According to Zhang et al., 2009 I can select frequent subgraphs of either three or four edges, in order to save computation time and not take into account the labels for vertices or edges for the same reason. I have found that we can further optimize this by selecting only the frequent subgraphs with that number of edges that are also found in each of the intersection-graphs. We can easily do this by checking for each “where” list if all of the original 100 graph IDs can be found.

Next, in a unidimensional array with its length equal to the width of the described matrix, we will store in each element the sum of all the elements from each column. We will retrieve the three highest valued elements and then their corresponding frequent subgraphs by using the column coordinate as the graph ID.

These will be the top three most frequent patterns for which we will count the existence in the query graph and the data graph. For the following procedure I have multiple attempts and due to implementation difficulties, I will describe it as a future development plan.

The number of occurrences of each of the three most frequent patterns will be returned by Δ NDS (vertex_1, vertex_2, Pi) like this: just like before we will need to generate an intersection-graph, but only for the two vertices given, and then using gSpan we will obtain the most frequent subgraphs for it and then count how many times we find the selected most frequent pattern Pi in these subgraphs.

We then return this counter as output data of the method. Since, as mentioned before, gSpan reassigns IDs for vertices as 1, 2, and so on, we only have to check the equality between the IDs of the vertices. I also provide for this method input parameters to specify the radius of the neighbourhood graphs and if the method should search in either the query or the data graph.

Due to the small implementation difficulty described previously, I attempted an alternative approach to generate the three most frequent subgraphs, without using a mining tool (Yanagiba, 2013). Its execution time is larger, but it is easier to understand the process of generating such patterns. Here I used only subgraphs with three edges. First, using NetworkX we generate a complete graph with three edges that will serve as a model for the frequent subgraphs.

By trying combinations of three edges at a time taken from the data graph, we verify which of these edges are connected between each other. For those that are, we store them in a list. I make a copy of the list and for each element in one list, I verify if it is isomorphic with each one from the second. We could optimize this by recording which of the subgraphs in the second list are isomorphic with the selected one from the first list, such that when we reach them in the first list, we could simply skip them. Then, whenever two such subgraphs are isomorphic, we count that as an occurrence and at the end of this procedure we will select the subgraphs with the top three number of occurrences.

Whenever we will call Δ NDS (vertex_1, vertex_2, Pi), we will do it for each of these three and count their occurrences in the intersection-graph generated for the two input vertices in the same manner as we did before. The two vertices will be selected from the query graph and another two from the data graph and will be executed for all three most frequent subgraphs.

If the counting value of the first is less or equal to the counting value of the second, we proceed to apply the third pruning technique. As a small example, we have the following undirected graph represented as a set of edges: [(0, 1), (1, 2), (2, 3)]. It is isomorphic with [(1, 0), (1, 2), (2, 3)], [(1, 2), (0, 1), (2, 3)] and [(1, 2), (1, 0), (2, 3)]. It is not isomorphic with a graph having four edges, so to do this check we must extract all the subgraphs with three edges from it.

3) the shortest distance between u' and u is greater than or equal to the shortest distance between v' and v .

We can do this by using NetworkX for returning the shortest path length for each of the two vertices. The vertex v' belongs to the neighbourhood of radius k for the vertex v . We have the same for u' and u .

For VF2 there are the following three pruning rules to refine the data vertex candidates:

(1) I remove any candidate vertex of the query vertex such that they are not connected from already matched data vertices. With this, I am sure that no such candidate data vertex has any edge between it and any of the candidates that have been matched with query vertices.

(2) Let M_q and M_g be a set of matched query vertices and a set of matched data vertices, respectively. Let C_q and C_g be a set of adjacent and not-yet-matched query vertices connected from M_q and a set of adjacent and not-yet-matched data vertices connected from M_g , respectively. Let $adj(u)$ be a set of adjacent vertices to a vertex u . Then, prune out any vertex v in $C(u)$ such that $|C_q \cap adj(u)| > |C_g \cap adj(v)|$. For this, we make a list in which we hold the candidate vertices in lexicographic order. We make the first intersection which is $C_q \cap adj(u)$, we do the same for $C_g \cap adj(v)$. The next step is to check if the number of elements in the first set is larger than the ones in the second set. If true, we eliminate v from a separate list in which we keep the candidates and from which we can safely remove them as necessary.

