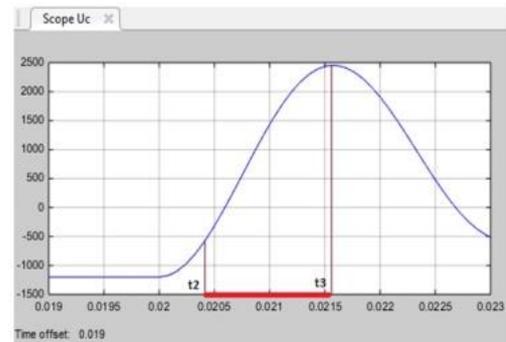

Fig.13 The variation of the voltage on the condenser in the interval $[t_2-t_3]$

At the moment t_3 the current of the sources reaches the value zero, while the condenser C_c is completely charged, as it can be seen in Fig.13.

4. Conclusions

The quality of switching with DC hybrid breakers is dependent on the correct sizing of the arc extinguishing group that appears between its contacts.

This is possible through a detailed analysis of the switching phenomenon and by an appropriate choice of the values of the elements of the extinguishing group using the relations and diagrams obtained and presented in the paper.

The commutation manoeuvre of the charge can take place in the situations in which S_2 is either with unidirectional conduction or with bidirectional conduction.

If the auxiliary switch S_2 is chosen to be a unidirectional (thyristor), the counter-current that emerges in the resonant circuit LC can produce two zero currents, in which case there are two opportunities to extinguish the arc.

Another method of interrupting the charge current assumes the use of a bidirectional switcher. In this case, having commutated the current of the source, the oscillations of the current continue on the duration of some time periods until the final voltage on the condenser becomes equal with the voltage of the source. During the oscillations the energy is transferred between the source and the circuit LC. Using a vacuum breaker is an excellent method for interrupting the charge current.

Depending on the value of the commutation current, an adequate switch can be chosen from the available power semiconductors. The devices with static interruption are frequently vulnerable at the rising of the current slope. The switch must be able to resist the countercurrents when connected and the overvoltage when disconnected. In principle, the power semiconductors allowed that the high current to be commutated by lowering its frequency. When the frequencies of the circuit LC are high, a good method for interrupting the charge current consists of using the vacuum breakers.

Management of the optimal operating states of electrical distribution stations

Leon Pana^{a*}, Dragos Pasculescu^a, Florentiu Deliu^b

^aUniversity of Petrosani, 20 Universitatii street, Petrosani, Romania

^b„Mircea cel Batran” Naval Academy, Fulgerului Street, no.1, 900218, Constanta, Romania

Abstract

This paper presents the up-to-date methods employed of analytical evaluation of optimal power of electric stations within the framework of electric energy conversion and distribution stations or substations. Evaluation of optimal power of electrical transformers has been made on the basis of economically criterions, which to take in account the cost of transformers as well as power and energy damages.

Keywords: operating states; power transformer; loading coefficient; optimal power; electric stations.

1. Introduction

When designing the connection with power systems of the power supply distribution systems, the solving of the following problems is taken in account:

- Satisfying the mining consumers requests
- Ensuring the optimal degree of safety for each development stage (of the mining consumer area), of some simple and economic solutions, adapted on consumer categories and classes
- Adopting some modular and elastic schemes to allow, in any stage, the adaptation to the modern solutions which can intervene in the electro energetic installations, the possibility of power supplying for some unforeseen objectives (Pana, 2006).
- Adopting a flexible structure of the optimization criterion to allow the highlighting of some possible differential evolutions of the influence factors (Ionescu and Pop,1998).

Generally speaking the distribution stations usually operate with a transformer in hot or cold reserve, and the one in operation rarely reach a charging of 50% S_{nT} . The concerns regarding the optimization of the nominal power of the electric transformers and respectively for the optimization of the distribution stations configuration regarding the industrial consumers supplying, according to the absorbed power, are justified through the important energy savings that can be obtained in this regard (Pana, 2006), (Ionescu and Pop,1998), (Ionescu and Baci, 1981), (Dusa and Vaida, 2001), (Ignat and Popovici, 2003), (Pasculescu et al. 2017a), (Pasculescu et al., 2017b).

2. Analysis of the configuration 2x100%

The operation of the electric transformers according to the chart of the optimal regime assumes establishing the number of the operating transformers and their charging, so that the total energy loss to be minimum.

In this situation, the problem of the connection or the disconnection of a transformer arises, at the variation of the total charge on the station, so that to permanently check the optimal functioning chart. The single line diagrams, frequently met for the electric stations, are presented in figure 1.

In order to perform the analyze, the following basic hypotheses are admitted: the nominal power of the transformers is the optimal one, the characteristics of the switchgear of the same type are identical and the momentary apparent absorbed power (S), expressed in kVA or MVA is considered to be variable in time (during a working day).

* Corresponding author. +4-072-912-9138.
E-mail address: leon_pana@yahoo.com

The switchgear can be provided with an automatic reclosing system.

We mark with:

1. the status with only one power path in operation (passive reserve)
2. the status with both power paths in operation.

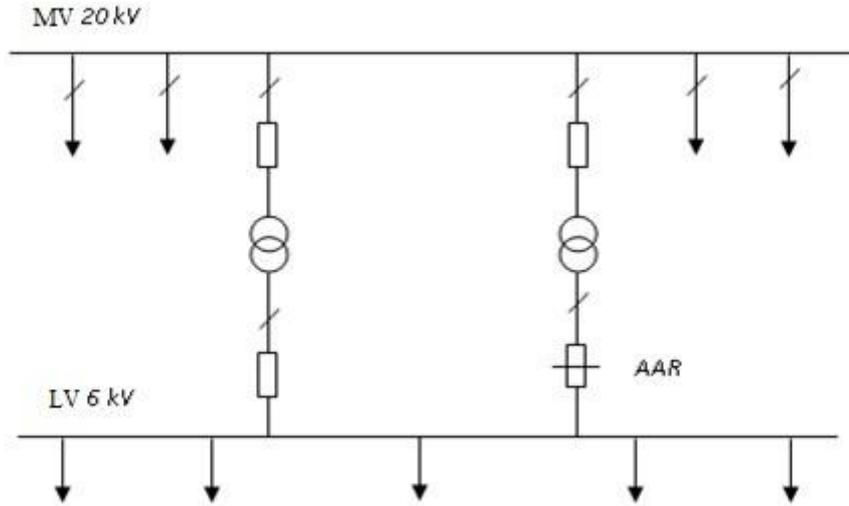

Fig.1 The single line diagram of the electrical distribution station, of MV/LV, (configuration type 2x100%)

3. The analytical model of calculation

We continue presenting the calculation relations for the absorbed power to which the commutation between the two states is required, according to the applied optimization criteria and the considered factors of influence.

Taking in account the two possible states, previously mentioned, and applying the criteria of the minimum loss of power, noting with:

$$\Delta P_{12} = \Delta P_1 - \Delta P_2 \quad (1)$$

the difference of the total losses of power in the transformers, expressed in kW, with reference to the two states, the following relations are achieved:

- If the losses of reactive power are neglected:

$$\Delta P_{12} = \frac{\Delta P_{kn}}{2} \cdot \left(\frac{S}{S_{nT}} \right)^2 - \Delta P_0$$

$$S = S_{nT} \cdot \sqrt{\frac{2 \cdot \Delta P_0}{\Delta P_{kn}}} \quad (2)$$

If also the losses of reactive power are considered:

$$\Delta P_{12} = \frac{1}{2} \cdot (\Delta P_{kn} + k_e \cdot \Delta Q_{kn}) \cdot \left(\frac{S}{S_{nT}} \right)^2 - (\Delta P_0 + k_e \cdot \Delta Q_0)$$

$$S = S_{nT} \cdot \sqrt{\frac{2 \cdot (\Delta P_0 + k_e \cdot \Delta Q_0)}{(\Delta P_{kn} + k_e \cdot \Delta Q_{kn})}} \quad (3)$$

The signification of the ratings that appear in the above relations is the following one:

- S_{nT} is the apparent nominal power of the transformer, in kVA
- ΔP_0 the losses of active power in iron (the losses of active power when idle) of the transformer, in kW
- ΔP_{kn} the nominal losses of active power when operating in short circuit (the transformer operating at the nominal charge), in kW
- ΔQ_0 the losses of reactive power in iron or when idle, of the transformer, in kVAr
- ΔQ_{kn} the nominal losses of reactive power when operating in short circuit (the transformer operating at the nominal charge), in kVAr
- k_e the electro energetic equivalent, expressed in kW/kVAr

The optimal or economic power to which the transformers commutation is justified, with reference to the two states, applying the criteria of the cost of the minimum losses of power and energy, is determined based on the relation:

$$\frac{1}{2} \cdot (\Delta P_{kn} + k_e \cdot \Delta Q_{kn}) \cdot \left(\frac{S}{S_{nT}}\right)^2 \cdot C_k - (\Delta P_0 + k_e \cdot \Delta Q_0) \cdot C_0 = 0 \quad (4)$$

in which:

$$\begin{aligned} C_0 &= C_p + C_w \cdot T_f \cdot T_{20} \\ C_k &= C_p + C_w \cdot \tau \cdot T_{20} \cdot m_r \end{aligned} \quad (5)$$

- C_0 is the cost of the updated value of a unit of power loss in iron for n years running time, in €/kW
- C_k the cost in updated values of a unit of active power losses in short circuit and in the hypothesis of a r growth rate of the annual charge peak, in €/kW
- C_p the basic specific cost of the power installed in the power plants of equivalence, in updated values, in €/kW
- C_w the average specific cost on system of losses kilowatt hour calculated at the level of the HV/MV or MV/LV distribution station, in €/kWh
- m_r charge multiplier and has the expression:

$$m_r = \frac{1}{(1+a) \cdot T_n} \cdot \sum_{m=0}^{n-1} \frac{(1+r)^{2m}}{(1+a)^m} \quad (6)$$

in which:

- r is the growing rate of the annual charge peaks in that period, and a is the update rate. In case it is considered $r = 0$ and $n = 20$ years, respectively $n=30$ years, the charge multiplier $m_r=1$;
- τ calculation duration of the annual technological power losses, in h/yr, of which value can be taken from the diagrams or can be calculated with the relation:

$$\begin{aligned} \tau &= T_{SM} \cdot \frac{10000 + T_{SM}}{27520 - T_{SM}} \\ \tau &= T_{SM} \cdot \frac{10000 + T_{SM}}{27520 - T_{SM}} \end{aligned} \quad (7)$$

- T_{SM} the use duration of the annual maximum apparent power, expressed in h/yr
- T_f the operating duration of the transformer, in h.

The optimal charging coefficient k_V for the annual charge peak is determined with the relation:

$$k_V = \frac{S_{ec}}{S_{nT}} \cdot \sqrt{\frac{2 \cdot (\Delta P_0 + k_e \cdot \Delta Q_0) \cdot C_0}{(\Delta P_{kn} + k_e \cdot \Delta Q_{kn}) \cdot C_k}} \quad (8)$$

Replacing the relations (5) in the relation (8), equation (9) is given by:

$$k_V = \frac{S_{ec}}{S_{nT}} \cdot \sqrt{\frac{2 \cdot (\Delta P_0 + k_e \cdot \Delta Q_0) \cdot (C_p + C_w \cdot T_f \cdot T_{20})}{(\Delta P_{kn} + k_e \cdot \Delta Q_{kn}) \cdot (C_p + C_w \cdot \tau \cdot m_r \cdot T_{20})}} \quad (9)$$

In figure 3 a, b, c, d, e, f and g presented below it can be seen that all the characteristics of the different values specific to the cost of the losses kilowatt hour C_w pass through a same point D (figure 3) in which the derivative:

$$\frac{dk_V}{dc_w} = 0 \quad (10)$$

The value of the intersection point ordinate, D (figure 3), is determined with the relation:

$$\tau_D = \frac{T_f}{m_r} \quad (11)$$

The value of the intersection point ordinate D corresponds to the specific cost of the energy losses $C_w = 0$.

With the growth of the specific cost of the energy losses C_w , the optimal degree of charging at the peak decreases or increases according to the number of hours of using the maximum charge T_{SM} is higher or lower than $T_{max,D}$ calculated according to the relation presented below:

$$T_{\max,D} = 10^4 \sqrt{\frac{\tau_D}{8760} - 1240} \quad (12)$$

Analogically to the case of the minimum cost of losses energy criteria applied for determining the optimal charging coefficient in the first year of operation of a transformer, in this case too, in the hypothesis of a minimum of the cost regarding the power and electricity losses, theoretical domain of variation of the optimal charge at the annual charge peak (figure 3 a, b, c, d, e, f and g) is limited by two characteristics.

$$k_{V1} = k_{VD} = \lim_{c_w \rightarrow 0} k_V = \sqrt{\frac{2 \cdot (\Delta P_0 + k_e \cdot \Delta Q_0)}{\Delta P_{kn} + k_e \cdot \Delta Q_{kn}}} \quad (13)$$

$$k_{V2} = \lim_{c_w \rightarrow \infty} k_V = \sqrt{\frac{2 \cdot (\Delta P_0 + k_e \cdot \Delta Q_0) \cdot T_f}{(\Delta P_{kn} + k_e \cdot \Delta Q_{kn}) \cdot \tau \cdot m_r}} \quad (14)$$

4. Case study

The configuration of electric distribution station analyzed is presented in figure 2 and is provided with a double system of busbars to which cells are connected. The electric station is equipped with two transformers TTU-NL of 16 MVA, 20/6 kV through which the electricity distribution is performed and two transformers TTU-NL of 1000 kVA, 20/0.4 kV to supply the consumers. From the four transformers only two are in operation, the other two are in reserve. The transformers parameters and the results of the simulation are presented in table 1.

For the growth rate of the annual charge peaks r , respectively the duration of n years of the transformers operating same distribution station, the values of the charge multiplier m_r have a narrower range of variation. With the help of the relation (6), in which it was considered $n=20$ years, $a=0.01$ and for $r = [0.02, 0.05]$, it resulted $m_r = [1.5, 1.53]$.

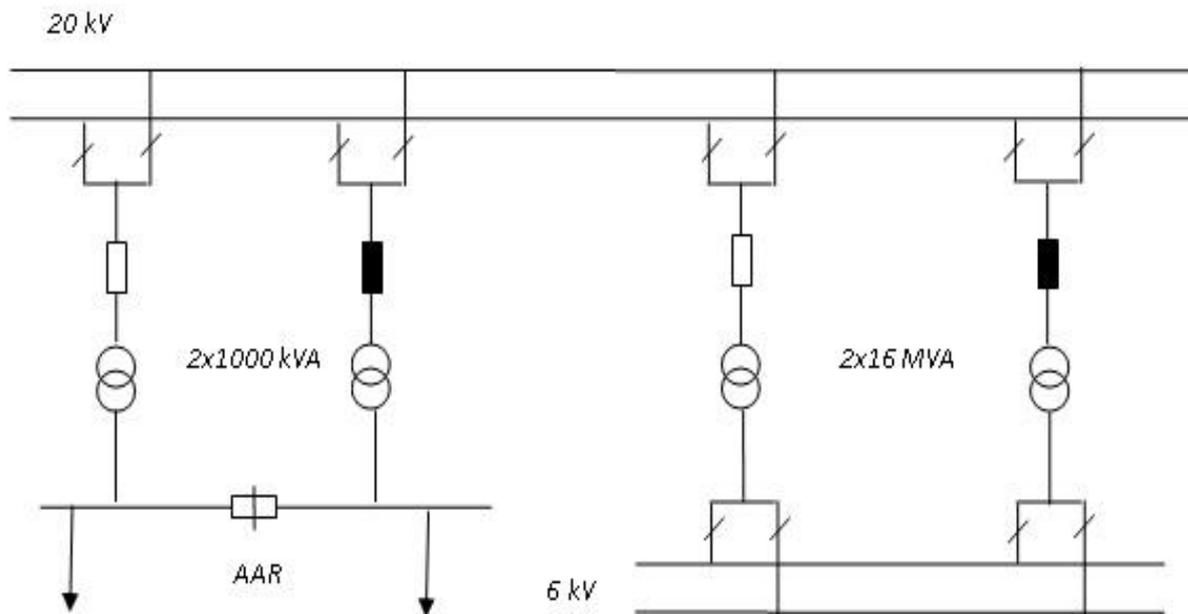

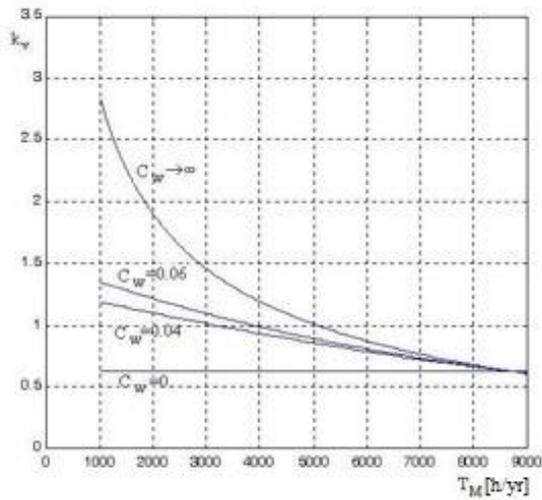

Fig. 2 Single line wiring diagram of the distribution station analyzed

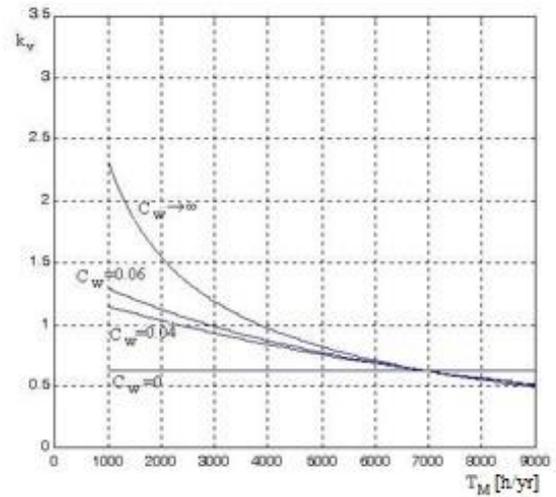

Table 1. The input data for the series of transformers type TTU-NL, of MV/LV

S_{nT} [kVA]	U_1/U_2 [kV/kV]	ΔP_0 [kW]	ΔP_k [kW]	i_0 [%]	u_k [%]	k_e [kW/kVAr]	ΔQ_0 [kVAr]	ΔQ_k [kVAr]
1000	20/0.4	1.7	10.5	1.4	6	0.15	14	60
1600	20/0.4	2.2	14.960	1.4	6	0.15	22.4	96
16000	20/6	16.5	85	2.08	8.5	0.15	332.8	1360

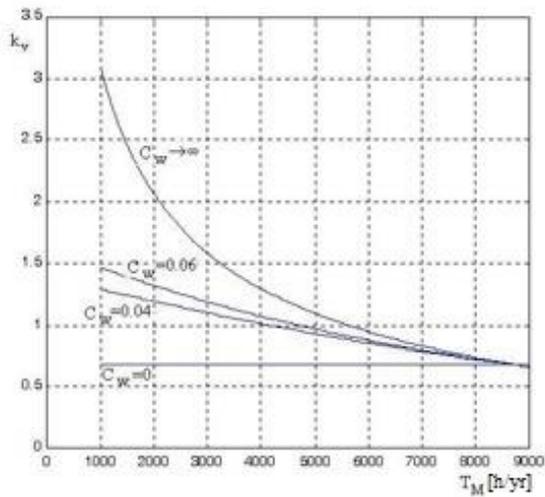

In figure 3 a, c, e ($r=0$), b, d, f ($r=0.02$) and g ($r=0.05$) there are presented the values of the charging coefficients corresponding to the optimal operating states of the electric distribution stations of 20/6 kV analyzed had configuration presented in figure 2.

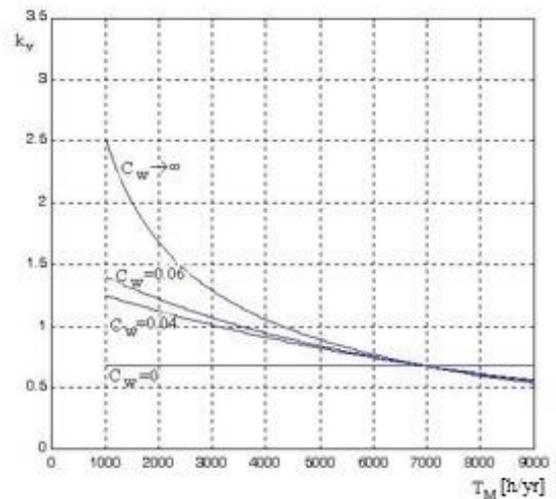

a)

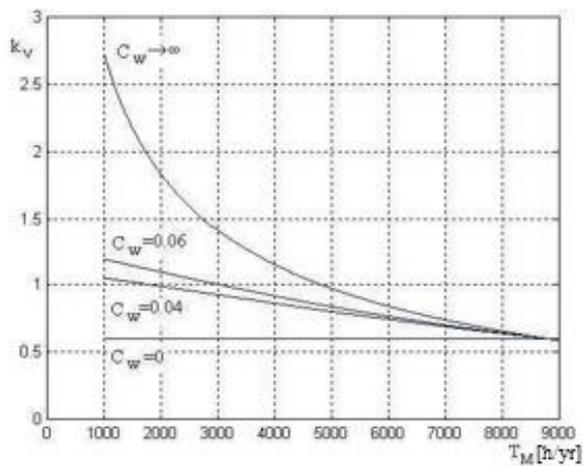

b)

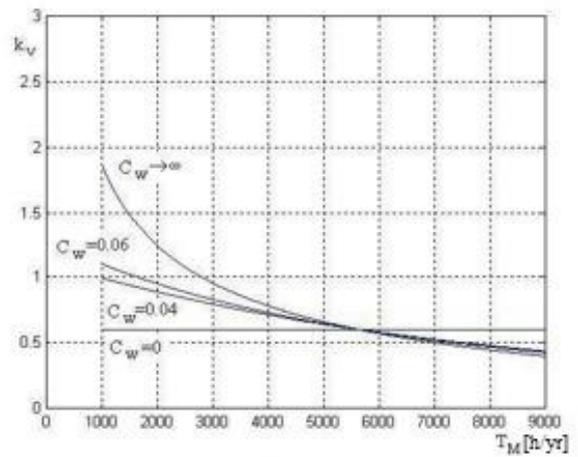

c)

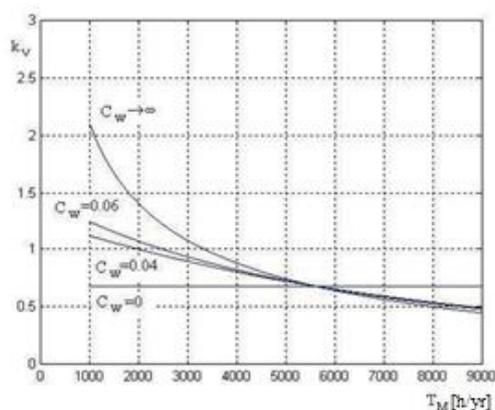

d)

e)

f)

g)

Fig. 3 The values of the charging coefficients at the inferior limit corresponding to the optimal operating states of the electric stations, according to the time of use of the maximum annual charge, for different values of the kilowatt hour cost corresponding to the stages at which the electricity distribution is made and of the values of the charging growth coefficient

a)	2x1000 kVA, $r=0$	b)	2x1000 kVA, $r=0.02$	c)	2x16000 kVA, $r=0$
d)	2x16000 kVA, $r=0.02$	e)	2x1600 kVA, $r=0$	f)	2x1600 kVA, $r=0.02$
g)	2x16000 kVA, $r=0.05$				

In the case of the transformers, from the electric stations, operating in parallel, it is noticeable that with the growth of the coefficient r , the optimal charging coefficient at the annual charge peak also grows. In this case too it was demonstrated that if the charge is constant during a year, then $r = 0$ and the losses time is equal with the operating time, meaning $\tau = T_f = 8760$ h/yr. Analyzing the diagrams from the figure 3 a, b, c, d, e, f, g it results that the optimal value of the charging coefficient at the lower limit is in the range [0.52, 0.55].

5. Conclusions

In conclusion, it results that in the electric distribution stations equipped with more transformers it is not economical to be used with all the transformers connected in parallel, irrespective of the electric charge and nor with only one at charges considered low, when these exceed the nominal power of the transformer.

The optimal operating regime in the case previously analyzed is the one in which the cost of the total power and energy losses (active and reactive) are minimum.

To obtain an optimal operating regime of the electric stations, it also must be determined the optimal power of the station, as follows:

- In normal operating regime at the maximum economically power, (minimum losses reported to the circulated energy).
- In emergency mode it will be taken account the reservation possibilities through the medium or low voltage networks that will be charged up to their thermal limit, the overcharge possibilities over the economical limit of a transformer in the case of failure in the neighbor station or of the second transformer from the same station.

The diagram of the transformation station presented in figure 3 has a transformer in reserve and an operating one, the one can in reserve, through automatics, replace (AAR – automatic reclosing system) the second transformer.

Abstract

The use of electricity in potentially explosive atmospheres has many features for which the issues concerning the design of electrical equipment and installations raise many difficulties. For low current electrical equipment (interlocking, command, data communications, signaling) the assessment of explosion protection is often carried out by calculation using the technical data available in the specific standard related to protection to explosion requirements.

Currently, the method of calculation uses simplified but covering models. The major advantage of the outcome's certainty on the confirmation of the explosion protection is balanced by the increased rate of rejection. Complex equipment which cannot be assessed by calculation is tested in explosive atmospheres in compliance with the requirements set out in the relevant standard.

In this paper are presented the analysis and characterization of linear sources from within intrinsic safety circuits and issues to be taken into account for the evaluation of these circuits.

Keywords: explosive atmosphere; explosion protection; electrical equipment.

1. Introduction

In industrial installations in which are processed, used or stored flammable or combustible substances is likely to occur an explosive atmosphere, generating an explosion hazard. In this regard, in order to ensure explosion protection, the electrical equipment used in such installations must be correctly chosen to ensure the level of health and safety at the workplace and to prevent their being built into a source of ignition for explosive atmospheres, (Burian S. et al., 2007).

In this paper are presented the analysis and characterization of linear sources from within intrinsic safety circuits and issues to be taken into account for the evaluation of these circuits.

Explosion prevention and explosion protection are of major importance for occupational health and safety in order to minimize losses (both human and material). Explosive atmospheres are defined as a mixture with air, under atmospheric conditions, of flammable substances in the form of flammable gases, mist vapors or combustible dusts, in which, after ignition, combustion is spread throughout the unburned mixture, (Prodan M. et al., 2014).

The mechanism of an explosion generated by a mixture of flammable gas, vapor or mist with air can be expressed by the well-known explosion triangle shown in Figure 1. Thus, the occurrence of an explosion is conditioned by the simultaneous presence of the following three factors:

1. fuel (flammable gases, vapours, dusts /powders, mists);
2. comburent (oxygen, oxidizing substances);
3. efficient ignition source for ensuring the activation of molecules in order to ignite and propagate the fast combustion reaction, (Burian S. et al., 2014).

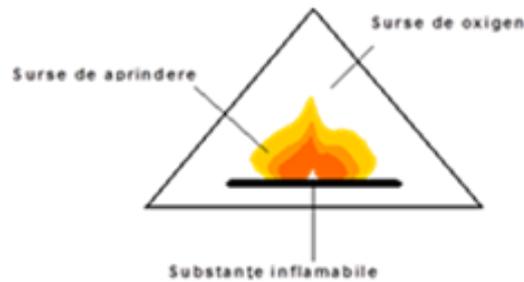

Fig. 1. The explosion triangle

Evaluation and testing of equipment which is part of an explosion protect system in purpose of certification, considers that the risk of explosion has to be minimized in order to ensure security of life and human health, as well as to prevent damage to property and, last but not least, the environment, (Csaszar T. et al., 2012).

All equipment included in a system under construction explosion-protected equipment used in spaces endangered by potentially explosive atmosphere shall meet the following requirements:

- be adequately protected from the explosion;
- to maintain the level of protection for the environmental conditions for which it was built;
- to be able to withstanding all requests (predictable) to which they are subjected during storage, transport, installation and operation of the system. (EN Directive, 2014).

Explosion protection for low current installations can be implemented using the intrinsic safety type of protection.

Intrinsic safety type of protection, based on the separation of the circuit is protected from other circuits and limiting the energy that is protected so that it cannot ignite the explosive atmosphere, (Darie M. et al., 2012).

The explosion protection evaluation for low current equipment involves a process of analyzing the equipment documentation with respect to compliance with the requirements of the relevant explosion protection standards.

The current trend in assessing explosion protection of low current electrical equipment protected by the type of explosion protection intrinsic safety is to increase the share of assessments by calculation applied to equipment using reference tables and charts presented in the relevant standard SR EN 60079- 0; SR EN 60079-11.

Intrinsic safety equipment and parts with intrinsic safety of the associated equipment are classified after recalled above standard as having levels of protection: "ia", "ib" or "ic", (SR EN (IEC) 60079-11, 2012).

2. Evaluation of simple circuits with intrinsic safety

Explosion protection implemented by intrinsic safety protection type is based on two main guidelines: limiting the transited and stored energy but also the adoption of separations between intrinsically safe circuits and other circuits.

To evaluate the active intrinsic safety circuits, it is necessary to know first the internal resistance and supply voltage.

For the simplest case, the source can be characterized by two electric constant values, either idle voltage U_0 and internal resistance R_i or the idle voltage U_0 and short-circuit current I_0 as shown in Figure 2.

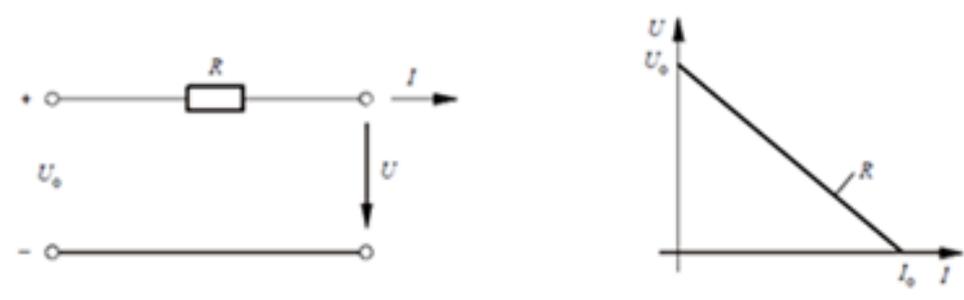

Fig. 2. Resistive circuit with linear characteristic

When the circuit to be evaluated, in terms of capacity, is approximated as a simple circuit, for which there are experimentally curves determined in reference accredited laboratories and recognized at international level, the charts in carts A1 ÷ A6 can be used for evaluation. Specific values of these charts can be processed in tabular form. In both cases, however, the defective conditions and safety coefficients should be considered.

The information given by the following figures relate only to simple circuits and in some cases it can be difficult to apply the information to design practical circuits.

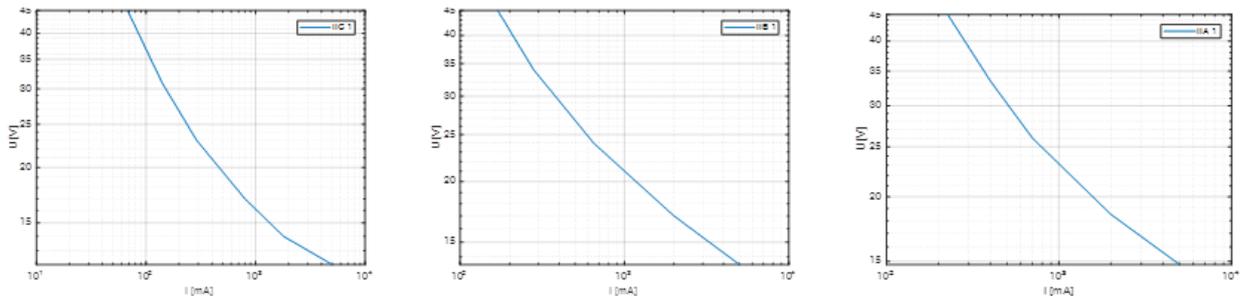

Fig. 3. Curves for evaluation of resistive circuits, group II, safety coefficient 1

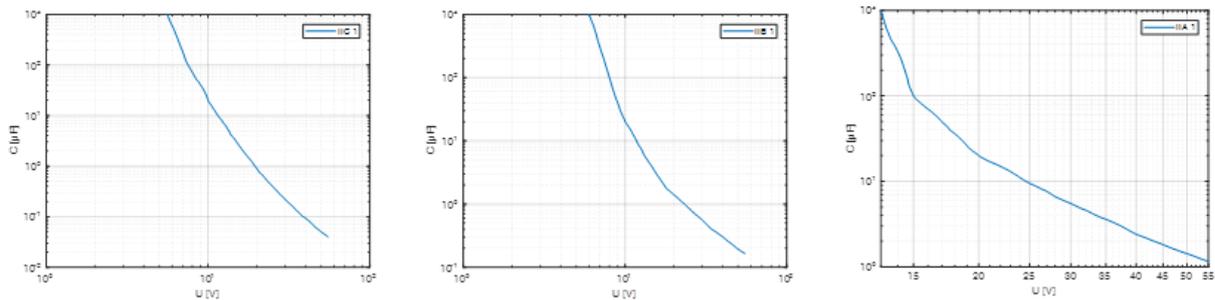

Fig. 4. Curves for evaluation of capacitive circuits, group II, safety coefficient 1

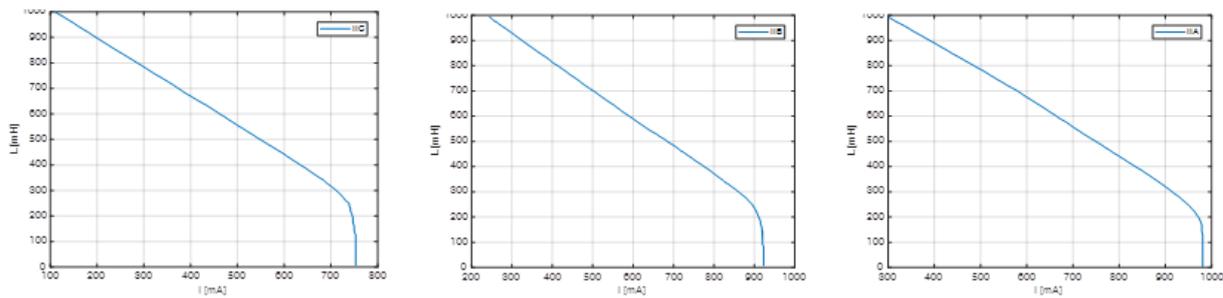

Fig. 5. Curves for evaluation of inductive circuits, group II

A circuit intended for use in potentially explosive environments, with the protection type intrinsic safety "i" must satisfy three basic criteria:

a) does not result in any electrical spark ignition owed when the circuit is rated or tried in accordance with the specified protection level and specified electrical equipment group. This requirement may be satisfied through evaluation, information, current and voltage information on circuit parameters such as inductance and capacity.

b) the temperature class of the equipment with the intrinsic safety is established so as to ensure that the ignition is not caused by hot surfaces. This requirement can be satisfied by estimating the maximum surface temperatures of the components, from the knowledge of their behavior and thermal maximum power to which they may be subjected in operation/fault conditions. The temperature classes of flammable substances (Table 1) are as follows:

Table 1. Temperature classes of flammable substances

Temperature class	Auto-ignition temperature range (AIT) (°C)
T1	≥ 450
T2	$300 \leq \text{AIT} \leq 450$
T3	$200 \leq \text{AIT} \leq 300$
T4	$135 \leq \text{AIT} \leq 200$
T5	$100 \leq \text{AIT} \leq 135$
T6	$85 \leq \text{AIT} \leq 100$

c) the circuit should be separated by the other circuits. This can be satisfied by providing isolation distances on the surface and in air insulation distance, electro insulating material, compound or galvanic separation elements.

The following diagram is presented for the evaluation of a circuit intended for use in potentially explosive atmospheres having that type of protection intrinsic safety "i", Figure 6. The steps that you must follow are:

- faling the circuit in one of the levels of protection imposed: "ia", "ib" or "ic";
- identify the values for the U_m respective U_i ;
- is determined by the coefficient shall be applied to the security parameters of the electrical circuit rated you as well as for evaluation of surface temperature;
- shall be determined points of application defects in circuit rated depending on the level of protection circuit is employed;
- calculate the maximum values for parameters U_i , I_i , respectively P_i , taking into account the tolerance values of components depends on the type of protection;
- compare the values obtained with the diagrams of acceptability standard.

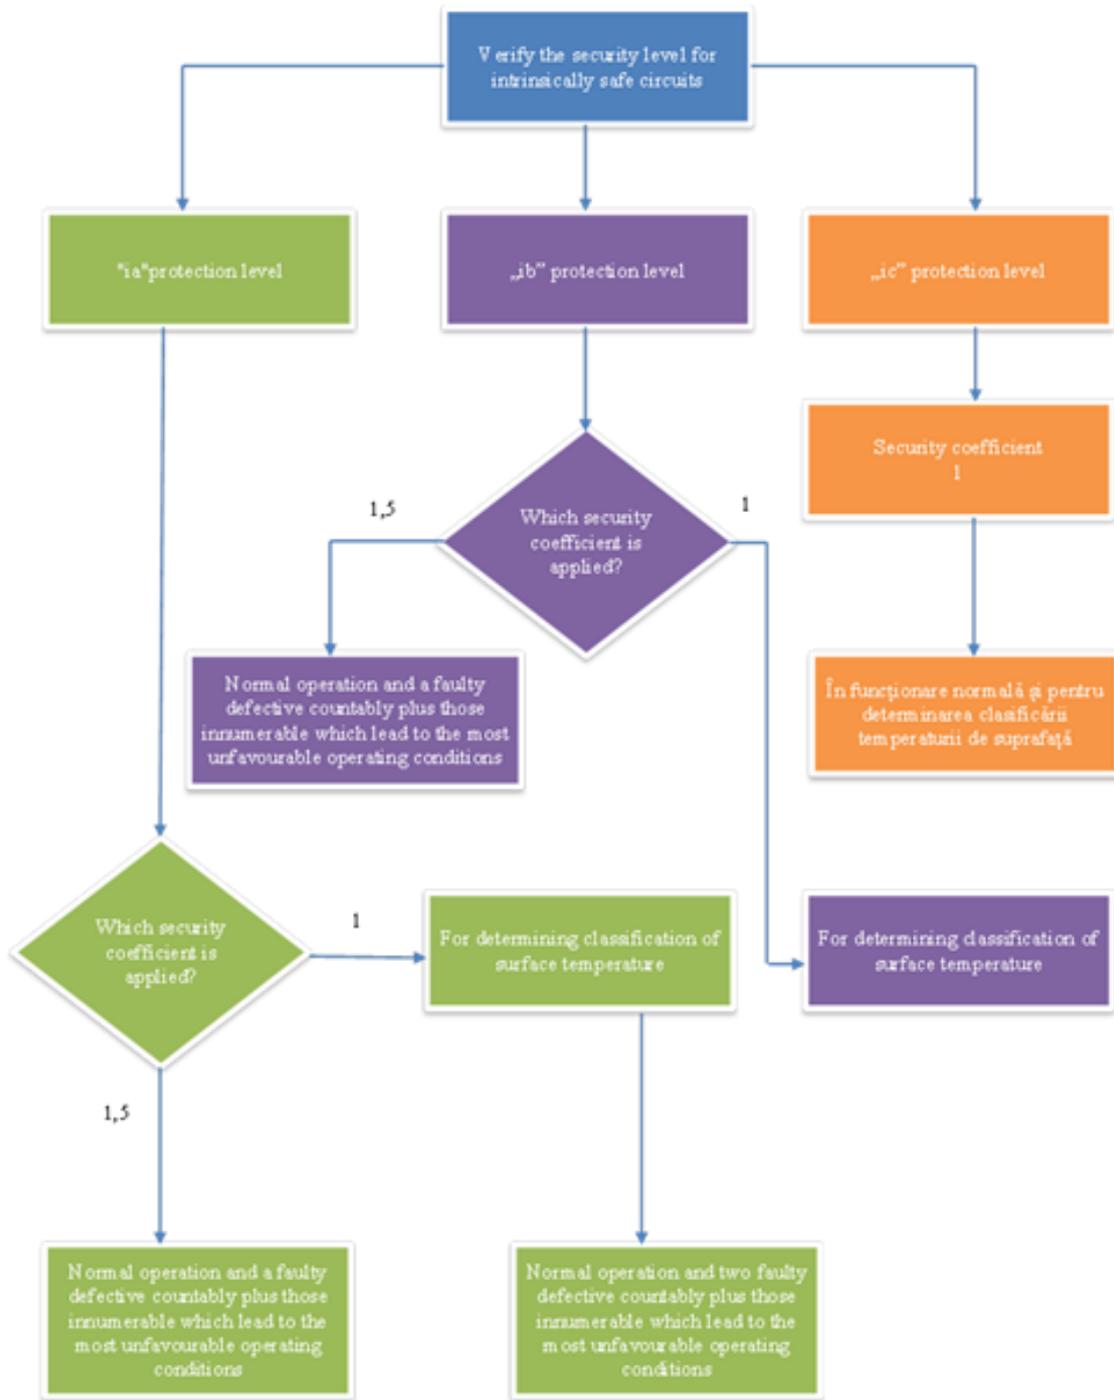

Fig. 6. Diagram of evaluation circuit with intrinsic safety "i"

Based on circuit analysis, a MATLAB computing application was developed to evaluate simple linear circuits using curves and reference tables. Specific values of these diagrams were processed and tabular form. In both cases, however, defective conditions and safety coefficients should be considered.

In Figure 7 is represented the capture of the user interface. This interface allows you to choose the type of simple circuit, the coefficient of safety and gas subgroup required in the evaluation process, based on the charts values, in tabular form inserted and processed in MATLAB in the form of .mat file, graphically indicating validation or invalidation of the protection taking into account the input data (voltage U, resistance R, capacitance C, inductance L).