(3) We also remove any vertex v in $C(u)$ such that $|adj(u) \setminus C_q \setminus M_q| > |adj(v) \setminus C_g \setminus M_g|$. In this case, we make the first subtraction. For every element in C_q , we remove the ones that have the same ID as any of the neighbours of radius = 1 of u . We do the same for M_q and we repeat the whole procedure for the data vertex v .

3. Experimental results

Table 1. Execution times, first match $M = [{"u1"}, {"v3"}]$ for the small dataset, $M = [{"0"}, {"0"}]$ (test for result accuracy) and $M = [{"0"}, {"1173"}]$ for the large dataset (Ferro et al.).

Algorithm name	Small dataset[han], $M = [{"u1"}, {"v3"}]$	Large dataset[RI], $M = [{"0"}, {"0"}]$	Large dataset[RI], $M = [{"0"}, {"1173"}]$
VF2	0.0025462 seconds	2.4848946 seconds	7.5494961 seconds
GADDI, radius = 2	94.5596868 seconds	6 to 12 hours	6 to 12 hours

3.1 Computer specifications:

- Processor: Intel(R) Core(TM) i7-6700HQ CPU @ 2.60GHz
- RAM: 8.00 GB
- System type: Windows 10, 64-bit
- Disk: Intel SSD 240 GB.
- Python version: Anaconda, Python version 3.6

4. Future development

- Prevent the case when sometimes 1 or 2 extra edges would appear in the final result.
- Finish the Δ NDS (vertex_1, vertex_2, Pi) version in which I use gSpan.

5. Conclusions

In this paper I have studied two algorithms for isomorphism finding: GADDI and VF2. For this, I made my own implementation without using the original authors' source code, but only by studying the articles. I described the essential parts of the implementation and made a comparison of the execution times using a small and a large dataset.

Abstract

The main objective of this paper is to investigate control tracking performance of a digital Proportional Integral Derivative (PID) controller, used as an alternative to a continuous PID controller, in order to prove the effectiveness of this control design approach for improving plasma quality of a Reactive Ion Etching process in semiconductor manufacturing industry. The design methodology presented takes place in an attractive real-time MATLAB SIMULINK environment as one of the most powerful software tools provided on the IT software market. Reactive Ion Etching process is a critical technology for modern VLSI circuit fabrication used in many stages of the manufacturing process. This research work is motivated by the fact that in most of cases the semiconductor equipment is designed to operate at low efficiency in open-loop. Moreover, the Reactive Ion Etching (RIE) is a highly nonlinear and multivariable process, thus the standard continuous PID controllers are not very robust, requiring frequent parameters tuning to achieve acceptable plasma quality performance for different operating points. All of these investigations lead us to the conclusion that by using a most accurate linear Autoregressive Moving Average (ARMA) model of a fully decoupled open-loop RIE process for closed-loop digital PID control design approach it has the capability for controlling the appropriate key plasma parameters such as the Fluorine concentration ions and their dc energy, and is feasible to improve the plasma etching quality indicators of the reactive ion etchers in terms of their selectivity, uniformity, anisotropy and etch depth.

Keywords: Plasma RIE quality etcher; Digital PID control design; ARMA model; PGS.

1. Introduction

The Reactive Ion Etching (RIE) process in radiofrequency glow discharges is among the most methods used for forming via holes in between metals layers in a multichip modules (MCPs) and for achieving the level details necessary to define small features in films as is mentioned in (May et al., 1991), (Tudoroiu, 2001), (Tudoroiu et al., 2003). It is an increasing demand for using the plasma process, especially in VLSI thin film etching applications. Plasma processing assures a valuable control of the composition and of the profile for these components and processes. Vital requirements such as achieving robustness and high quality of the electrical connections and minimum feature sizes for the Metal Oxide Semiconductor (MOS) devices are obtained by controlling the main etching characteristics of the RIE process, among them can be mentioned the etching rate, anisotropy, selectivity, uniformity and etching layer depth. For an application, the etching rates to obtain a good enough throughput in a single wafer tools while the wafer sizes increase, as well as of the anisotropic profiles, the selectivity over thin gate oxides, uniformity and the directionality of plasma processes are optimized by choosing an appropriate selection of the chemical reactants and of the operating conditions for the RIE process equipment. Better insight view of the etching process is essential in improving the control of the etching characteristics of the RIE process to assure a high quality and the future productivity for at very large-scale integration (VLSI) fabrication processes. The paper is organized as follows: in section 2 a brief overview of the RIE process will be covered. In section 3 we present a standard digital PID control design based on a discrete ARMA PGS plant model approach, as preliminary result from our research in this field obtained in (Tudoroiu, 2001). In section 4 will be presented the main MATLAB simulation results for the proposed approach.