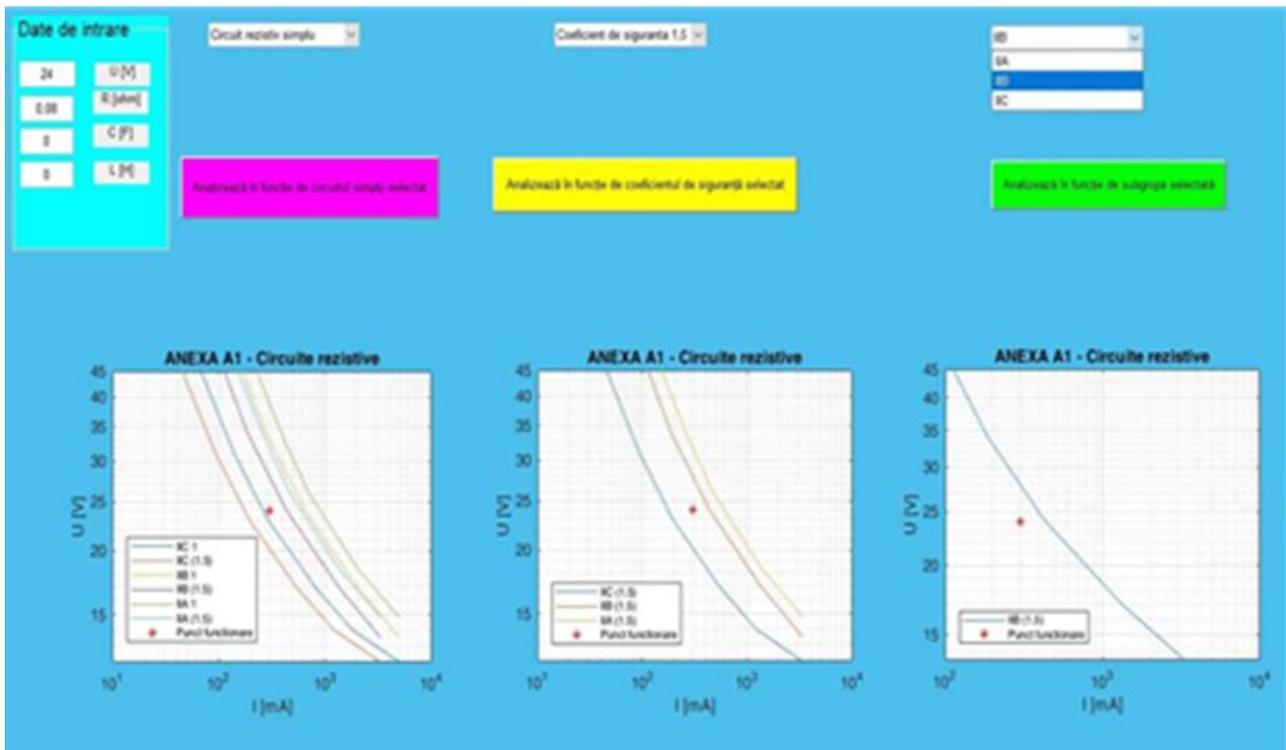

Fig. 7. The user interface of the application

3. Conclusion

Joining the IECEx scheme for products certification has imposed the implementation of appropriate methods for assessing the low current circuits in testing laboratory infrastructure. This position involves maintaining a process of updating the procedures for conformity assessment and testing and suitability for carrying out the necessary tests required by the process.

Explosion prevention and explosion protection are of major importance for occupational health and safety in order to minimize losses (both human and material).

This paper aims to increase the ability to evaluate intrinsically safe protection equipment by using the standardized means and the simulation based on the ignition diagrams within the equipment certification body to perform tests on low current equipment protected by the type of protection intrinsic safety intended for use in explosive atmospheres by implementing specific requirements

For simple circuits, especially those with a linear characteristic, it is possible to assess the non-ignition capability using the standardized means and the simulation based on the ignition diagrams.

The increased complexity for the circuits of the equipment involves in the evaluation process, the use of simplified models of circuits that are comprehensive in terms of explosion protection.

Abstract

The equipment designed for use in explosive atmospheres has to fulfil the requirements of ATEX Directive 2014/34/EU (transposed into Romanian legislation by GD 245/2016).

In order to verify the explosion protection characteristics of equipment these shall be subjected to type tests. In case of fluorescent luminaires with type of protection increased safety “e”, supplied by electronic ballasts, these shall be subjected to the asymmetric pulse and asymmetric power tests.

The purpose of this paper is to present the importance of the asymmetric pulse and asymmetric power tests, and also, to underline the testing methodology developed based on the requirements imposed by the applicable standards.

Keywords: type tests; asymmetric pulse; asymmetric power.

1. Introduction

Assessment of equipment designed for use in potentially explosive atmospheres, represents an important aspect considering the existing explosion risk which has to be minimized in order to ensure people's health and safety, as well as to prevent goods damage and protection of the environment (Moldovan et al., 2012), (Cioca and Moraru, 2012). Assessment of equipment designed to operate in potentially explosive atmospheres is made by verification of the technical documentation and tests (Csaszar T. et al., 2012).

The equipment operating in hazardous explosive atmospheres has to be subjected to conformity assessment procedures, according ATEX Directive 2014/34/EU (transposed in Romanian legislation by Government Decision no. 245/2016) (Directive 2014/34/EU, 2014).

The provisions of the harmonized standards from the SR EN 60079 series are generally used in case of electrical equipment designed for use in potentially explosive atmospheres. The standard SR EN 60079-0 (SR EN 60079-0, 2013) and one or more of the standards containing the specific requirements for the type(s) of protection applied to equipment (ex. SR EN 60079-1 for the type of protection flameproof enclosure "d", SR EN 60079-7 for the type of protection increased safety "e", SR EN 60079-11 for the type of protection intrinsic safety "i") are used for performing the assessment. The evaluation of explosion-proof electrical equipment comprises also type tests (Moldovan et al., 2014).

The type of protection increased safety “e” is based on applying additional measures so as to give increased security against the possibility of excessive temperatures and the occurrence of arcs and sparks in normal service or under specified abnormal conditions (SR EN 60079-7, 2016), (SR EN 60079-14, 2014). Thus, this type of protection can be applied only to electrical equipment that does not produces electrical arcs and sparks in normal operation (i.e. junction boxes, certain types of luminaires, electric motors, heating resistances etc.).

* Corresponding author. Tel.: +40254541621; fax: +40254546277.
E-mail address: lucian.moldovan@insemex.ro

The standard SR EN 60079-0 indicates the type tests to which all the explosion-proof electrical equipment shall be subjected and the order in which these tests shall be performed (Moldovan et al., 2014).

The specific tests for the type of protection increased safety “e” are specified in the standard SR EN 60079-7 – specific for the type of protection increased safety “e”.

Among the type tests prescribed in this standard, in case of fluorescent luminaires supplied by electronic ballasts, are also included the asymmetric pulse and asymmetric power tests (SR EN 60079-7, 2016).

2. Specific conditions for luminaires supplied by electronic ballasts

Among the equipment operating in potentially explosive atmospheres (chemical plants, refineries, fuel deposits, etc.) luminaires are also included. An important part is represented by luminaires equipped with fluorescent tube lamps using also the type of protection increased safety “e” to provide protection to explosion.

The types of fluorescent tube lamps allowed for use in the type of protection increased safety are as follows:

- for Level of Protection “eb” or “ec”, fluorescent lamps of the cold starting type (CCFL) in accordance with IEC 60081 with single-pin caps (Fa6) in accordance with IEC 60061-1 (SR EN 60079-7, 2016);
- for Level of Protection “eb” or “ec”, tubular fluorescent bi-pin lamps in accordance with IEC 60081 with G5 or G13 lamp caps in accordance with IEC 61195 with pins made of brass. Such lamps shall be connected in a circuit in which they start and run without preheating of the cathodes; only T8, T10, or T12 lamps shall be used. T5 lamps shall be permitted only up to 8 watts (SR EN 60079-7, 2016).
- for Level of Protection “ec”, tubular fluorescent bi-pin lamps in accordance with IEC 60081 with G5 or G13 lamp caps in accordance with IEC 61195 with pins made of brass. Such lamps may be connected in a circuit in which they start and run with preheating of the cathodes; only T5-type HE according IEC 60081 sheet 6520 (14 W), sheet 6530 (21 W), sheet 6640 (28 W), sheet 6650 (35 W), T8, T10, or T12 lamps shall be used (SR EN 60079-7, 2016).

These fluorescent lamp tube luminaires are equipped with electronic ballasts. When using fluorescent lamps equipped with electronic ballasts it is required to provide an additional protection, so as not to allow the supplying of the fluorescent tube by the electronic ballast in case the fluorescent tube reaches the end of life (EOL). This protection has to be provided because at the end of life of the fluorescent tube, the voltage drop at the cathodes level can increase (during the operation of fluorescent lamps, the electron-emitting material on the electrodes is consumed resulting into an increase of energy to release the electrons, that can lead to a higher voltage drop at the electrodes of the fluorescent lamps) and result in a temperature increase in the cathodes area (Stahl, 2018).

Because the electronic ballast functions as a constant current source, a higher voltage drop will lead to a power consumption increase. The increase of temperature can exceed the maximum surface temperature of the luminaire (for the type of protection increased safety the maximum surface temperature is determined considering both the temperature measured on external surfaces and the temperature measured on the internal surfaces of the equipment).

Thus, the maximum dissipated power at the cathodes level shall not exceed certain levels over which the operational safety cannot be guaranteed (when operating in a potentially explosive atmosphere).

In order to achieve explosion protection for a luminaire equipped with fluorescent lamps supplied by electronic ballasts there are certain specific condition that have to be fulfilled, as provided in the specific standard SR EN 60079-7.

In case of luminaires equipped with tubular fluorescent bi-pin lamps employing electronic ballasts, the maximum ambient temperature shall not exceed 60 °C. Also the temperature classes T5 and T6 are not be permitted (SR EN 60079-7, 2016).

2.1. Power dissipation of cathodes of lamps supplied by electronic ballasts

2.1.1. Luminaires in Level of Protection “eb”

The asymmetric pulse test and the asymmetric power dissipation test shall be conducted (according SR EN 60079-7). The maximum cathode power observed during the test shall not exceed the values given in Table 1. The tests shall be conducted at the minimum and maximum ambient temperature of the luminaire (SR EN 60079-7, 2016).

2.1.2. Luminaires in Level of Protection “ec”

The asymmetric pulse test and the asymmetric power dissipation test shall be conducted (in accordance with IEC 61347-2-3). The maximum cathode power observed during the test shall not exceed the values given in Table 1. The tests shall be conducted at the minimum and maximum ambient temperature of the luminaire (SR EN 60079-7, 2016).

Table 1 – Power dissipation of cathodes of lamps supplied by electronic ballasts

Fluorescent tube type	Level of protection		Ambient temperature for the luminaire °C	Temperature class allowed	maximum cathode power W
	eb	ec

T8 /T10/T12	Permitted	Permitted	≤ 60	T4	8
T8 /T10/T12	Permitted	Permitted	≤ 60	T3	10
T5 (8 W)	Permitted	Permitted	≤ 40	T4	4
T5 (8 W)	Permitted	Permitted	≤ 60	T3	4
T5-HE (8 W to 35 W)	Excluded	Permitted	≤ 60	T4	5

In case of testing the fluorescent tube luminaires to verify the end of life conditions any of the tests (asymmetric pulse test, asymmetric power test and open filament test) can be used according IEC 61347-2-3 (IEC 61347-2-3, 2018).

2.2. The asymmetric pulse test

The ballast shall have adequate protection to prevent lamp cap overheating at the end of the lamp life. The electronic diagram needed to perform the test is presented in Figure 1 (SR EN 60079-7, 2016). When subjected to the asymmetric pulse test, the maximum cathode power shall not exceed the values given in Table 1 (SR EN 60079-7, 2016).

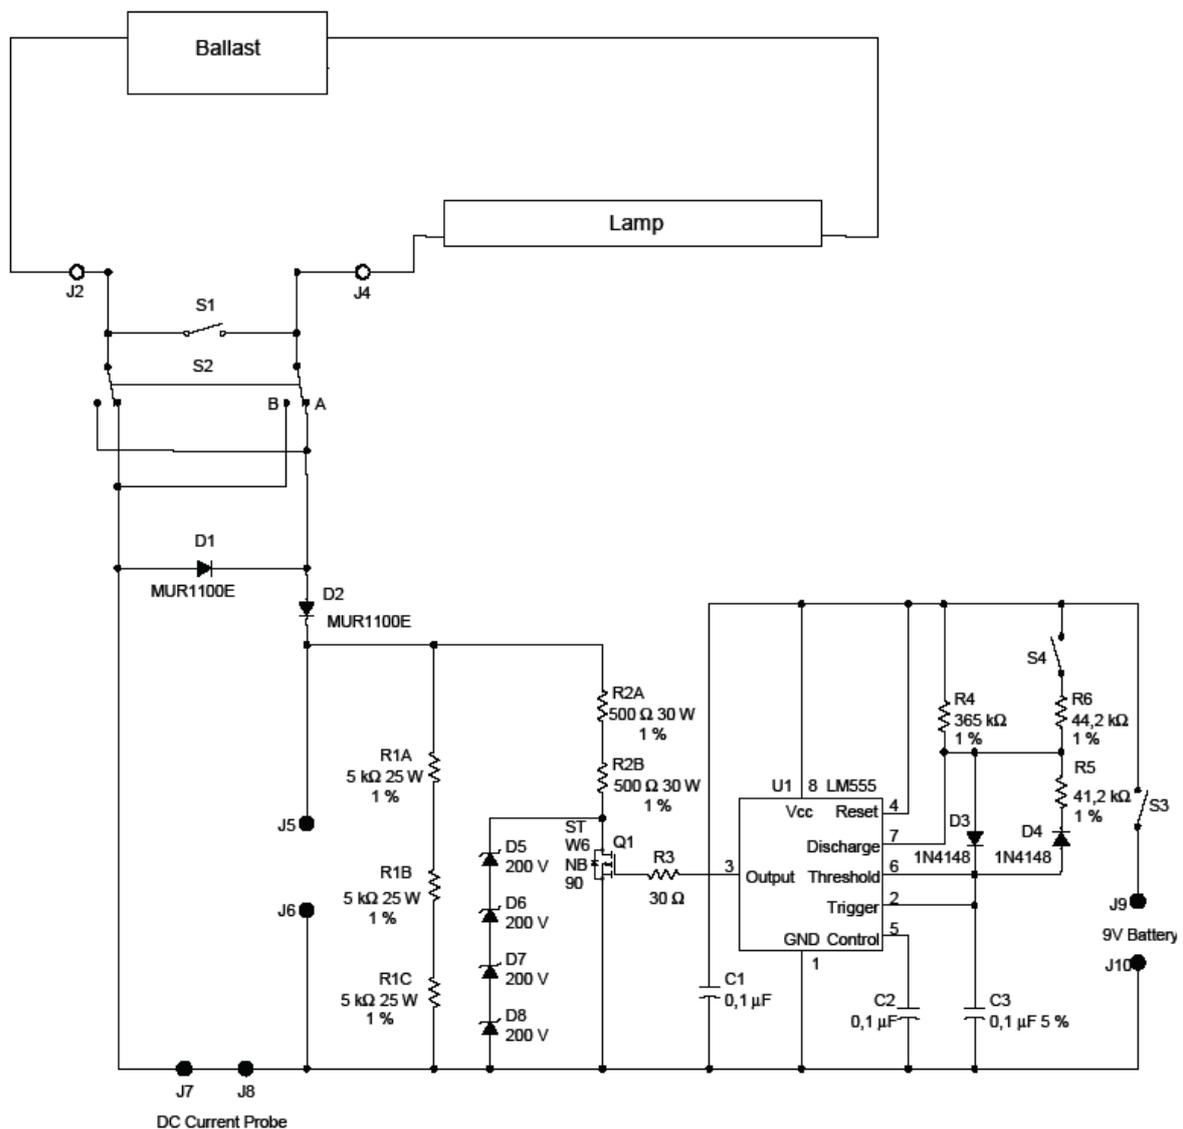

Fig. 1 Asymmetric pulse test circuit (SR EN 60079-7, 2016)

Generally speaking, the testing procedure consists in measuring the sum of the average power dissipated in the power resistors, R1A to R1C and R2A, R2B and the Zener diodes, D5 to D8. This power should be measured as the average value of the product of the voltage between terminals J5 and J6 times the current flowing from J8 to J7. The voltage should be measured with a differential voltage probe, and the current should be measured with a d.c. current probe. A digital oscilloscope can be used for the multiplication and averaging functions. If the ballast operates in a cycling mode, the averaging interval should be set to cover an integer number of cycles (each cycle is typically greater than 1 s). The sampling rate and number of samples included in the calculations should be sufficient to avoid aliasing errors (SR EN 60079-7, 2016).

In case the measured power is greater than the values given in Table 1, the ballast has failed and the test is discontinued (SR EN 60079-7, 2016).

If the protection circuit in the ballast has switched off the lamp, then the ballast shall be restarted (close S1).

The average power dissipated in the resistors shall be measured for both positions “A” and “B”. The ballast shall pass both position 'A' and position 'B' tests (SR EN 60079-7, 2016).

For multi-lamp ballasts, the tests shall be made for each lamp position. A multi-lamp ballast shall pass the tests for each lamp position (SR EN 60079-7, 2016).

For ballasts that operate multiple lamp types, each lamp type specified shall be tested (SR EN 60079-7, 2016).

The mounting for testing of fluorescent lamps used in level of protection “ec” is similar to the one in Figure 1. This includes also the possibility of testing fluorescent lamps with preheating of the cathodes (using a specific circuit and a transformer between J2 and J4).

2.3. Asymmetric power test

The ballast shall have adequate protection to prevent lamp cap overheating at the end of the lamp life. When subjected to the asymmetric power test, the maximum cathode power shall not exceed the values given in Table 1 with the lamp at a temperature representative of its maximum service temperature (SR EN 60079-7, 2016).

The testing procedure considers the electronic diagram in Figure 2. The inductance of resistor R1 has to be as low as possible (ohmic resistor) due to the high frequency of this circuit (SR EN 60079-7, 2016).

The electronic ballast shall be tested so as to demonstrate that it will be able to turn off the lamp when the power required by the cathodes circuit is higher than the values in Table 1 (SR EN 60079-7, 2016).

First, the resistance of R1 will be increased rapidly (within 15 s), until the power dissipated by resistor R1 equals the test wattage value of 20 W (or 8 W for the T5 lamp 8 W). If the ballast switches off before reaching the test wattage, or after reaching the test wattage, the ballast shall be retested to demonstrate that the maximum possible continuous power, without switching off, is less than or equal to the values given in Table 1 (SR EN 60079-7, 2016).

Then, the resistance of R1 will be increased rapidly (within 15 s) until the power dissipated by resistor R1 equals approximately 5 W (or 2 W for the T5 lamp 8 W). If the ballast fails to turn off in 2 min, the test is stopped and repeated with an increased resistance in R1 until approaching a target power dissipation of the values given in Table 1 (three or four steps is sufficient) (SR EN 60079-7, 2016).

If the ballast fails to switch off within 2 min at a power less than or equal to the values given in Table 1, the ballast has failed and the test is discontinued. If the ballast does not switch off in the previous test, but limits the power in R1 to a value less than the test wattage of 20 W (or 8 W for the T5 lamp 8 W), the value of R1 is set to the value which produces the maximum wattage (SR EN 60079-7, 2016).

If the 20 W (or 8 W for the T5 lamp 8 W) value was reached (when testing from 5W (or 2 W for the T5 lamp 8 W) to the values prescribed in Table 1), an additional period of 15 s will be considered. If the 20 W (8 W for the T5 lamp 8 W) value was not reached in that test and the limitation obtained (to a maximum value of 20 W (or 8 W for the T5 lamp 8 W)) is applicable, an additional period of 30 s will be considered. The measured power in resistor R1 should be reduced to the values given in Table 1 or less, otherwise the ballast has failed and the test is discontinued (SR EN 60079-7, 2016).

The ballast shall pass the test in both positions “A” and “B” (SR EN 60079-7, 2016).

For multi-lamp ballasts, the test procedure is repeated for each lamp position. A multi-lamp ballast shall pass the tests for each lamp position (SR EN 60079-7, 2016).

For ballasts that operate multiple lamp types each lamp type specified shall be tested (SR EN 60079-7, 2016).

In any of the configurations, if the power in resistor R1 is greater than the values given in Table 1, the ballast has failed and the test is discontinued (SR EN 60079-7, 2016).

To perform the test in case of fluorescent tube luminaires in level of protection “ec” the test scheme from the standard IEC 61347-2-3 shall be used (which allows also the testing of fluorescent lamps with preheating of the cathodes).

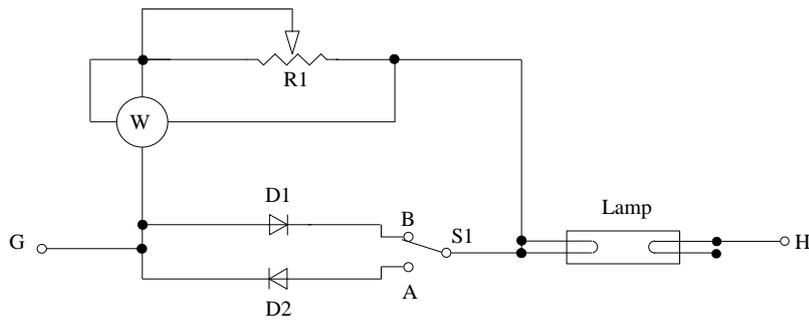

Fig. 2 Asymmetric power detection circuit (SR EN 60079-7, 2016)

3. Conclusions

In this paper were presented aspects regarding the end of life of fluorescent tubes, the requirements that shall be fulfilled by electronic ballasts related to the type of protection increased safety “e”, the specific tests that are to be applied in this case (asymmetric pulse test and asymmetric power test) and the testing methodology as required by standards.

The electronic ballasts used to supply luminaires equipped with fluorescent tubes shall ensure adequate protection against overheating of lamp cap(s) at the end of life of the fluorescent tube (EOL).

The asymmetric pulse test and the asymmetric power test are two important tests that shall be applied in case of fluorescent tube luminaires equipped with electronic ballasts in order to verify the adequate protection against end of life (EOL).

Even if IEC 61347-2-3 provides multiple methods to test the EOL protection ensured by the electronic ballast (testing by one single method if considered enough), in case of luminaires with type of protection increased safety (because they are intended for use in potentially explosive atmospheres) both tests shall be passed (asymmetric pulse test and asymmetric power test) in order to qualify an electronic ballast.

Abstract

The evaluation of explosion-proof electrical equipment for certification is particularly important given the risk of explosion and must be minimized. This in order to ensure the safety of life, health of workers, to prevent damage to goods and the environment when they meet the essential security requirements at European level.

Directive 2014/34 / EU states that equipment used in explosive atmospheres must be designed to operate without endangering the environment for which it is intended.

This paper proposes the study and evaluation of the requirements for the breathing and drainage devices. In order to verify explosion protection, the representative samples made available by explosion-protected equipment manufacturers are tested under the worst possible conditions that may occur in practice.

Keyword: Flameproof enclosure; explosion protection; breathing and draining devices; explosive atmosphere; permeable metallic materials.

1. Introduction

The paper deals with the study of the requirements for the testing of drainage and breathing devices used in electrical equipment with flameproof enclosures type of protection. Several studies have been conducted on the reliability of electrical equipment and installations.

Types of protection are all the specific measures applied to electrical equipment to avoid the ignition of an ambient explosive atmosphere.

According to Directive 2014/34 / EU, users of technological installations in areas with explosive atmospheres have to follow successively three stages. Preventing the formation of explosive atmospheres, avoiding the ignition of explosive atmospheres, limiting the harmful effects of an explosion to ensure the health and safety of workers (Directive 2014/34/EU, 2014).

2. Additional requirements for drainage and breathing devices.

2.1 General

Drainage and breathing devices are generally used for electric motors with a flameproof enclosure protection. For the design and construction of motors with a type of flameproof enclosure protection, it is necessary for the beneficiary to formulate precisely and in detail the requirements regarding the operation of the motors in accordance with the ATEX directive. (Directive 2014/34/EU, 2014)

Being designed to operate installations in explosive atmospheres (chemical industry, petroleum industry, mining industry, etc.), these engines are often built into the flameproof enclosure protection module, its outer part (case, shields, terminal box, clamping elements) having to withstand an internal explosion of an explosive mixture that penetrated the interior without suffering deformations and without transmitting the flame from the inside out to an explosive atmosphere surrounding the casing. (Directive 2014/34/EU, 2014)

* Corresponding author. Tel.: +40733546114;
E-mail address: marcel.rad@insemex.ro

For this, it is necessary to have maximum admissible interstices at joints or other passageways, depending on explosion categories and subcategories (ATEX). (Directive 1999/92/Ec) The engines are distinguished by a robust mechanical construction, made in a wide range of constructive shapes normalized by the major manufacturers of electric machines. The external shape of the casing depends on the type of motor protection as well as on the cooling mode. In the case of a closed machine equipped with an axial cooling system, the casing is constructed with ribs to increase the cooling surface. In the case of an internal cooling machine, the casing is smooth outside. (Rad, 2018)

Standard SR EN 60079-1 shows all types of possible joints encountered when making flameproof enclosures as well as joint parameter values. The standard also mentions the materials used for the carcasses.

3 Breathing and draining devices which form part of a flameproof enclosure

3.1 General

Breathing and draining devices shall incorporate permeable elements which can withstand the pressure created by an internal explosion in the enclosure to which they are fitted, and which shall prevent the transmission of the explosion to the explosive atmosphere surrounding the enclosure. (SR EN 60079-1, 2015)

They shall also withstand the dynamic effects of explosions within the flameproof enclosure without permanent distortion or damage which would impair their flame-arresting properties. They are not intended to withstand continuous burning on their surfaces. (Rad, 2018)

These requirements apply equally to devices for the transmission of sound but do not cover devices for relief of pressure in the event of internal explosion, use with pressure lines containing gas which is capable of forming an explosive mixture with air and is at a pressure in excess of 1,1 times atmospheric pressure. (SR EN 60079-0, 2013)

3.2 Openings for breathing or draining

The openings for breathing or draining shall not be produced by deliberate enlargement of gaps of flanged joints.

The composition limits of the materials used in the device shall be specified either directly or by reference to an existing applicable specification.

The elements of breathing or draining devices for use in an explosive gas atmosphere containing acetylene shall comprise not more than 60 % of copper by mass to limit acetylide formation.

The dimensions of the breathing and draining devices and their component parts shall be specified. (SR EN 60079-0, 2013)

4 Type tests for breathing and draining devices used as Ex components

4.1 General

Attachment of the sample device under test shall be made on the end of the test rig enclosure in the same manner as it would normally be mounted on a flameproof enclosure. The test shall be performed on the sample after the impact test. (SR EN 60079-1, 2015)

The impact test may be performed on the sample, separate from the test enclosure, when it is mounted on a plate that forms the end part of the test rig enclosure.

For devices with non-measurable paths, the maximum bubble test pore size of the sample shall be not less than 85 % of the specified maximum bubble test pore size. (SR EN 60079-0, 2013)

4.2 Bubble test

For buloscopic verification of sintered materials, materials used for making drainage and breathing devices, is shown in Fig. 1.

The buloscopic hair size corresponds to the minimum differential pressure at which the first bubbles appear continuously. For this reason, this pressure is sometimes called the minimum bubble pressure or the first bubble. The appropriate capillary diameter is called maximum pore diameter or maximum pore size.

When the pressure exceeds the minimum burst pressure (the first bubble point), more bubbles appear on the sample. For a given aspect, the corresponding pressure can lead to the definition of a conventional pore size. (SR EN 24003 - 1996)

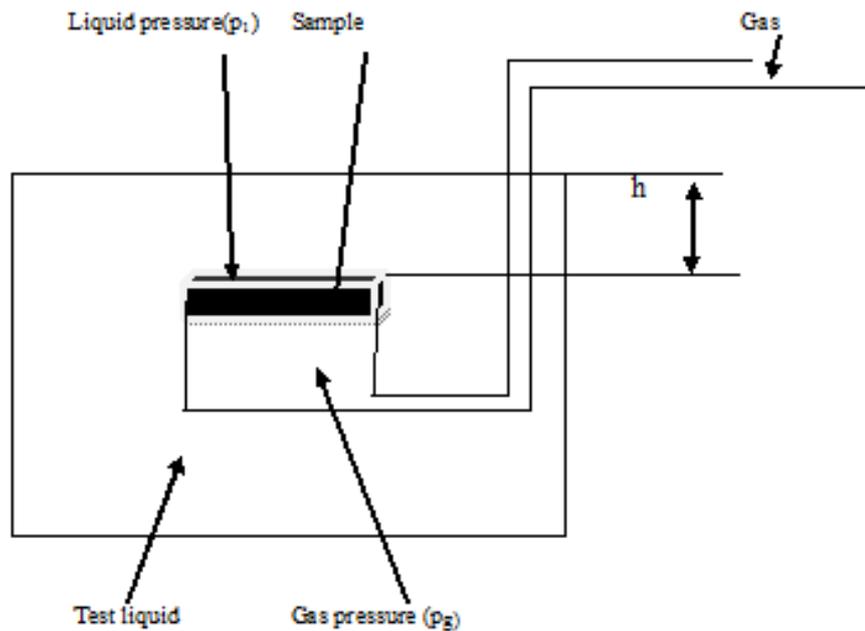

Fig. 1. Block diagram for bulboscopic determination

4.3 Thermal tests

4.3.1 General

After the bubble test, breathing and draining devices as Ex components shall be subjected to the thermal tests based on the maximum intended flameproof enclosure volume, but no less than the volume of the test rig in Figure 2. (SR EN 60079-1, 2015)

Breathing and draining devices intended for multiple use in any single flameproof enclosure shall be tested additionally with the enclosure.

4.3.2 Test procedure

For enclosure volumes of less than or equal to 2,5 l, the test rig assembly with all four sections, as shown in Figure 2, shall be used, and the test procedure shall be carried out as follows:

- the position of the ignition source shall be at the enclosure inlet and 50 mm from the inside of the end-plate housing the device and the results observed;
- the test mixtures shall;
- the temperature of the external surface of the device shall be monitored during tests;
- any device shall be operated as specified by the manufacturer's documentation. After each of five tests, the explosive mixture shall be maintained external to the device for a sufficient time to allow any continuous burning on the face of the device to become evident, for at least 10 min, so as to increase the temperature of the external surface of the device or to make temperature transfer to the outer face possible; and
- the tests shall be carried out five times for each gas mixture for the gas groups in which the device is intended for use.

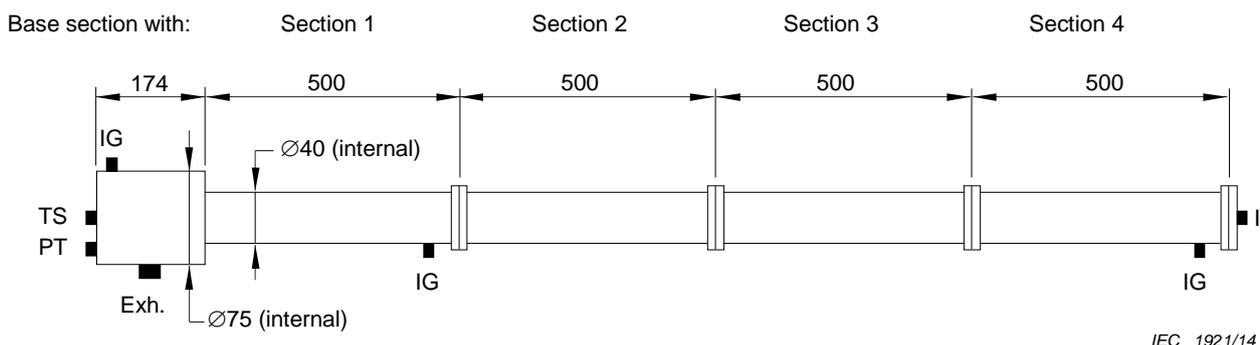

Fig 2. Component test rig for breathing and draining devices

For enclosure volumes of greater than 2,5 l, a representative enclosure of the intended volume shall be used, and the test procedure shall be carried out as follows:

the test mixtures shall, as appropriate;

the temperature of the external surface of the device shall be monitored during tests;

any device shall be operated as specified by the manufacturer's documentation.

After each of five tests, the explosive mixture shall be maintained external to the device for a sufficient time to allow any continuous burning on the face of the device to become evident, for at least 10 min, so as to increase the temperature of the external surface of the device or to make temperature transfer to the outer face possible; and the tests shall be carried out five times for each gas mixture for the gas groups in which the device is intended for use. (SR EN 60079-1, 2015)

4.3.3 Acceptance criteria

During the thermal tests, no flame transmission shall occur and no continuous burning shall be observed. The device shall show no evidence of thermal or mechanical damage or deformation which could affect its flame-arresting properties.

The measured external surface temperature rise of the device shall be multiplied by a safety factor of 1,2 and added to the maximum service temperature of the device for the determination of the temperature class of the electrical equipment.

4.4 Test for non-transmission of an internal ignition

4.4.1 General

After the bubble test, this test shall be carried out on a standard test rig, as illustrated in Figure 2, with the following additions and modifications.

4.4.2 Test procedure

- The position of the ignition source shall be as shown in Figure 2:
 - a) at the inlet end; and
 - b) at 50 mm from the inside of the end-plate housing the device.
 - For the purposes of the test, the test rig shall be assembled for each gas group, in accordance with Figure 2, and have the following number of sections:
 - Group I and Group IIA: one section of test rig assembly;
 - Group IIB and Group IIC: four sections of test rig assembly.
 - The gas mixture within the test rig enclosure shall be ignited and the tests shall be made five times at each ignition point.
 - For breathing and draining devices of Groups I, IIA and IIB having either measurable paths or non-measurable paths.
 - For breathing and draining devices of Group IIC with measurable paths,.
- For breathing or draining devices of Group IIC with non-measurable paths.

4.4.3 Acceptance criteria

During the test, no ignition shall be transmitted to the surrounding test chamber.

4.5. Test of the ability of the breathing and draining device to withstand pressure

4.5.1 Test procedure

The reference test pressures in each gas group are:

Group I	1 200 kPa,
Group IIA	1 350 kPa,
Group IIB	2 500 kPa,
Group IIC	4 000 kPa.

For the purpose of the test, a thin flexible membrane is fitted over the inner surfaces of the breathing and draining devices. The reference pressure shall be one of the relevant pressures given above for the gas group for which the component is intended. (SR EN 60079-1, 2015) One of the following overpressure tests shall be applied:

- 1,5 times the reference pressure for a period of at least 10 s. Then each component shall be submitted to a routine test;
- or
- 4 times the reference pressure for a period of at least 10 s. If this test is successful, the manufacturer is not required to apply the routine test to all future components of the tested type.

4.5.2 Acceptance criteria

After the overpressure tests, the device shall show no permanent deformation or damage affecting the type of protection.

4.6. Ex component certificate

The Ex component certificate shall include, in the schedule of limitations, the details necessary to properly select a breathing or draining device for attachment to a type tested flameproof enclosure. The schedule of limitations shall include, as a minimum, the following:

- a. the maximum recorded surface temperature obtained during the type test corrected to 40 °C, or to the higher marked ambient;
- b. service temperature range for non-metallic enclosures and non-metallic parts of enclosures;
- c. the maximum permitted enclosure volume (based on the thermal test) if greater than 2,5 l;
- d. a requirement that each Ex component or package of Ex components be accompanied by a copy of the certificate, together with the manufacturer's declaration stating compliance with the certificate conditions, and confirmation of the material, maximum bubble test pore size and minimum density, where applicable; and special mounting instructions, if any.

5. Conclusions

As a result of the work titled: "Study and evaluation of the requirements regarding the breathing and drainage devices ", the following conclusions were drawn:

- the requirements of standard SR EN 60079-0 for electrical equipment used in explosive environments have been analyzed;
- the requirements of standard SR EN 60079-1 for drainage and breathing devices;
- the requirements of standard SR EN 60079-1 have been analyzed regarding the necessary tests to be performed on drainage and breathing devices;
- the test requirements for the drainage and blowing devices in bulk, correlated with the other specific tests to which the equipment is to be subjected, have been presented in the paper, establishing the order of the tests in accordance with the specific standard;
- the components required to achieve the test bench for the pressure and non-explosion test for the drainage and blowing devices have been established;
- the required components for the test stand were prepared for the buloscopic test of drainage and breathing devices;
- the block diagram of stalls for pressure, explosion-proof and buloscopic test stands that meet the test requirements specified in the standard.

Abstract

Evaluation of explosion-proof protected electrical equipment in scope of certification is extremely important considering the risk of explosion that has to be minimized in order to ensure life safety and health of workers and to prevent damaging of property and the environment, as well as free movement of goods when they meet the essential safety requirements at European level. The purpose of this paper is to present aspects regarding the importance of thermal endurance tests performed on the electrical equipment used in potentially explosive atmosphere. The paper also presents laboratory facilities for performing the thermal endurance test.

Keywords: thermal test; flameproof enclosure; increased safety; certification; explosive atmosphere.

1. Introduction

Using electric energy in potentially explosive atmospheres brings forward several particularities therefore the problems that appear during the design, construction and operation of electrical devices and installations brings forward numerous difficulties, their approach requiring special attention considering all the technical, economical and labor safety aspects. (Fotău et al., 2017).

The risk of explosion may appear in all the fields of activity in which flammable substances are involved, such as gases, vapors, dusts, mists, which mixed with air may result in potentially explosive atmospheres. (Ghicioi et al., 2017)

In order to increase the occupational health and safety level in potentially explosive atmospheres generated by flammable gases or explosive dusts we have to prevent the ignition of explosive atmospheres. In order to do this the electrical equipment used in such areas must be made with different types of protection so that it cannot ignite the explosive mixture surrounding it. (Fotău et al., 2016).

The type of protection means the specific measures applied to electrical equipment (Pasculescu et al., 2012), to avoid ignition of a surrounding explosive atmosphere. (Standard IEC 60079-0., 2013).

For each type of protection applied to electrical equipment used in potentially explosive atmosphere, a wide range of type tests have been developed so that they can be used safely. (Standard IEC 60079-0., 2013).

In addition to type tests, on the equipment the thermal endurance test must be performed.

2. Thermal endurance tests performed on equipment used in potentially explosive atmosphere

The enclosure of the equipment, due to unfriendly conditions in which they operate, can be damaged quite easily. In order to preserve the type of protection of the equipment it is very important that their enclosures remain intact in the event of an accidental impact.

* Corresponding author. Tel.: +4-073-139-0816; fax: +40-254-546-277.
E-mail address: dragos.fotau@insemex.ro.

During the certification process, the equipment is subjected to an impact test to determine the resistance of the enclosure. According to the standardized requirements before carrying out these tests, the equipment enclosure must be subjected to thermal endurance tests. This test is performed using the climate chamber, specifically designed for testing enclosures. (Standard IEC 60079-0., 2013).

2.1. Thermal endurance to heat

The thermal endurance to heat shall be determined by submitting the enclosures or parts of enclosures in non-metallic materials, on which the integrity of the type of protection depends, to tests according to Table 1. (Standard IEC 60079-0., 2013), (Standard IEC 60079-1., 2015).

Table 1 – Thermal endurance test

Service temperature Ts	Test condition	Alternative test condition
Ts ≤ 70 °C	672 ⁰ ₊₃₀ h at (90 ± 5) % RH, at Ts + 20 ± 2 K (but not less than 80 °C test temperature)	
70 °C < Ts ≤ 75 °C	672 ⁰ ₊₃₀ h at (90 ± 5) % RH at Ts + 20 ± 2 K	504 ⁰ ₊₃₀ h at (90 ± 5) % RH at (90 ± 2) °C followed by 336 ⁰ ₊₃₀ h dry at Ts +20 ± 2 K
Ts > 75 °C	336 ⁰ ₊₃₀ h at (90 ± 5) % RH at (95 ± 2) °C, followed by 336 ⁰ ₊₃₀ h dry at Ts + 20 ± 2 K	504 ⁰ ₊₃₀ h at (90 ± 5) % RH at (90±2) °C followed by 336 ⁰ ₊₃₀ h dry at Ts +20 ± 2 K

At the conclusion of the test according to Table 1, the enclosures or parts of enclosures in non-metallic materials that were tested shall be subjected to (20 ± 5) °C at (50 ± 10) % relative humidity for 24 0 +48 h, and then immediately followed by the thermal endurance to cold test. (Standard IEC 60079-0., 2013).

The test values given in Table 1 include two test conditions. The conditions shown in the 2nd column were used in previous editions of this standard and allow previously obtained test results to remain valid for this edition.

The conditions shown in the 3rd column have been added to allow testing at temperature/humidity conditions that are more readily achieved, although at an increased test time. (Standard IEC 60079-0., 2013).

It is generally acknowledged that glass and ceramic materials are not adversely affected by the thermal endurance to heat test, and testing may not be necessary. (Standard IEC 60079-0., 2013).

2.2. Thermal endurance to cold

The thermal endurance to cold shall be determined by submitting the enclosures and parts of enclosures of non-metallic materials, on which the type of protection depends, to storage for 24 h 0+2 + in an ambient temperature corresponding to the minimum service temperature reduced according to standardized requests. (Standard IEC 60079-0., 2013) (Standard IEC 60079-7., 2016).

It is generally acknowledged that glass and ceramic materials are not adversely affected by the thermal endurance to cold test, and testing may not be necessary. (Standard IEC 60079-0., 2013) (Standard IEC 60079-7., 2016).

3. Results obtained

During the process of certification of a equipment used in potentially explosive atmosphere (Pasculescu et al., 2017a, and Pasculescu et al., 2017b), at National Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX laboratories are performed thermal endurance tests. The equipment is tested in the climatic chamber.

After the equipment was submitted to thermal endurance to cold and to heat, it was tested for resistance to impact. Following this test, the equipment did not suffer deformations or cracks, so it can be safely used in explosive atmosphere for which it was designed. This test is essential in the process of certification of equipment used in explosive areas.

Table 2 Results of the resistance to impact test.

Equipment subjected to resistance to impact test.	The height from which the equipment is hit	Impact energy (m*g*h)	Results
Lamp used in potentially explosive atmosphere	0.4 m	1 kg*9.8m/s ² *0.4m =3.92 Joul	The equipment has not been deformed or cracked

Following numerous applications for product certification received by INSEMEX, it has been decided to purchase a larger climate chamber to test a wide range of products.

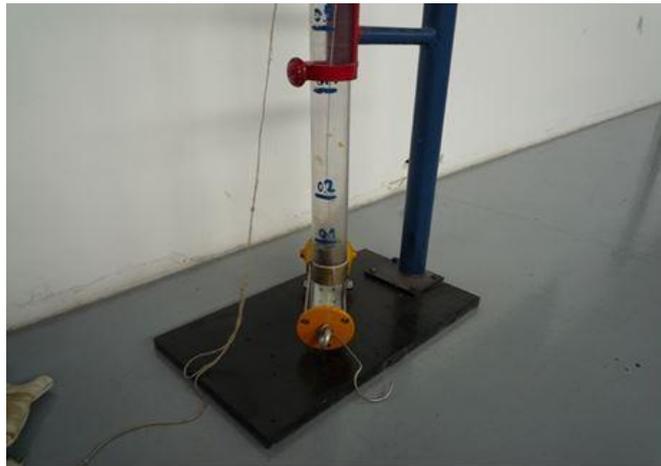

Fig.3. Lamp subjected to resistance to impact test.

4. Conclusions

To protect people who work in explosive environments, it is important that equipment operating in such areas to comply with the requirements in force, and be properly maintained.

According to the requirements in force, in the process of certification of Ex equipment call of them must be tested in order to verify if the explosion protection characteristics are maintained at their level. In this paper was revealed the importance of thermal endurance tests performed on equipment used in potentially explosive atmosphere. Also after the studies made in the laboratories, it became necessary to acquire a large climate chamber, which will be done within this year.

Abstract

The use of electrical energy in potentially explosive atmospheres involves various particularities, fact for which there have been raised a lot of issues concerning the design, construction and exploitation of electrical equipment and installations intended to be used in these atmospheres. This paper presents the explosion protection principles implemented for the type of protection encapsulation “m” which are based on the adoption of certain separations between the encapsulated circuits and the other circuits, by including them in a compound. The paper describes the test methodologies for explosion-proof electrical equipment with type of protection encapsulation “m”.

Keywords: type of protection; encapsulation; electrical equipment; compound; type test.

1. Introduction

In health and security domain, it is noted a rising trend of the security level in conformity with scientific knowledge state and with taking in consideration of the new risk factors due to economic development. It also follows the same trend the protection of low currents installations utilized in workplaces with risk of explosives atmospheres. Directive 2014/34/EU states that equipment and installations utilized in explosive atmospheres must have compatible specifications with the ones of explosive atmosphere there are about to work, (Burian et al., 2007).

In order to evaluate the equipment for protection to explosion, encapsulation type, one has to follow an investigation process of the equipment in terms of its conformity with relevant standard requirements for protection to explosion, (Darie et al., 2015). As to evaluate the electric equipment for protection to explosion, type encapsulation “m”, the current trend is to increase the evaluation share through applicable calculus on the equipment, using tables and diagrams presented in applicable standards SR EN 60079-0; SR EN 60079-18. This paper follows the study and assessment of the requirements concerning absorption test for electric equipment with type “m” protection.

2. Encapsulated equipment, technical documentation, description, generalities

The conformity assessment of technical documentation for equipment used in potentially explosive atmospheres is made in accordance with Directive 2014/34/EU, annex 3. The documentation submitted to the notified body must include the following. (EN Directive, 2014):

- a general type-description;
- design and manufacturing drawings and layouts of components, subassemblies, circuits, etc.;
- descriptions and explanations necessary for the understanding of said drawings and layouts and the operation of the product;
- a list of the standards referred to in Article 5, applied in full or in part, and descriptions of the solutions adopted to meet the essential requirements of the Directive where the standards referred to in Article 5 have not been applied;
- results of design calculations made, examinations carried out, etc.;
- tests reports.

* Corresponding author. Tel.: +40763618571; fax: +40254546277
E-mail address: cosmin.colda@insemex.ro.

The notified body shall:

- examine the technical documentation, verify that the type has been manufactured in conformity with the technical documentation and identify the elements which have been designed in accordance with the relevant provisions of the standards referred to in Article 5, as well as the components which have been designed without applying the relevant provisions of those standards;
- perform or have performed the appropriate examinations and necessary tests to check whether the solutions adopted by the manufacturer meet the essential requirements of the Directive where the standards referred to in Article 5 have not been applied;
- perform or have performed the appropriate examinations and necessary tests to check whether these have actually been applied, where the manufacturer has chosen to apply the relevant standards;
- agree with the applicant the location where the examinations and necessary tests shall be carried out.

Equipment/installations of low currents are those equipment / electrical installation in which the electric components utilized for info transfer, for mini-macro movements also for the components whose nominal voltage doesn't exceed 11 kV, are included in a compound.

A brief review on these protection type encapsulation installations following their objectives: equipment and installations in automation field, data communication, interlocks, controls; Monitoring and alarm equipment and installations for water leaks, explosive and toxic gases, respectively for fire; equipment and installations for access control, warning device for surveillance; equipment and installations for (video) intercom, telephony and sound; equipment and installations for data transmission and VDI; equipment and installations for data cable CATV and other circuit parts (Figure 1).

Fig. 1. Encapsulated equipment and electrical installations

The protection type in which the parts that can ignite an explosive atmosphere either by spark or by heating, are included in a compound, so that the given explosive atmosphere can't be lit in normal operating conditions is referred to as encapsulation "m".

The electric encapsulated "m" equipment can be with:

- a) protection level "ma" (EPL "Ma, Ga, Da"),
- b) protection level "mb" (EPL "Mb, Gb, Db") or
- c) protection level "mc" (EPL "Gc, Dc").

3. Tests on the apparatus

The test sequence and number of samples are shown below (SR EN (IEC) 60079-18, 2015):

3.1. Maximum temperature

A sample of "m" equipment shall be subjected to a type test to ensure that:

- a) the temperature limits are not exceeded in normal operation;
- b) for level of protection "ma" and "mb" the maximum surface temperature is not exceeded under fault conditions.

For "m" equipment without an external load, the test shall be carried out in accordance with the temperature measurements of IEC 60079-0 taking into account the supply conditions.

3.2. Thermal endurance test

3.2.1. Thermal endurance to heat

- for level of protection “ma” and “mb”, the test shall be carried out in accordance with IEC 60079-0. The temperature to be used as the reference service temperature for the test shall be either:

a) the maximum surface temperature of the test sample under normal operation plus 20 K;
or

b) the maximum temperature at the component surface in the compound under normal operation, see 6.2.2.

- for level of protection “mc”, the test shall be carried out in accordance with IEC 60079-0.

The temperature to be used as the reference service temperature for the test shall be the maximum surface temperature under normal operation.

3.2.2. Thermal endurance to cold

The test shall be carried out in accordance with IEC 60079-0.

After each test the sample shall be subjected to a visual inspection. No visible damage to the compound that could impair the type of protection shall be evident, for example cracks in the compound, exposure of encapsulated parts, failure of adhesion, inadmissible shrinkage, discoloration, swelling, decomposition or softening. A discoloration on the surface of the compound is permissible (for example oxidation in the case of epoxy resin).

3.3. Dielectric strength test

The test shall be carried out on the following arrangements of circuits as applicable:

a) between galvanically isolated circuits;

b) between each circuit and all earthed parts;

c) between each circuit and the surface of the compound or the non-metallic enclosure that, if necessary, can be clad with a conductive foil.

For arrangement a), the voltage U to be used shall be the sum of the rated voltages of the two circuits being tested and for arrangements b) and c), the voltage U to be used shall be the rated voltage of the circuit being tested.

For arrangement b), circuits that contain transient suppression components connected between the circuit and the earthed parts, a special test sample without these components shall be permitted for the type test.

Dielectric strength shall be verified by test:

- either as given in a relevant industrial standard for the individual items of electrical equipment or,
- at the test voltage according to 1) or 2) below, and increased steadily within a period of not less than 10 s until it reaches the prescribed value, and it shall then be maintained for at least 60 s without dielectric breakdown occurring.

The test voltage shall be increased steadily within a period of not less than 10 s until it reaches the prescribed value, and it shall then be maintained for at least 60 s.

3.4. Cable pull test

The test shall be carried out on one sample, previously unstressed and at $21\text{ °C} \pm 2\text{ °C}$.

A further test sample shall be subjected to the cable pull test after conditioning at the maximum temperature at the cable entry point. The tensile force (in Newton) applied shall either be 20 times the value in millimeters of the diameter of the cable or 5 times the mass (in kilograms) of the “m” equipment, whichever is the lower value. This value can be reduced to 25 % of the required value in the case of permanent installations. The minimum tensile force shall be 1 N and the minimum duration shall be 1 h. The force shall be applied in the least favorable direction.

After testing, the sample shall be subjected to a visual inspection. Visible displacement of the cable, which affects the type of protection, shall not be evident. No damage to the compound or cable that could impair the type of protection shall be evident, for example, cracks in the compound, exposure of the encapsulated components or failure of adhesion.

3.5. Pressure test for Group I and Group II electrical equipment

For level of protection “ma” with any individual free spaces between 1 cm³ and 10 cm³ and level of protection “mb” with any individual free spaces between 10 cm³ and 100 cm³, two test samples shall be prepared with a pressure connection. Where there is more than one free space of a size requiring testing, the pressure test shall be carried out simultaneously in all those free spaces. The pressure test shall be carried out on samples that have already been submitted to the thermal endurance tests. The test shall be carried out with a pressure as shown in Table 1 applied for at least 10 s.

Table 1. Test pressure

Minimum ambient temperature °C	Test pressure kPa
≥ -20 (a)	1 000
≥ -30	1 370
≥ -40	1 450
≥ -50	1 530
≥ -60	1 620

a) This covers equipment designed for the standard ambient temperature range specified in IEC 60079-0.

As an alternative for ‘mb’ equipment if the component with a free space up to 100 cm³, prior to encapsulation, passes the Leakage test on sealed devices specified in IEC 60079-15 (without the conditioning, voltage, or dielectric withstand testing) it can be encapsulated without requiring the pressure test. After testing, the samples shall be visually inspected. No compound damage (such as cracks in the compound, exposure of the encapsulated components or failure of adhesion) that could impair the type of protection shall be evident. For constructions that are permitted to have no thickness of compound between a free space and a non-metallic enclosure wall, there shall also be no damage to the non-metallic enclosure wall(s).

3.6. Sealing test for built-in protective devices

The test is to be performed on five samples. With the test samples at an initial temperature of (25 ± 2) °C, they are suddenly immersed in water at a temperature of (50 ± 2) °C to a depth of not less than 25 mm for at least 1 min. The devices are considered to be satisfactory if no bubbles emerge from the samples during this test.

4. Conclusion

Being a part of IECEx system, means implementing some appropriate methods for water absorption testing in testing laboratory. This paper presents the main tests for electrical apparatus with encapsulation protection type. Analysis specific requirements of the standard SR EN 60079-18 on the evaluation equipment with type of protection encapsulation "m" highlighted compound role in the determination of applicable defects in the phase of explosion protection evaluation. Presentation in the requirements of water absorption test for explosion-protected equipment through the types of protection encapsulation "m", being one of the basis tests for these.

The increased complexity of the circuits of the equipment involved in the production process using a compound and conceiving with regard to protection from explosion due to thermal effects to which they may be subjected to. Standardized values imposed by the requirements of isolation distances resulting from the simplified assessment process are superior to those which can be implemented which often leads to rejection of rated equipment.

The aim is to study different types of compound to satisfy the mechanical and thermal resistance, to dissipate the thermal effects caused by overheating the electric and electronic components included in the compound without them affecting the electric equipment safety of use. This aspect is primarily important due to a high number of equipment which operates in explosive atmospheres hazardous areas where the temperature varies between - 30° C ÷ +50° C.

Influence of the volume and geometrical shape of large electric motor enclosures on the explosion pressures when tested in explosive mixtures

Mihai Magyari^a, Sorin Burian^a, Lucian Moldovan^a, Dragoş Fotău^a, Marcel Rad^{a*}

National Institute for Research and Development in Mine Safety and Protection to Explosion – INSEMEX, 32-34 G-ral Vasile Milea street, Petroşani, 332047, Romania

Abstract

The purpose of the paper is to perform a thorough study upon the way in which the internal volume, the dimensions, the geometrical shape, as well as the internal arrangement of explosion protected flameproof large rotative electrical machine enclosures, influence the maximum explosion pressures and the explosion pressure development, while testing in explosive mixtures of gases and vapors. The researches conducted in the specialized Laboratory of INSEMEX Petrosani have identified as causes for the occurrence of pressure peaks in the case of large electric motor enclosures, the extremely great internal volume, the geometrical shape of motor enclosures and the very complex internal arrangement of these motors, having in mind the motor manufacturers for the chemical and petrochemical industry trend to manufacture ever more complex geometrical shape motors.

Keywords: electric motor; explosive atmospheres; flameproof; pressure.

1. Introduction

As widely known, in case of flameproof electric motors as well as in case of most of the technical equipment in general, design and manufacture exceeded long time ago the stage when the manufacturers used to apply their own design methods. At present, the design and manufacture methods for the flameproof type of protection are fully determined by the provisions in the standard (Romanian Standard, 2015), according to which all new motors are manufactured. The electric motors with type of protection flameproof enclosure have to withstand the following type tests and verifications, in order to be certified having in view to their placing on the market: reference pressure determination and overpressure test and test for non-transmission of an internal ignition (Government Decision, 2016; Romanian Standard 2015; Romanian Standard, 2013). The most important subassemblies of flameproof enclosure motors that endorse the type of protection are: stator casing, shields, rotor, fan and fan hood, terminal box, terminal box cover, as shown in Fig.1.

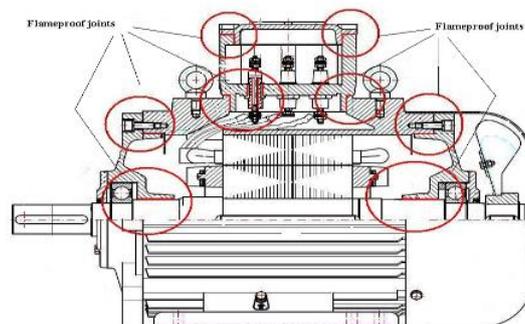

Fig. 1. Flameproof enclosure motor assembly

E-mail address: marcel.rad@insemex.ro.

2. Factors which influence the explosion pressures inside the flameproof enclosure

The maximum internal pressure developed due to the ignition of an explosive mixture inside the motor enclosure depends directly of the volume of gases discharged through the flameproof gaps and other discharge devices if present. Still, the flameproof joints of motors cannot be designed for the purpose of discharging the explosion pressures and they have to be secured to the safety dimensions at which the ignition transfer to the surrounding environment is prevented (Wolfhard and Bruszak, 1960).

2.1. Static pressure

In case there is no anticipation for the occurrence of higher than normal explosion pressures for the motor, the manufacturer will carry out the routine overpressure test at 20 bar, for one minute maximum, for each motor enclosure.

Having in mind that the maximum explosion pressures as a result of pressure pilling cannot be foreseen, the motor enclosure should be designed assuming that pressure pilling will not occur and the manufacturer should have in mind the recommendations regarding the avoidance of this phenomenon, described in the following paragraphs.

2.2. Dynamic pressure

Figure 2 presents an example of pressure diagram normally obtained in a group II C flameproof motor enclosure during the maximum pressure determination test.

Normally, the explosion pressures are measured in three distinct areas during each test: at each of the end shields of the motor and under the terminal plate of the motor, having in mind that from the experience of the testing laboratory, these areas have been responsible for generating the maximum explosion pressures, regardless of the explosion test mixture (Magyari, 2017), (Magyari, 2015).

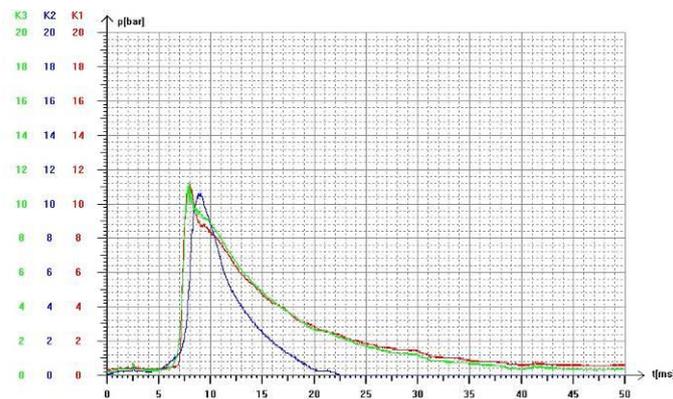

Fig. 2. Example of explosion pressure diagram, using 3 pressure transducers setup

In order to analyze the response of the enclosure when submitted to an internal explosion, it is necessary to know the maximum explosion pressure, the pressure rise time and the pressure persistence time.

2.2.1 Maximum explosion pressure

Usual pressure values measured in the laboratory are 14 or 15 bar, on different types of motor enclosures, provided there is no pressure pilling phenomenon. Thus, the designer of the motor enclosure should have in mind a value of 20 – 22 bar for the enclosure, as a reasonable figure, unless there are solid arguments for designing the enclosure for an increased pressure.

For example, the dynamic pressure foreseen for the designing the motor enclosure can be increased if the particular geometrical shape of the enclosure is expected to generate increased pressure values, due to pressure pilling (Magyari, 2017), (Magyari et al., 2015).

2.2.2 Pressure rise time

In order to determine the minimum pressure rise time, it is useful to use the maximum increase explosion pressure rate (dp/dt). The use of a minimum determined pressure increase rate, for example in the case of spherical enclosures, will not guarantee a resulting minimum pressure increase time for all types of enclosures, but the use of an estimated minimum pressure increase time is conservative, that is why this approach is suitable for designing enclosures having a different geometrical shape than spherical, such as is the case of electrical motor enclosures (Magyari et al., 2011).

2.2.3 Pressure pilling

The term “pressure pilling” as used in the paper, refers to a pressure increase in one of the motor enclosure compartments, above the values normally expected to occur in that compartment, if that subdivision did not exist. This increase of the explosion pressure can be considered as abnormal as compared to the pressure resulted from a burning process in a constant volume, having an initial pressure of the testing mixture equal or as equal to atmospheric pressure (Magyari, 2017), (Magyari et al., 2015), (Magyari, 2015).

3. Main causes for pressure peaks occurrence inside flameproof enclosures

The causes for the occurrence of high pressure peaks in the case of large electrical motor enclosures are the extremely large internal volume (of hundreds and thousands of liters of explosive mixture), the geometrical shape of the motor enclosures, having in mind the latest tendency of motor manufacturers for the chemical and oil and gas industry to manufacture motors having ever more complex geometrical shapes, due to the cooling and mounting means, as well as the internal arrangement of these motors, which differ from the classical ones and from small frame size motors. The existence of several cooling fans, inside and outside of the large motor enclosures, as well as the cooling pipes designed to provide an efficient cooling of these motors having high and very high power, result in an extremely complex and complicated inner configuration of these motors, thus generating a different explosion behaviour from the usual one, with much higher pressure peaks and smaller pressure rise times than normally envisaged (Magyari, 2017).

So far it is unknown for sure the extent to which the geometrical shape, the internal arrangement, the location of the ignition source and its nature, the influence of the explosive testing mixture can be used in order to be able to predict when these pressure peaks are likely to occur and if so, what the resulting pressures will be.

The main causes for the occurrence of pressure peaks in the case of large rotating electrical machines:

- The geometrical shape of the motor enclosure;
- The internal arrangement / division of the motor enclosure;
- The type of gas used and the test mixture concentration;
- The test mixture ignition source;
- Pre compression of the testing mixture;
- Flame front acceleration and flame front instability.

3.1. The geometrical shape of the motor enclosure

The geometrical shape of the motor enclosures plays an important role especially if the ratio between the length of the enclosure and the cross-sectional dimensions is significant. In this case, when the burning is initiated from one end side of the motor, the flame front can be accelerated across the length of the enclosure, being capable even of making the transition from deflagration to detonation in certain extreme cases.

Figure 3 shows 2 examples of large electrical motors having standardized geometrical shapes, whose designs has been checked in the course of the time as being suitable for successful testing in explosive air – gas mixtures. The first example is that of a motor completely designed in flameproof enclosure type of protection – both the stator of the motor and the terminal boxes are Ex d; the second example is that of an Ex d e motor – the stator of the motor is Ex d and the terminal boxes are Ex e increased safety type of protection (Magyari, 2017).

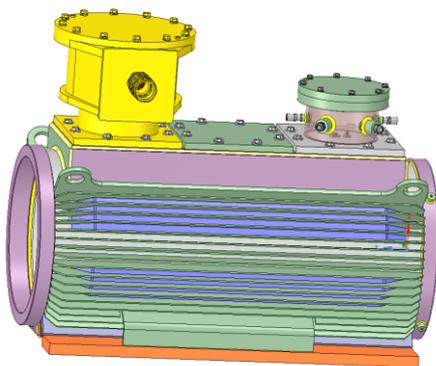

Fig. 3. (a) Ex d II electric motor

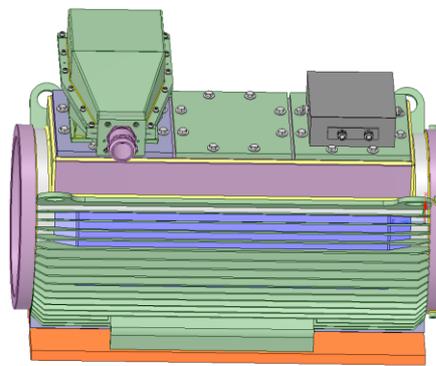

Fig. 3. (b) Ex d e II electric motor

3.2. Motor enclosure subdivision

The motor enclosure subdivision is one of the main causes for pressure peaks occurrence. These pressure peaks occur mostly in the smaller volume subdivision after the ignition took place in the higher volume subdivision. The small surfaces or the passages which connect the two subdivisions increase the likelihood of pressure peaks occurrence. If there are a series of subdivisions connected to each other, the explosion pressure will tend to increase as the the flame front propagates from one subdivision to another, reaching the maximum value in the last subdivision (Magyari, 2017), (Magyari et al., 2015).

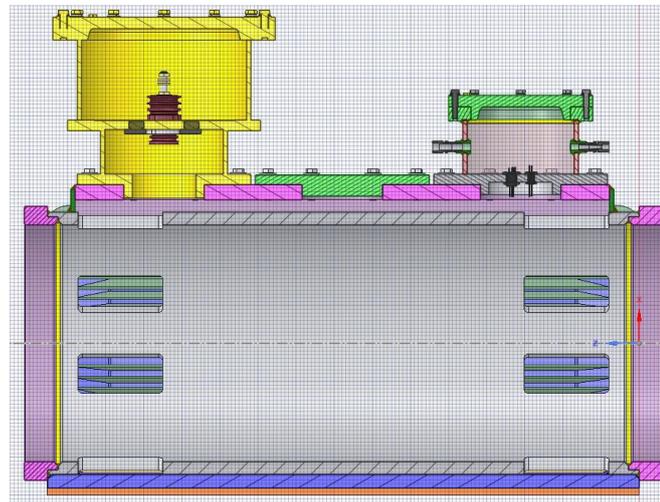

Fig. 4. (a) Internal arrangement in an Ex d II electric motor

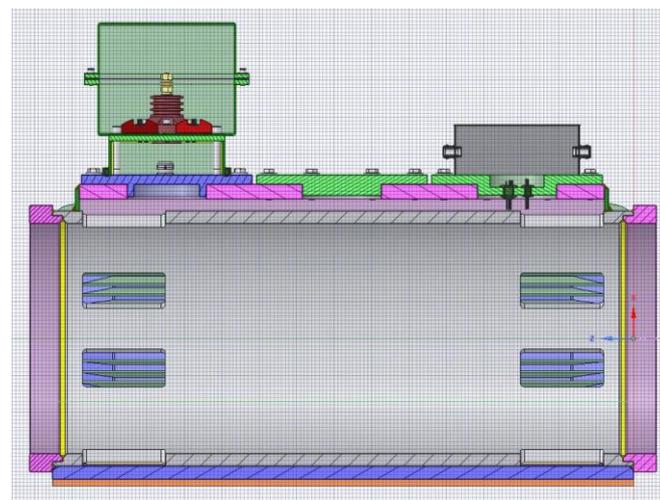

Fig. 4. (b) Internal arrangement in an Ex d e II electric motor

3.3. The type of gas used and the explosive mixture concentration

Gases having a greater explosion potential (such as is the case of hydrogen and acetylene), can produce higher explosion pressures and have a higher tendency to generate higher explosion peaks; also, a concentration which is near to the stoichiometric concentration is likely to result in much higher explosion pressures (Magyari, 2015).

3.4. Ignition source

High power ignition sources generate higher explosion pressures than the normal 12 V ignition sources used in the laboratory for the ignition of the explosive test mixture. An ignition source such as an electrical arc, whose energy is far greater than that of a 12 V sparking plug, used in the laboratory, will always produce higher explosion pressures.

Also, the location of the ignition source can have an influence on the explosion pressure values. The location of the ignition source in the central area of an ordinary enclosure seems to generate the highest explosion pressures; but in the case of higher length enclosures (such as is the case of electric motors), the ignition at one of the end sides of the motor will lead to the occurrence of the highest explosion pressures (Magyari, 2017), (Magyari 2015), (Magyari et al., 2015).

3.5. Pre compression of the explosion testing mixtures

The phenomenon of pre compression of the testing mixture occurs usually in the the case of subdivided enclosures, such as is the case of motor enclosures or in the case of interconnected enclosures. Igniting in one of the enclosure subdivision, especially if we are talking about the higher volume subdivision, is likely to produce higher than the ambient pressure initial pressure in the other subdivision of the enclosure. The final values of the explosion pressures are a direct function of the testing mixture pre compression, regardless of the causes which are responsible for the occurrence of the pre compression of the testing mixture (Magyari, 2017).

As regards design solutions, in case subdivision cannot be avoided – the case of motor enclosures (and not only), then the pre compression in the second subdivision, before the ignition of the testing mixture takes place in it, can be estimated as being the final explosion pressure in the first subdivision (Wolfhard and Bruszak, 1960), (Magyari, 2017).

For these considerations, the value of the initial pressure in the second subdivision is:

$$p_i = p_a \times V_1 / (V_1 + V_2) \quad (1)$$

p_a = atmospherical pressure;

V_1 = volume of the first subdivision;

V_2 = volume of the second subdivision.

This equation has the role to indicate the value of the pressures in the worst case scenario that can be produced because of pre compression and is too conservative for normal designing of enclosures. Too high pressure values obtained by calculus in the case of subdivided enclosures should encourage apparatus designers either to change the equipment design or to have it tested effectively in explosive test mixtures in order to establish more realistic final explosion pressure values that can occur.

3.6. Flame front acceleration and flame front instability

Flame front acceleration can be caused by several factors. These include the acceleration induced due to the mixture flow, the turbulence of the mixture and the flame front instability. The acceleration of the gas flow can occur at the openings and passages which connect the enclosure subdivisions. It can also be produced by the turbulence generated by certain obstacles which add resistance in the mixture flow way or by the flame front instability due to acoustic resonance (usually associated with ventilation, during motor running) and due to normal differences existing at the interface of the burned and unburned mixture (Magyari et al., 2015).

Clearly, the designer will not be able to eliminate the required apparatus inside the enclosure. The designer has to focus mainly on avoiding enclosure subdivision (when possible) by carefully arranging the inner apparatus and, in case enclosure subdivision cannot be avoided, the designer has to eliminate the obstacles which are not necessary or the restrictions on the passages between different enclosure subdivisions (Magyari, 2017), (Magyari et al., 2011).

4. Conclusions

Applying these considerations by manufacturers of explosion protected apparatus would result in an increased likelihood that these motors will successfully pass the particularly severe type tests, from the first stage of motor design project, thus making later modifications on the motor's constructive project unnecessary should the motor fail these type tests, fact that would transpose into an increased time required for finalizing the certification project, implicitly increased certification costs - which represents an essential criterion in the present economical framework where local Ex motors manufacturers have to compete on the European Union market with well known manufacturers from developed countries.

Aspects on small components ignition test using explosive gas mixtures

Abstract

Avoiding the ignition of an explosive atmosphere by the equipment intended for use in such atmospheres is achieved by applying one or more types of explosion protection specific to this equipment.

Certification of electrical equipment intended for use in potentially explosive atmospheres involves the evaluation and testing of this equipment for the specific application.

The first part of the paper presents the specific requirements to perform the ignition test of flammable mixture by the small components of the electrical equipment intended for use in potentially explosive atmospheres

In the second part of the paper are presented the constructional particularities of the test stand used for the ignition test of the flammable mixture by the small components of the electrical equipment intended for use in potentially explosive atmospheres

The third part of the paper presents the procedure used for functional testing of the test stand.

Keywords: Explosive atmospheres; small components; test stand.

1. Introduction

In order to certify the equipment that is part of a system in explosion-protected construction, it is necessary to evaluate and test them by point of view of explosion risk. This risk must be minimized by the user in order to ensure the safety of people's life and health, as well as to prevent damage to property and, last but not least, damage to the environment.

At European level, the certification of electrical and non-electrical equipment intended for use in explosive atmospheres is carried out in accordance with (Directive 2014/34/EU, 2014), commonly named as the ATEX Directive. Considering the fact that each member state of the European Union has the obligation to harmonize its legislation in this field, at national level the ATEX Directive was fully transposed in national legislation.

Compliance of equipment and protective systems intended for use in potentially explosive atmospheres with harmonized European standards in the field of the (Directive 2014/34/EU, 2014) is a method of assessing the essential health and safety requirements provided in the Directive. Compliance with standards is not mandatory but is generally used to assess products covered by the Directive.

At the world level, the IECEx certification scheme for explosion-proof equipment is the framework for the recognition of assessing and testing of equipment intended for use in potentially explosive atmospheres carried out for their certification in order to operate in such atmospheres. In this case, full compliance with IEC standards is mandatory.

2. Specific requirements for evaluation and testing of small components

The assessment and testing of electrical equipment intended for use in explosive atmospheres it is necessary to consider both spark ignition and ignition by thermal effects (Burian et al., 2014).

In the assessment of ignition by thermal effects of the electrical equipment it is necessary to consider the ambient temperatures range in which the equipment will operate, the service temperature of the equipment and the maximum

* Corresponding author. Tel.: + 4-0254-541-621; + 4-0254-541-622; fax: + 4-0254-546-277
E-mail address: adriana.andris@insemex.ro

surface temperature of the equipment that must not exceed the temperature class assigned to the equipment (IEC 60079-11, 2011).

Small components of electrical equipment intended for use in explosive atmospheres may reach a temperature higher than the assigned temperature class of the equipment during operation. This is permitted according to (IEC 60079-0, 2017) only if the small components do not produce the ignition of the specific flammable mixture when subjected to the ignition test.

Another situation where it is permissible to exceed the temperature class at an ambient temperature of 40 °C is when, depending on the surface area of the small component, the exceeding of the maximum surface temperature is limited to the values in Figure 1:

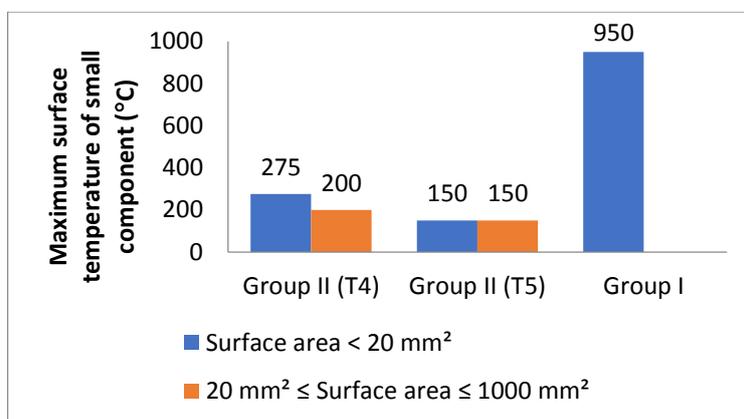

Fig. 1. The maximum permissible surface temperature of the small component at an ambient temperature of 40 °C

Exceeding the temperature class of the equipment by the small components is also permitted if the values for the maximum power dissipated on the component with the surface area $\geq 20 \text{ mm}^2$ in Figure 2 are not exceeded at the maximum operating ambient temperature.

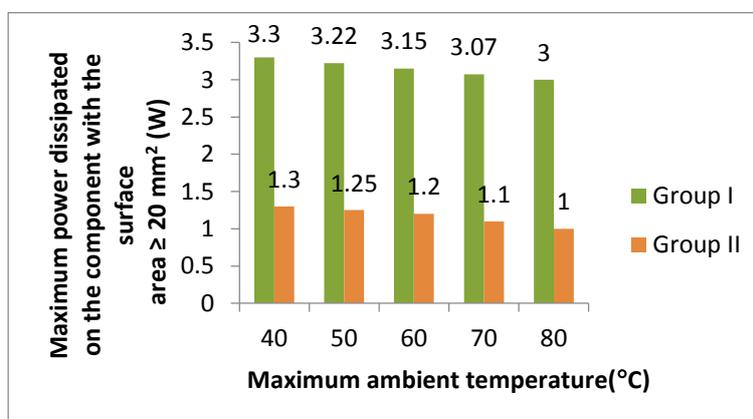

Fig. 2. The variation of maximum power dissipation on component with the ambient temperature

The ignition test for small components is required to demonstrate that in normal operation or fault specified conditions these components are not capable of igniting the flammable test mixture by increasing the surface temperature above the assigned temperature class of the equipment.

For small components with a surface area not exceeding 1 000 mm², their surface temperature may exceed the temperature given by the temperature class marked on the Group II electrical equipment or the corresponding maximum surface temperature for Group I electrical equipment, if there is no risk of ignition due to these surfaces, with a safety margin of

- 50 K for temperature class T1, T2 and T3,
- 25 K for temperature class T4, T5 and T6 and Group I.

During the tests, the safety limit can be ensured by increasing the ambient temperature or by increasing the dissipated power of the component. For methane (Group I) the second option is recommended and the test mixture shall be a homogeneous mixture of between 6,2 % and 6,8 % v/v methane and air.

For temperature class T4, the mixture shall be:

- a homogeneous mixture between 22,5 % and 23,5 % v/v diethyl ether and air, or
- a mixture of diethyl ether and air obtained by allowing the evaporation of a small quantity of diethyl ether inside the test chamber during the ignition test.

The testing of small components may be carried out with the component installed in the equipment as designed and it must be ensured that the test mixture (Andriş et al., 2017) is in contact with the component or with the component mounted in a model that provides representative results.

The component shall be tested in normal operation or in fault conditions leading to reaching the highest surface temperature value. The test must be continued until the thermal equilibrium of the component and the surrounding parts is reached or the temperature of the component decreases.

If a cold flame occurs during the test, it is considered as an ignition. Ignition can be visually detected or by measuring the temperature for example with a thermocouple.

If no ignition occurs during the test, the presence of the flammable mixture must be checked by igniting the mixture by other means.

3. Description of the test stand used for the ignition test for small components

To the perform of ignition test for small components from the equipment intended for use in explosive atmospheres, a test stand has been designed whose block diagram is shown in Figure 3.

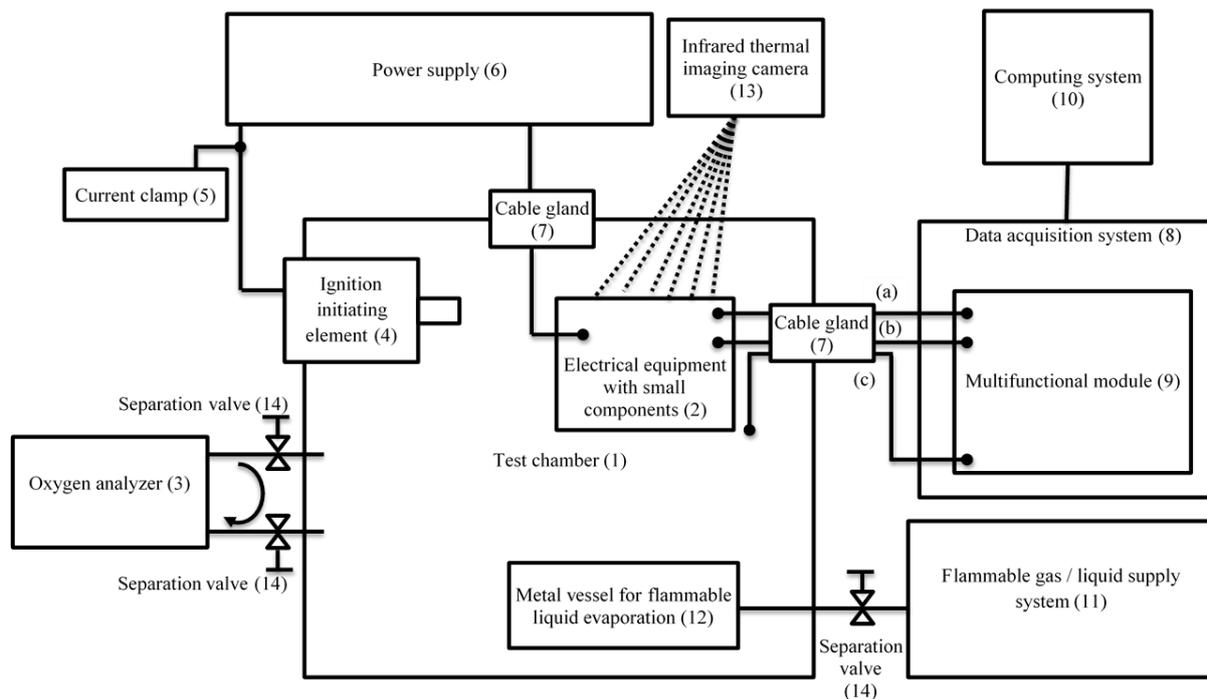

Fig. 3. Block diagram of the test bench for small components from the equipment intended for use in explosive atmospheres

The components of the test stand are as follow:

(1) - test chamber. It is made of metallic material and is provided with two cable glands (7). The equipment with the small components subjected to the test (2) are placed in this test chamber (1), and the test explosive mixture is also carried out here;

(2) - electrical equipment with small components subjected to testing. The object of the test is the small component that heats over the temperature class assigned to the equipment. Testing of small components is done with the component mounted in the equipment as it is designed;

(3) - oxygen analyser. It is used to measure the test mixture. To determine the concentration of the explosive test mixture inside the test chamber (1) measure the concentration indirectly with the oxygen analyser (3);

(4) - ignition initiating element of the test mixture. It is a glow plug powered from the double source (6). The ignition initiating element of the test mixture (4) shall only be used in situations where ignition caused by the heating of the small component (2) does not occur during the test. In these cases, it is necessary to ignite the test mixture by another means, thereby proving the presence and quality of the explosive test mixture within the test chamber (1);

(5) - current clamp placed on the circuit of the initiating element (4) and has the role of confirming the supply of the initiating element to nominal parameters;

(6) - power supply. It is a DC double source supplying both the electrical equipment with the small components which are tested (2) and the ignition initiating element of the test mixture (4);

(7) - cable glands. They are provided on the housing of the test chamber (1) and are intended to facilitate the tight introducing of the electrical conductors for the electrical equipment with the small components which are tested (2), the connection facilities (b) for measuring the electrical parameters in the small components circuit and of thermocouples (a) and (c);

(8) - data acquisition system;

(9) - multifunctional module;

(10) - computing system;

(11) - flammable gas/liquid delivery system. The preliminary quantity of flammable liquid is determined by calculation for a given concentration and introduced through the flammable liquid delivery system (11) into the test chamber (1) and the concentration value is monitored by the oxygen analyser (3);

(12) - metal vessel for flammable liquid evaporation. It is located in the test chamber (1) and is intended to allow evaporation of the amount of flammable liquid introduced by dripping through the delivery system (11);

(13) - infrared thermal imaging camera. It is used to supervise the general thermal regime of the equipment (2) during the test;

(14) - separation valves. After the explosive test mixture has been obtained, the separation valves will close before connecting the electrical equipment with small components (2) to the power supply;

(a), (c) - thermocouples of type K/J for measuring the surface temperature of small components (2) and ambient temperature inside the test chamber (1);

(b) - connection facilities for measuring the electrical parameters in small components circuit.

4. Functional testing of the test stand

The test stand achieved was tested functionally according to the following methodology:

Step 1:

- the test conditions regarding the test explosive mixture parameters, the ambient temperature inside the test chamber during the test, and the electrical supply parameters of the equipment with the small components (2) have been established.

A mixture of 23 % v/v diethyl ether in air, obtained by evaporating the flammable substance introduced into the test chamber (1) through the delivery system (12), was used. The amount of liquid diethyl ether that was introduced into the test chamber was calculated according to formula from relation (1) resulting a value of 6,5 ml:

$$V_l = \frac{P_{atm} \cdot c_{subs} \cdot V_{cam} \cdot \mu_{subst}}{R \cdot T_{abs} \cdot \rho_{subst}} \quad (1)$$

where:

V_l – amount of flammable liquid (m^3);

P_{atm} – atmospheric pressure (N/m^2) = 94200 N/m^2 ;

c_{subs} – concentration of flammable substance (% v/v) = 23 % diethyl ether;

V_{cam} – test chamber volume (m^3) = $7,554 \cdot 10^{-3} m^3$;

μ_{subs} – molar mass of the flammable substance (g/mol) = 0,07412 kg/mol;

R – universal constant of the ideal gas = 8,314 J/mol*K;

T_{abs} – absolute ambient temperature (K); for $t_{amb} = 40 \text{ }^\circ\text{C}$ result $T_{abs} = 313,15 \text{ K}$;

ρ_{subs} – density of flammable substance (kg/m^3) = 713 kg/m^3 ;

The test sample used in the experimentation of test stand was the following limitation circuit:

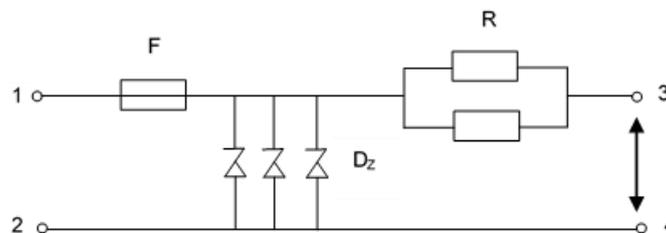

Fig. 4. Test sample used for the ignition test for small components

The electrical parameters of the circuit were:

$U = 6 \text{ V}$; $I = 586 \text{ mA}$ between the terminals (1) and (2);

$D_z : 3 \times 5V6$;

$R : 2 \times 30 \text{ } \Omega$; 0,5 W.