E-mail address: ntudoroiu@gmail.com

Also, for comparison purpose will be analyzed the quality performance and will be proved its effectiveness such that to be used successful in RIE process control. In section 5 will summarize the main contributions of the research paper and we will address some guidelines for the future work.

2. The Reactive Ion Etcher description

In this section a brief description from control perspective of the RIE process, equipment and system architecture is made. The attention is focused only on the overall system behavior rather than on individual physical or chemical processes within the plasma reactor and the wafer. The control design is a very hard task since the RIE process is highly nonlinear and multivariable as is revealed in detail and well documented in (Elta et al., 1993), (May et al., 1991), (Hamby et al., 1995), (Hankinson et al., 1997), (Patterson et al., 1977), (Rashap et al., 1995), (Tudoroiu et al., 2003), (Tudoroiu, 2001), (Vincent et al., 1997). Most of plasma control systems are conceived to control the wafer etcher characteristics with the input variables pressure and Radio Frequency (RF) supplied power, and gas flow rates. Well there is no a particular standard and known procedure to follow for inputs selection to predict the etch performance in different machines or identically, or even in the same machine on two different runs as is shown in (Elta et al., 1993), (Hamby et al., 1995), (Hankinson et al., 1997), (Patterson et al., 1977), (Rashap et al., 1995), (Vincent et al., 1997), explained by the variations in plasma properties, and the presence of the disturbances inside the plasma reactor. Also, there is a significant amount of uncertainty in open-loop control system. This is our motivation to design a robust controller that takes into consideration all these disturbances and uncertainties about the process, as well as the nonlinearity and multivariable nature of the RIE process. The RIE process considered in our case study takes place in a plasma reactor – an Applied Materials 8300 Hexode reactive Ion Etcher used at the Control Laboratory of the Michigan University. It is equipped with a high-tech data acquisition system, actuators and sensors appropriate for real-time open-loop or closed-loop feedback control architectures. This reactor is a parallel plate Plasma Reactor Etching system 1000TP type whose configuration is shown in Fig. 1, as in (Elta et al., 1993), (Tudoroiu et al., 2003), (Tudoroiu, 2001).