A short circuit fault between the terminals (3) and (4) was simulated during the test to obtain the highest temperature at the surface of the resistors.

Step 2:

- the test sample was placed in the test chamber (1) and the electrical connections with the power supply (6) were made;

Step 3:

- the thermocouples of type K/J have been placed on the small component surface under test (R) and inside the test chamber (1) for measuring ambient temperature;

Step 4:

- the multifunction module (9) has been connected to the small component (R) circuit for monitoring the electrical parameters during the test;

Step 5:

- the oxygen analyzer (3) has been checked / calibrated; the indication of the oxygen analyzer was calculated based on the diethyl ether concentration using the calculation formula from relation (2), obtaining the value of 15,89 % oxygen.

$$C_{required} = \frac{C_{oxygen\ before\ mixing} \% * (100 - C_{subs})}{100} \quad (2)$$

where:

$C_{oxygen\ before\ mixing}$ – the indication of the oxygen analyser before the introduction of the flammable substance (% v/v) = 20,64 %;

C_{subs} – required concentration of the flammable substance (% v/v) = 23 % diethyl ether;

Step 6:

- after the test chamber was closed with a transparent plastic film, the heating process inside of the test chamber (1) was initiated until the temperature reached 40 ° C;

Step 7:

- the flammable test mixture was made in the test chamber (1) and the concentration of the explosive test mixture was confirmed with the oxygen analyser (3);

Step 8:

- the separation valves (14) was closed;

Step 9:

- after reaching the ambient temperature set inside the test chamber (1), the test sample having short-circuited terminals 3 and 4 was powered from the dual power supply (6) and the general thermal regime was monitored by the infrared thermal imaging chamber (13);

The test was carried out until it was noted that the temperature was decreased on the small monitored component (R resistance).

Step 10:

- considering the fact that during the test the explosive test mixture was not ignited by the heated surface of the small component monitored, the test sample was disconnected from the power supply and the explosive test mixture was ignited by the ignition initiating element (4).

5. Conclusions

The structure of the test stand and the performance of the component parts used enable that the ignition test for small components from the equipment intended for use in potentially explosive atmospheres to be successfully carried out.

An additional advantage of the test stand is that it allows the investigation of the thermal regime for small size components in order to determine the eligibility also for the type of protection encapsulation "m".

By using the transparent plastic film to close the test chamber, both the thermal regime visualization and the redundant indication of the ignition of the test mixture were facilitated.

The limits of electrical grid for increasing the quality in three phases systems through the power flow control

Maria Daniela Stochitoiu^{a*}, Ilie Utu^a

^aUniversity of Petrosani, Universitatii str.20, Petrosani 332057, Romania

Abstract

Power systems components are loaded up to their limits and power trading with fast varying load patterns is leading to an increasing congestion. Taking into account the low possibilities to stock the electrical energy in alternative current systems it is necessary to balance the generated power and absorbed power. If the generated power is lower than absorbed power the frequency and the voltage are reducing, so the consumed power is decreasing for balancing the supplying power. If the voltage is maintained by the reactive power source than the load will be increase and the frequency will be keep to a low value and the power system will be crash; if there aren't a reactive power source a crack-up voltage will appear in the system.

Keywords: power factor; distortion effect; static Var compensator; capacity; inductance

1. Introduction

The only way to prevent the occurrence of voltage collapse is either to reduce the reactive power load or to provide the system with additional supply of reactive power before the system reaches the point of voltage collapse. This can be done by connecting sources of reactive power, i.e., shunt capacitors and/or Flexible AC Transmission System (FACTS) controllers at appropriate locations in the system. Flexible AC Transmission Systems (FACTS) technology helps utilities in reducing transmission congestion and in utilizing more efficiently the existing transmission system without compromising the reliability and security of the system. Their fast response offers high potential for power system stability enhancement apart from steady state flow control (Badea et al., 2013).

2. The concept of power flow control

It is considering an electrical line with the phase voltages at the ends:

$$\underline{U}_1 = U_1 \cdot e^{j\delta_1} \text{ and } \underline{U}_2 = U_2 \cdot e^{j\delta_2} \quad (1)$$

Using the ``long`` line equations (without losses $g_0 \approx 0$, $r_0 \approx 0$) it obtains active power transmitted by line between nodes 1 and 2 is directly proportional with the voltages U_1 and U_2 also difference between load angles δ_1 and δ_2 and inversely proportional to the resultant reactance (impedance) of the line X_{line} (Golovanov, 2009):

$$P_{12} = \frac{U_1 \cdot U_2}{X_{line}} \sin(\delta_1 - \delta_2) \quad (2)$$

$$X_{line} = Z_C \sin \varphi_{line} \quad (3)$$

Z_C = the line characteristics impedance

$\varphi_{line} = \frac{2\pi L}{\lambda}$ the transmission angle corresponding to line (L-length)

λ = the electromagnetically wave length

* Corresponding author. Tel.: +40-726-278-241.
E-mail address: danielastochitoiu@upet.ro

$$\begin{aligned}
 U_A &= U_B = U \\
 \delta_1 &= \delta, \delta_2 = 0 \Rightarrow \\
 P_{12} &= \frac{U^2}{X_{line}} \sin(\delta_1 - \delta_2)
 \end{aligned} \tag{4}$$

P_n - the natural power

$$P_n = \frac{U^2}{Z_C} \Rightarrow P_{12} = P_n \frac{\sin \delta}{\sin \varphi_L} \tag{5}$$

From that equation is seen that is possible influence the power flow lines by change the resulting reactance (impedance) transmission path.

For increase the transferable active power using specifically compensate devices it can notice:

- the highest power is corresponding for $\delta = \frac{\pi}{2}$;
- the highest power can be increase through decreasing the characteristic impedance and the transmission angle, separately or simultaneous.

Taking into account the distributed compensate concept [Kimbark], it follows the P_n natural power modify in dependence with transmits power, the involved parameters without compensate stage are:

$$Z_{C0} = \sqrt{\frac{X_{L0}}{B_{C0}}} ; \varphi_{L0} = \sqrt{X_{L0} \cdot B_{C0}} ; P_{n0} = U^2 \sqrt{\frac{B_{C0}}{X_{L0}}} \tag{6}$$

3. The control of transmits power through parallel compensation

$$B = B_{C0} - B_{der} = B_{C0}(1 - k_{der}) \tag{7}$$

Be $k_{der} = \frac{B_{der}}{B_{C0}}$ the derivation degree ($k_{der} > 0$ for inductive derivation and $k_{der} < 0$ for capacitive derivation). The relations between parameters are:

$$Z_C = \frac{Z_{C0}}{\sqrt{1 - k_{der}}} \tag{8}$$

$$P_n = P_{n0} \sqrt{1 - k_{der}} \tag{9}$$

It can notice:

- using capacitors in parallel for derivate compensation, the characteristic impedance decreases but the transmission angle and natural power are increasing;
- through the inductive parallel compensation, the characteristic impedance is increasing but the transmission angle and natural power is decreasing.

4. The control of transmits power through serial compensation

The inductive reactance of transmission line is modified using serial compensation with capacitors. Be $k_{serie} = \frac{X_{L0}}{\omega C_{serie}}$, so $X_L = X_{L0}(1 - k_{serie})$, the relations between parameters without compensation and with compensation line are:

$$Z_C = Z_{C0} \sqrt{1 - k_{serie}} \tag{10}$$

$$P_n = \frac{P_{n0}}{\sqrt{1 - k_{serie}}} \tag{11}$$

It notices that increasing the serial compensation degree the characteristic impedance and transmission angle are decreasing but the natural power is increasing (Eremia, 2017).

5. How is influenced the load capacity of electrical line

Voltage stability is the ability of a power system to maintain voltages of power system buses after a disturbance in operating condition. On the other hand, voltage stability is the ability of power system to maintain or restore equilibrium point between demand and supply (Asuhaimi et al., 2016). Otherwise, instability results in progressive fall or rise of voltages in buses. Generally, loss of large loads, cascading outage of transmission lines and power system apparatus by protective schemes are pushing power system to voltage instability. Loss of generators synchronism event by outages or operating conditions is made to violate field current limitation. Hence, conventional methods for improving static stability are (Bindeshwar et al., 2011): Increasing the voltage; constructing new transmission lines; decreasing line series reactance by bundling; Installing series capacitors in transmission lines, decreasing transformers series reactance.

Total transmission capacity represents the highest power interchanged between two nodes without influencing of security power changes.

TCC={thermal limit, voltage limit, stability limit}

If one of those limits is takeover the power system operating will be affect.

From insulation point of view the voltage level couldn't takeover some highest values. In operating a 10% of voltage increasing is acceptable. A lower voltage level increases the voltage stability and can determine the voltage crash-up phenomena. FACTS technology can be used for assure the conditions of overvoltage and power circulation.

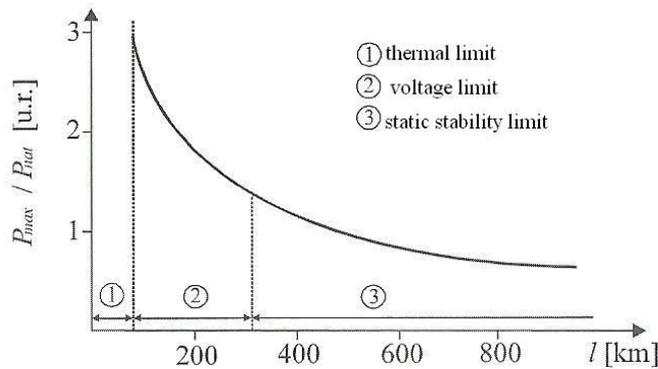

Fig.1. The highest heritable power for an electrical line

In the trans boundary power systems are a lot of electrical and magnetically interactions due to randomize customers and electric power plants behaviour which cause important oscillations of power, voltage and frequency (dynamic stability, static stability, voltage crash-up, synchronic resonance). Using the FACTS devices some stability limits can be annihilated.

The only way to prevent the occurrence of voltage collapse is either to reduce the reactive power load or to provide the system with additional supply of reactive power before the system reaches the point of voltage collapse. This can be done by connecting sources of reactive power, i.e., shunt capacitors and/or Flexible AC Transmission System (FACTS) controllers at appropriate locations in the system. Flexible AC Transmission Systems (FACTS) technology helps utilities in reducing transmission congestion and in utilizing more efficiently the existing transmission system without compromising the reliability and security of the system. Their fast response offers high potential for power system stability enhancement apart from steady state flow control (Badea et al., 2013). The benefits of employing FACTS are many: improvement of the dynamic and transient stability, voltage stability and security improvement, less active and reactive power loss, voltage and power profile improvement, power quality improvement, increasing power flow capability through the transmission line, voltage regulation and efficiency of power system operation improvement, steady state power flow improvement, voltage margin improvement, loss minimization, line capacity and load ability of the system improvement (Lascu, 2004).

A discussion of power system harmonics is incomplete without discussing the effects of power factor correction capacitors. In an industrial plant containing power factor correction capacitors, harmonic currents and voltages can be magnified considerably due to the interaction of the capacitors with the service transformer. This is referred to as harmonic resonance or parallel resonance. For a typical plant containing power factor correction capacitors, the resonant frequency (frequency at which amplification occurs) normally falls in the vicinity of the 5th to the 13th harmonic. Because nonlinear loads typically inject currents at the 5th, 7th, 11th, and 13th harmonics, a resonant or near-resonant condition will often result if drives and capacitors are installed on the same system (Stochitoiu et al., 2012).

In practice, power factor correction (PFC) techniques will influence both. There are two general forms of PFC, active (a-PFC) and passive (p-PFC).

As the name suggests, a-PFC utilises active electronic components to control the harmonic emissions. Due to the active control, the resulting input current waveform is very close to the ideal sinusoid, with a displacement power factor very close to unity and a very low THD I .

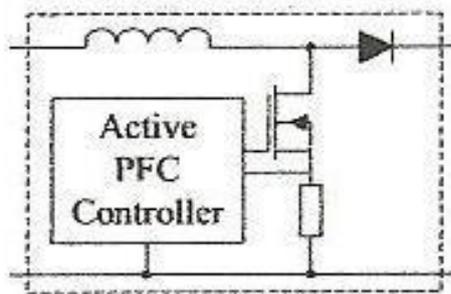

Fig.2. Active power filter correction

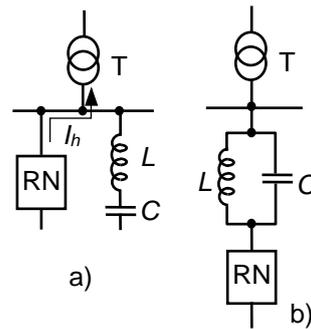

Fig.3. Passive Power Filter correction a) parallel b) serial

For stricter harmonic legislation, it may be necessary to include additional passive components in the circuit to satisfy harmonic limits. This is classified as passive-PFC (Golovanov, 2009). The most common p-PFC approach in the power electronics load category is to include an additional inductance in the conduction path to reduce the harmonic emissions. As inductors oppose the change of current, this will effectively reduce the rate of change of the current pulse and 'smooth' the input current waveform.

There are numerous benefits to be gained through power factor correction. These benefits range from reduced demand charges on your power system to increased load carrying capabilities in your existing circuits and overall reduced power system losses (Martínez et al., 2017). And the benefits of power factor correction aren't just limited to the balance sheet; there are also huge environmental benefits associated with power factor correction, which means your company is reducing its carbon footprint and helping the environment.

Innovative and quality solutions with HVDC and FACTS – face to the new challenges

Maria Daniela Stochitoiu^{a*}, Marius Daniel Marcu^a

^aUniversity of Petrosani, Petrosani Universitatii 20, 332006, Romania

Abstract

HVDC and FACTS provide the necessary features to avoid technical problems in the power systems that increase transmission capacity and system stability very efficiently and they assist in prevention of cascading disturbances. They support the great access of renewable energy resources and reduce the transmission losses by optimization of power flows.

Keywords: renewable energy, static Var compensator, capacity, inductance

1. Introduction

Energy is a key factor for worldwide technology development, in providing a lifestyle and enhancing quality of life. An important energy production is based on fossil energy production.

Global demand for renewable energy is pushing renewable energy to the side of fossil fuel energy production. Fossil fuel has limited resources in the world and increasing production has increasing pollution problems. Central power stations are low efficient, high polluting stations which contribute to environmental issues. In order to overcome these problems structural changes are needed in power production to change non-renewable based production to renewable based energy production. Due to public interest, appears a pressure to develop technical solutions to increase amount of renewable energy in power production, and to use opportunities to utilize renewable energy resources and address the technical challenges.

Carbon dioxide concentrations are rising mostly because of the fossil fuels that people are burning for energy. Fossil fuels like coal and oil contain carbon that plants pulled out of the atmosphere through photosynthesis over the span of many millions of years; we are returning that carbon to the atmosphere in just a few hundred years.

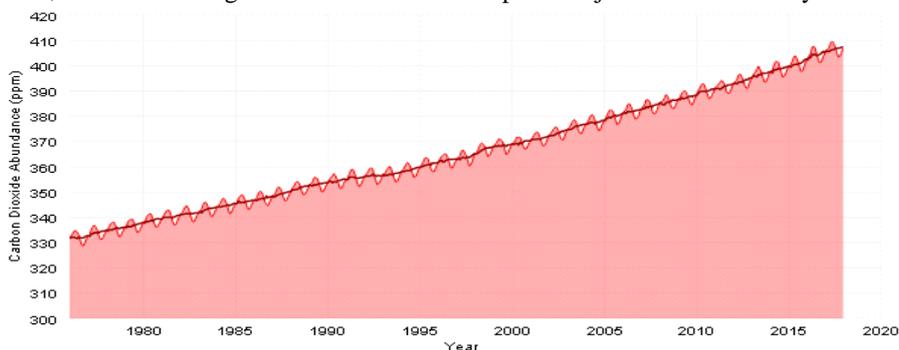

Fig.1 The evolution of CO abundance www.climate.gov

Worldwide interest towards renewable energy is a driving force to employ new technologies. Small-scale power production is replacing large-scale centralized power production. Intermittent energy as wind power and solar energy are causing negative effects to power quality, voltage, frequency and reliability. An increasing amount of intermittent energy increases problems for the grid.

2. HVDC and FACTS converter technology

HVDC and FACTS controllers based on line commutated converter technology have a long and successful technology. Thyristor was the key components of this converter topology and have reached a high degree of maturity due to their robust technology and their high reliability. HVDC transmission technology offers new dimensions for long distance transmission. In general, for transmission distances above 700km, DC transmission is more economical than AC transmission at least 1GW.

HVDC and FACTS provide the necessary features to avoid technical problems in the power systems that increase transmission capacity and system stability very efficiently and they assist in prevention of cascading disturbances. They support the great access of renewable energy resources and reduce the transmission losses by optimization of power flows.

The power systems work with transmission alternative voltage lines 220kV, 400kV, 750kV and continuous voltage $\pm 200\text{kV} \dots \pm 800\text{kV}$.

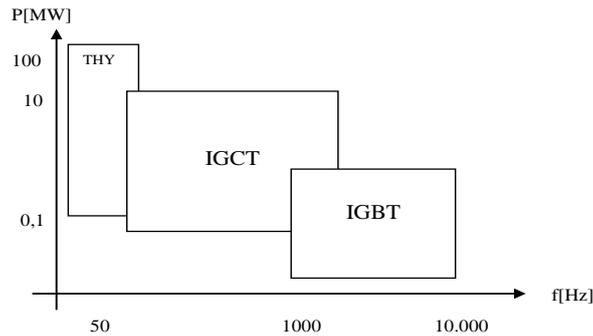

Fig. 2 Evolution of Si power electronics devices

Advances in power electronic technologies together with sophisticated electronic control methods made possible the development of fast static compensators namely Flexible AC Transmission Systems (FACTS). The FACTS technology has become one of the most valuable compensation techniques, because it applies the latest advances in power electronics to achieve additional and more effective control of the parameters of the electrical systems. This represents the most efficient combination of conventional primary equipment, high power semiconductor devices, microelectronics and telecommunications equipment, allowing a most flexible power electric system, (***, 2012).

Table 1. The semiconductors characteristics for HVDC and FACTS

Types of semiconductors	Symbol	Characteristics				
		Highest turn-off voltage [kV]	Highest direct current [kA]	The commutation frequency [Hz]	The nominal power	t_{off} [μs]
Thyristor		8	5,5	50/60	kW-GW	50
Gate Turn Off Thyristor		4,5	4	<500	MW	10
Integrated Gate Commutated Thyristor		6,5	1,5	<1000	MW	5
Isolated Gate Bipolar Transistor		6,5	2,4	<1000	MW	2

Till today, the thyristor having the highest voltages and currents are used in almost all FACTS technologies and in some HVDC lines having $\pm 800\text{kV}$ and power of 8GW. The thyristors are also using in static commutations from LCT (inductance controlled thyristor) and CCT (Capacity switched thyristor) in converters for static VAr compensator.

Especially in applications of wind plants off-shore the devices for HVDC must to have small dimensions so, more devices can be integrated in the same semiconductors structure.

The main definition of FACTS is the A.C. Transmission System which incorporate static commutates based on power electronics which improve the controllability and increase the transmission capacity. Flexible AC Transmission Systems (FACTS) technology helps utilities in reducing transmission congestion and in utilizing more efficiently the existing transmission system without compromising the reliability and security of the system. Their fast response offers high potential for power system stability enhancement apart from steady state flow control, (Bindeshwar et al., 2011). The benefits of employing FACTS are many: improvement of the dynamic and transient stability, voltage stability and security improvement, less active and reactive power loss, voltage and power profile improvement, power quality improvement, increasing power flow capability through the transmission line, voltage regulation and efficiency of power system operation improvement, steady state power flow improvement, voltage margin improvement, loss minimization, line capacity and load ability of the system improvement, (Eremia et al., 2011).

The abbreviation for used FACTS devices are:

- TSSC – Thyristor Switched Series Capacitor
- SSSC – Static Synchronous Series Compensator
- TCVR- Thyristor Controlled Voltage Compensator
- CSC – Convertible Static Compensator
- SVC – Static VAr Compensator
- TCSC – Thyristor Controlled Series Capacitors
- STATCOM – Static Synchronous Compensator

In the last years, some mechanical switchers of parallel capacitors/inductances were being replaced by static switchers with thyristors. Nowadays the most used parallel devices are SVC and STATCOM. The modern devices of serial compensation are TSSC, TCSC and SSSC. The different FACTS devices contain as parallel components as well serial components connected together in the transmission system (as UPFC – Unified Power Flow Controller and IPFC – Interline Power Flow Controller), (Stochitioiu et al., 2018). These devices can control the important parameters of energy as line voltage, impedance, angle or active power flow and reactive power flow.

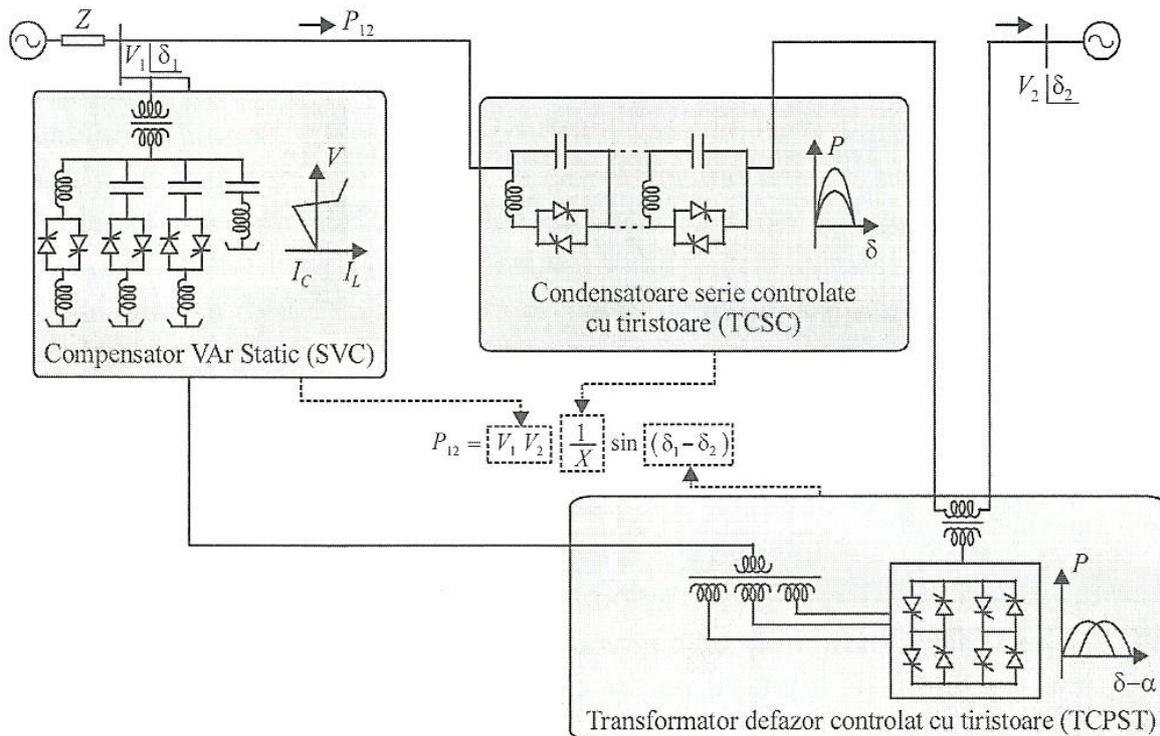

Fig.3 FACTS devices based on the conventional thyristors

In according with IEEE definition, Static VAr Compensator represents a reactive static power generator that is characterized by output parameters which can be modified by switching the inductive or capacitive current to control specific parameters of energetic system, especially the nodes voltage. Today the world faces a great challenge for providing energy, one of the most necessary resources, under the constraints to avoid the emission of pollutant substances and the rapid depletion of fossil fuel resources.

3. Conclusions

Modern power systems are large, interconnected and involves thousands of buses and hundreds of generators. Power system protection devices also form a large part of the system. Environmental as well as economic factors primarily govern the installation of new power system and to transport this power, new transmission line construction are needed to meet the ever increasing load demand.

Influence of power quality and efficiency for an energy delivery system real study case application

Mariana Dumitrescu^{a*}

^a“Dunarea de Jos” University of Galati, 47 Domneasca Str., Galati, 800008, Romania

Abstract

The paper presents an analysis of the efficiency and quality concerning a real case study for an electric delivery system. The purpose of the study is to find the potential negative effect of the unbalanced-non-linear loads on the delivery system. Giving the analysis results, a study about the possible techniques that will minimize this impact is done. Considering the real information from a supervisory-management system and using the professional designing/analysis software in the domain, the load duration curves are built for the HV/LV transformer stations. For the analyzed real study case delivery network, an algorithm and procedure of implementation of the methods improving efficiency and quality is accomplished. A solution for optimal sizing and location of the capacitors including harmonic filters is proposed, taking in consideration the optimal active and reactive power flow and also the rated bus tension levels to be maintained.

Keywords: Power systems; power delivery; power quality; power efficiency.

1. Introduction

Electrical networks reactive power flow and power factor compensation study uses the technical-economic optimizations for a Power Delivery-PD system case. From economically point of view reactive power sources can be installed if they decrease the active power losses in the network and the investment is justified. Specialist are taking in account to verify if the resulted reactive power compensation systems, proposed on economical-criteria, respect the voltage limits of normal conditions, which is only possible after the power flow computing (Bantras, 2012).

According with the PD theory, if compensation systems (reactive power sources-kvar) is implemented in the PD, financial savings are done, directly by reducing the billing rates and indirectly because of the smaller wires sizes (can still support the loads/the conductors cross-section is inversely proportional to power factor). On the contrary, when compensation of the PD is not done, it increases the power companies cost of power supplying and can cause overloaded generators/transformers/lines, reducing the load capability of the power systems in general (Masoudipour and Samed, 2013). Measurements are often taken to determine/reduce the level of harmonic pollution for the power system, due to unbalanced-non-linear loads. Harmonic measurements, done in a systematic way, are expensive/time consuming or error can appear due to the inaccuracies of measuring instruments or perhaps their wrong utilization. More and more the measurements are used mainly to validate power system modelling results, from the computer digital simulations.

2. Delivery System Study Case Efficiency

For the PD study case was done a simulation of the power flow for the initial operational stage, using the professional analysis and design software EDSA. The objective is to minimize the power losses for the analyzed PD system and also to minimize the total energy cost. This conduct to the maximization of the net annual cost saving, due to addition of the kvar compensation systems. The software was used for the power flow simulation and the power losses computation.

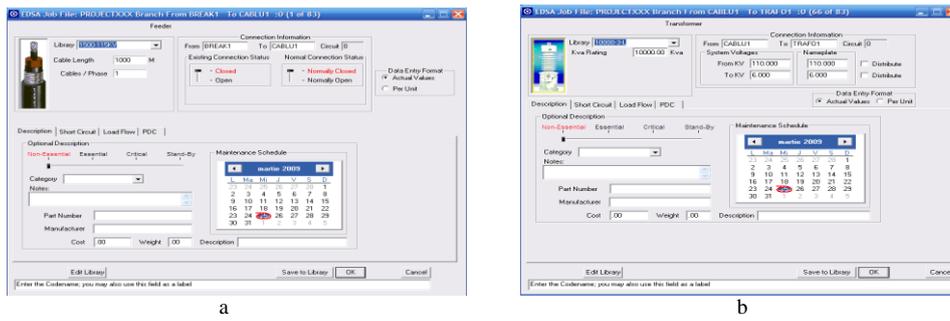

Fig.1. Data base to select the cables (a) and transformers (b) using the computer simulation

The introduced feeders input data are presented in Table 1 and the general system data are the following: kVCharge Cost=25.00(Euro/kVA/Year), kWh Energy Loss Cost=0.05(Euro/kWh), kvar Capacitor Investment Cost=2.00(E/kvar/Year. Fig. 1 presents the selection for the cables and transformers, with the help of the data base of the professional software, which are used in the analyzed industrial power delivery system network. In Fig. 2 is shown the single diagram for the analyzed power delivery system having radial feeders, designed in EDSA software. There are 6 transformation posts-PT, 6/0.4kV to insure the power supply for low power-LP consumers. The algorithm to find the optimal capacitors bank characteristics, in order to adapt the capacitor bank kvar at the load-reactive power curve, is conducting to a minimal reactive power supply from the system. Reactive power-load curves analysis has generally very large variations, showing kvar picks at evening and morning, but also kvar deeps during night and day.

13	396	3	33.14	10.24	342.43	54.26	400

3. Harmonic Regime Analysis

The capacitor function is correlated with the automations systems from the PD system and for optimal locating the capacitors we made measurement regarding the harmonic regime, with verification of the resonance with superior harmonics, because a possible failure of capacitor equipments can appear (Armonvipas and Hofmann, 2011), (Wangsong and Yonghai, 2013). For PD system, 6kV voltage, in the measure point-secondary of the electric transformer- 0.4kV, the parameters of harmonic regime need to be (IEEE Standard 519-1992): maximum total voltage distortions coefficient VTHD - 5%; maximum individual voltage distortion coefficient VTHD -3%; maximum total harmonic current distortion ATHD – 5% for Isc/I value less then 20 and ATHD – 15% for Isc/I value in 20- 1000 interval. Considering 519 IEEE Standard, Isc value means maximum short circuit current at the measure point and I value means maximum demand load current at the measure point, computed to be the average of the maximum demand over the last 12 months.

Total harmonic current distortion quantifies the harmonic current distortion as a percentage of the maximum demand load current obtained in operating conditions lasting at least one hour. The level of voltage and current harmonics is standardized by CEI 1000-2-2/90 until the 40th harmonic. Fig. 3 and 4 show the results of the harmonic regime monitored by Qualistar-electrical power analyzer. They show a variable ATHD coefficient 11.5%-24.5% and a too big value for individual ATHD in case of L1 electrical circuit phase. For L1 electrical circuit phase case, ATHD distortion coefficient is bigger than its superior limit-15%, consideringr the interval of two monitoring hours (Cuk et al, 2013), (Mousavi, 2009).

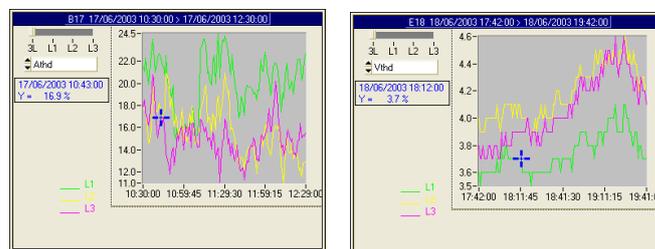

Fig. 3 ATHD and VTHD for L1, L2, L3 electrical circuit three phases for transformation post-PT 29

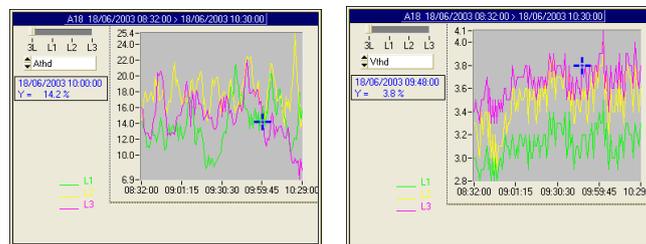

Fig. 4 ATHD and VTHD for L1, L2, L3 electrical circuit three phases for transformation post-PT 163.

The VTHD-coefficient, shown in Fig. 3, is over the superior limit 3%, considering the monitoring interval-two hours, but for L2 and L3 electrical circuit phases there are even bigger VTHD values than in L1-case. Fig. 4 shows ATHD and VTHD measure for L1, L2, L3 electrical circuit phases in PT 163-transformation post. The limits of individual ATHD values are 6.9% and 25.4%. The biggest value for individual ATHD is shown in the case of L2 electrical circuit phase. The individual VTHD coefficient is 2.8% - 4.1%, but L2 and L3 electrical circuit phases have VTHD values over 3% for the monitoring interval-two hours.

4. Power Delivery System Efficiency Improvement

Daily active and reactive power load curves were obtained using a measure data base for 6/0.4kV transformers secondary busbar, from the nominated transformer posts proposed for kvar compensation. Using the information were built daily active and reactive power load curves for the consumers. In Fig. 5-6 are shown the maximum values for active, reactive power flow for low voltage-LV network and also on for medium voltage-MV. Computation is made in seven consecutive days, considering the average values corresponding to five working days and two days of weekend, (Mousavi, 2009). We concluded that significant for the active and reactive power flow and efficiency improvement are the load curves for the working day, because for the weekend, power flow is low comparing with the working days.

Adding a capacitor on a radial distribution feeder means that it is capable to supply the customer reactive power and there will be no penalty for the company. The power company doesn't pay for reactive power delivered to consumers and also save a lot of the active power losses in feeders and transformers. For the analyzed power delivery system, have been proposed compensation capacitors system with harmonics filters to reduce the effect of harmonics and power losses (Hagh et al, 2011).

The computation is made for the hole day considering 15 minutes period, meaning 96 daily computations. It is necessary to use a capacitor banks solution, having power steps, so we elaborated an optimal algorithm of power steps computation. The optimal criteria is the efficient economical utilizations of the steps (not enveloped in the paper) and the results concerning the optimal solution are presented in the Table 2.

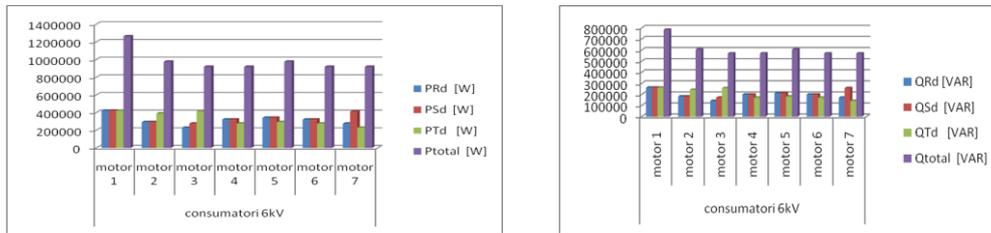

Fig.5. Active power flow, reactive power flow for MV network

BUS 13	13,35.....20,21	13,35/16,76/19,21

5. Conclusions

Today we must consider the technological developments and energy saving devices that have been developed in the last years. The new generation of electrical equipment has brought the need to include more and more the important task of the digital computer to make complex simulation of the regime. EDSA software is able to give adequate electric power system analysis, design and makes much easier the task for specialists in PD efficiency and quality improvement.

Intelligent electrical micro network application with distributed energy resources

Mariana Dumitrescu^{a*}

^a“Dunarea de Jos” University of Galati, 47 Domneasca Str., Galati, 800008, Romania

Abstract

The operational benefits of the micro networks and also their environmental and economic benefits conduct in consequence to their acceptability and their possible degree of proliferation in the utility power industry, which are determined by the operational features. The automation, control, management and operational strategies for the micro networks can be very complex and also bring a significant conceptual difference, than the case of the networks used for the classical power systems. It depends of course on the type and penetration depth of the distributed energy resource units, supplying the micro network. The degree of dependence belongs to the load characteristics, power quality indicators and market participation strategies. This paper is presenting an overview of the importance and complexity of the micro network automation, control, strategies in the power and energy management. It describes their potential to the market participation and gives a practical sample.

Keywords: Power systems; electric distribution; micro networks; distributed energy resources; power quality.

1. Introduction

A micro network-MN is usually a part of the electric power distribution system that is located downstream of the distribution electrical substation. There are used, for the operational MN purpose, a wide variety of distributed energy resources-DER units which supply a wide variety of end consumers for electricity or combined heat-electricity. DER units are divided in two types: conventional or rotary units-interfaced to the micro network through rotating machines -, electronically coupled units - utilizing power electronic converters to provide coupling with the host system. The electrical connection point of the micro network to the utility system, at the low-voltage bus of substation transformers, constitutes the micro network point common coupling-PCC (Agarwal, et al, 2011), (Blaabjerg, et al, 2006). The MN serves a variety of residential buildings, commercial entities, and industrial parks. The MN can provide sufficient generation capacity, controls, and operational strategies to supply at least a portion of the load after being disconnected from the distribution system at the PCC and still remain operational in an autonomous way (Katiraei and Iravani, 2006).

2. Micro networks overview

In a conventional distributed generation unit-DGU the rotating machine is transforming the power of the energy resource into electrical power and is coupling, as an interface, the source with the MN. In an electronically coupled DGU case, the coupling converter can provide another layer of conversion and/or control, which acts to be an interface medium-MN. DER units include DGU and distributed storage-DS being usually connected at either medium- or low-voltage levels to the host MN. In Fig.1 is represented the block diagram for the DGU. The input power to the converter can be ac/dc fixed of variable frequency from the source side and it has a 50/60 Hz from the MN side of the converter. From power flow automation-control point of view, a DGU is dispatchable-DDGU or not dispatchable-NDDGU. A DDGU can become externally controlled using set points provided by a supervisory control system. The output power of a NDDGU is controlled based on the optimal operating condition of its primary energy resources. In Fig. 2 are represented the usual types for electronically interfaced DER units, a NDDGU photovoltaic (PV)-based DGU for which the PV array is interfaced to the host micro grid. From these three it can be highlighted the fact that a DGU with a non dispatchable power provider through a dc-ac/dc-dc/ac-dc converter can provide a dispatchable power at the output of the unit (Katiraei and Iravani, 2006), (Guerrero, 2013), (Katiraei et al, 2008).

E-mail address: mariana.dumitrescu@ugal.ro.

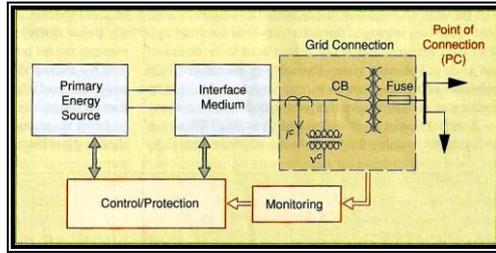

Fig. 1. Diagram of the block representation for a DGU

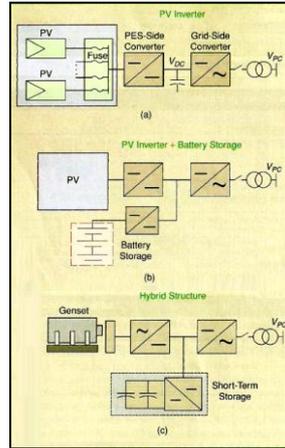

Fig. 2. Typical structures used for an electronically coupled DGU (a), NDDGU (b) and DDGU (c)

DER has dynamic response through its interface converter and the converter can provide also the limitation of the short circuit for the unit at 2 times the rated current. Due of the interface converter system there is a degree of electrical decoupling between the primary energy source and the distribution system limiting the dynamic interactions between the two subsystems, meaning the effects are less dangerous with the case of a conventional DGU (Llaria et al, 2011). In an autonomous operation it is necessary to maintain the power balance and consequently to stabilize the micro network voltage/angle. It means the operational strategy must take in account that the critical loads of the MN have priority. Furthermore, operation of a MN should accommodate functions such as customer service, power quality enhancement of specific load, reliability improvement of load categories. Load control can also be used to optimize the ratings of DS units and DDGU by reducing the peak load and by reducing the load excessive variations. DER can supply electrical and/or thermal consumers. In a conventional way the utility distribution system can be considered as supplying/absorbing any power discrepancy in the MN-generated power to maintain the net power balance. For loads, within a MN, is also an option if the imported/exported power has strong limits for operational strategies or contractual obligations. A part of a non-sensitive load can be considered a controllable and entered into a demand response control strategy, to either reduce the peak load and smooth out the load profile, or to schedule the load serving for specific time intervals when additional power, as from intermittent DGU is available. The non-controllable part of a non-sensitive load is the first candidate for load shedding. Load shedding and demand response are normally executed and supervised through the energy management controller of the MN.

DER units within a MN controls are selected based on the required functions and possible operational alternatives. Controls of a DER unit are also depending of the nature in interactions with the system and in other DER units. The main control parameters for a DER unit are voltage and frequency and / or active / reactive power control. The grid power export control strategy is often used to control the DER output power within the voltage and frequency. The control strategy can be implemented in the synchronous “dq0”, that specifies the direct (d-axis) and quadrature (q-axis) components of the converter, output currents corresponding to the real and reactive output power. Fig.3 shows a block diagram representation of a “dq0” frame controller (Lopes et al, 2006), (Olivares et al, 2011).

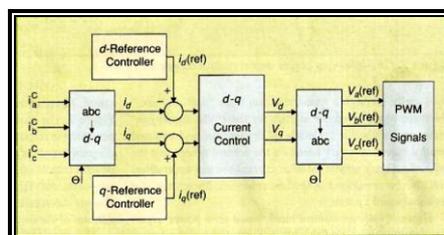

Fig. 3. The interfaced DER control block diagram

The control strategy emulates the behavior of a “swing source” in an autonomous MN. A grid within a MN can regulate the voltage at the PCC and to set mainly the system frequency. The DER should be large enough and have adequate reserve power capacity to supply the power balance. The power can be set by a supervisory power system-management system or it can be locally calculated according to a set power profile on purpose to optimize the active-reactive power export from the unit. In the case of more active DER units in MN frequency stability and voltage control, then frequency-droop and voltage-droop control strategies are used to share active-reactive power. This conducts to MN level of voltage and frequency which may deviate from the rated values, with respect to the acceptable limits, but depending on the load level and the droop characteristics. The controller inputs are the locally measured deviations in frequency and voltage for the unit. If DER units have different capacities, the slope of each droop characteristic is selected proportional to the rated capacity of the corresponding unit to prevent overloading.

Two DER units, working especially in an autonomous mode, require a power management strategy-PMS and an energy management strategy-EMS. Fast response of PMS/EMS for a MN is more critical compared with a conventional power system. Fig. 4 shows information/data flow and functions of a PMS/EMS for a MN, (Katiraei and Iravani, 2006), (Guerrero, 2013), (Katiraei et al, 2008).