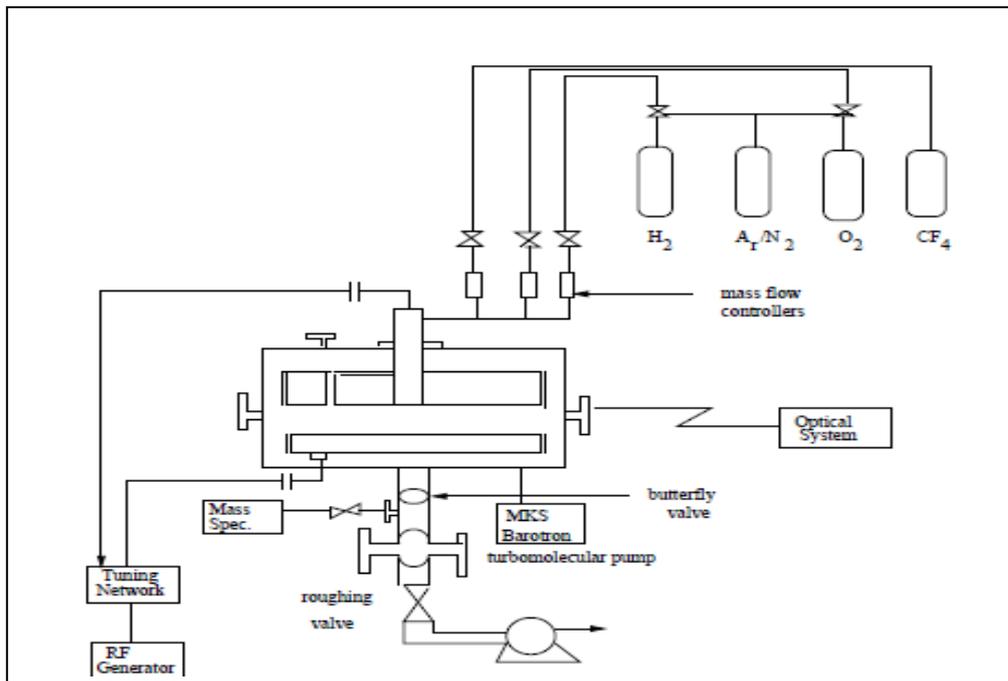

Fig. 1. The layout of the plasma reactor etching system (snapshot view from Tudoroiu, 2001)

More details about this type of plasma reactor can be found in (Elta et al., 1993). Its conceptual decomposition is shown also in figure 2, consisting of two main functional blocks:

- Plasma Generation Subsystem (PGS);
- Wafer Etch Subsystem (WEF).

These sequential subsystems separate the generation of the important chemicals and physical species from the etching action on the surface of the wafer, as is mentioned also in (Tudoroiu et al., 2003), (Tudoroiu, 2001). The two inputs chosen for the PGS are the RF Power and throttle valve position, and as outputs are considered two key plasma parameters fluorine concentration $[F]$ and dc bias Voltage $[V_{bias}]$. Consequently, the PGS subsystem is a Multi-Input Multi-Output (MIMO) control system (*multivariable*) with 2 inputs and 2 outputs, as is shown in Fig.2, (Tudoroiu, 2001).

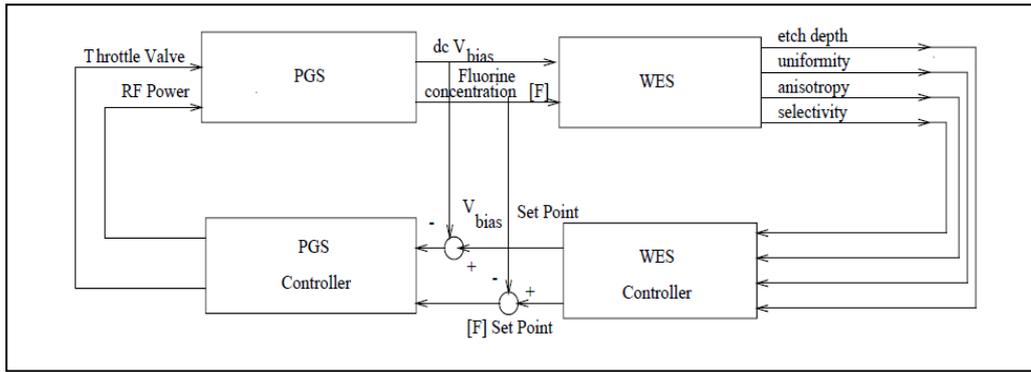

Fig. 2. Schematic diagram of the decomposed structure of the RIE system (snapshot view from Tudoroiu, 2001)

3. Digital PID real time controller driving a PGS plant ARMA model design approach

To develop and implement a real-time control strategy in this approach, the PGS is considered as a coupling MIMO control system with two inputs (RF power, and the throttle position of the control valve respectively), and two controlled outputs (dc Bias Voltage and fluorine concentration). The disturbances are the wafer load and the water vapor, considered as deterministic. The fluorine is the dominant etchant species of the chemical reactions that take place in the plasma reactor and the dc Bias Voltage is chosen as measure of the physical energy of the impinging ions. To get a good insight on PGS architecture, its SIMULINK model is shown in Fig.3.

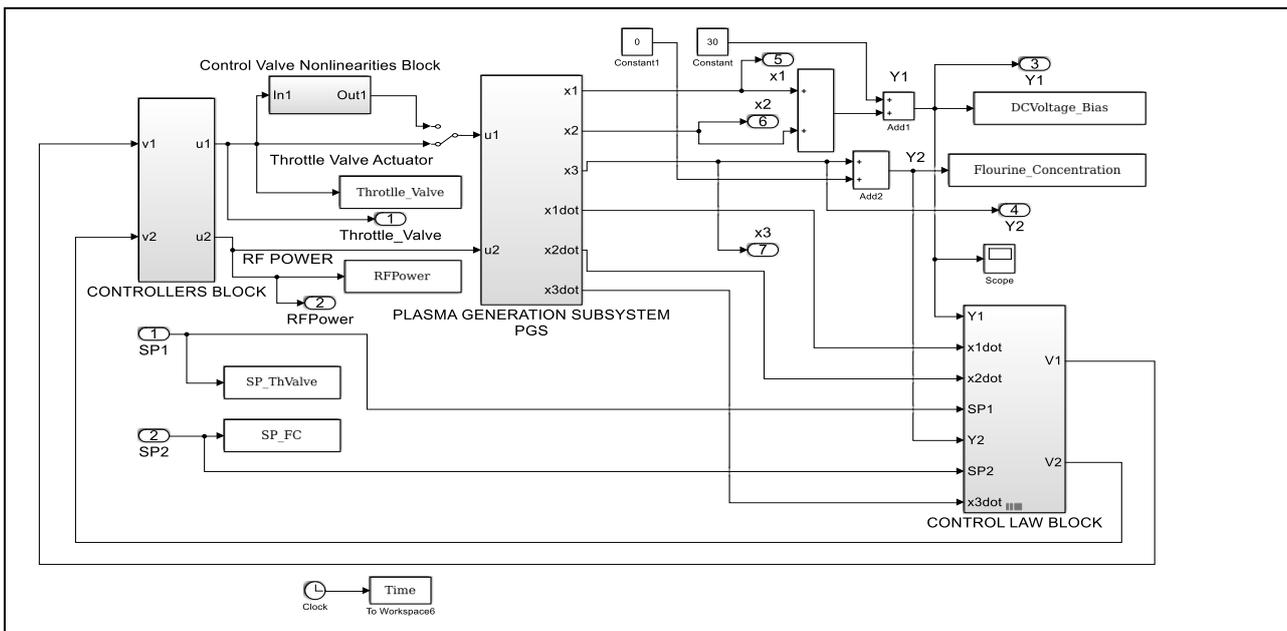

Fig.3. The SIMULINK model of PGS architecture

Technically speaking, the main reason to choose these variables as inputs and outputs of the PGS is firstly to obtain a simple practicable model easy for implementation and a useful support to design different real-time closed-loop control strategies, e.g. a digital PID closed-loop control structure as in our case study. In this approach we consider an Auto Regressive Moving Average (ARMA) PGS model developed in (Tudoroiu, 2001), described by the discrete time decoupled equations:

$$y_1(k+1) = 0.4978y_1(k) + 0.494y_1(k-1) - 2.6879u_1(k) + 2.939u_1(k-1) \tag{1}$$

$$y_2(k+1) = 0.9455y_2(k) + 0.044y_2(k-1) - 0.00001u_2(k) + 0.999923u_2(k-1) \tag{2}$$

Based on the transfer functions in the complex z-domain for each independent channel the design of both PID digital controllers with the SIMULINK blocks is shown in Fig. 4.