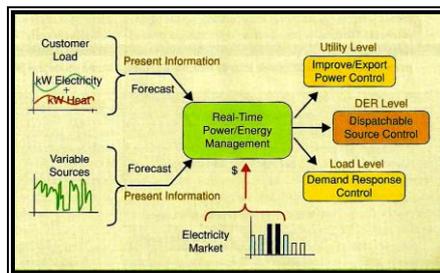

Fig. 4. PMS/EMS information flow and functions for a MN

The real-time power/energy/management block receives the present and the forecasted values of load, generation, and market information to impose appropriate controls on power flow, output generation, consumption level of the utility grid, dispatchable sources and controllable load, respectively. Through centralized control, can be optimized the MN-exchanged power with the host system, maximizing the local production which are depending on the market prices and security constraints. A nondispatchable control intends to provide the maximum autonomy for the DER units and load in a MN. The autonomy of the MNs implies that they are intelligent and can communicate with each other to form a larger intelligent system. In the nondispatchable control, the main task of each controller is not necessarily to improve the overall performance of the MN.

3. A Study Case

The MN in the proposed research topic is a real project implemented in the EB105 room located inside the Electrical Faculty UP Bucharest. The laboratory, having research and educational purpose, is equipped with adjustable DC voltage, 300V maximum voltage control (Fig. 5). These sources are: the main sources-SR photovoltaic type/ fuel cell type and DC stabilized source-SS fed from the classic network. The last can take over a part of electric charge when there is an important electrical load on the DC network, which exceeds the power produced by renewable sources. Provide energy storage battery is 240Ah.

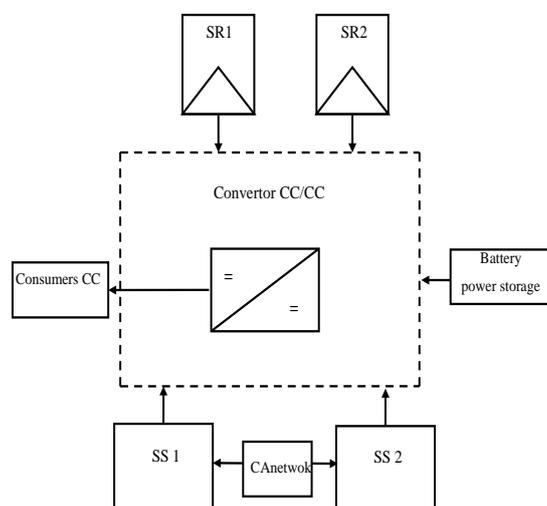

Fig. 5. MN case study structure

The available sources to provide electric power 230V DC, according with the laboratory need and its power consumers, have the following power ratings: SR1-1kW, SR2-1kW, SS1-920kW (230Vx4A), SS2-1380kW (230Vx6A). The electrical loads of the DC study case MN are intended for general lighting and required computing research activities (computers, monitors, lap-top). The loads are power supplied by the MN having two types of consumers: lamps, computers. The answer of the consumers, power supplied from the study case MN, will be tested in the two cases: DC smart grid, AC classical grid. For this analysis we used the following: the software- Labview programming environment; the hardware voltage transducers-current transducers-purchase card; USB/RS232 adapter; c.c. programmable sources, consumers (Fig. 6,7,8).

Fig. 6. Study case – research working bench

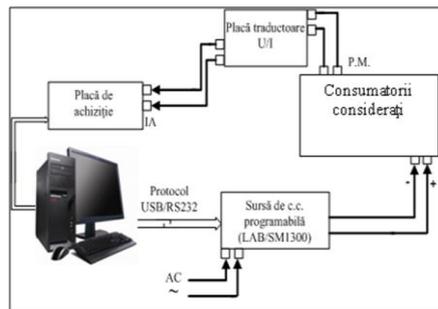

Fig. 7. Data analysis diagram

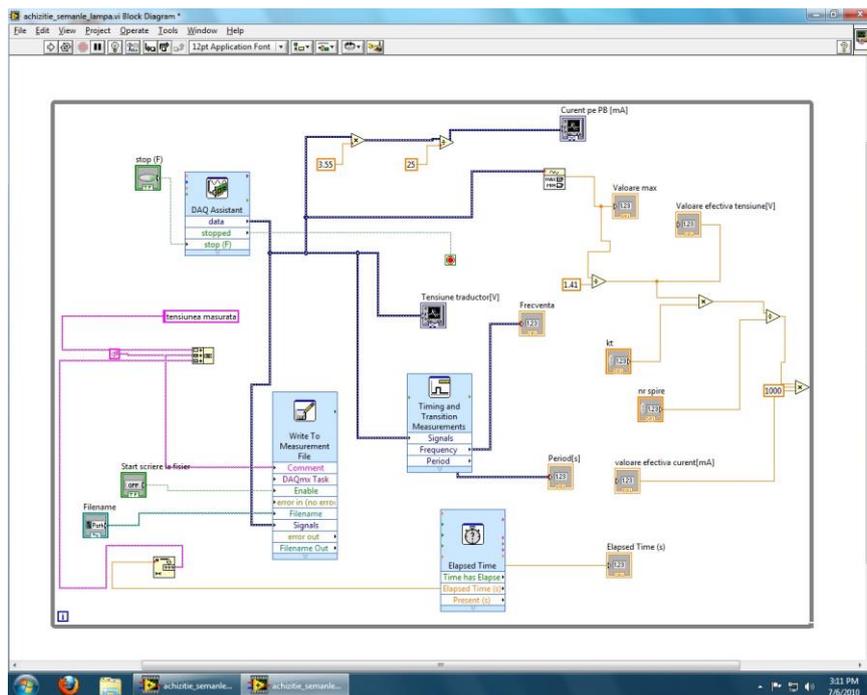

Fig. 8. Block diagram for MN-DC parameter control and computing

Two types of consumers were power supplied: fluorescent lamps and sources of computers in the both alternatives a) MN-DC, b) AC national power system. Both consumer types are switched to the different networks and power supplies. The proposed approach makes it possible to supply the consumers with the AC classical network or the smart DC-MN respectively. The effectiveness of tested components is the same in both alternatives, MN-DC or AC grid. The level of power supply voltage is ranged from a minimum of 40V, for the lamps and 100V for the computers, supplying till up to the rate voltage value. For an analyzed lamp, the diagram in Fig. 9 presents the differences of the current functions can be observed by variation of the voltage in the two cases a) or b), meaning MN-DC or AC grid.

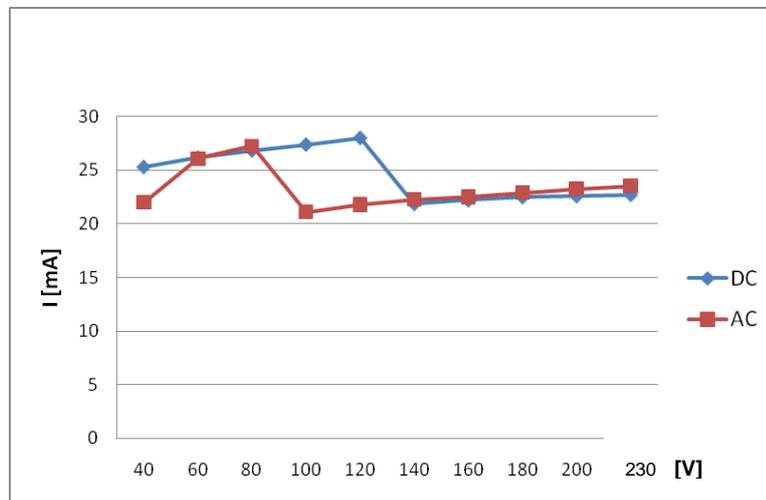

Fig. 9. Current variation in DC /AC for the tested lamp supplied by MN-DC/AC classical grid

For an analyzed computer, the diagram in Fig. 9 presents the differences of the current functions can be observed by variation of the voltage in the two cases a) or b), meaning MN-DC or AC grid.

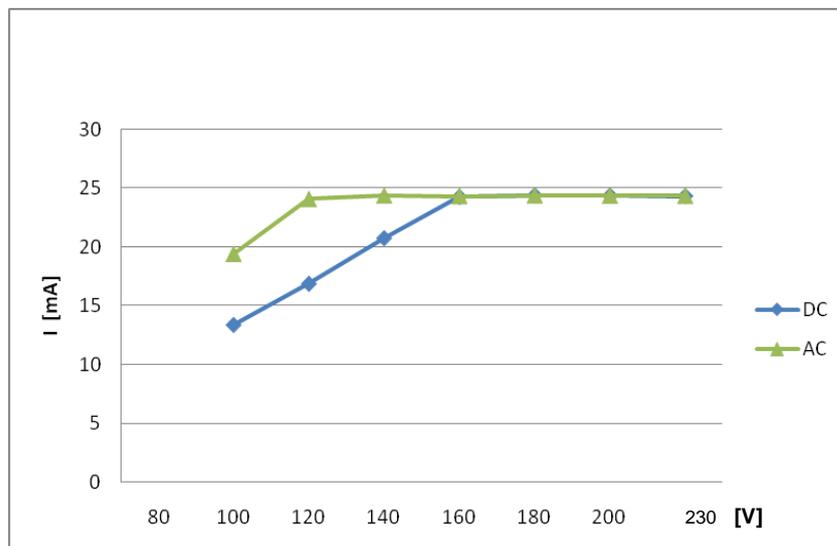

Fig. 10. Current variation in DC /AC for the tested computer supplied by MN-DC/AC classical grid

4. Conclusions

This paper presented the most important differences between micro networks and classical power systems and advanced the research of using the micro networks in real study case application for a residential purpose. It clear up the development of control and operational strategies for micro networks, which were seen as miniaturized versions of the conventional power systems, and intuitively their control/operational concepts were based on scaled-down and simplified versions of control-operational-management strategies concepts of the classical power systems. Market availability for the DER units technologies and the gradual and consistent increase in their way to penetrate the power

systems, have generated significant interest in integration, controls, and optimal operation DER units in the context of micro networks. The real study case, presented in the paper, implemented the proposed DC micro network and safely supplied the consumers, which were tested and efficiently adapted to MN-DC- power supply.

Abstract

The paper inhere presents results of measurements in regard with current harmonics, injected in the electrical power system by various LED lighting sources. Measured values have been analyzed according to the international standard IEC 61000 (Electromagnetic compatibility (EMC) - Part 3-2: Limits for harmonic current emissions (equipment with input currents up to 16 A per phase). A relation has been found between the intensity of current harmonics and the luminous flux flicker.

Keywords: Electromagnetic compatibility (EMC); LED; current harmonics; luminous flux; flux pulsation.

1. Introduction

In the recent years, energy efficient compact fluorescent lamps (CFLs) and LED lamps are widely used as electrical lighting sources. Along with that, their power supplying units generate significant harmonic current, which are flowing back into the electricity supplying power network, causing excessive active power losses and other negative effects. Nowadays, the mass use of such lighting sources in households, public and industrial buildings and outdoors could lead to a deterioration of the electrical energy quality, supplied to consumers and to problems in their operation. The most common issues of electrical equipment, related to high levels of harmonics in the electricity supply are: excessive heat in the ferromagnetic cores of power transformers and electrical rotating machinery; over currents in capacitors as a result of the decrease of their impedance for the higher harmonics, present in the mains (Istalianov and Voivodov, 2014), (Jettanasen and Pothisarn, 2014), (Uddin et.al., 2012).

In Europe, the main legal document regulating the emission limits of harmonic currents (for devices and equipment with input currents up to and including 16 A per phase) is EN 61000-3-2: 2014 (IEC 61000-3-2: 2014).

The objective of the paper below is to investigate the harmonic "pollution" in electrical power supplying installations for lighting, caused by the use of LED lamps.

2. Legal requirements for harmonic emissions limits and measurement setup

According to the standard EN 61000-3-2: 2014 electricity operated appliances and equipment are divided into 4 classes:

- class A - symmetrical three-phase electrical equipment, domestic appliances, non-portable electric tools, audio equipment, etc.;
- class B - includes hand-held portable electric tools and equipment not referring to professional and arc welding.
- class C - comprises lighting devices (luminaires).
- class D - electrical appliances and equipment with rated power less than 600 W (PCs, monitors, TVs, etc.)

Harmonic emission limits for electrical equipment class C are divided into two groups – for equipment with power rating up to 25 W and over 25 W.

* Corresponding author. Tel.: +359-899-821-208
E-mail address: g.velev@gmail.com

Having in mind electrical installations, supplying lighting sources with rated power above 25 W, the following harmonic emissions limits are shown in Table 1.

Table 1. Harmonics emissions limits for equipment class C, with rated power over 25 W

Harmonic order	Maximum permissible harmonic current expressed as a percentage of the input current at the fundamental frequency, %
2	2
3	$30 * \lambda$

	2
λ – power factor	

The performed study for measuring the harmonic “pollution” in an electrical system supplying lighting sources comprises lamps and luminaires, produced by leading companies on the Bulgarian market. There have been tested lamps with different color temperatures and power ratings more than 25W. Intentionally the names of the producing companies are not specified. The technical specifications of the lamps that have been tested are provided in Table 2.

The following measuring instruments have been used in regard with the electrical parameters needed for the study: electrical power network analyzer HT GSC53N and a digital oscilloscope Hantek DSO5102P. Each light source has been studied independently.

Table 2. Technical specifications of LED luminaires that have been tested

№ of lamp	Rated Power, W	Technical specifications
1	30	LED floodlight, 220V
2	30	LED floodlight 6000K, 2600lm, 120°, 85V ÷ 265V
3	30	LED floodlight 6400K, 2500lm, 120°, -20 °C ÷ + 40 °C, 90V ÷ 260V
4	50	LED floodlight 6000K, 4300lm, 120°, 85V ÷ 265V
5	50	LED floodlight 6400K, 4000lm, 120°, -20 °C ÷ + 40 °C, 220V ÷ 240V
6	50	LED floodlight 6000K, 5000lm, 120°, -30 °C ÷ + 45° C, 220V ÷ 240V

3. Measurement results and interpretation

Summarized data from the preformed measurements is presented in Table 3 and Table 4. Table 3 comprises results for lighting sources with numbers from 1 to 11 in regard with their harmonic currents, in absolute values and respectively as a percentage of the fundamental harmonic.

The total harmonic distortion of the current curve THDi, % in Table 3 has been calculated by expression (1).

$$THDi = \frac{\sqrt{I_2^2 + I_3^2 + I_4^2 + I_5^2 + \dots}}{I_1} \cdot 100, \% \tag{1}$$

, where I_i is the current of the i^{th} harmonic.

Luminous flux pulsation (flicker) can be calculated according to expression (2). It is the ratio of the difference and the sum of the maximum and minimum values of the luminous flux (Petrov and Varbov, 2007).

$$Flic = \frac{\Phi_{MAX} - \Phi_{MIN}}{\Phi_{MAX} + \Phi_{MIN}} \tag{2}$$

Table 3. Measurement results for lighting sources 1-11

Figures 1 and 2 illustrate the curves of current variation against time flowing through the LED lamp (in yellow) and the luminous flux emitted by the lamp (in blue color). The offset of the luminous flux curve in the time domain relative to the “x” axis allows determination of the luminous flux pulsation coefficient (flicker).

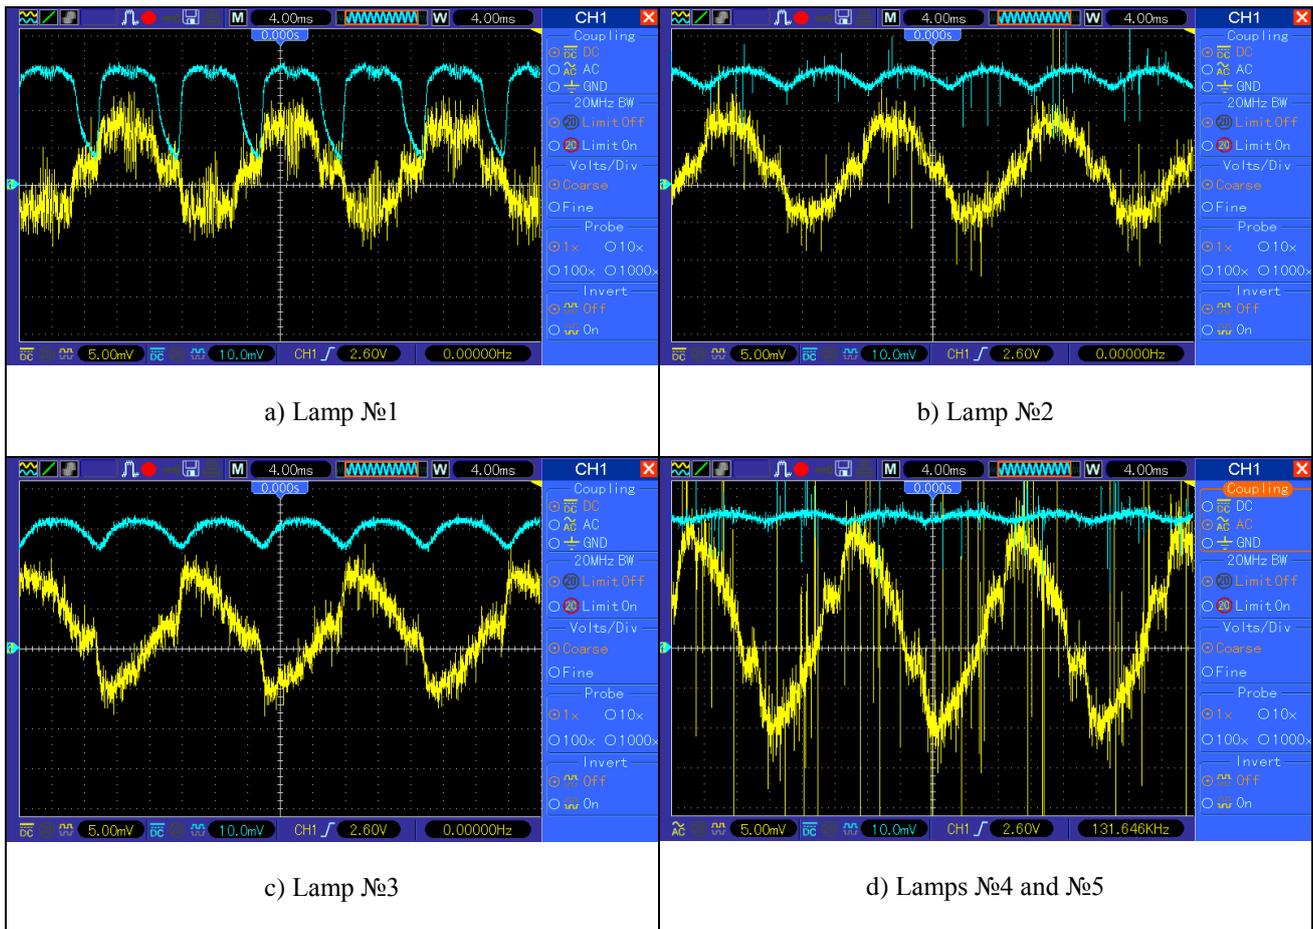

Fig. 1. Time diagrams for the operation of LED lamp №1(a), №2(b), №3(c), №4 and №5 (d)

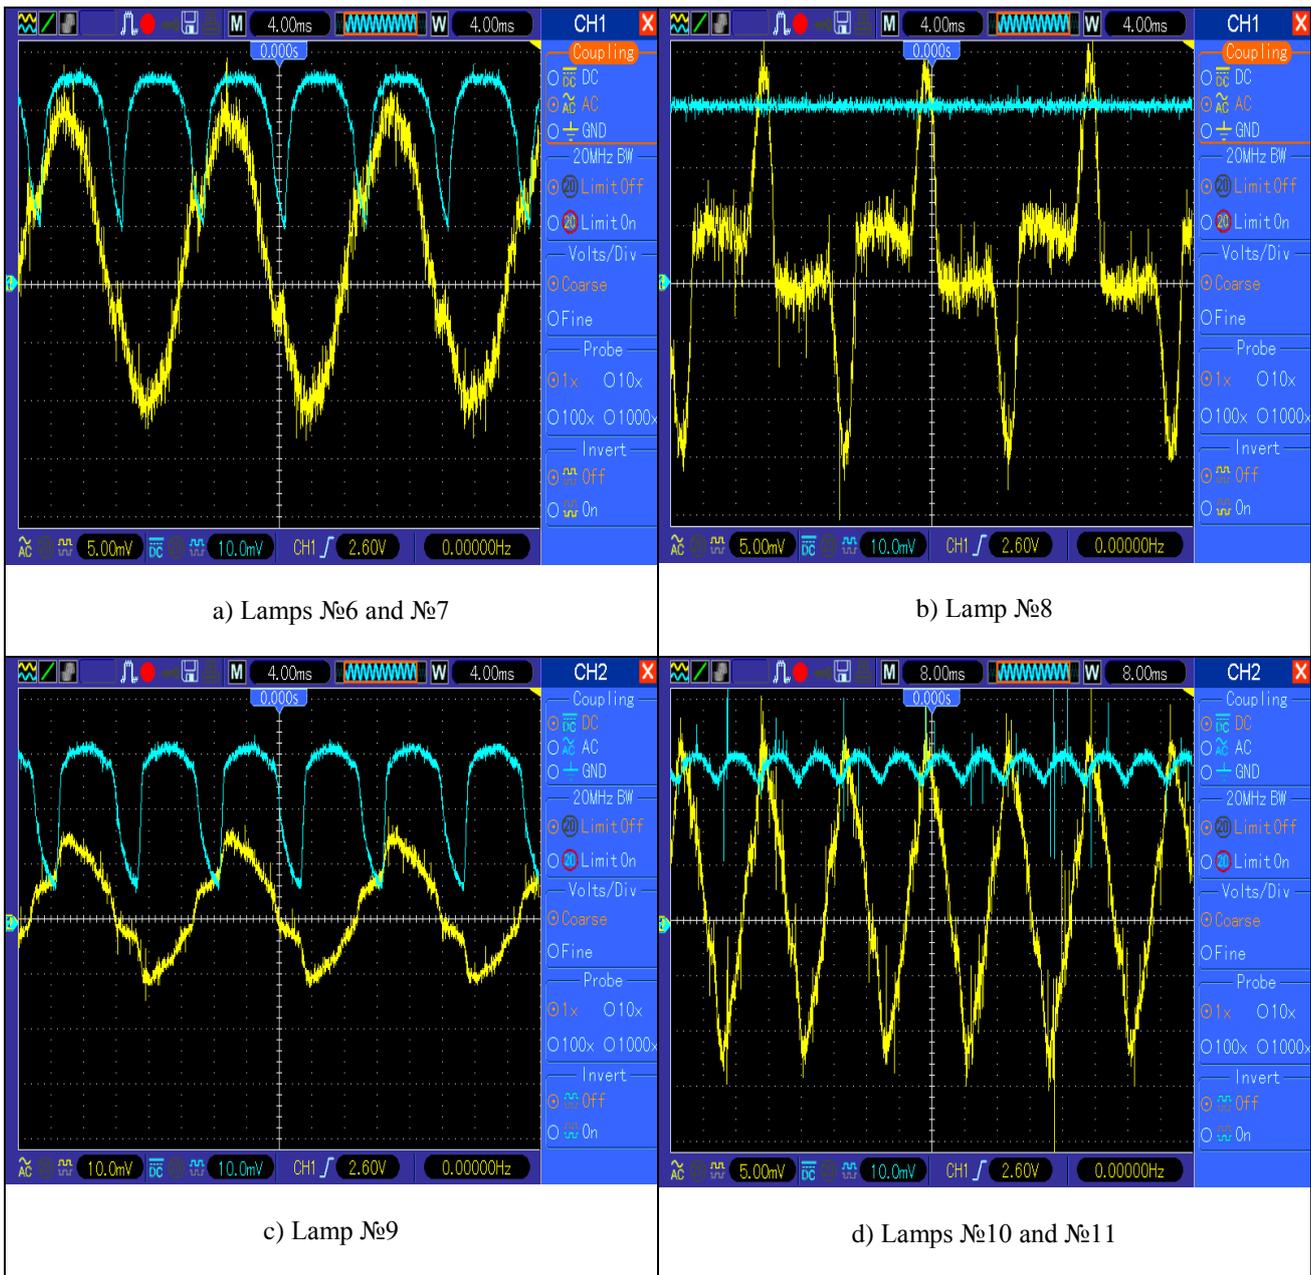

Fig. 2. Time diagrams, observed under the operation of LED lamp №6(a), №7 and №8 (b), №9(c), №10 and №11(d)

LED lamps №4 and №5 and №10 and №11 have similar variations of the flowing current and the luminous flux with time.

Observing the results for LED lamps №2, №3, №4, №5, №6, №7 and №9 it can be concluded that they meet the limit requirements for emission of odd harmonic currents and total harmonic distortion in the current curve according to standard EN 61000-3-2: 2014 (IEC 61000-3-2: 2014).

LED lamp №1 has harmonic current and THDi values slightly exceeding the limit values.

LED lamps №8, №10 and №11 are exceeding the emission limits for harmonic current components in accordance to standard EN 61000-3-2: 2014 (IEC 61000-3-2: 2014). Lamp №8, which exceeds the emission limit values for odd harmonic currents and THDi doesn't have pulsation of the luminous flux. Lamps №10 and №11 are also exceeding the emission limits for odd harmonic currents and THDi, but compared to №8 has noticeable luminous flux pulsations.

LED lamps №1, №6, №7 and №9 do not exceed emission limits of harmonic currents, but they have significant luminous flux pulsations.

LED lamps №2, №3, №4, №5 and №6 also do not exceed emission limits of harmonic currents, but they have very slight luminous flux pulsations.

3.1. Influence of operating voltage over the emission of harmonic currents

The following Table 4 comprises results associated with the influence of the operating voltage over the emission of harmonic currents tested for LED lamps №2, №3 and №4. Operation voltage under test has been regulated in accordance with the requirements for voltage deviation in the range $U_N \pm 10\%$ for public power distribution networks as regulated in the standard EN50160: 2010 (Tsanev and Tsvetkova, 2011).

After the test it has been generalized that operating voltage doesn't affect significantly harmonic currents emission. For the tested LED lamps' samples there is now exceeding of the harmonic emission limits.

In general, we have found an important correlation between luminous flux pulsations and the increased emission of harmonic currents for LED lamps №8, №10 and №11. At the same time the intensive luminous flux pulsations of LED lamps №1, №6, №7 and №9 are not associated with exceeding the emission limits of harmonic currents.

LED lamps №8, №11 and 10 have high levels of harmonic currents emission and increased THDi rates.

Table 4. Influence of operating voltage upon harmonic currents emission

4. Conclusions

Based on the performed study for harmonic current "pollution" in low-voltage electrical power installations, supplying LED lamps with rated power more than 25W, the following conclusions are made:

- 50% of the LED lamps with respect to the intensity of harmonic currents that they emit, have high levels of luminous flux pulsations;
- Power factor of the tested LED lamps is generally higher than 0.9 with the exception of two lamps that have values to about 0.65.
- Reduction of luminous flux pulsations in 3 of the LED lamps (27%) is related with exceeding the admissible limit values of harmonic currents and THDi;
- Reduction of luminous flux pulsations improves the lighting quality and eliminates the possibly for occurrence of stroboscopic effect, which is important technical indicator in occupational safety.
- The comparatively small share of LED lamps and luminaires with their installed power rating, compared to the other high power loads attached to the electricity system, doesn't cause increase in the total harmonic distortion of the voltage curve ($THDU$).

Acknowledgements

All experiments have been performed in the laboratories of the Technical University of Gabrovo at the department "Basic Principles of Electrical and Power Engineering". The used LED lamp samples are from leading manufacturers in the country and worldwide. Authors would like to thank sincerely to the producers, retailers and representatives of the LED lamps that have been kindly provided them for this study.

Abstract

The current paper provides an analysis on the lighting within a production hall, case in which the visual comfort of workers has to be ensured by inducing them positive sensations during their activity, such as visual performance, which determines the fast and clear perception of the visual load, even in difficult conditions and for long periods, so that the workers to be able to visually perceive the surrounding environment. Therefore, there is carried out a comparative study on the general lighting of a production hall, between the case of fluorescent lamps and the case of LED technology. Following the performed study, there is revealed the necessity of using quality lighting for the development of production processes in best conditions, as well as for an as low as possible power consumption.

Keywords: lighting quality; solid state lighting; fluorescent lamps; LED; lighting installation.

1. Introduction

The artificial lighting is provided in all the places from inside the buildings in which conducting a production activity is necessary. When designing the lighting fixtures (Pasculescu, 2011), the regulated values will be ensured, regarding the lighting quantity meaning the lightings or the lighting levels and the lighting quality, more exactly the lighting uniformities, the luminance, the colours of the light etc. In order to distinguish the visual task (tasks), its modelling and accentuation, the luminous flux must be suitably directed to this (these). In this way the details of the visual task are accentuated, their visibility is increased, and the visual task is more easily to achieve.

The modelling (accentuation) is achieved from the proportion of the directed flow and the diffused flow. The directed flow must be directed in only one direction, but without being exaggerated, as a proportion to the diffuse one, in order not to create strong shadows and contrasts. The lightning systems must ensure the comfortable bright climate according to the requirements of that space, the visual task and the activities from it. This must be achieved without energy loss, but without favouring the aspects regarding the reduction of the energy consumption detrimental to the visual aspects of the lighting system (Pasculescu et al., 2017a), (Pasculescu et al., 2017b).

When choosing the light sources (the lamps) the designers must take into account the necessity to correctly render the colours, therefore, in the rooms where the colour rendering is necessarily required, lamps with colour rendering index are chosen depending to its destination.

In order to explore the advantages of the LED to the fluorescent tubes, we must firstly understand how the two lighting technologies work. The way they were designed and how they function are the attributes that determine pluses and minuses for each lighting technology.

The fluorescent tubes (neon) and their close akin, the compact economic light bulbs (Compact Fluorescent Light), function totally different to the LED. The fluorescent tube is made from a glass tube, with metal cap at each end, where the electric current flows. Inside the glass tube there is a small quantity of magnesium and inert gas (a gas that normally doesn't react to stimulus such as heat or electricity), usually argon (Ar). The inside of the glass tube is covered with a layer of phosphorus dust (Tanase, 2008), (Romanian Academy, 2005). When the electricity passes through the metallic

* Corresponding author. Tel. +4-072-170-5284.

E-mail address: pdragos_74@yahoo.com.

contacts from the ends of the tube, it determines the excitement of the magnesium from inside the tube. The magnesium atoms release energy in the form of ultraviolet light, the light that is invisible to the human eye (Hu, 2017), (Jafari, 2016). When the ultraviolet light reaches the phosphorus layer, this layer starts to shine, creating the light (visible).

LED is the acronym Light Emitting Diode – The light emitting diode. Compared to the fluorescent and the incandescent lighting, the LED light bulb doesn't contain gases or filaments. The LED is made from a material named semiconductor. This material can be found in the nature in solid state (Sfetcu, 2016), therefore the LED is more durable. When the electric current flows through this semiconductor material, the electrons from the material access higher levels of energy and start to emit energy in the form of visible light.

2. The analyze regarding the lighting of a production hall

The maximum of the light spectrum ϕ_λ of the human light is at 555,5 nm where the spectral sensitivity k_λ presents a unit value.

$$k_\lambda = \frac{\phi_\lambda}{p_\lambda} \tag{1}$$

The luminous flux Φ can be determined from the relation

$$\Phi = \int_{380 \text{ nm}}^{760 \text{ nm}} \phi_\lambda \cdot d\lambda = \int_{380 \text{ nm}}^{760 \text{ nm}} k_\lambda \cdot p_\lambda \cdot d\lambda \tag{2}$$

The luminous efficiency η of a light source represents the ratio between the luminous flux Φ emitted by the source, and the power absorbed from the electrical network P by the light source.

$$\eta = \frac{\Phi}{P} = \frac{\int_{380 \text{ nm}}^{760 \text{ nm}} \phi_\lambda \cdot d\lambda}{\int_0^\infty p_\lambda \cdot d\lambda} \tag{3}$$

The luminous efficiency is an economic indicator of a light source.

The reverse value of the maintenance factor M is the depreciation factor Δ (table).

Table 1. The maintenance factor and the depreciation factor

The reduction of the light level due to dirt and aging of the lamps, to the lighting fixtures and to the walls of the room	The maintenance factor M	The depreciation factor Δ
normal	0,8	1,25
increased	0,7	1,43
strong	0,6	1,67

The repartition of the lighting level on a surface is indicated through isolux curves. These result by joining the points with the same lighting level.

It was considered a production hall where, according to the regulatory norm NP-061-02, regarding the requirements of luxes on the useful plan (0 m) this being in the category of general traffic corridor, 150 luxes and colour rendering (Ra-0,8) are needed. Of course the hall contains more working areas such as: areas of mechanical reaming, areas of sheet bending, areas of manoeuvring the guillotine, where the regulatory norm NP-061-02 provides that the luxes needed on the useful plan (0,8 m), this being in the category of the metallurgical cutting, bending, marking, to be of 250 luxes and the colour rendering (Ra-0,8), and also in the areas of welding where 200 luxes are needed and the colour rendering (Ra-0,8).

The basic surface of the hall is around 800 m², with a height of 5,2 m, the reflection degrees being for the ceiling 70%, walls 50%, floor 20%, and the maintenance factor of 0,80.

In a first phase lighting fittings with fluorescent tubes type CEAG 12267881103 eLLK 92058/58 CG-S were chosen, which have a luminous yield of 79,10%, a luminous flux of 8227 lm, 130 W power and a luminous efficiency of 63,3 lm/W (Fig.1).

Fig.1 Lighting fitting with fluorescent tubes type CEAG 12267881103 eLLK 92058/58 CG-S

Following the simulations that were performed, the luminous yield results for the lighting fittings with fluorescent tubes as it can be observed in (Fig. 2).

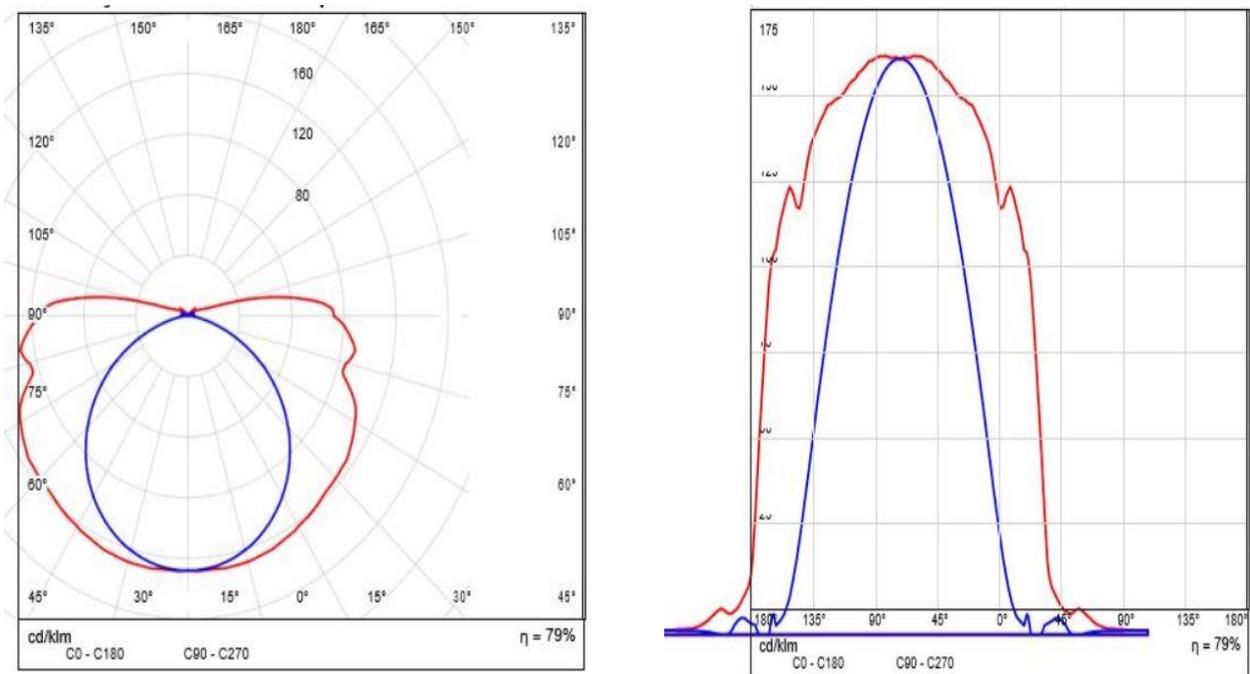

Fig.2 The luminous distribution at the lighting fittings with fluorescent tubes

Further on, lighting fittings with LED technology type ES-SYSTEM 7350301L LEDEX TOP 3000 were used, which have a luminous yield of 100%, a luminous flux of 17000 lm, 131 W power and a luminous efficiency of 129,8 lm/W illustrated in (Fig.3).

Fig.3 Lighting fitting with LED technology type ES-SYSTEM 7350301L LEDEX TOP 3000

Following the simulations that were performed, the luminous yield results for the lighting fittings with LED technology as it can be observed in (Fig. 4).

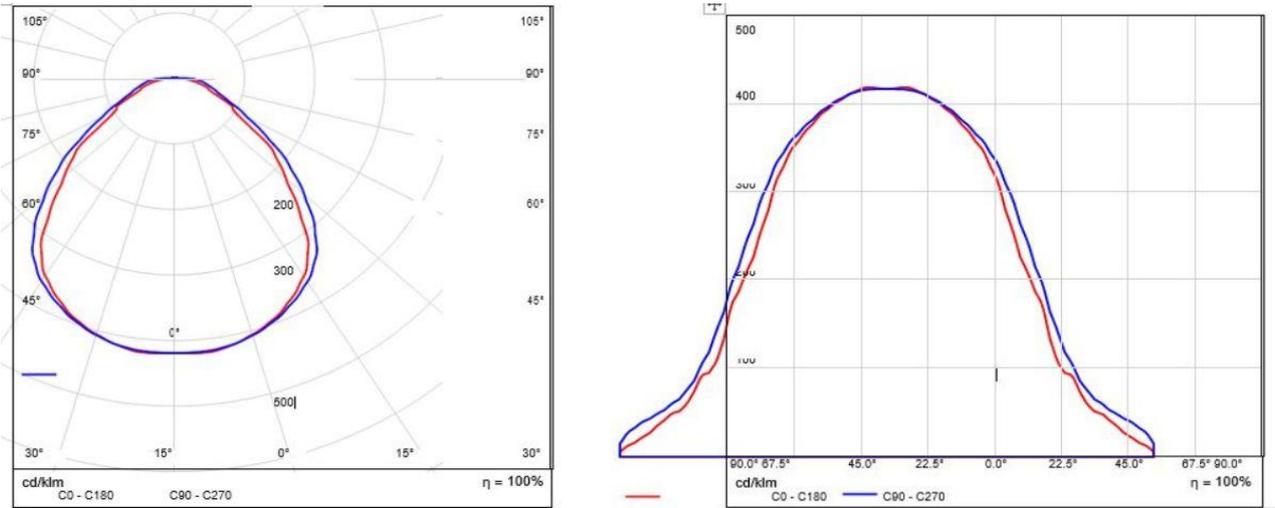

Fig.4 Luminous distribution lighting fittings with LED technology

According to the data that were used it can also be observed the intensity of the vertical lighting which is particularly important taking into account the fact that a qualitative lighting is wanted, from all points of view. As it can be also seen in (Fig. 5) and (Fig. 6) the number of luxes needed for each surface according to the normative (Masoud and Murnick, 2013, and Technical Norm, 2007) is by far much more satisfactory and uniform in the case of the lighting fittings with LED technology to the detriment of those with fluorescent tubes.

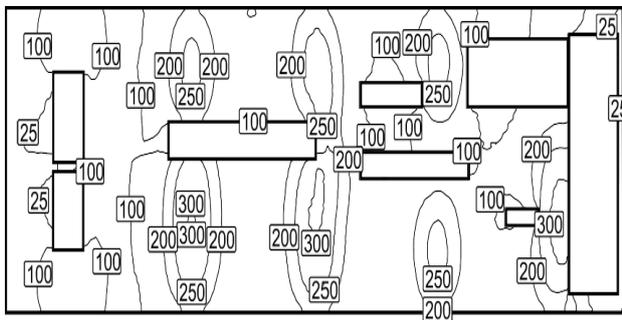

Fig.5 Isolines – lighting fittings fluorescent tubes [lx]

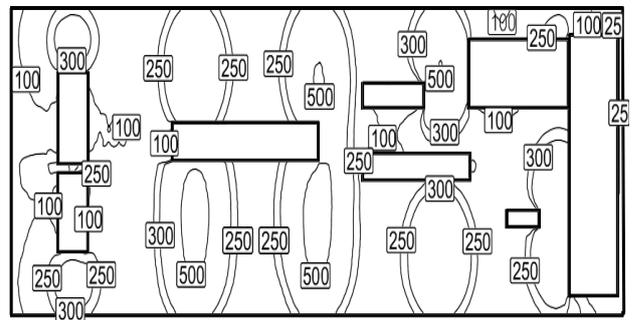

Fig.6 Izolines – lighting fittings LED technology [lx]

For a fast and easy interpretation of the calculation results, the false visualization of the colours helps pretty much. The settings of the colours false values are valid for the entire project, therefore they are also called "global false colours". The value set for a colour is used in all the diagrams and visualizations. (Fig 7) and (Fig. 8).