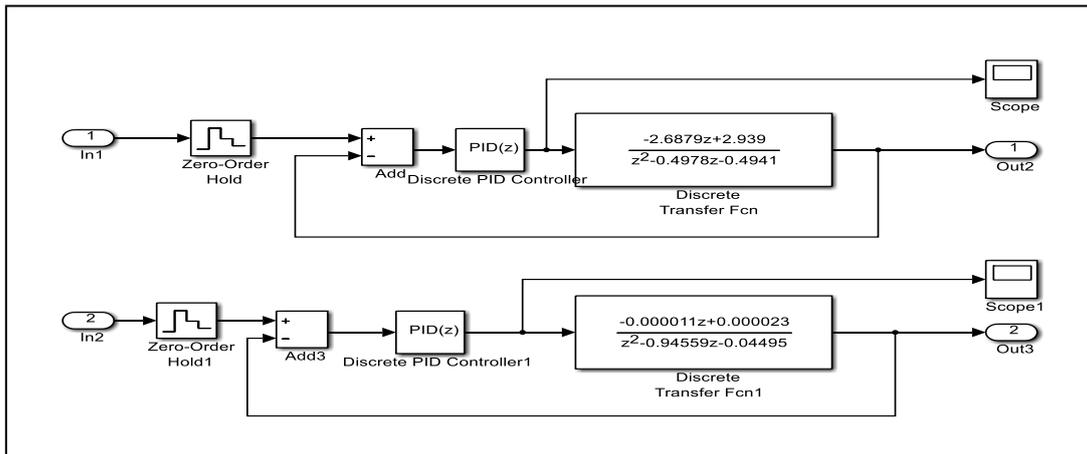

Fig. 4. The SIMULINK model of digital PID PGS ARMA model control approach

4. Simulation results for digital PID ARMA model control design approach

The MATLAB and SIMULINK simulations results for the third control design approach are shown in the Figs. 5 -8.

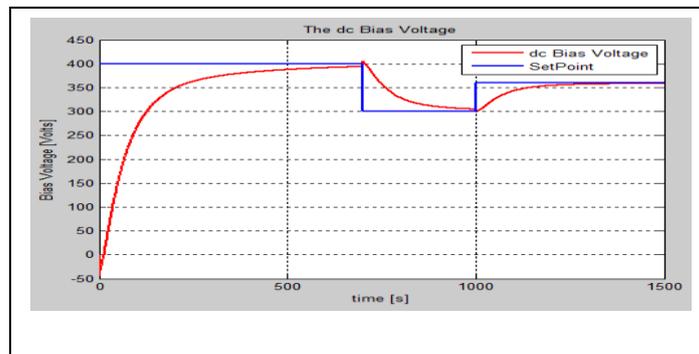

Fig. 5. The MATLAB simulation results for dc Bias Voltage with set point changes

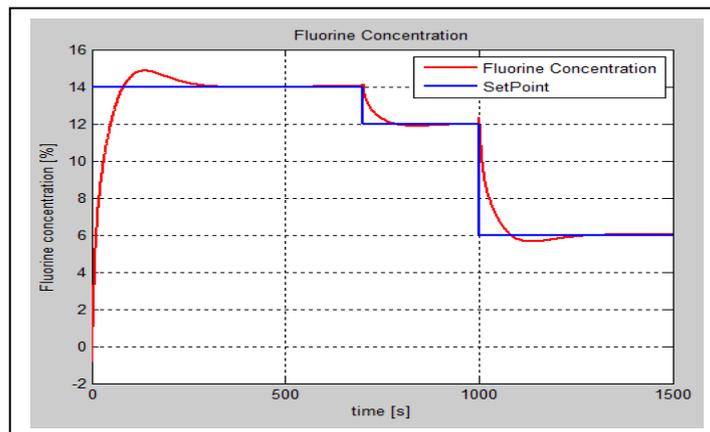

Fig. 6. The MATLAB simulation results for Fluorine concentration with set point changes

In Fig. 5 is shown the evolution of the dc Bias Voltage in this approach with changes in the set point, and similar in Fig. 6 is shown the evolution of Fluorine concentration.

In the both cases we notice a high accuracy of the controllers, but during a long transient, compared to the other control design approaches well developed in [2], for this reason the time scale is changed to $t \in [0, 1500]$ seconds.

In Fig. 7 is shown the efforts of first controller RF Power control u_1 to track the dc Bias Voltage to the changes in input set point.