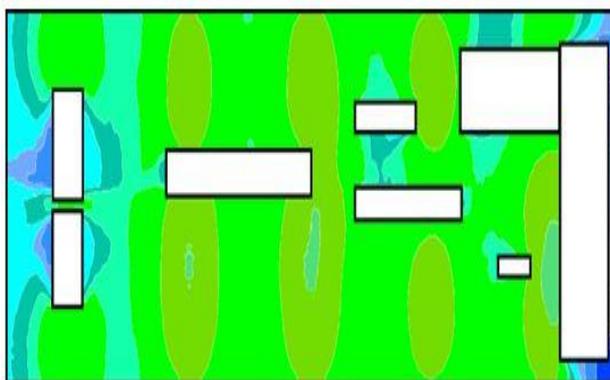

Fig.7 False colours – lighting fittings fluorescent tubes [lx]

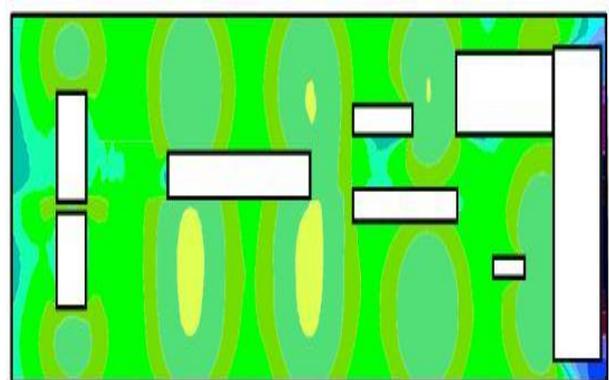

Fig.8 False colours – lighting fittings LED technology [lx]

For both implementations presented in the case study simulations were performed with the help of the professional software Dialux, in order to accordingly dimension the number of the lamps and their positioning, in the end resulting a number of 42 lighting fittings with fluorescent tubes and 36 lighting fittings with LED technology on the same useful plan, practically resulting, in time, a pretty consistent saving of electrical energy.

3. Conclusions

The light generated by LED uses more efficiently the electrical energy than in the case of other light sources, the optic system that was used being superior in terms of losses. The efficiency of the power supplies is another very important factor. All these, cumulatively, lead to a much higher efficiency than the classical solutions. This will be reflected in the electricity consumption. The energy saving frequently exceeds 50% than the traditional sources. The life span of the LEDs (35.000-100.000 ore) substantially exceeds the one of the fluorescent light sources (8.000-15.000 hours). In addition, the light sources with LED are much more resistant to temperature variations, vibrations and mechanical shocks, therefore it is more reliable than the traditional ones. The LEDs don't need filters in order to produce the light of a certain colour. The colour is generated by the semi-conductor material.

The light is directed where it is needed. The traditional light sources emit the light in all directions. For many applications a great part of the light is wasted if no reflector or special optic device is used. The LEDs, being mounted on a plane surface, emit the light hemispherically therefore reducing the light that is not used

When they are subjected to shocks and vibrations, their filament or the glass balloon are not damaged as it happens in the case of other types of lamps. The classical lamps with incandescence and gas discharge can be affected in the case of functioning in environments subjected to excessive vibrations. No warming time is needed. The fluorescent lamps, especially those based on amalgam need up to three minutes in order to get to the maximum of light emission. The lamps with high intensity discharge have warming times between a few minutes for the metallic halogens up to 10 minutes for the sodium lamps. They also need a supplementary time (10-20 minute) from the moment of their switching off until they can be switched on again, time interval that can be reduced to 2-8 minutes in the case of using the ballasts with pulse switching on. The LEDs reach the maximum brightness almost instantly and can be switched on again immediately after having been switched off.

The traditional lamps get broken more rapidly if they are subjected to frequent cycles of switch on-switch off because, in the case of the fluorescent and with gas discharge ones the switch on the switch on voltage erode the transmitter coating of the electrode. The life span of the LED and its luminous flux is not affected by the rapid cycles. This characteristic makes the lamps with LED to be adequate for applications with presence sensors or beacons.

The LED lamps are compatible with electronic control devices for the adjustment of the light level and of the colour characteristics. The efficient traditional light sources have limitations regarding the control of the illumination level (Argatu et al., 2010).

The LEDs for lighting do not emit –infrared or ultraviolet radiations. The fluorescent lamps convert about 20% from the energy into light, and the economic ones emit ultraviolet radiations that make necessary the presence of the special protection devices, in order not to affect the occupants of the room. The infrared radiations can produce burnings, and the ultraviolet ones damage the art objects, artefacts, cloth and the eyes. The LEDs conserve the energy and do not contain substances dangerous for the environment in contrast to the light sources with gas discharge that contain mercury. The much longer lifespan makes the LED light sources to be more attractive in terms of environmental protection.

The main disadvantage of the LED light bulbs is the higher price compared to other models. Such a light bulb generally costs a few dozens of lei more than other types of light bulbs. Therefore, the lighting of a production hall with LED light bulbs could prove to be an expensive investment. However, the price will pay for itself pretty fast through the significantly reduced energy consumption.

It was demonstrated that buying a lighting system with LED linear lamps becomes in time a profitable investment due to the decreased costs of the energy and due to the lack of the maintenance activities over the life of the LED.

The world trend is to give up the classical light sources, that are not energetically efficient and to promote the high performance light source, category that the LEDs belong to. The European legislation provides that until 2020 the lighting sources with incandescence and with gas discharge to be replaced.

In EU, the total consumption of the internal lighting is of approximately 86 TWh and it is expected to increase to 102 TWh until 2020. The widespread implementation of the SSL technologies could significantly contribute to the achievement of the Europe 2020 Strategy objectives for an intelligent, durable increase and favourable to the inclusion, especially for achieving the target of increasing the energetic efficiency (until 2020: increase with 20% of the energetic efficiency to the levels from 1990). It would have a significant impact on the European users (both consumers and professional users) and on the competitiveness of the European lighting industry.

Abstract

The energy output of the Sun is fairly constant, but the solar irradiance varies significantly from one hour to another and changes throughout the day. In this paper we are presenting the design of a simple MPPT (Maximum Power Point Tracker) charge controller based on perturb and observe algorithm embedded into Atmega 2560 microcontroller. The voltage of the solar panels operating at their peak power point at Standard Testing Conditions is 25C° is higher than the battery's voltage. As solar module operating temperature goes down, the voltage increases so the MPPT controller is able to capture the excess module voltage to charge the batteries. As a result, a MPPT controller in low temperature conditions can produce up to 30%. The charge controller will use the microcontroller, DC-DC buck boost circuit, sensors that will read the electrical information from the photovoltaic panel and the battery.

Keywords: algorithm; tracking; controller; conversion; photovoltaic.

1. Introduction

The energy output of the Sun is fairly constant, but the solar irradiance varies significantly from one hour to another and changes throughout the day. Sunlight sometimes only reaches the parts of the panels that are facing the Sun at a given time, and the most intense irradiance is experienced by those parts that are not shadowed from the Sun. The other significant factor that modifies the conversion is the temperature at the surface of the PV.

So this problem can be solved by a battery charge controller but in two quite different ways. Maximum Power Point Tracking method, frequently used as MPPT, is an electronic system that operates the PV modules in a way that allows the modules to inject all the power they are capable of.

2. The design of the MPPT system

We are presenting the design of a simple but effective MPPT charge controller based on ATmega 2560 microcontroller (Figure 1).

The charge controller will house the microcontroller and DC-DC buck boost circuitry in addition to the sensors that will read the electrical information from the photovoltaic panel and the battery.

The charge controller will measure the voltage and current of both the solar panel and battery bank. Using this sensor information, a regulated output will be delivered to the battery bank. The goal is to have efficient charging of the battery bank using the MPPT algorithms implemented in software by the microcontroller (Hohm and Ropp, 2003).

Similarly, the current sensors send an analog voltage value to the microcontroller, which will determine the nominal value of the current. The current sensors will function alongside the voltage sensors to sense current coming into and out of the charge controller.

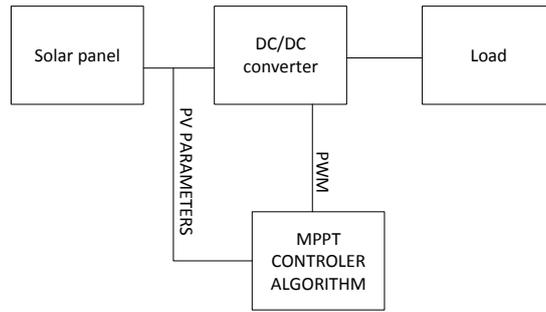

Fig. 1. Block diagram of Typical MPPT system

3. Perturb and observe algorithm

One of the most efficient method is “perturb and observe” algorithm. Using the MPPT algorithm when solar radiation intensity is changing, there is an increase in the collection of energy (Rekioua and Matagne, 2012).

In Figure 2 and 3, the P&O algorithm and the related schematic are presented. The way to find MPP is by repeated attempts, by modifying the voltage at the generator terminals and comparing the power delivered in this case with the power from the previous step.

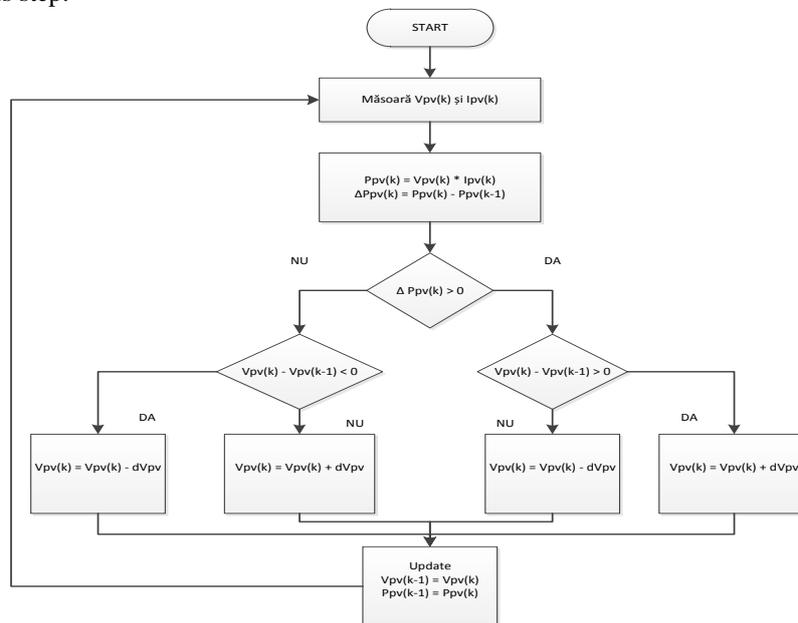

Fig. 2. Perturb and observe algorithm

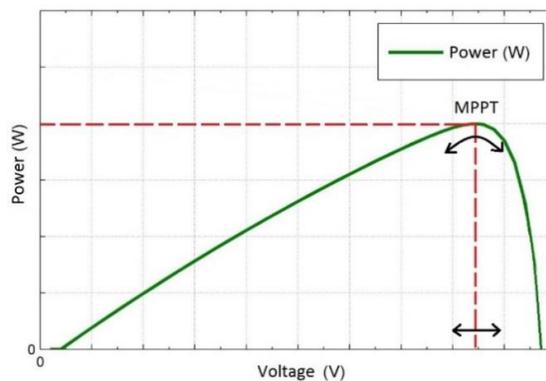

Fig. 3. MPPT working logic

If the power at the current step is higher, the voltage change continues in the same direction, and if not then it is modified in the other way. This method of finding the maximum point leads to oscillations around this point, even in stationary conditions, and in the case of sudden change of solar radiation, it can even lead to searching in the opposite direction of the maximum power point (Marcu et al., 2014), (Cabal et al., 2007).

4. Reading parameters of the photovoltaic panel

A key part of the system is the sensor block that senses the current and the voltage of the PV. Sensors then send the voltage and the current information into the microcontroller and therefore it compares them with the preset instruction and changes them accordingly.

4.1. Voltage reading

Using low voltages, the circuit needs only up to 25V sensor. Therefore, the voltage on the PV panel is read with a simple voltage divider as presented in the figure 4:

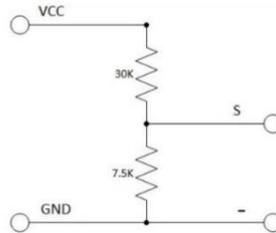

Fig. 4. Voltage sensor schematic

The code that was implemented into the microcontroller that will read the voltage info is shown below:

```

int analogInput = A1;
float vout = 0.0;
float vin = 0.0;
float R1 = 30000.0;
float R2 = 7500.0;
int value = 0;
void setup(){
    pinMode(analogInput, INPUT);
}
Serial.begin(9600);
void loop(){
    value=analogRead(analogInput);
    vout=(value * 5.0) / 1024.0;
    vin=vout / (R2/(R1+R2));
    delay(500); }
    
```

Calibration of this sensor is made by accurately measuring the values of the two resistors of 7.5K and 30K ohms, modifying the values in the program accordingly.

4.2. Current reading

For current measurement we used a hall effect current sensor (Figure 5). The ACS711 sensor read the current value and convert it into a relevant voltage value. The value that links the two measurements is sensitivity. The sensor can measure positive and negative currents.

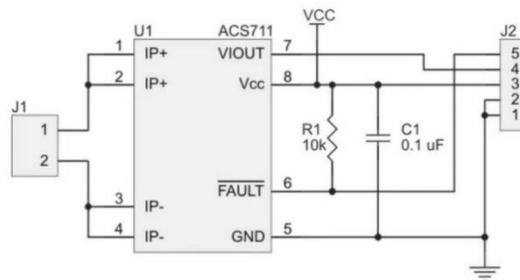

Fig. 5. Current sensor schematic

The current according to the voltage value is determined by the relations:

$$V_{out} = \frac{V_{cc}}{2} + i \frac{V_{cc}}{36.7} \tag{2}$$

$$i = 36.7 \cdot \frac{V_{out}}{V_{cc}} - 18.3 \tag{3}$$

where:

- i - is the measured current
- V_{OUT} - is the voltage given by the sensor directly proportional to the value of measured current
- V_{cc} - is the logic supply voltage of 5V

The code that was implemented into the microcontroller that will read the voltage info is shown below:

```

const int analogIn = A0;
int mVperAmp = 185;
int RawValue= 0;
int ACSOffset = 2500;
double Voltage = 0;
double Amps = 0;

void setup(){
    Serial.begin(9600);
}

void loop(){
    RawValue = analogRead(analogIn);
    Voltage = (RawValue / 1024.0) * 5000;
    Amps = ((Voltage - ACSOffset) /
    mVperAmp);
    delay(2500);
}
    
```

The current value is given by the Amps variable in the code and it's processed by the microcontroller to evaluate the power given at the generator terminals.

5. Description of the circuit

A microcontroller cannot turn on a MOSFET transistor as it cannot supply enough current to charge the MOSFET because its gate is capacitive. That is why a MOSFET driver will be used. The driver itself will supply the current that the transistor will need (Figure 6). As we are using DC converter the PWM signal will be applied with respect to transistor source (Rekioua and Matagne, 2012).

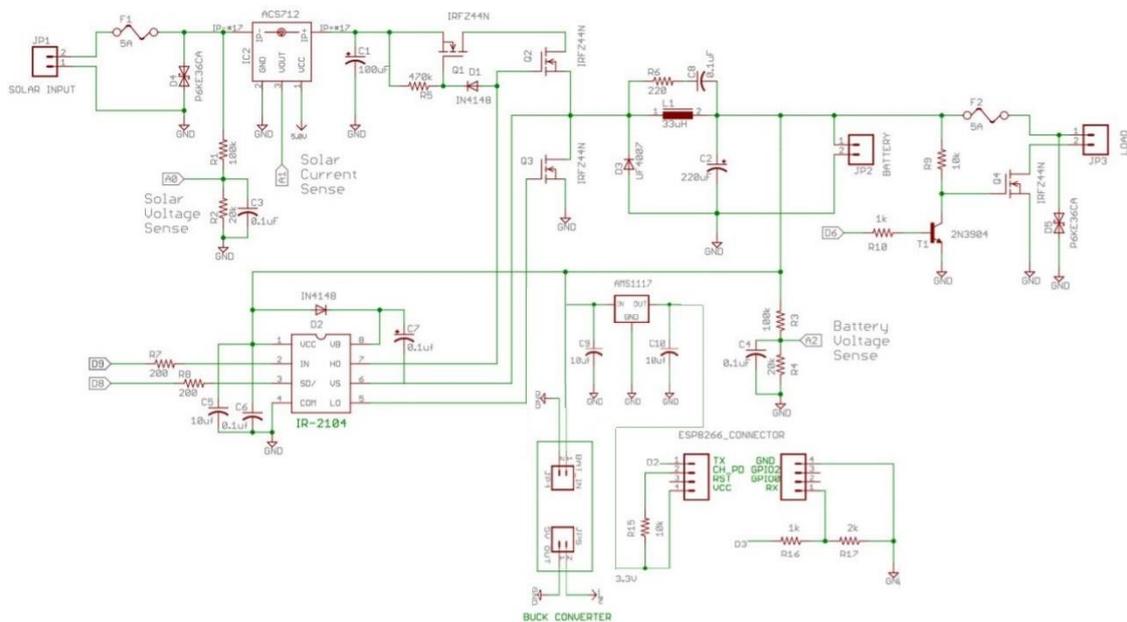

Fig. 6. The circuit connected to the Atmega 2560 microcontroller

The voltage and the current sensors provide the values to the microcontroller which based on the algorithm will send a signal according to the DC converter.

Switching of a DC-DC converter need two of operation: a controller stage and a power stage. The controller stage supervises the precision of power supply stage by regulating voltage. Therefore, pulse width modulation technique is introduced here for regulating the voltage.

PWM refers to the method of achieving analog signal by digital means. In this system we are using a microcontroller and also switching mechanism is involved so PWM technique has been integrated. PWM works by changing the duty cycle ratio of the switches to produce a constant output voltage.

The microcontroller configuration will be connected to a computer, allowing it to communicate via USB with the baud rate set at 9600bit/s. The serial data that is received will be stored to laptop.

After testing the PV system exposed to the Sun, the most conclusive data is shown in the figure 7. The measurements were made on a polycrystalline 30W photovoltaic panel.

The testing conditions were for the nominal irradiation of 1000 W/m² since the region is rated at this irradiance during the peak solar position. And temperature of the ambient air was around 20 °C, the short circuit current is about 300 A/m².

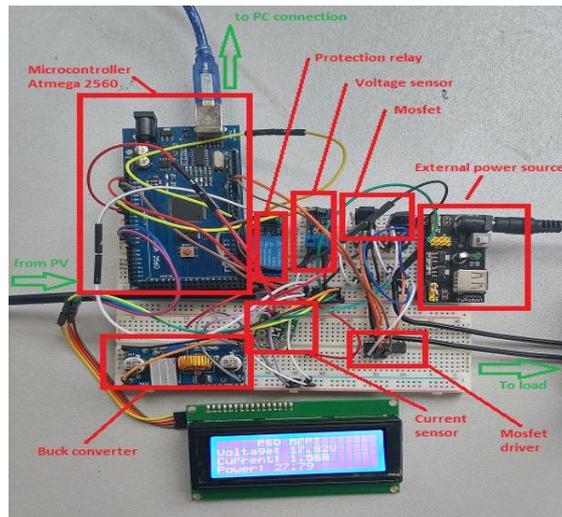

Fig. 7. The physical MPPT circuit

For different temperatures, the short circuit current has to be modified by 0.2% for every 1°C. The efficiency of the solar panel has been calculated at different values of the panel temperature.

Table 1. Calculated temperature versus Efficiency of the polycrystalline photovoltaic panel

Temperature	28°C	50°C	60°C	70°C
Efficiency	9.6%	8.9%	8.2%	7.1%

The power provided by the photovoltaic panel to the battery is presented in figures 8-11 for different temperatures.

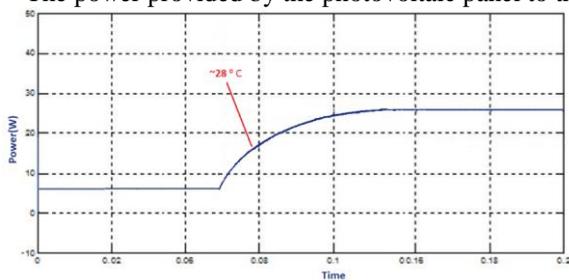

Fig. 8. The power provided by the photovoltaic panel to the battery as the working MPPT circuit is working at ~28° C

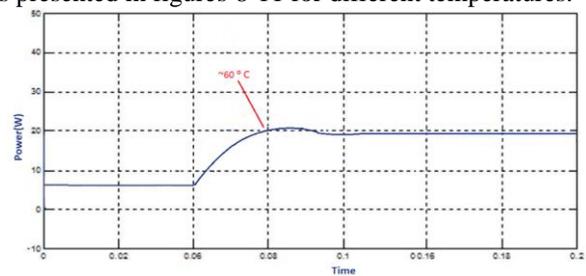

Fig. 10. The power provided by the photovoltaic panel to the battery as the working MPPT circuit is working at ~60° C

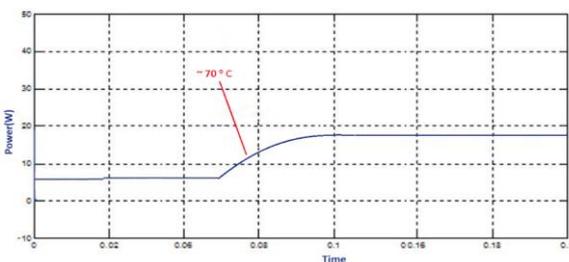

Fig. 9. The power provided by the photovoltaic panel to the battery as the working MPPT circuit is working at ~70° C

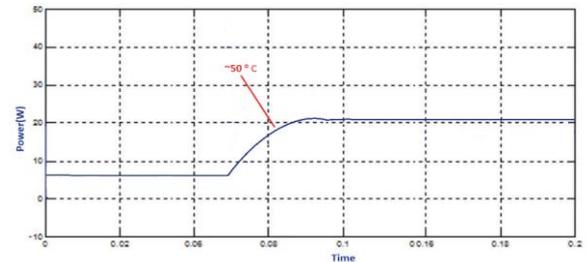

Fig. 11. The power provided by the photovoltaic panel to the battery as the working MPPT circuit is working at ~50° C

Since the testing of the circuit with operating MPPT algorithm requires only a short time, we have been selected the moment when the algorithm is turned on, so on the selected timescale the P&O algorithm is started at ~0.07 and the power delivered by the charge controller to the battery bank is increasing steadily to a point where it reaches a flat region characterized by the nominal data of the photovoltaic panel when the measurement was made at ~28°C at the surface of the panel.

If the measurement is made at different temperatures it shows how the P&O algorithm is useful due to lower temperature of the panel. At 28 degrees the circuit and microcontroller manages to absorb more power from the panel compared to the other 3 measurements, at 50°C, 60°C, 70°C.

When the operating point is not close to the maximum power point, high perturbation levels are made, and little levels are made if in near to the MPP. So the algorithm has to know the position of the maximum power point. Also, the exact spot of it is not necessary due to the fact that this algorithm will work near the real maximum power point. In this method, the level of the perturbation is determined by the equation:

$$\Delta V(V) = f(V_{M,est} - V) + \Delta V_{min} \quad (3)$$

- ΔV - is the perturbation step;
- $V_{M,est}$ - is the estimated voltage at MPP;
- V - is the measured voltage;
- ΔV_{min} - is the minimum value of the perturbation.

From the images above it can be observed that after starting the MPPT algorithm in the microcontroller, the charge controller manages to inject a much higher power into the battery, proving that the use of this method is resourceful.

6. Conclusion

The use of a microcontroller has its advantages as low cost of production and reliability. It provides a simple and efficient design of a solar charge controller and DC-DC converters bring a significant improvement in overall system performance and are thus considered a key device in designing such a photovoltaic system. This Atmega2560 microcontroller is widely available and through the C programming language becomes a very flexible and useful tool for improving the energy management of a photovoltaic system.

Ensuring good conversion of solar energy into electricity depends both on the use of high-efficiency components within the photovoltaic system as well as the planning and design of the system. Right after the MPPT algorithm is starting, the power provided by the circuit is increased significantly. Therefore, an increase of the power generated by the PV panel can be observed in the measurements.

Improving the quality of measurements in electrical processes using NI USB data acquisition systems

Titu Niculescu^{a*}, Florin Gabriel Popescu^a, Marius Marcu^a, Ioan Razvan Slusariuc^a

^aUniversity of Petrosani, Petrosani Universitatii 20, 332006, Romania

Abstract

For the study, the evaluation and visualization of switching processes, modern computer-aided measurement elements associated with high-speed data acquisition systems are used. In the paper is presented a method of study of switching phenomena using a NI USB data acquisition system produced by National Instruments. It is well known that the acquisition software provided by the manufacturing company is LabView. In the paper is presented a more efficient alternative method, based on the use of MATLAB software, and a design interface circuit attached to the NI USB system. In industrial electrical installations frequently occur situations where inductive circuits are connected to alternating current sources. Two methods of data acquisition are presented in the paper. The first method to study this, is the acquisition of data using a MATLAB program designed for the interface circuit presented in the paper and the NI USB data acquisition system. The second method of measurement is based on the use of the Simulink program package. Because there is no support software for data acquisition in Simulink in 64-bit systems, the paper presents a method that does this. The measurement method highlights its superiority compared to the use of LabView software. In the paper, both aspects of the switching are addressed, both by connecting an inductive circuit to an alternative voltage source and by disconnecting it from the source.

Keywords: coil; connection; data acquisition; diagram; disconnection; NI USB; MATLAB; Simulink.

1. Introduction

In industrial electrical installations frequent switching of inductive circuits occurs at alternating voltage sources, this phenomenon leading to the occurrence of transient modes that may become dangerous under certain conditions. At the coil terminals they often cause overvoltages that can become dangerous if they are not evaluated and no specific action is taken. In the paper is described a modern method of analysis of such modes based on the use of a high resolution data acquisition system produced by National Instruments and the MATLAB software. For the measurements, an interface circuit was designed, which takes the electrical signals and introduces them into the acquisition system connected to the PC. Two representative situation of an inductive circuit for different circuit inductance values were considered for the study.

As it is known, the software provided by National Instruments, for such applications is the LabView. In the paper, the switching phenomena of inductive loads are studied with MATLAB software. The superior processing capabilities of the results are well known by using this software, compared to the one provided by the DAQ system maker.

In the beginning of the paper is presented the theoretical phenomenon that considers ideal circuit elements, both when connecting and disconnecting an inductive circuit. To achieve this goal is presented in the paper a circuit of its own design interface, which make the connection between the circuit-specific electrical quantities and the NI USB 6003 data acquisition system.

Two methods of data acquisition are presented in the paper. The first method is based on programming. A MATLAB program was developed that drives the data acquisition process and is presented in the paper. It generates, along with the whole system, the variation diagrams of voltage, current and instantaneous power on the coil.

The second measurement method is based on the Simulink program package. As is well known, MathWorks provides support software for data acquisition in Simulink for 32-bit systems only. In the last part of the paper is presented a procedure that makes possible the acquisition of data in Simulink on 64-bit systems.

E-mail address: niculescu_titu@yahoo.com.

In the conclusions, the differences between the theoretical situation described in the paper and the practical result of the measurement process are highlighted. It is emphasized the use of this acquisition method in studying fast electrical processes.

2. Theoretical considerations

2.1. Connection mode

It is considered an inductive resistance circuit R and inductance L that initially connects to an alternating voltage source (Niculescu, 2012a), (Niculescu, 2012c):

$$e(t) = \sqrt{2}E \sin(\omega t + \beta) \quad (1)$$

If the parasitic capacities and the power supply cable capacity are neglected and circuit elements are considered to be ideal, the expression of the transient current in the circuit is:

$$i(t) = \sqrt{2}I \sin \left[\sin(\omega t + \beta - \varphi) - \sin(\beta - \varphi) \cdot e^{-\frac{t}{T}} \right] \quad (2)$$

is the actual value of the current and φ is the phase difference between the voltage at the coil terminals and the current in the circuit.

The voltage at the coil terminals during the transient mode has the expression:

$$u_L(t) = \sqrt{2}LI \left[\omega \cdot \cos(\omega t + \beta - \varphi) + \frac{1}{T} \sin(\beta - \varphi) \cdot e^{-\frac{t}{T}} \right] \quad (3)$$

2.2. Disconnection mode

It is considered an inductive circuit with a resistance R and inductance L that is powered by an alternating voltage source and at initial moment it is disconnected. It is believed that the disconnection is done when the current is zero, and the voltage source has the expression:

$$e(t) = U_m \sin(\omega t + \varphi) \quad (4)$$

Where U_m is the voltage amplitude and φ is the phase difference between the voltage and the current in the inductive circuit.

If the real case is considered where the power cord has C capacity, the electrical scheme of the circuit with concentrated parameters is presented in fig.1.

At the initial moment it is considered that the circuit breaker k opens.

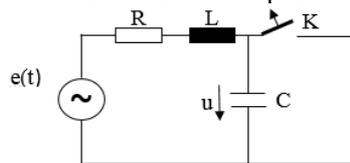

Fig. 1. The electrical scheme of the disconnected circuit

The differential equation of the voltages in the circuit is:

$$R \cdot i + L \frac{di}{dt} + u = e(t) \quad (5)$$

Laplace transform applied to the circuit leads to obtaining the expression of disconnection current that takes the form (Golovanov et al., 2009):

$$i = I_m \cdot \cos(\omega t + \varphi - \phi_1) + \frac{DU_m e^{-\delta t}}{2\omega_e L} \cdot \left[\cos(\omega_e t - \gamma) - \frac{\delta}{\omega_0} \sin(\omega_e t - \gamma) \right] \quad (6)$$

Transient voltage at the coil terminal takes the following form:

$$u_L(t) = L \frac{di}{dt} = \frac{D \cdot U_m}{2} \left[\left(\frac{\omega_p}{\omega_e} \right)^2 e^{-\delta t} \cdot \sin(\omega_e t - \gamma) - 2 \frac{\delta}{\omega_e} e^{-\delta t} \cdot \cos(\omega_e t - \gamma) \right] - I_m \omega L \cdot \sin(\omega t + \varphi - \phi_1) \quad (7)$$

3. Interface circuits

For the experimental evaluation of electrical quantities, a NI-USB 6003 data acquisition system was used with a 100kS sampling rate produced by National Instruments, and the software environment used is the MATLAB program. To make the measurements, it was necessary to design an interface circuit that takes the electrical quantities from the inductive circuit and transfer it to the data acquisition system. The circuit of the interface is presented in figure 2, (Niculescu, 2012b).

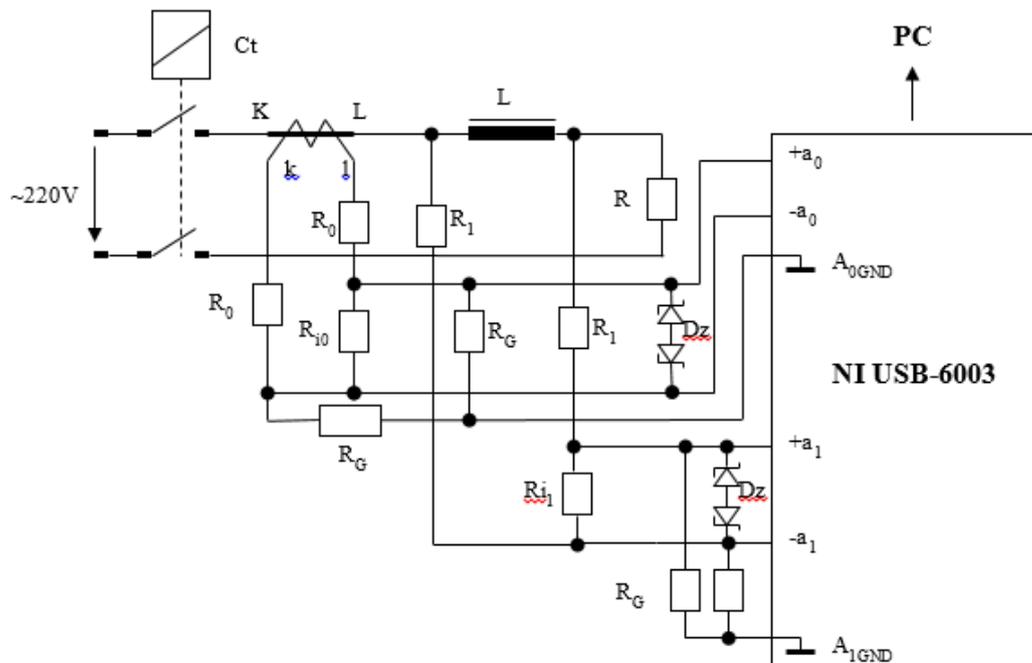

Fig. 2. The electrical circuit of the measurement system

To avoid the connection of the voltage phase directly to the input of the acquisition system, symmetrical voltage dividers were used at which R_{i0} and R_{i1} resistors are connected in parallel with the inputs of the measurement system a_0 and a_1 . The drops voltage on these resistors are proportional to the inductive voltage and current in the circuit. For the protection of analog inputs against destructive surges which exceed the range $-10V \dots +10V$, four Dz Zener diodes have been used, (Loackahart and Tilleson, 2017), (NI USB-6001/6002/6003 User Guide), (Maurizio 2013).

4. Measuring process in MATLAB

Measurements were made with the NI-USB 6003 data acquisition system with a 100kS sampling rate. The software used was MATLAB 2014b which, prior to the measurements, required the creation of a specific program for the acquisition process. It allows the acquisition of electrical signal from the interface and the display of the variations of voltage on the coil, the current in the circuit and the instantaneous power dissipated on the coil. The MATLAB program allows you to trace induction voltage variation and inductive current curves on the same graph and instantaneous power curve (Mendel, 2016), (Loackahart and Tilleson, 2017), (Software Matlab 2014b).

As can be seen from the program, it has three groups of instructions. The first group makes it possible to acquire the data for 1.5 seconds for two measurands, each with a sampling rate of 45000S.

The second set of instructions generates the inductive voltage and current circuits in the circuit on the same graph, and the third generates the instantaneous power diagram dissipated on the coil.

Two constants with values of 163 and 27 were used in the program.

These were determined experimentally, taking into account the resistance values in the resistive dividers and the fact that the physical measurement system has a finite input impedance.

5. Experimental Results

The measurements were made for two values of the coil inductance. The following circuit parameter values were used for the first measurement:

- $L=12\text{mH}$; $R=100\Omega$; $U=220\text{V}$.

For the situations of connection and disconnection several diagrams were plotted with the voltage and current variations, but also instantaneous power dissipated on the coil.

For the situation of connecting of an inductive load to an alternating power source, the following diagrams were obtained:

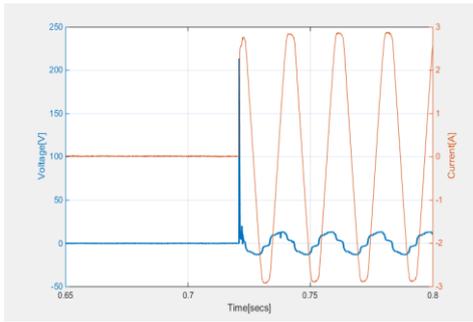

Fig. 3. Voltage variation on the coil and the current at connecting for $L=12\text{mH}$

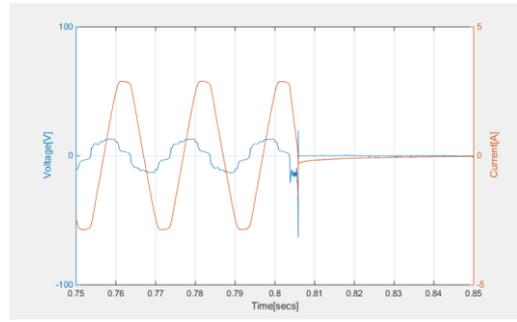

Fig. 5. Voltage variation on the coil and the current at disconnecting for $L=12\text{mH}$

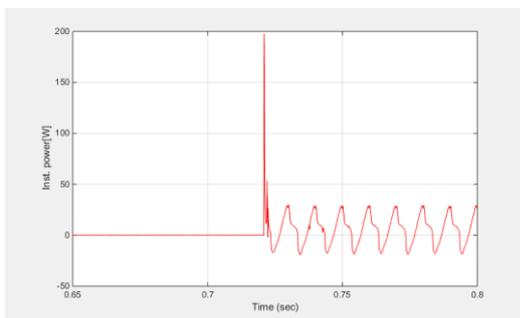

Fig 4. Instantaneous power variation on the coil at connecting for $L=12\text{mH}$

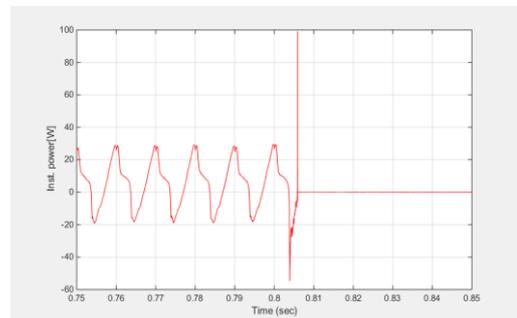

Fig. 6. Instantaneous power variation on the coil at disconnecting for $L=12\text{mH}$

In the case of connecting of the inductive circuit is observed and commutation overvoltage that appears immediately after closing the circuit. The value of this overvoltage is dependent of the value of circuit's inductivity. It has to be remembered that this overvoltage is not constant in all the measurements that were made, it depends on the moment of disconnecting the circuit. This overvoltage is also reflected in the instantaneous power curb at the coil terminals. The peak of the inductive voltage leads to the apparition of a power spike, right after connection. Several measurements were made and the most representative case was presented here (Marinov and Valchev 2010).

In the care of disconnecting the circuit the following diagrams were obtained:

At disconnection point is observed the appearance of a commutation overvoltage right after disconnecting the circuit from the power source. The value of the overvoltage is dependent of the inductivity of the circuit. This overvoltage is not constant in all the measurements we made, for it depends of the moment of disconnecting the circuit. This overvoltage is also reflected in the instantaneous power curb at the coil terminals. The peak of the inductive voltage leads to the apparition of a power spike, right after disconnection. Out of the all the measurements that were made, the most representative case was presented here.

6. Measuring process in SIMULINK

Another method of measuring and studying switching phenomena is the data acquisition in Simulink. This paragraph presents a new and modern method to study the transient phenomena that occurs when switching the inductive charges to an AC power source, using the MATLAB-SIMULINK software package. It is known that NI-USB data acquisition systems manufactured by National Instruments are not recognized by the Simulink software package in 64-bit systems. That is why a 32-bit system is obligatory. From this point of view, the paragraph presents a method by which this disadvantage is eliminated, making the data acquisition process possible in Simulink software package in 64-bit systems (Software Matlab 2018a).

Experimental measurements were made with a data acquisition system type NI USB-6003 with a rate of 100kS/ sec., and the measurements were processed by 2018a MATLAB version, which recognizes only data acquisition system in MATLAB, not in Simulink.

At this moment the Data folder from the Workspace can be read from a Simulink simulation model. This is shown in Figure 7 (Eshkabilov 2016):

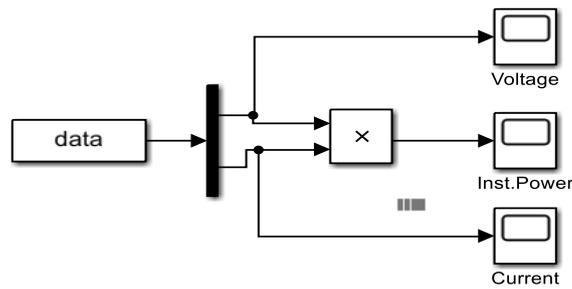

Fig. 7. Simulink model for study the transient phenomena

The application of the previously described process has led to the experimental results described below. Because the transient phenomena are less significant in the current variation curve, it was chosen to show only the voltage variation at the coil terminals and the instantaneous power dissipated thereon. The situation of connecting and disconnecting an inductive load has been considered (Karris 2011).

For electrical parameter values:

- $L=12\text{mH}$; $R=100\Omega$; $U=220\text{V}$, the following diagrams were obtained:

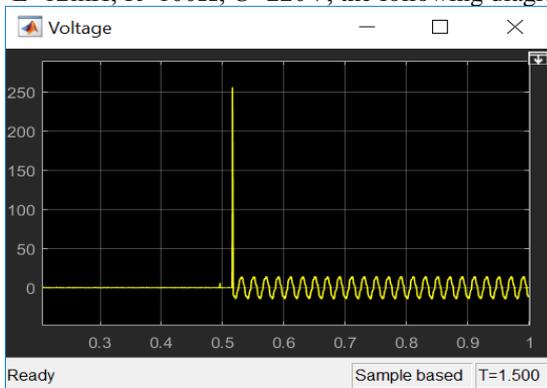

Fig. 8. Voltage variation on the coil at connecting for $L=12\text{mH}$

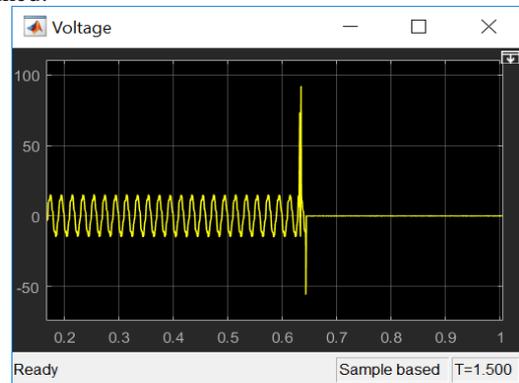

Fig. 10. Voltage variation on the coil at disconnecting for $L=12\text{mH}$

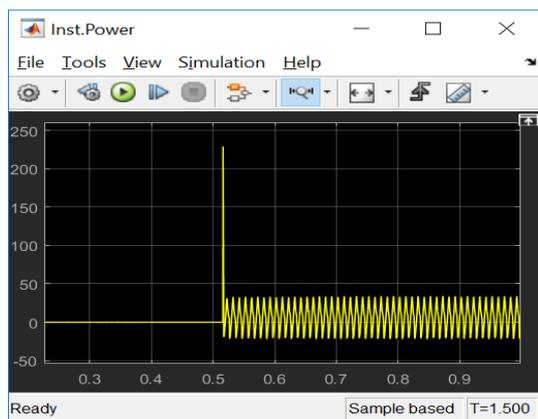

Fig. 9. Instantaneous power variation on the coil at connecting for $L=12\text{mH}$

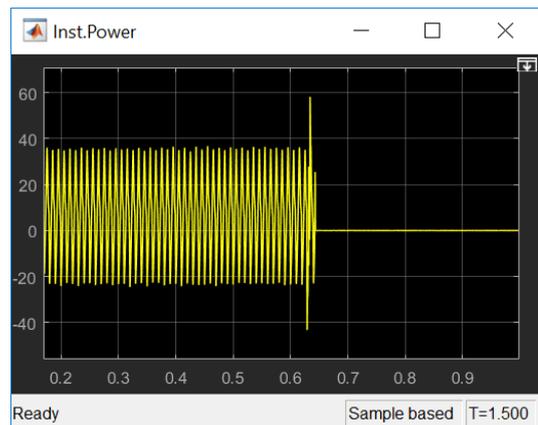

Fig. 11. Instantaneous power variation on the coil at disconnecting for $L=12\text{mH}$

7. Conclusions

The diagrams presented in the paper show that when switching inductive circuits to an alternative voltage source, there is a very high slope overvoltage that can become dangerous for the physical elements of the circuit. This voltage peak is dependent on the value of the inductance and the moment of the circuit switching. Various measurements were chosen from the most representative cases. From the measurements made it was observed that the ratio between the overvoltage and the voltage on the coil prior to switching is the higher when the value of the inductance decreases. Also, the duration of the overvoltage pulse decreases as the inductance decreases.