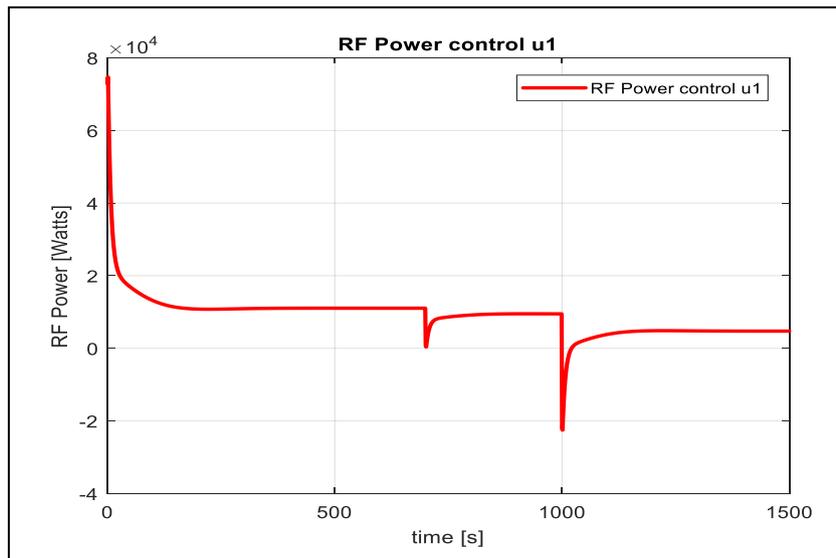

Fig. 7. The RF Power control u_1 efforts to track the dc Bias Voltage

Similar, in Fig.8 is shown the efforts of second controller Throttle valve position control u_2 to track the Fluorine concentration to the changes in input set point.

Also, some robustness tests were made in terms of level noises in the measurement sensors and process, as well as to some deterministic disturbances, and the results were encouraging. Due to space limitations we don't show these additional results. In a future work we will present the results of these robustness tests.

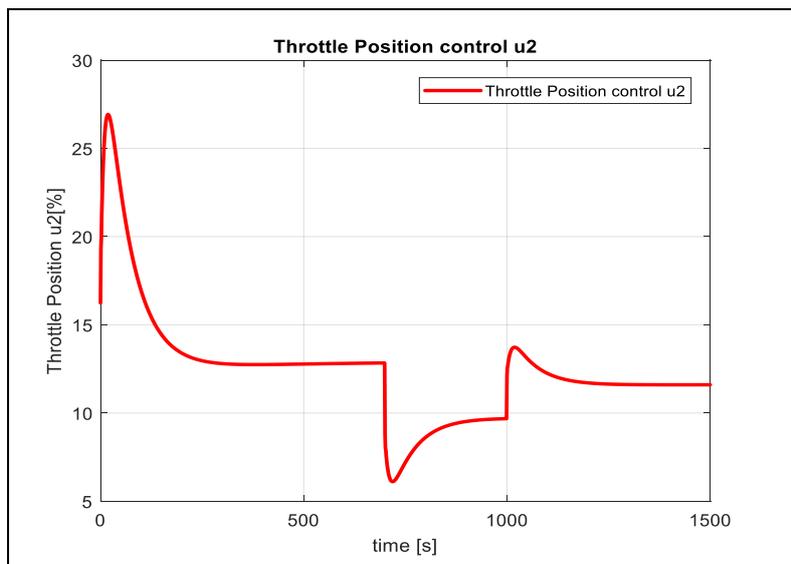

Fig. 8. The Throttle valve position control u_2 efforts to track the Fluorine concentration

5. Conclusion

The novelty of this paper is the implementation in real time of a digital PID controller design based on a PGS ARMA discrete model for a highly nonlinear process such as two-scale plasma RIE process, as alternative to an Observer estimator combined with a robust controller as is developed in Tudoroiu et al., 2003. The simulation results are carried out in an attractive real-time MATLAB and SIMULINK simulation environment and reveal the weakness and the strengths of the proposed control design approach to increase the plasma quality performance in RIE etchers. Closing, it is worth to remark that the quality of control design is dependent of nonlinear process characteristics. Consequently, changing the process a new tuning procedure for the parameters values of the process and controllers must be repeated.