The method of study of the switching phenomenon of inductive loads to alternative voltage sources based on the use of data acquisition systems is a modern one and allows for focusing on the event at any time of the transient switching mode.

The electrical capacities that appear in the circuit in the real situation make the diagrams obtained by the measurements to be different from the theoretical situation presented in the paper, where the phenomenon was presented and these capacities were neglected, the elements of the circuit being considered ideal. Their presence leads to the emergence of short-duration oscillating modes and very high amplitude compared to the permanent regime.

The measurement method is based on the use of the MATLAB program that has the possibility of further processing of the results of the measurements with superior accuracy, compared to those resulting from the use of the LabView software provided by the manufacturer.

It is necessary to mention that high-speed data acquisition systems are required for the study of fast electrical processes. The NI USB 6003 Data Acquisition System, which has a sampling rate of 100kS, is sufficient to study such switching phenomena.

As presented in the paper, a modern and efficient method of studying these kinds of phenomena is based on data acquisition in Simulink. Subsequent possibilities of processing the results through this method are huge. MATLAB 2014b software was used for data acquisition, and MATLAB 2018a was used to process the results. Two versions of MATLAB were used, as the latter does not have support software for NI USB data acquisition systems, but has superior processing capabilities for data acquisition results.

Abstract

This research studies the directional protection that is a form of protection that utilizes measurements to determine the direction of the fault. Directional protection enables better discrimination of the faulty part of the network than with overcurrent protection. The direction in which the fault occurs is detected by measuring the direction of current flow, or in other words the phase displacement between the current and voltage. Directional phase protection equipment may be preferred to differential protection equipment to protect two parallel connected transformers, especially if the two busbars are quite far apart. The study proves the vectorial approach of the directional protection in three phase power networks using high speed microcontrollers.

Keywords: directional protection; smart grid; high speed microcontroller; computational protection.

1. Introduction

Directional elements respond to the phase shift between a polarizing quantity and an operate quantity. In figure 1 is presented the general circuit diagram of directional protection. In this diagram the faulted phase voltage, V , is the polarizing quantity, and the faulted phase current, I , is the operate quantity.

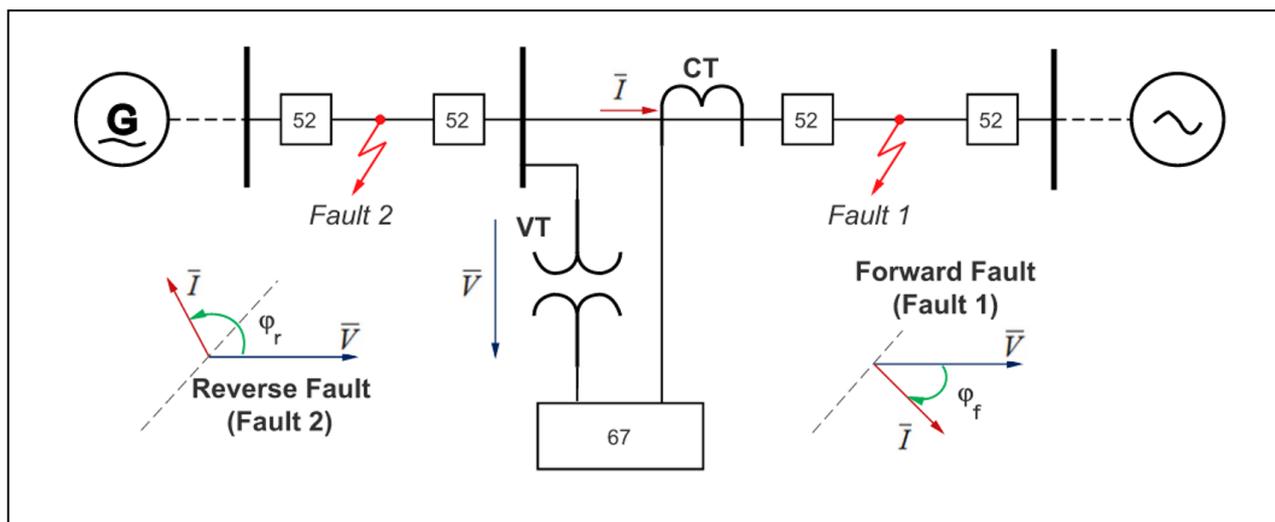

Fig. 1. Single line diagram for directional relay connection. The fault location, with best disconnecting decision by the breakers (pairs of two 52 devices), is done by the AC directional overcurrent relay (67).

* Corresponding author. Tel.: 0258/811512

E-mail address: remusdobra@uab.ro.

Because lines are predominantly inductive, I lags V by the fault loop impedance angle, ϕ_f , for forward line faults. For reverse faults on the adjacent line, I leads V by approximately 180 degrees minus the fault loop impedance angle, ϕ_f . The options for selecting polarizing and operate signals vary and include voltage or current signals or phase.

Directional relays have a settable characteristic angle to take into account the transmission line angle. Usually, the operating region is ± 90 degrees from the characteristic angle. Variations of this basic directional technique include having a separate forward and reverse operation region for enhanced security (Chen W., et al., 2003).

2. Vectorial analysis of directional protection

The relay operational mode $f(a)$ correspond to three possibilities: 1. Disable = Non-Directional; 2. Sup. = Directional Supervision; 3. Dir. = Total Directional. On each phase the relay measures the current “ I_x ” and its displacement “ ϕ_x ” from the relevant phase-to-neutral voltage “ E_x ”. The overcurrent element operates independently from the current direction (Radojevic Z., et al., 2000).

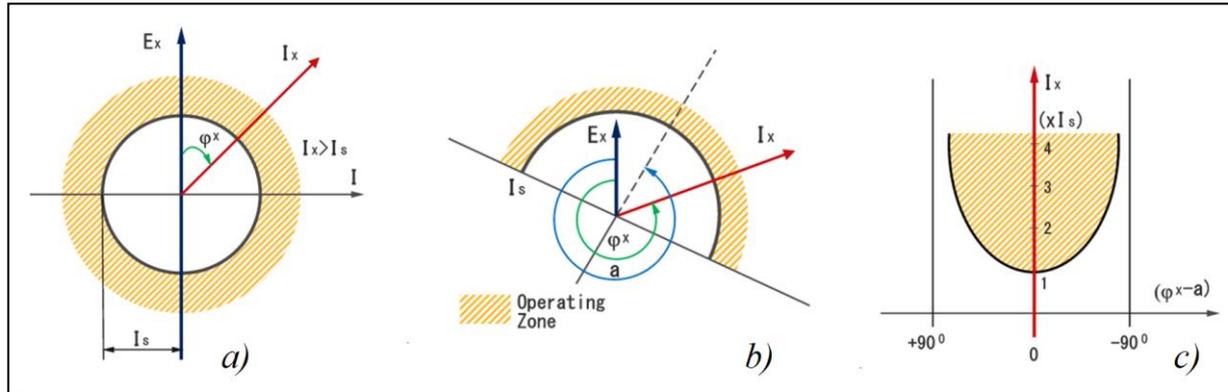

Fig. 2. Directional protection vectorial approach: a) The protection area is configured when directional relay characteristic function is disabled $f(a) = \text{Disab.}$; b) Protected area when directional relay characteristic function is settled as $f(a) = \text{Sup.}$; c) Both directions detection: directional relay characteristic function is settled $f(a) = \text{Dir.}$

2.1. Non-directional mode

Different operation modes are possible according to the programming of the variable “ $f(a)$ ” from the relay software. The meaning of the main variables are:

- I_s = Minimum operation current level.
- a = Operation reference angle (phase x ; $x = A, B, C$).
- I_x = Measured input current (largest among the three phase currents I_A, I_B, I_C).
- ϕ_x = Phase displacement of current “ I_x ” from phase-to-neutral “ E_x ” ($X = A, B, C$).

2.2. Directional mode

The Overcurrent element only supervises the direction of the current and the operation conditions are:

- Input voltage above 1-2% of the rated input value.
- Input current above the set level: $I_x > [I_s]$
- Phase displacement “ ϕ_x ” within $\pm 90^\circ$ from the reference direction “ a ”.

2.3. Total directional mode

Recommended reference angles for different applications:

- Measurement of resistive component of current (active power):
Direct: $a = 0^\circ$ - Reverse : $a = 180^\circ$
- Directional phase fault detection:
Direct: $a = 300^\circ$ (60° lag) – Reverse : $a = 120^\circ$
- Measurement of inductive reactive component:
Direct: $a = 270^\circ$ (90° lag) - Reverse : $a = 90^\circ$
- Measurement of capacitive reactive component:
Direct: $a = 90^\circ$ (90° lead) - Reverse: $a = 270^\circ$

3. Directional protection programming

The configuration of the digital relay is done by connecting it and PC via a USB – RS485 cable. Based on dedicated software the relay was set up in terms of directional protection. The main screen of the software look likes the graphical interface presented in the next figure. After started MSCom2, the relay can be connected by clicking the “On serial port”.

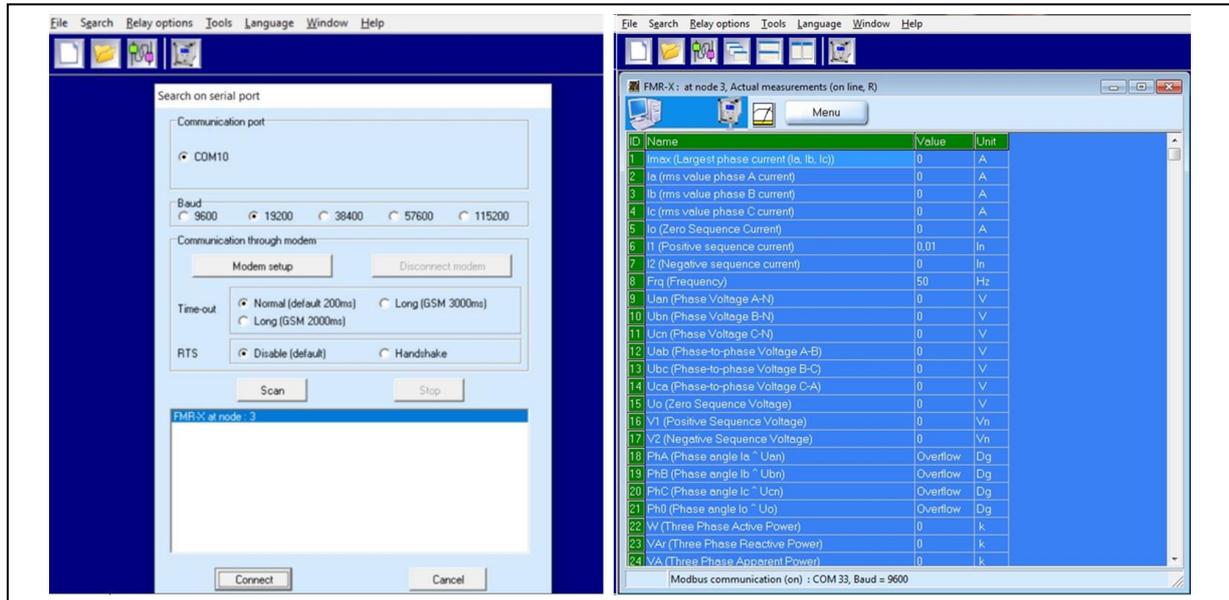

Fig. 3. The “Scan” option, must be used when we want to connect to the relay through a serial port (real or virtual). MSCom2 can open more than one relay at the same time.

Directional overcurrent relays utilize the reference voltage phasor for estimating the direction of the fault (Valsan S., aet al., 2007). This requires measurement of both current and voltage using specific sensors (current and voltage transformers). The information regarding the current is represented by I_{L1} , I_{L2} , I_{L3} and for the voltage measurement the digital relay uses V_{L1-0} , V_{L2-0} , V_{L3-0} .

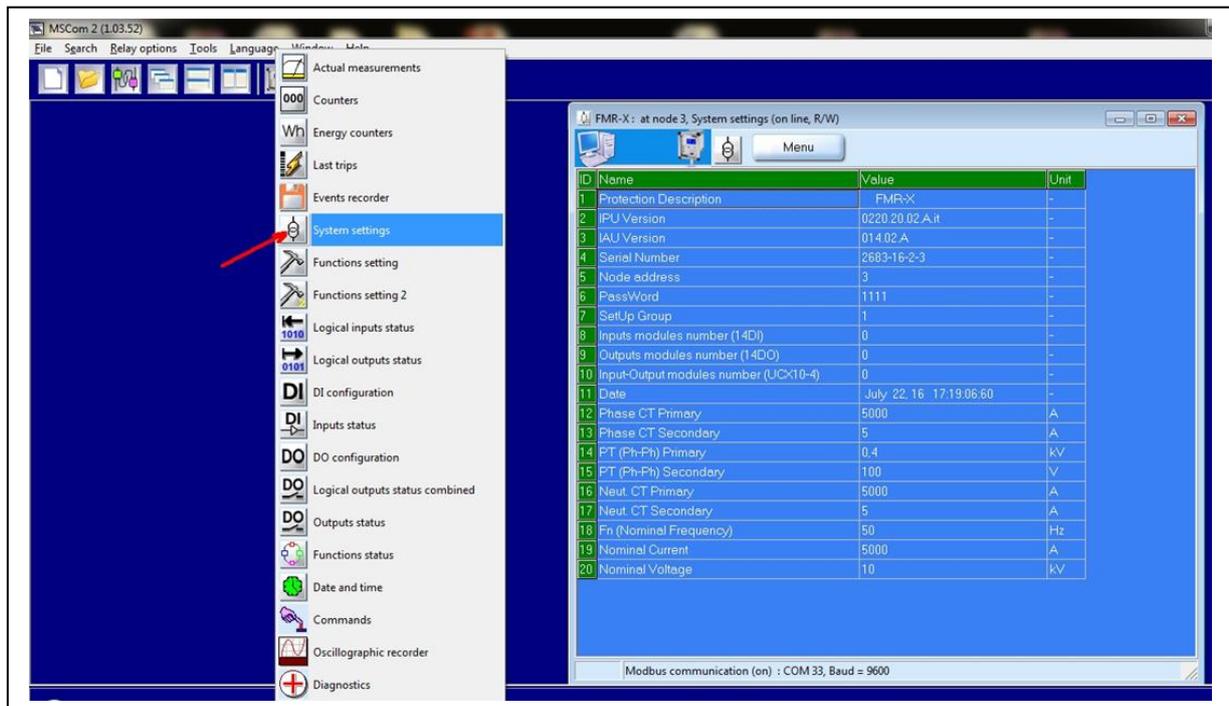

Fig. 4. Directional protection configuration from system settings

The directional relay was configured by entering in to the “Settings” option from relay software. From this window you can set up the main parameters of the equipment. Set up the rated current at 5000mA.

3.1. Non-directional mode relay programming

The relay based on high speed microcontroller will function when the AC input current exceeds a predetermined value on non-directional. By increasing the resistive load will cause a current higher than 500mA that was the trip level of the relay. It can be observed in figure 5 that only the amplitude of the current on second phase (I_b) is greater than the set-up trip level. It can be observed in figure 6 that the amplitude of the current on first phase (I_a) is greater than the set-up trip level. In this case also the phase displacement “ ϕ_x ” within $\pm 90^\circ$ is greater than the reference direction “a”.

Because the relay was programmed to work as non-directional protection the relay didn't trip. The overcurrent element operates independently from the current direction.

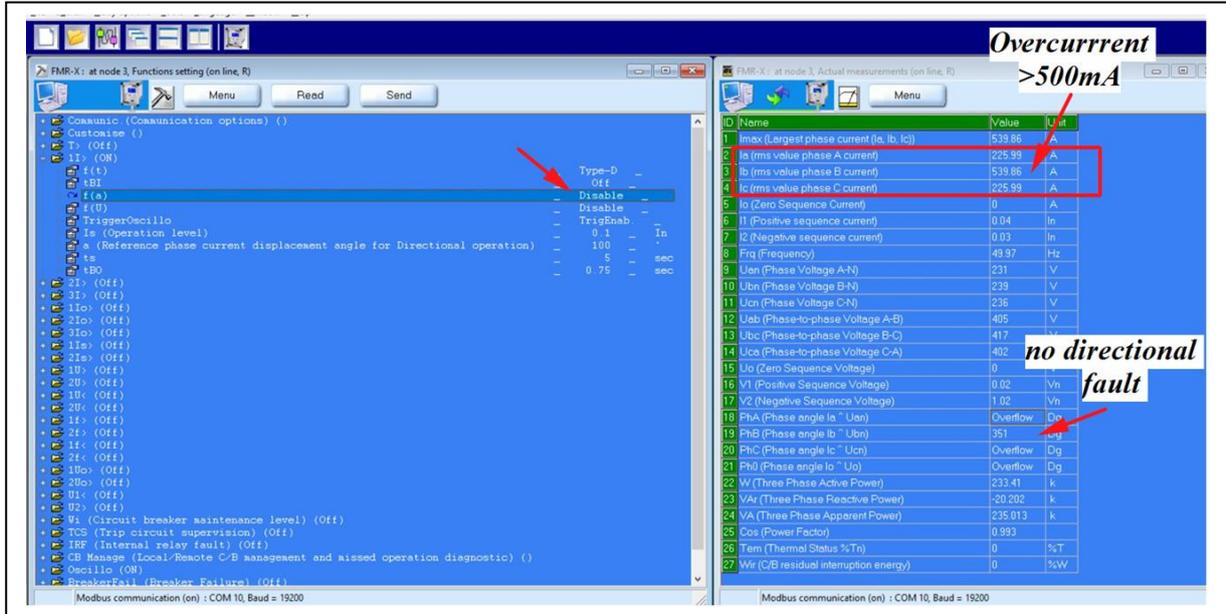

Fig. 5. Overcurrent fault (set-up directional relay as disable).

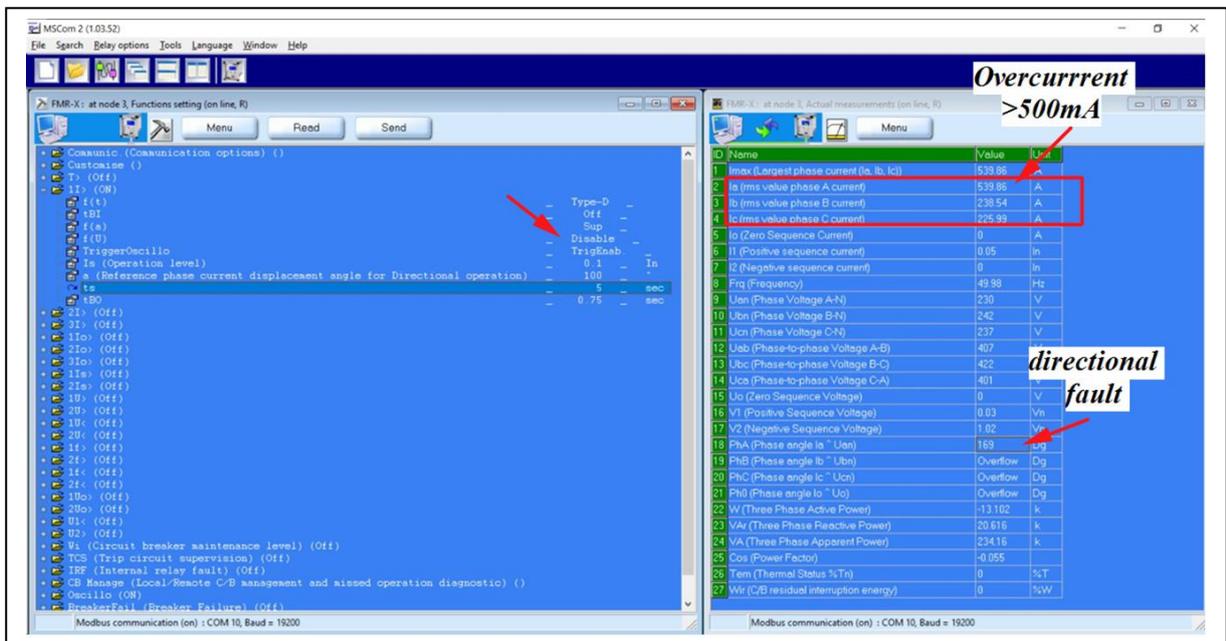

Fig. 6. Overcurrent and directional current fault (set-up directional relay as disable).

3.2. Directional mode relay programming

Set the 1I> to ON and the f(t) to Type-D. Select operation function f(a) as “Sup” and press OK. This will configure the directional relay to work in supervision mode, based on the characteristic described in next figure. Set the reference phase current displacement angle at 100 degrees.

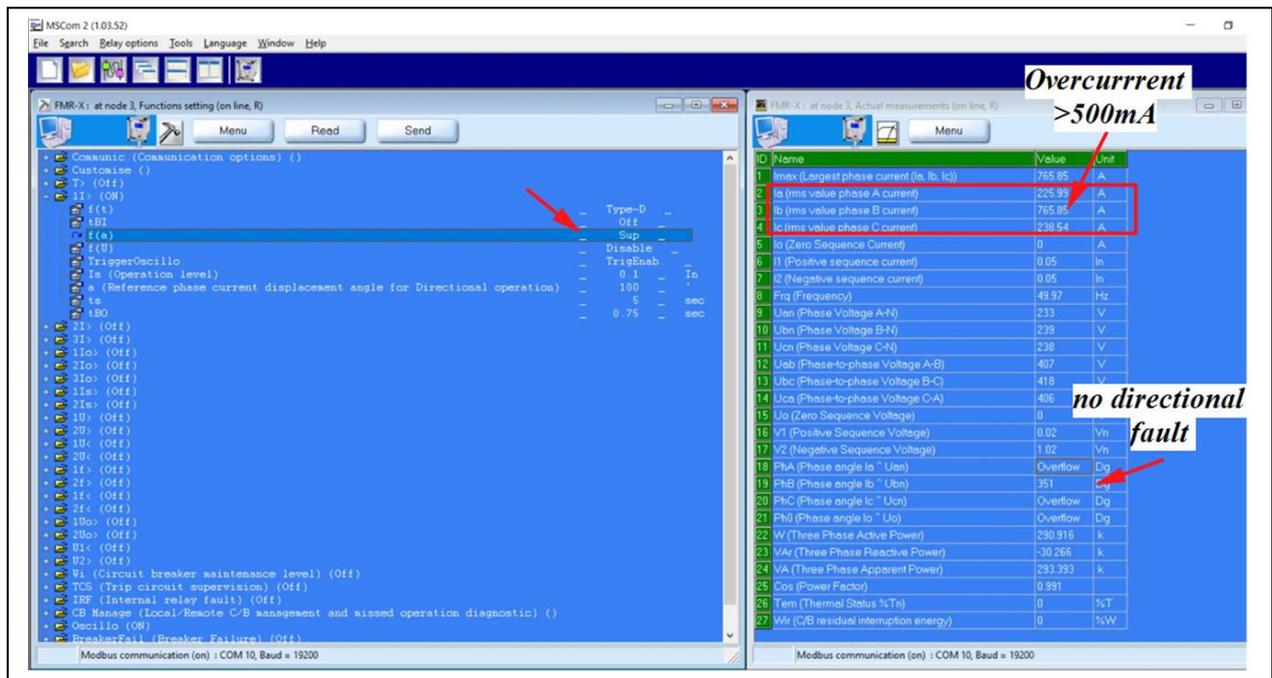

Fig. 7. Overcurrent fault (set-up directional relay as Sup).

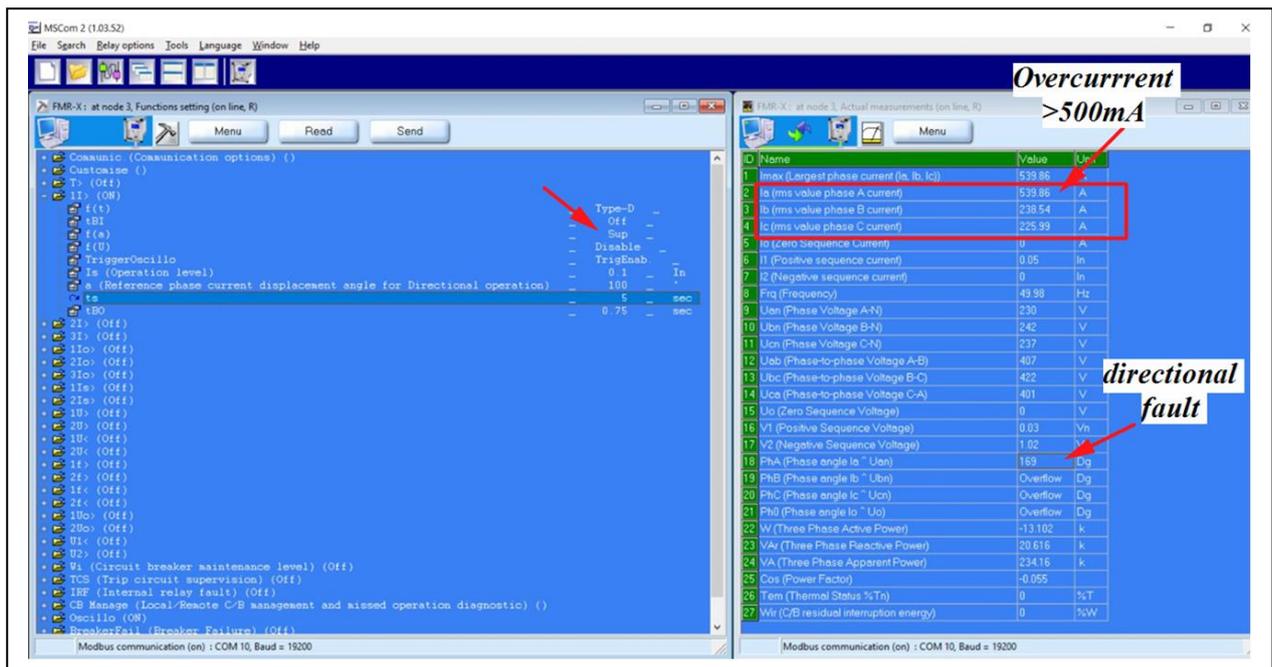

Fig. 8. Overcurrent and directional current fault (set-up directional relay as Sup)

Increasing the load current over the threshold and by simulating a directional fault will cause the relay to trip. By recording the current and voltages curves, as is presented in figure 9, we can observe the phase displacement in between current I_A (from phase 1) and U_{an}. In figure 9a the displacement occurred when we have reversed the direction of the current. In figure 9.b with normal flowing of current the I_b (on phase 2) and U_{an} there is no displacement.

When the angle in between the maximum current and the maximum voltage exceeds a set threshold, the directional relay trip and give the switching off command to the circuit breaker.

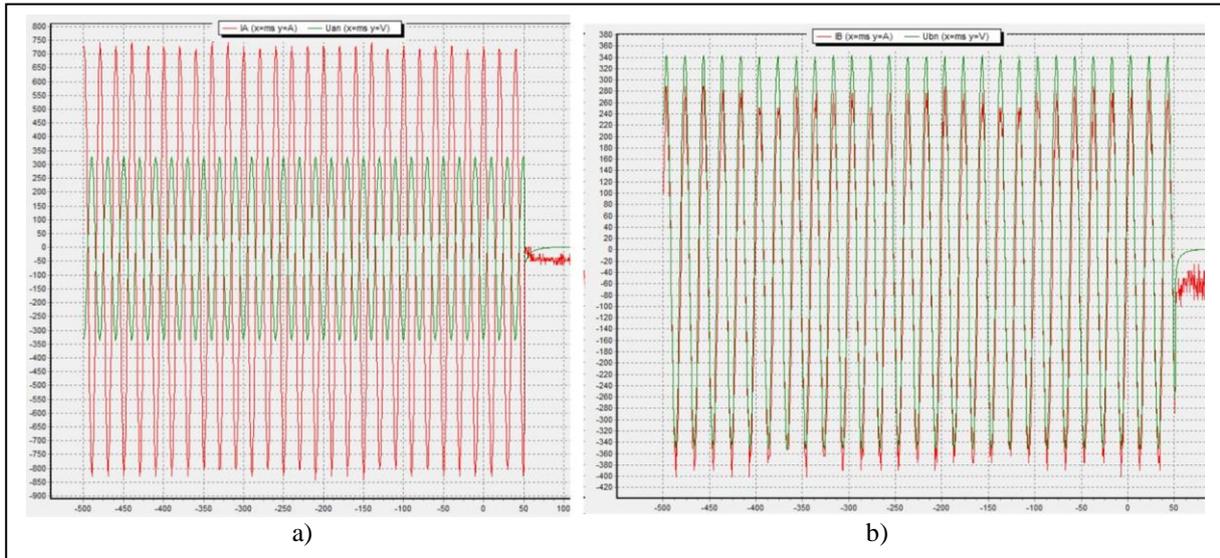

Fig. 9. Measured curves of line currents and voltages

4. Conclusions

The proposed architecture for the future work is shown above. There is a need to separate the process levels than management level. The link between them is based by communication support.

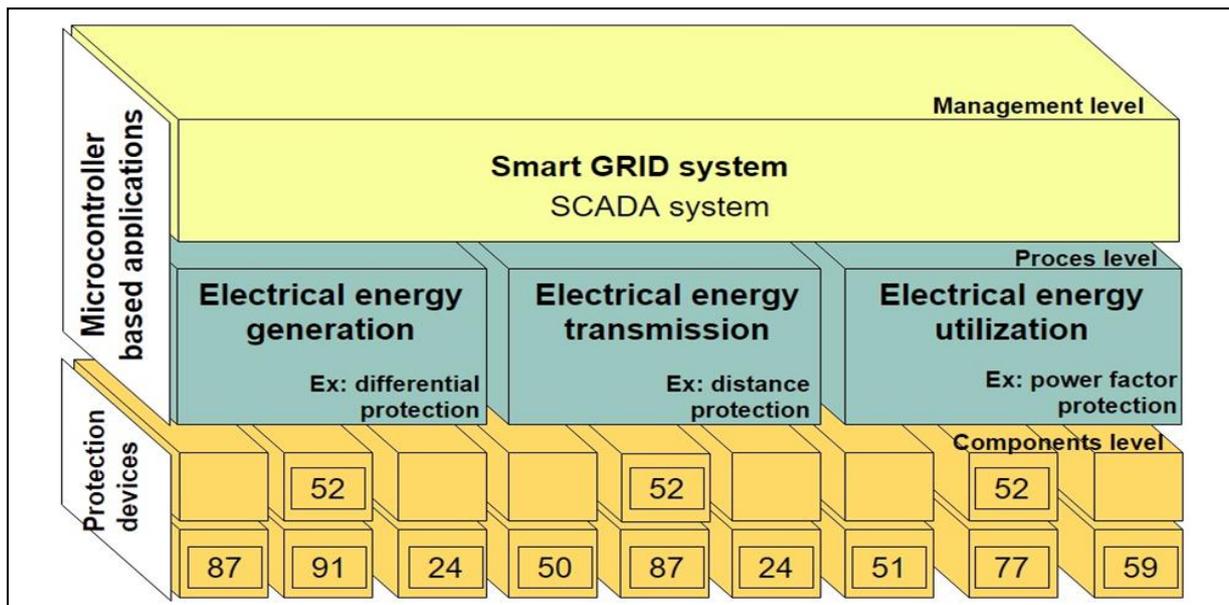

Fig. 10. Designed architecture of the directional protection integrated in high level processing

Abstract

Differential relaying systems are used for most of electrical power network components, such as generators, transformers, stations buses and transmission lines. We will focus is this experiment on the transmission lines differential protection. In this method, the differential relay will compare the incoming phase currents of a network component to the outgoing phase currents of it. If these currents differ from each other as to the amplitude or phase angle or both more than allowed by the setting values of the relay, the relay will trip.

Keywords: differential protection; power transformer; synchronous generator; computational protection method.

1. Introduction

Electrical energy generated by various electrical power stations is gathered by a central electrical grid and then redistributed to various users based on real-time supply and demand characteristics. In electrical power system, the main functional requirement of a protection relay, for a protection relay to operate effectively, it must fulfill some major functions (Ziegler, 2011):

- Reliability: when a fault occurs, they should respond as quickly as possible, and in any circumstances.
- Selectivity: the protection system should respond only when a fault occurs, and it must only operate on the section that has experienced a fault to avoid unnecessary power.
- Sensitivity: the protection system should be highly sensitive so that it can be relied on to provide the required detection.
- Speed: the protection system equipment must operate at the required speed. It should not delay so as to give time for system equipment to get destroyed. It should also not be too fast to cause undesired operation.

The transmission line protection based on the microcontroller technology use the electric power system currents and voltages provided through several conversions – the instrument transformers and secondary circuits in the substation, as well as the analog inputs and internal processing in the device. The secondary currents and voltages that are applied to the distance protection relay are filtered and processed in the analog input module and provide instantaneous sampled values to the internal digital data bus of the transmission line protection (Loko, 2010).

2. Smart differential protection method

Differential protection can be used to detect internal faults in the windings of generators, including ground faults, short circuits and open circuits. Transformer protection methods that use its terminal behavior are based on differential protection is considered as a most widely used technique to perform the protection function. Potential causes of faults are damaged insulation due to aging, overheating, over-voltage and mechanical damage (Gguzman, 2001).

* Corresponding author. Tel.: 0258/811512

E-mail address: remusdobra@uab.ro.

There are two current transformers: one CT is connected to the line side of the generator and the other is connected to the neutral side of the generator in each phase. The characteristics of all current transformers installed against each phase must be matched. If there is any major mismatch in the current transformer's characteristics of both sides of the generator, there may be a high chance of malfunctioning of the differential relay during the fault external to the stator winding and maybe during the normal operating conditions of the generator.

2.1. Power transformer differential protection

Differential protection scheme can be used to protect both the primary and secondary windings of a three-phase transformer. The fundamental operating principle of transformer differential protection is based on comparison of the transformer primary and secondary winding currents, as is presented in figure 1.

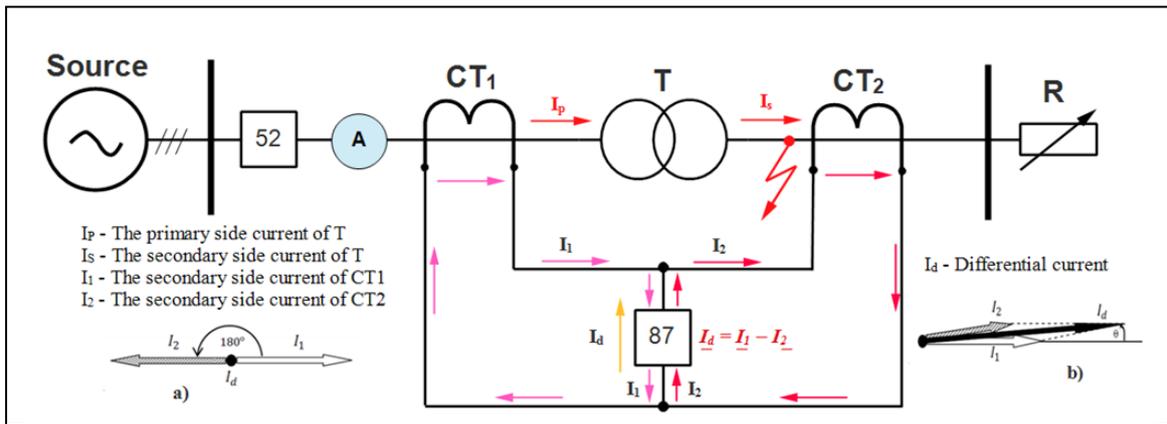

Fig. 1. Single line diagram of differential protection for power transformer (87- differential protective relay compares currents differences at both primary and secondary windings of a three-phase transformer through CT1 and CT2 systems, then, based by differences value sends commands the breakers-52 to insulate the fault)

If there is no internal fault occurring within the power transformer protected zone, the currents I_1 and I_2 are assumed equal in magnitude and opposite in direction. That means the differential current $I_d = 0$ as presented in figure 1.a. If there is any fault in the power transformer protected zone, the currents I_1 and I_2 are no longer equal in magnitude and opposite in direction. That means the differential current I_d has a significant value as shown in figure 1.b.

The amount of current $I_d = I_d \angle \theta$ induces the differential relay (87) to operate in order to send a trip signal to the circuit breakers (52) to isolate the transformer.

2.2. Synchronous generator differential protection

In generators with single windings per phase, the differential protection is similar to the transformer protection.

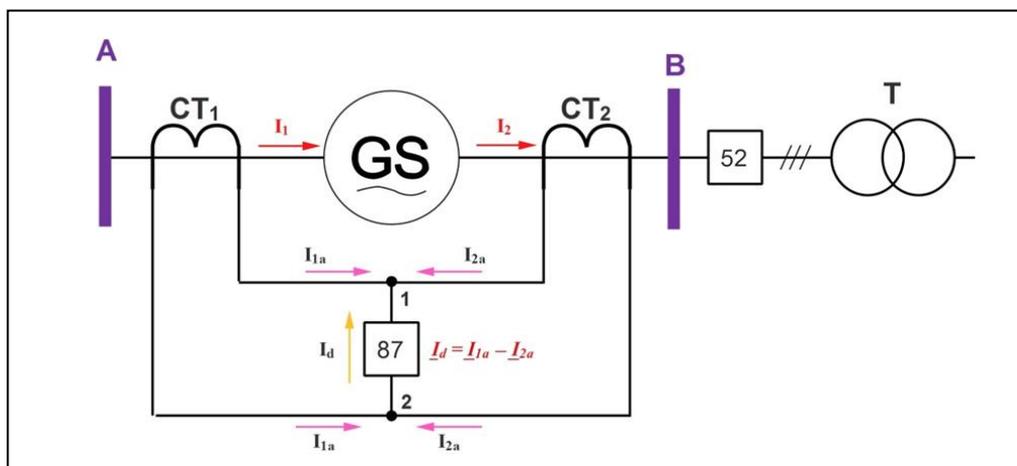

Fig. 2. Single line diagram for differential generator protection (87- differential protective relay compares currents differences at both ends of the generator through CT1 and CT2 systems, then, based by differences value sends commands the breakers-52 to insulate the fault).

2.3. Method description

In figure 3 is presented the operating characteristic of the differential current relay that correlates the currents on either side of the protected transmission line. The operation of the differential relay is based on the comparison of the currents on either side of the protected area. The programmable levels must be done heaving as reference the point P.

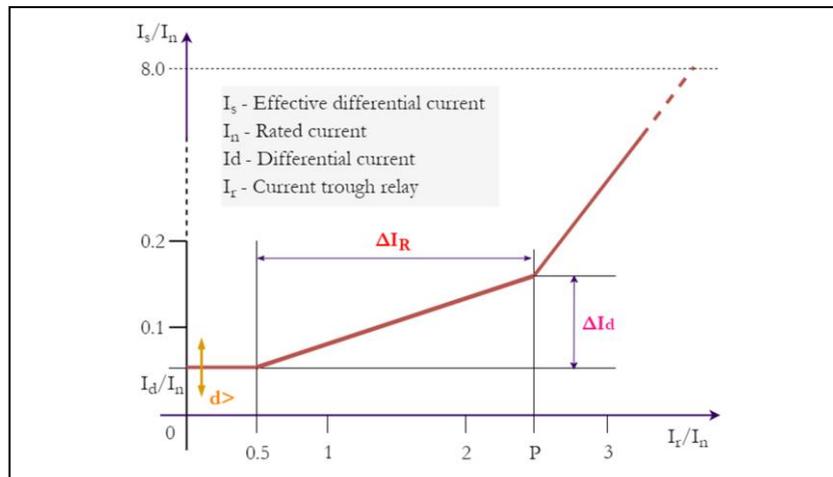

Fig. 3. Operating characteristic of the smart differential protection

A numerical differential protection has two typical slopes, based on which the relay will trip if the magnitude of the differential current is more than a fixed percentage of the restraining current. A dual-slope differential characteristic increases security for high-current external faults by applying greater restraint for greater currents to accommodate CT saturation errors, while allowing more sensitive operation for low-current internal faults.

3. Computational differential protection

This technique involves the comparison of the currents of each phase at each line terminal. A communication path is therefore an essential requirement of any such scheme. The basic operating principle of differential protection is to calculate the difference between the currents entering and leaving a protected zone. The protection operates when this difference exceeds a set threshold (Taalab et al., 2007).

In many practical situations the generator neutral is often grounded through a distribution transformer. This energizes a relay which operates the generator main and field breakers when a ground fault occurs in the generator or transformer. The ground fault is usually limited to about 10A by the distribution transformer or a resistor, although an inductor has some advantages. The field circuit of the generator must be opened when the differential protection operates in order to avoid the machine feeding the fault (Tripathy et al., 2010).

When loss of excitation occurs, reactive power (Q) flows into the machine, and if the system is able to supply this, the machine will operate as an induction generator, still supplying power to the network. The generator output will oscillate slightly as it attempts to lock into synchronism. Relays are connected to isolate the machine when a loss of field occurs, which can be readily detected by a reactance relay.

In power transformers the current-magnitude differences are corrected by adjusting the turns ratio of the current transformers to account for the voltage ratio at the transformer terminals. In a differential scheme the phase of the secondary currents in the pilot wires must also be accounted for with star-delta transformers (Yang et al., 2003).

3.1. Software description

To calculate differential current between line ends it is necessary that the current samples from each end are taken at the same moment in time. This can be achieved by the continuous calculation of the propagation delay between line ends. The line parameters Z contain the R, L, C components. At the extremities of the zone to be protected, the currents are continuously compared and balanced by suitable relays. Provided that the currents flowing into and out of the zone are equal in magnitude and phase, no relay operation will occur. If, however, an internal fault (inside the protected zone) occurs, this balance will be disturbed, and the relay will operate.

If the current value of the supply voltage is less than 20% of the rated value; if the supply voltage is above the threshold of 20% reliable function, the system will generate a unique identifier numeric specific to the equipment. In this figure for differential protection is used the microcontroller relay. In order to give the switching off command to the circuit breaker the numerical differential relay has for output relays available. The relays are normally deenergized and are user programmable.

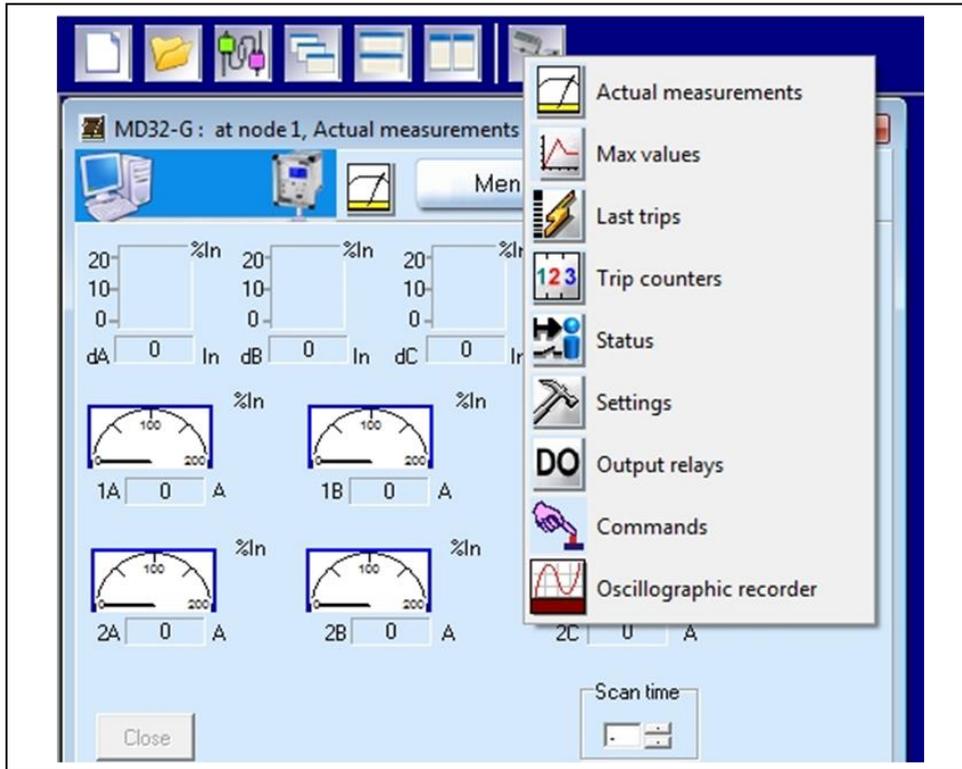

Fig. 4. Main window of the differential protection software

Using the graphical interface of the programming differential software from figure 5a the user can set up de trip values of the relay.

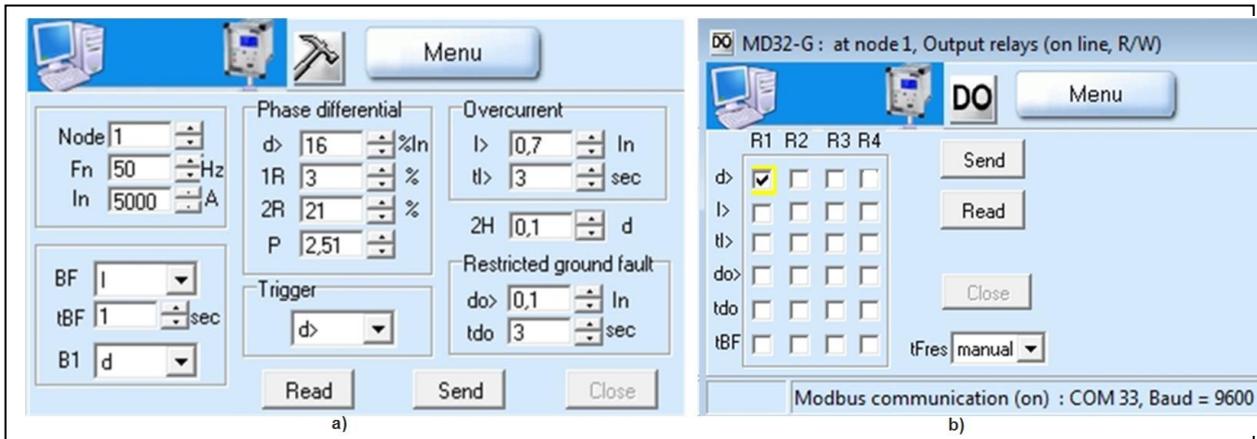

Fig. 5. Differential relay trip programming: a) main window, b) set up the differential output relay

The principle of operation of differential protection is similar to the differential systems for protecting generators and transformers, but the relays have different settings because the breakers at the ends of the line are more widely separated. For output relays are available (R1, R2, R3, R4). The relays R1, R2, R3, R4 are normally de-energized (energized on trip): these output relays are user programmable and any of them can be associated to any of the smart differential relay functions. For the function d> both instantaneous and time delayed elements are provided. The reset after tripping of the relays (when the tripping cause has been cleared) can be programmable as Manual or Automatic (Variable RR=Man/Aut).

Based on this protection software we can select distinct types of parameters, described in the table below. For differential protection the selected variable will be d>.

Table 1. Smart differential protection variable setup

Variable	Default	Relay parameter description
Fn	50	Rated primary current of current transformers
In	500	Rated primary current of current transformers
d>	0.15	Basic minimum pick-up level of low set phase differential element
I>	5.00	Minimum pick-up level of over-current element
tl>	3.00	Time delay of over-current element
do>	0.1	Minimum pick-up level of Earth Fault element
tdo	500	Time delay of Earth Fault element
TGR	d>	Trigger for oscillography records is internal (TRG=d>, I>, do>)

The differential relay was programmed to trip at a 6% differential current in the protected area. In normal conditions in the actual measurements software interface the three phase currents should be equal to zero. On phase L3 (see differential current dC) was created a fault (just before the relay trip 0.053%)

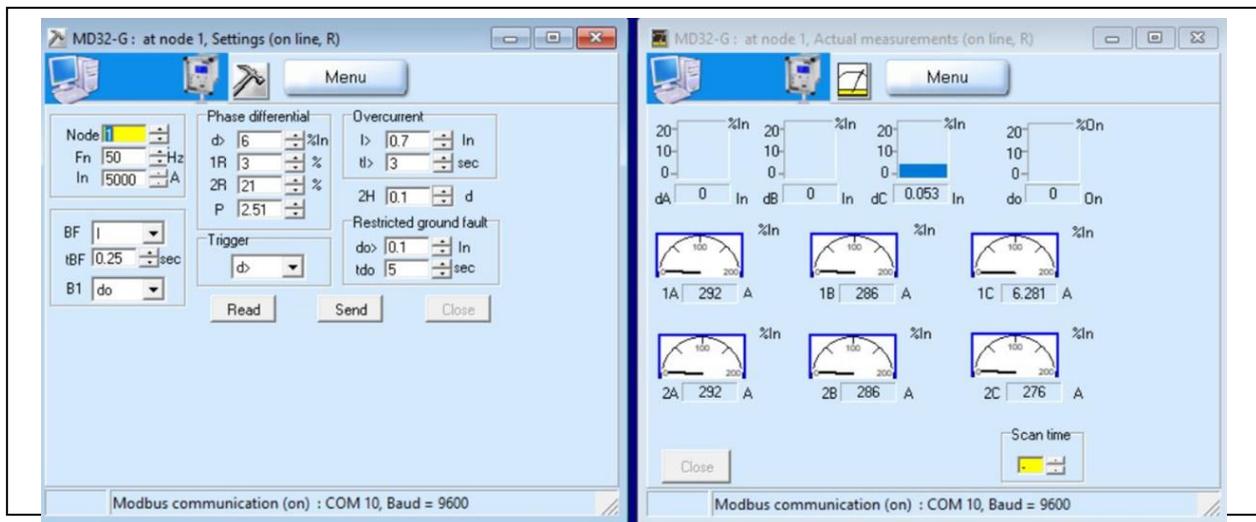

Fig. 6. Measurements recorded based on deferent loads (with differential fault on phase 3)

3.2. Recorded curves using digital differential protection

The form of differential protection using only one set of relays is not suitable for long overhead lines since the ends of a line are too far apart to be able to interconnect the CT secondaries satisfactorily.

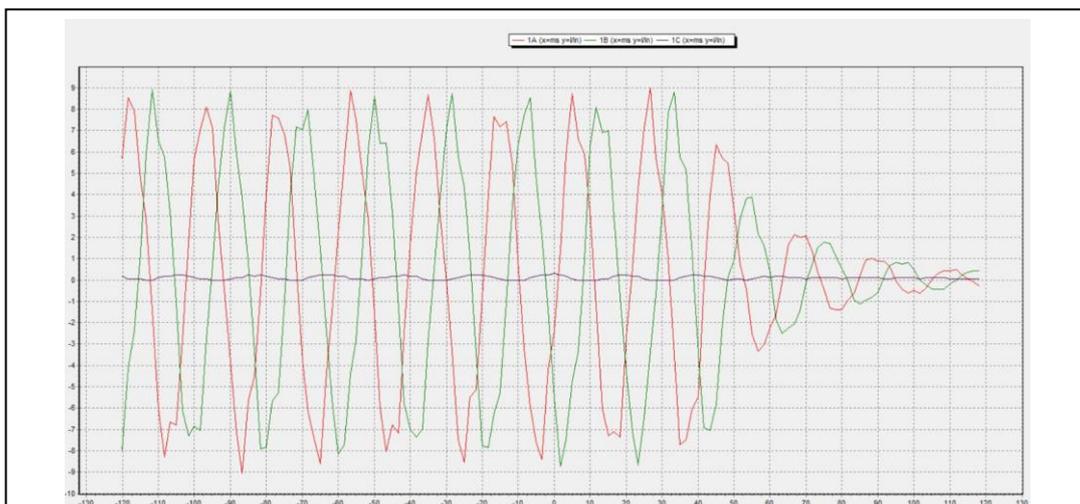

Fig.7. Measured currents on the input differential relay (1A, 1B, 1C).

It is therefore necessary to install a set of relays at each end of the circuit and interconnect them by some suitable communication link. Numerical differential protection (indicates that there is an interconnecting channel between the ends of the lines through which information can be transmitted) is an adaptation of the principles of differential protection. In figure 8 the register was obtained by making a differential fault by short-circuited the current transformer from the output relay (see figure 1 – relay CT2).

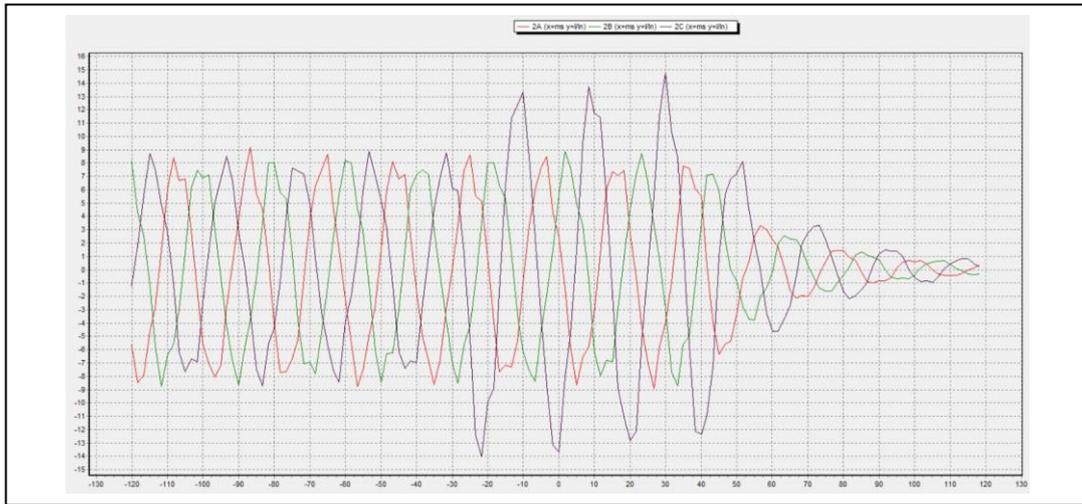

Fig. 8. Measured currents on the input differential relay (2A, 2B, 2C).

The connection of the protection device to the current transformers must be done in such a way that comparison of the currents can be carried out with respect to r.m.s. value and phase - angle. Protection schemes of transformers with vector groups different from 0° additionally require intermediate transformers to correct the differences in phase - angle between the HV and LV sides.

With three - winding transformers all windings have to be included in the differential protection scheme. With transformers having vector group YNyn_d, which are not grounded permanently, intermediate transformers likewise have to be planned, in order to ensure selectivity and avoid malfunction in the case of single - phase short - circuits by measuring the partial short - circuit current through the neutral.

4. Conclusions

With shown and proved results, the implemented device runs differential protection and creates objects to a higher-level processing. By using a transmission line, generator and transformer simulator with real current transformers, the students create lines short-circuit scenarios, and see different reactions of the differential relay from the selectivity criteria point of view.

The blockchain as a backbone of GDPR compliant frameworks

Peyo Hristov^{a*}, W. Dimitrov^a

^aUniversity of Library Studies and Information Technologies, "Tzarigradsko shose" Str.119, Sofia 1784, Bulgaria

Abstract

General data protection regulation (GDPR) is applied since 25 May 2018. It is designed to harmonize data privacy laws in European Union. It clearly defines what personal data is and identifies involved objects as Controller, Processor and Data subject. Although it focuses over the procedures in the organizations that have contact with personal data, it raises technological challenges about data storage, data processing, access control, identity management, system resilience, cybersecurity, post security breach measures, transactions traceability. We offer a new conceptual model with a trust management technology between controllers and data processors, which is based on the capabilities of the DLT. It can be useful in synthesizing software architectures, managing change due to the implementation of GDPR, ePrivacy, Policy Directive, and another forthcoming EU legislation. The article aims to present where the blockchain implementation can be helpful for the GDPR compliant operations. It doesn't cover the GDPR or blockchain in deep technical details, but just points out the important aspects where the DLT solution could be applicable. The paper is structured as follows: Section 1 introduces the paper. Section 2 describes the methodology used in this article. Section 3 introduces the GDPR and points out with short descriptions the key principles of the regulation. Section 4 covers brief explanation what blockchain is with examples from the Bitcoin implementation. Terms like transaction, transactions integrity, block, consensus are described here. Permissioned and permissionless blockchain implementations with their basic difference in the level of trust. Section 5 defines the main intersection points between GDPR compliance and the blockchain. Section 6 presents the Hyperledger fabric blockchain framework founded by Open Linux Foundation and IBM. The section focuses over the unique Hyperledger fabric abilities, which leads to increased confidentiality, transaction speed, traceability, access control, identity management, endorsement policies and smart contracts applications. Section 7 shows related research in this area. In conclusion the study reveals the biggest challenge in the blockchain application in the GDPR compliant frameworks.

Keywords: blockchain; confidentiality; GDPR; Hyperledger Fabric.

1. Introduction

General data protection regulation (GDPR) is applied since 25 May 2018. It is designed to harmonize data privacy laws in European Union. It clearly defines what personal data is and identifies involved objects as Controller, Processor and Data subject. Although it focuses over the procedures in the organizations that have contact with personal data, it raises technological challenges about data storage, data processing, access control, identity management, system resilience, cybersecurity, post security breach measures, transactions traceability. The blockchain became very popular since the end of 2017, because of the Bitcoin's price. But the blockchain as an implementation of the distributed ledger technology (DLT), has unique combination of some features like: traceability, transactions non-repudiation, very strong cryptographic nature, decentralization - which drew the attention of this study. In addition, smart contracts empower the blockchain with ability to automate transaction processing with programmed rules. The article aims to present where the blockchain implementation can be helpful for the GDPR compliant operations. It doesn't cover the GDPR or blockchain in deep technical details, but just points out the important aspects where the DLT solution could be applicable.

In this paper we offer a conceptual toolbox that solves three major problems:

- Strengthening the possibilities for complying with the principles of data processing and transmission and fulfilling accountability requirements;
- Operational mutual control over compliance with GDPR requirements in groups of related organizations;
- Provide opportunities for minimal impact of GDPR compliance on business continuity.

* Corresponding author. Tel.: +359-889-633-674
E-mail address: p.t.hristov@unibit.bg.

2. Methodology

The methodology of this article is based on a review over the essence of the GDPR and especially on the parts, where more complicated technical solution is needed. Bitcoin's blockchain is selected for the blockchain's overview, because it is quite simple and shows the most important aspects of the blockchain - transactions integrity, blocks sequence, consensus etc. Hyperledger Fabric official documentation and autor's experience in Hyperledger Fabric deployment and chaincode applications are used for explanation about multiple organizations (MSP) channels confidentiality and endorsement procedures, together with chaincode smart contracts. In the conclusion part the immutability vs. "Right to be forgotten" issue is raised as the main challenge in the GDPR and blockchain cooperation.

3. What a GDPR stands for?

GDPR is an abbreviation of General Data Protection Regulation. It replaces DPD (Data Protection Directive) 95/46/EC. It is designed to harmonize data privacy laws in EU to protect and empower all EU citizens data privacy and to reshape the way organizations across the region approach data privacy. In fact, GDPR is the most important change in data privacy regulation in 20 years (EU GDPR portal, 2018).

GDPR clearly identifies the following objects (ICO, 2018):

- Controller - determines the purposes and means of processing personal data.
- Processor - responsible for processing personal data on behalf of a controller.
- Data subject - a physical person. The personal data owner.

Definition of "personal data" and "processing" are also straightforward:

"personal data" means any information relating to an identified or identifiable natural person ('data subject'); an identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier such as a name, an identification number, location data, an online identifier or to one or more factors specific to the physical, physiological, genetic, mental, economic, cultural or social identity of that natural person;" (Concil of the European Union, 2016)

"processing" means any operation or set of operations which is performed on personal data or on sets of personal data, whether or not by automated means, such as collection, recording, organization, structuring, storage, adaptation or alteration, retrieval, consultation, use, disclosure by transmission, dissemination or otherwise making available, alignment or combination, restriction, erasure or destruction;"(Concil of the European Union, 2016)

At a first glance, it seems that the controller is free from GDPR obligations, but this assumption is far away from the truth - the GDPR places further obligations on you to ensure your contracts with processors comply with the GDPR ((ICO, 2018)).

From what has been said above is obvious, that the huge part of the business is affected by this regulation. Gartner clearly says, that organizations are unprepared for GDPR(Gartner,2017). Unfortunately, Forrester also predicts, that 80% of the companies affected by the regulation, will not fully comply to it until 25th of May 2018 (Forrester, 2017).

The goal of this article is not to reveal in deep GDPR, but for completeness we should mention the basic principles of the regulation - they are its heart:

- Lawfulness, fairness and transparency
- Purpose limitation
- Data minimization
- Accuracy
- Storage limitation
- Integrity and confidentiality (security)
- Accountability

It is maybe not accidentally, that "Lawfulness, fairness and transparency" is placed on first. Staying away from the legal aspects of this principle, the fairness and transparency are the really important pieces here from the present article's point of view. However, we should remember that they are very close linked together, and violation of any of three fails the whole. Fairness could be violated for example, when the controller obtains personal data but the data subject is misled or deceived in this process. Hence, this clarifies the transparency requirement. The data controller must provide a clean and open (transparent) way, to can data subject approve the lawfulness and fairness pieces of the principle.

Purpose limitation. Purposes for collecting personal data should be clear. The organization is obligated to specify these purposes in a clear way in the privacy information to the individuals. The personal data could not be used for other purposes, except in the cases they are compatible with the original or the organization have a new consent from the customer.

Accuracy is another key topic in this research. According to the regulation, personal data shall be accurate and, where necessary, kept up to date; every reasonable step must be taken to ensure that personal data that are inaccurate, having regard to the purposes for which they are processed, are erased or rectified without delay. (Concil of the European Union, 2016)

Storage limitation says, that you must not keeping personal data than you need it. After that you must take measures to erase or anonymize it. Not only at controller's side, but also at all processors side. And of course, the organization must be able to proof that.

Integrity and confidentiality looks as the most related to the cybersecurity. But this principle isn't limited only to the way organization store and transfer data - organizational security is the real keystone here. It covers also how the data can be altered, accessed, deleted etc. Have the accessing entity enough permissions to do so and what access level exactly have and of course - who grants these rights. Have the organization working solution how to recover data after an accident and how will ensure its integrity between the parties. Security awareness education of the organization's staff takes a place here. The right risk assessment of the personal data stored, both with used hardware equipment, also have important role in this principle.

And at the end, here comes the Accountability principle. In short, the organization should be able to proof its GDPR compliance. Most noticeable in the scope of this article is the ability to detect, record and report security breaches. Data protection by design and more importantly - by default, is mandatory requirement here.

4. The blockchain

"A 'blockchain' is a particular type of data structure used in some distributed ledgers which stores and transmits data in packages called 'blocks' that are connected to each other in a digital 'chain'. Blockchains employ cryptographic and algorithmic methods to record and synchronize data across a network in an immutable manner." (Natarajan et al., 2017)

The blockchain main concept for linked blocks is more clearly illustrated on Figure 1.

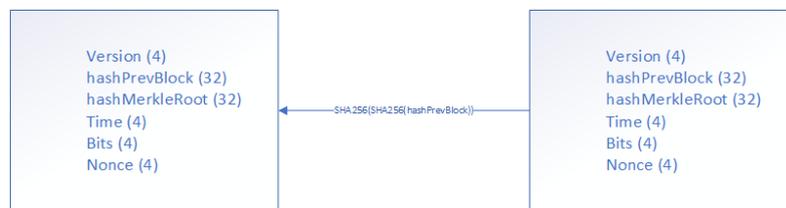

Fig. 1 - Bitcoin's linked blocks headers.

hashPrevBlock - the hash of the previous block = (SHA256(SHA256(block header)))

hashMerkleRoot - the root hash of the merkle tree of all transactions in the block

Inside every block, are stored the transactions. The transaction in a Bitcoin's blockchain means a ledger for transferred amount of cryptocurrency from one owner to another, as shown on Figure 2.

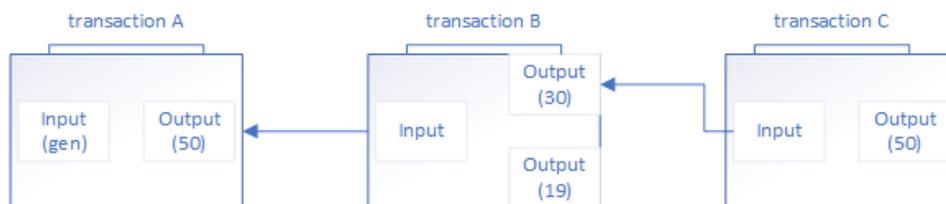

Fig. 2 - Transactions stored inside a Bitcoin's block. In transaction A, the owner initially owns 50 units. In transaction B, he sends 30 units to another owner in transaction C and keeps 19 units for himself. Note, one unit is lost for the transaction fee.

"Blockchains are distributed digital ledgers of cryptographically signed transactions that are grouped into blocks. Each block is cryptographically linked to the previous one after validation and undergoing a consensus decision. As new blocks are added, older blocks become more difficult to modify. New blocks are replicated across all copies of the ledger within the network, and any conflicts are resolved automatically using established rules." (Yaga et al., 2018)

As seen from Figure 1, every block (except the first block also called "genesis block") keeps the hash of the previous block header in hashPrevBlock header field. Noticeable here is hashMerkleRoot field, which keeps the integrity of the included in the block transactions. Hence hashPrevBlock relations between the blocks in the chain, protects the whole chain integrity. If an attacker modifies a transaction in earlier block, he will modify the hashMerkleRoot value which will affect attacked block header hash. After that, the next block's hashPrevBlock value will be wrong, so the attacker must alter all subsequent blocks in order to keep the blockchain's integrity. And here comes where the "Distributed" word in Distributed Ledger Technology takes place. Every new block or sequence of blocks (fork) should be successfully tested against some specific rules (for example longer fork wins) from a given amount of DLT nodes in order to be accepted. Moreover, every transaction must evaluate to true in a given application (also known as "smart contract") to become a part of a block. The whole process is called consensus.

According to the Hyperledger fabric documentation, consensus is a broader term overarching the entire transactional flow, which serves to generate an agreement on the order and to confirm the correctness of the set of transactions constituting a block. (Hyperledger, 2018)

The consensus is crucial part of the system based on DLT. That's because of the nature of different usage purposes. In the permissionless systems, there is an absence of trust. The consensus is based in a form of byzantine fault tolerance algorithm, based on "proof of work" which is based of huge waste of energy (Hern, 2017) and slows down the block acceptance speed and more practically important - the transaction speed.

But the enterprises or governments rare operates in environment with such lack of trust. They operate among a set of identified and known nodes. So, they operate in an environment with a certain degree of trust. Hence the permissioned model is more suitable for them and more simple and fast consensus protocols could be applied like crash fault tolerant and byzantine fault tolerant based. The DLT based on the permissioned consensus is in the focus of this article.

5. The points of interest

In a previous section, we take a brief look over the important concepts in GDPR. Specific organizational and technical measures should be taken in order to be compliant.

Transparency for example, is needed to the organization to can proof how the data is used. There should be a non-repudiation way to can organization proof who accessed this data.

Accuracy is another example. The data should be in-time altered or even erased if needed and all participating parties should receive the altered data or delete it.

Storage limitation is also complicated technical requirement. It also dictates, that data should be anonymized and deleted when no longer needed or at individual request. Also, reidentification risk should be taken in mind. Direct identifiers must be avoided - **“data that can be used to identify a person without additional information or with cross-linking through other information that is in the public domain.”** (ISO, 2008). Hence, the pseudonomization of personal data is a mandatory requirement.

Confidentiality and data integrity - how the data can be altered, accessed, deleted etc. Have the accessing entity enough permissions to do so and what access level exactly have and of course - who grants these rights.

Every data modification or access should be accounted. Data protection by design and more importantly - by default, is really required.

The requirements are so complex and of course single solution is hard to be found. At first glance, the DLT fits here. The blockchain implementation has its intrinsic abilities: data integrity, non-repudiation, data distribution. But at a second glance, some great issues can be found: lack of confidentiality, lack of access control, impossibility data to be forgotten etc. Yes, that is true. But only for the public (Zheng et al., 2017) blockchains like Bitcoin, Ethereum, Iota etc.

6. Hyperledger fabric

Hyperledger fabric framework (Hyperledger fabric, 2018) is one of the projects hosted by Linux Foundation together with IBM. With its modular architecture, it helps developers to create a blockchain based system for data distribution and control but avoiding permissionless blockchains drawbacks especially in the part of data confidentiality and access control. Thanks to its new architecture called execute-order-validate, the goals as flexibility, performance and confidentiality can be achieved in very convenient way.

Confidentiality comes together with a concept of channels. Channels are the virtual “way” to separate data available to organizations. Only allowed nodes could join the channel and it is nearly impossible rogue node to join in and eavesdrops the data in it. Node could be added in the channel only from an entity with the permission to do so. One node could join several channels. In the Figure 3 Organization 1 has two nodes in channel 1, but organization 2 has only one. However, Organization 1 peer 1 is joined in two channels channel 1 and channel 2, but channel 2 includes Organization 3 also.

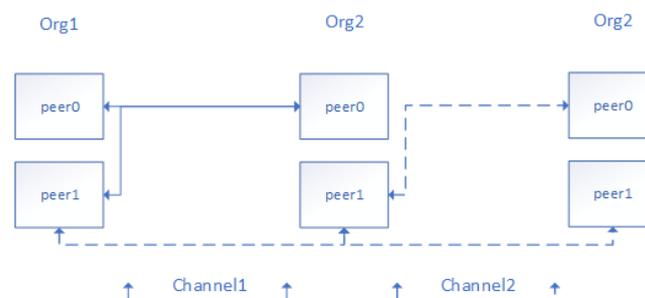

Fig. 3 - Hyperledger fabric channels concept. Three organizations with two channels. Transactions passed to the channel are distributed only over the participants in this channel. Every peer can join one or more channels (Org1.peer1), but they are still isolated from each other.

Node, that maintains the state of the ledger is called “peer”. But the peer can handle a special role as endorser. Once the channel is created and the allowed peers are joined, the chaincode should be installed. Chaincode is an application written on Golang or Node.js, which defines the “smart contract”.

Chaincode and the data in the channel are available only to the nodes, participating the channel, preserving confidentiality. Generally speaking, the chaincode “decides” if the proposed transaction is valid or no. In a greater detail, it could be very complex program with a lot of business logic inside.

Instantiation of the chaincode is important step afterwards. Instantiation must be completed on every peer, who should be an endorser. During instantiation endorsement policy is set. This policy defines which and how many peers (endorsers) should execute the installed chaincode on the selected channel against the transaction, in order to prepare it for future processing from the ordering service. The endorsement policy could look like:

“(Org1.peer0 OR Org1.peer1) AND (Org2.peer0)” which means the transaction must be endorsed from one of two Org1 peers and especially from Org2.peer0

If the received endorsements satisfy the policy, the client’s node will send the transaction to the ordering service node also known as “orderer”. Orderer “checks” the transaction endorsements again and if they are valid, “burns” the transaction into a block and broadcasts the block to the peers.

Hyperledger fabric provides identity management service that authenticates every network participant. Every step in the process flow is secured and satisfies “non-repudiation” principle.

From the GDPR’s point of view it fits well technically in Accountability and Traceability requirements. It is undeniable who, when and what sent to the channel. It is also clear when the given organization is added in this channel and who grants the permissions to a given entity to do so.

Cybersecurity aspect in GDPR also could get benefits. Exceptionally strong cryptographic nature of the blockchain combined with identity management provided by Hyperledger fabric, makes the data stored in the blockchain resistant from unauthorized modification. In his article focused over blockchain's role in a cybersecurity (Kshetri, N., 2017), Nir Kshetri makes a deeper research about blockchain's role in strengthening cybersecurity and data privacy. He also noticed the blockchain's role in a post-breach resilience plan and implementation.

The technology has also another great benefit - it is distributed. That means, that even a large set of peers to be out of order, if the topology is scaled properly the availability of the service is not affected. When the failed peer goes in active state, it could sync the blockchains from any other peer.

Hyperledger fabric is applicable in the Accuracy also. Hyperledger fabric distributed ledger consist of two components. World state and transaction log. World state keeps the current ledger state, but transaction log keeps all previous transactions which leads to the current world state. Thus, once the transaction is ordered and broadcasted to the peers, all parties included in the channel will see the new data almost immediately.

7. Related work

The possible blockchain usage together with GDPR frameworks isn't isolated research. An elegant solution for "The right to be forgotten" conflict with the blockchain's Immutability, proposed the Chainfrog company in its article (Chainfrog, 2017). They propose several options like: record personal data pseudo-anonymously; encrypt the data on the blockchain; store the data in a referenced encrypted database. But Chainfrog's article raises another concern, about the right of EU persons to contest automated decisions which addresses smart contracts - as programmed logic aka. automated decisions. Another article that analyzes the impact of the GDPR over the blockchain technology is "A guide of blockchain and data protection" (Maxwell and Salmon, 2017). It provides a good overview about hashing technology, variety of blockchain systems, blockchain data protection impact assessments and their impact with data protection principles. In parallel “Gran Thornton” company (Gran Thornton, 2018) also provides solution about data removal, data modification and confidentiality, based on logical "private channels" with encrypted data available only to the participating nodes. Each time when nodes need to update or remove data, the corresponding decryption key of the old data should be removed.

8. Conclusion

The blockchain framework Hyperledger fabric has a lot of advantages, which can be used in conjunction with any software for data processing, even those required for very strict GDPR operations. Hyperledger fabric scalability, modularity, all levels identity management, confidentiality and privacy features build on top of intrinsic blockchain distributed and secure nature, seems to be the right technology candidate here. The benefits from such framework architecture would be:

- It facilitates the fulfillment of contractual obligations of controllers and processors involved in the transmission and processing of personal data;
- It strengthens the credibility of participating organization's confidentiality policies;
- It integrates a level of trust in data exchange interfaces with other organizations;
- Ensures evidence in inspections and investigations;
- Creates opportunities for clear policies and procedures for personal data breaches.

But there is an issue. An issue which confirms the sentence “there is no single development, in either technology or management technique, which by itself promises even one order-of-magnitude improvement within a decade in productivity, in reliability, in simplicity”. (Brooks, F., 1986) The issue with a fundamental blockchain feature: The blockchain is immutable.

It is very difficult to do any modification in a block already added. That could lead to some difficulties from the GDPR point of view. Especially with one right of the data subject - Right to erasure ("Right to be forgotten"). Even if the controller issues a transaction to delete data from the world state component, the data is still in the transaction log. It is still in the blockchain, stored securely in every one peer's storage.

The present article leaves this problem for a future research. The possible solutions should not be searched with blockchain hacks like "editable blockchain" for example. The better approach should be to combine existing technologies patterns with the newly unleashed features of the blockchain.

Algorithms for graph isomorphism. A comparative study

Gheorghica Radu-Iulian^{a*}

^a Babeş-Bolyai University, Str. Mihail Kogălniceanu, nr. 1, Cluj-Napoca, 400084, Romania

Abstract

Motif graphs are subgraphs that occur multiple times in a network or a variety of networks. The matching of such graphs bears the name “graph isomorphism”. Each subgraph is defined by a set of interactions between nodes and can provide insight about the functionalities of a network that is why, counting them represents a challenge regarding execution times. Given a query graph q and a data graph g , we aim to find all occurrences of q in g . They have practical implementations in biochemistry, neurobiology and for any problem that can be modeled using graphs. We will describe a comparative study between two existing algorithms, namely VF2 and GADDI, by looking at their pruning techniques and execution times using the Python implementation that I have made in my training stage.

Keywords: Graph; motif; isomorphism; network.

1. Introduction

An induced subgraph (Wikipedia Induced Subgraph) is formed from a subset of the vertices of the graph from which it is extracted that also keeps the edges between them. A network motif is an induced subgraph with the number of occurrences of at least the value of a predetermined threshold. Finding a motif in a network describes a characteristic of said network and such detection is a computationally challenging problem. It has uses (Wikipedia Network Motif) in biochemistry (Figure 1), neurobiology, ecology, genetics, engineering and any domain whose problems can be represented as graphs.

2. Literature review. Definitions. Algorithms

There are two types of research directions:

- Subgraph isomorphism: Verifying the existence of a graph in one or more networks and deciding if such a graph is a “motif” according to a minimum number of occurrences (Ullmann (J. R. Ullmann, 1976), VF2 (Cordella et al., 2004), GADDI (Zhang et al., 2009), QuickSI (Shang et al., 2008), SPath (Zhao and Han, 2010), GraphQL (He and Singh, 2008))
- Graph mining: Verifying the existence and counting of frequent subgraphs in one or more networks (gSpan (Yan and Han, 2002)).

Definition (Wikipedia Induced Subgraph): Let $G = (V, E)$ and $G' = (V', E')$ be two graphs. Graph G' is a subgraph of graph G (written as $G' \subseteq G$) if $V' \subseteq V$ and $E' \subseteq E \cap (V' \times V')$. If $G' \subseteq G$ and G' contains all of the edges $\langle u, v \rangle \in E$ with $u, v \in V'$, then G' is an induced subgraph of G . We call G' and G isomorphic (written as $G' \leftrightarrow G$), if there exists a bijection (one-to-one) $f: V' \rightarrow V$ with $\langle u, v \rangle \in E' \Leftrightarrow \langle f(u), f(v) \rangle \in E$ for all $u, v \in V'$. The mapping f is called an isomorphism between G and G' (Diestel, 2005).

When $G'' \subset G$ and there exists an isomorphism between the subgraph G'' and a graph G' , this mapping represents an appearance of G' in G .

The number of appearances of graph G' in G is called the frequency F_G of G' in G . A graph is called recurrent (or frequent) in G , when its frequency $F_G(G')$ is above a predefined threshold or cut-off value.

13:     end for
14: end if

```

For the implementation of the following two algorithms I have used the Python programming language and NetworkX as a means for creating and manipulating undirected graphs. The core of these backtracking algorithms are the pruning techniques, designed for ruling out unnecessary candidates from the data graph.

Refining the candidate set for the query graph means less resources spent on trying to match the query algorithm to one of many data graph induced subgraphs.

Unless the query graph can be fully matched to one of the data graph subgraphs, we cannot consider it an embedding.

This means that at some point in the matching process if a part of the query graph cannot be matched, we already wasted system resources by attempting to find a full embedding, only to discard the already matched query vertices and restart the matching process while risking the same partial matching.

In the Figure 1 there are two examples.

GADDI removes any vertex v in the candidates set $C(u)$ if for each query vertex $u' \in N_k(u)$ there is no data vertex $v' \in N_k(v)$ satisfying the following conditions:

1) $L(u') \subseteq L(v')$ - The labels of the selected query graph vertex must be included or equal to the label of the selected candidate vertex from the data graph. For example, in Figure 1(a) we have node u_2 with label "B", which according to the first rule, can be considered for a match with vertices v_2, v_5, v_7 and v_8 , even if for vertices v_5 and v_7 we have composite labels. From the implementation point of view, we must verify if every element of the query vertex label set exists in the set which represents the data vertex label. If true, then we can proceed to apply the second pruning technique.

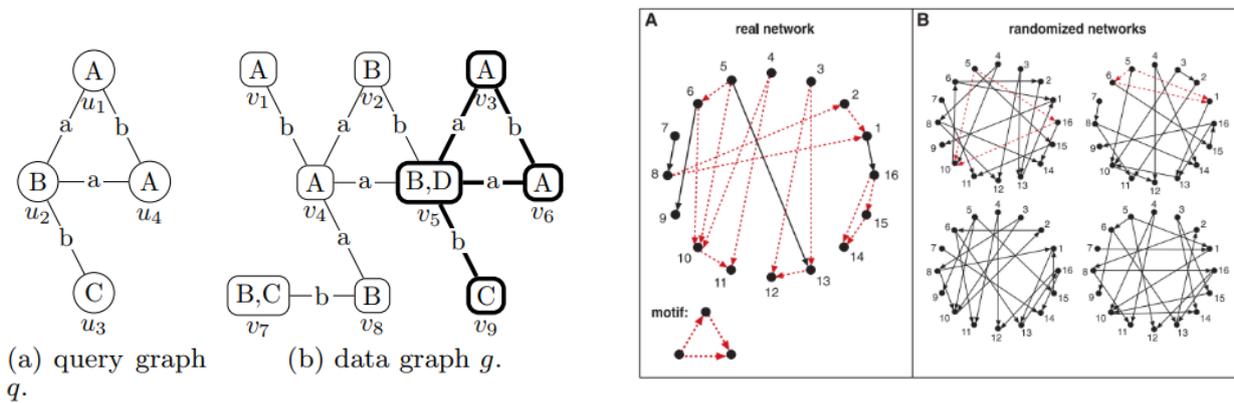

Fig. 1. (a) query graph and a data graph (Jinsoo Lee et al., 2012); (b) motif graph, a real network and randomized networks (Milo et al., 2002)

2) for each P_i in a given set of substructures, $\Delta NDS(u', u, P_i) \leq \Delta NDS(v', v, P_i)$ - First, we will see how we obtain the set of substructures. We can do this either by using a frequent subgraph mining tool or a subgraph isomorphism algorithm. The mining tool approach proceeds as follows: according to Jinsoo Lee et al., 2012 and Zhang et al., 2009 the three most frequent substructures are obtained by first randomly choosing 100 edges from the data graph. For each edge, we use its vertices to obtain two neighbourhood graphs of radius k , with k being an input parameter for the algorithm. For example, given a vertex, a neighbourhood graph of radius = 1 is formed by including the adjacent vertices of said vertex along with the edges between it and those neighbours and the edges connecting the neighbours.

For radius = 2 I include the neighbours of the previous neighbours and their respective edges and so on. After obtaining two such neighbourhoods we generate a graph by intersecting the sets of edges for them. In our case, even though our dataset graphs are undirected, the order of the vertices in an edge can still affect the outcome of this intersection. Thus, instead of doing an intersection of two edge lists, which in turn are lists of two elements representing vertices, I have used the “has_edge” method of NetworkX which returns “True” whenever the case, regardless of the order of vertices in the edges.

We store the 100 intersection-graphs in a file under a format that can be interpreted by a frequent subgraph mining tool. For this I have used a command line tool (Betterenvi, 2018) that implements the gSpan algorithm. This tool has another useful feature that makes possible specifying the graph in which each frequent subgraph is found. We will see further on how we apply this.

The manual tool usage is not feasible since due to the randomness of the 100 intersection-graphs, there are very small chances the input files will be the same. So one way I have implemented this is to initialize the console interface of the tool by using specific Python commands and issue the mining initialization automatically. This proved not to be useful, because the Python program would either not wait for the execution of the tool, or I would have to ask for keyboard input which would have been provided in case the tool was finished. It would only have been the initial problem under a different shape. Also, sometimes the tool would raise a memory error and the mining results would be partial.

So, using “pip”, the Python package manager, I have installed the mining tool, imported the package in the project, and called the methods of the tool, avoiding the usage of the console interface altogether. After generating the frequent subgraphs, we read the gSpan output files and generate undirected graph objects using NetworkX. The new graphs do not have the same vertex IDs (not labels; in Figure 1(a), the node with ID = u_1 has the label “A”). This can be considered a bridging between the different IDs of the generated graphs and the ones that will be generated and are necessary in order to have a complete implementation of the $\Delta NDS()$ method.

Afterwards, I create a matrix having 100 lines, corresponding to the 100 intersection-graphs, and as many columns as the number of frequent subgraphs generated by gSpan.

This is where we need the list of graphs in which each of the frequent subgraphs are found, as previously mentioned. For each frequent subgraph object, we attach its corresponding list as a property using NetworkX.

We need this in order to access the ID of each graph in the list and use it as a column selector. Each element of the matrix will either have its value equal to 1 or 0. This means that in an intersection-graph (a selected line of the matrix) either none of the frequent subgraphs exist, in which case the value on each column would be 0, some or all of them may exist, meaning that the corresponding element or elements in the matrix would be 1.