VLC embedded medical system architecture based on medical devices quality requirements

Simona Mirela Rîurean^{a*}, Monica Leba^a, Andreea Ionică^a

^aUniversity of Petrosani, Str.Universitatii, no.20, 332006, Petrosani, Romania

Abstract

Having all over the places wireless data communication has become lately one of the daily habits to all of us. However, as many devices and users hunger for fast wireless Gigabits in the radio frequency (RF) spectrum, the data traffic becomes slower and even jammed. Lately, due to intense research efforts, several possible alternatives to RF data communication has already become mature ready to be launched on the market. One of them is the Visible Light Communication (VLC) technology, not long time ago coined as LiFi. Considering that in many health institutions worldwide using RF for wireless communication is forbidden due to high interferences and therefore potential harmful for patients and damaging effects to medical devices, the VLC data communication emerged as one harmless and suitable alternative. The developed architecture provides communication with/between devices used in the medical environment. This architecture is based on the identification of quality requirements for medical devices according to standards in force.

Keywords: visible light communication; simulation; ISO 13485; EN 60601; medical healthcare.

1. Introduction

Data acquisition and remotely transmission of medical information acquired with the aim of providing expert-based medical care anytime, anywhere to any patient is known as telemedicine. Wireless technologies (Wi-Fi, Bluetooth or ZigBee, WiMAX) for telemedicine have become - for years already - increasingly common both in research studies and daily bases use of medical devices.

VLC, coined in 2011 by Prof Harald Haas - during a TED Conference - as LiFi, has emerged as a new viable alternative solution for wireless data communication, especially for indoor areas where Wi-Fi becomes overcrowded. A special importance for the LiFi is drawn by the medical situations (facilities or medical devices) where RF technologies are limited or even forbidden. LiFi refers to a fully networked, MIMO, full duplex, data wireless communication through light. The VLC prototypes proposed here are intended to be used in a Line of Sight (LOS) scenario for a simplex data wireless communication from one medical device to another in order to allow fast data wireless communication in RF's forbidden areas.

2. VLC Versus RF Communication for Telemedicine. Past and Future Challenges

Wireless technologies in telemedicine, support many applications, such as, preserving electronic medical records (EMR), monitoring vital signs, transmitting important information in real time from and to medical staff.

Wireless technologies that are currently being used in medical healthcare facilities and medical devices are most of them based on the Radio Frequency (RF), leading to Wireless Local Area Networks (WLAN), Wireless Personal Area Networks (WPAN), Wireless Body Area Networks (WBAN) built around some wireless standards such as Wi-Fi, Bluetooth, ZigBee or WiMAX (Ng and Chung, 2012). The U.S. Department of Health and Human Services (DHHS), published, in 1977, the first regulation to address the effect of electromagnetic interferences on medical equipment (Gutiérrez et al, 2014).

* Corresponding author. Tel.: +40-744-517-396.
E-mail address: simonariurean@upet.ro.

Since the use in medical healthcare of RF wireless technologies is dangerous because of the negative effects imposed by the electromagnetic interference (Warnowicz, 1983), (Silberberg, 1993), VLC emerged as a new, and proved to be, harmless wireless communication technology (Shoaib et al, 2016). RF may cause a wide range of medical devices to fail or send error messages and worst, compromise patients' health and safety (Tan et al., 2001), (Huang and Segal, 2012). Boyle, also showed that radiation from RF sources may result in potentially harmful effects towards patients' health (Boyle, 2016).

In contrast to the RF wireless communication that is subject of high interferences with lots of medical devices, VLC, using Light Emitting Diodes (LED) as main actors in the communication system, have been considered as a safe and suitable replacement for RF (Haas, 2017). Due to their advantages (long operational lifetime, energy efficient, high tolerance to humidity, mercury free, compact size and most important, fast switching) LEDs have already successfully replaced, the conventional incandescent, fluorescent and halogen light sources in many illumination networks.

Beside illumination, LEDs are proposed to serve for data wireless communication (Leba et al., 2017), therefore, the VLC technology using white LEDs to transmit data was first demonstrated by 2003 at Nakagawa Laboratory at Keio University in Japan, based on numerical analysis of optical transmission requirements (Tanaka et al, 2003). The most important quality of LEDs - as Solid-State Devices (SSD) is that they ensure communication due to the high frequency response, allowing the light beam to be intensity modulated to carry data piggybacked by illumination (Komine and Nakagawa, 2004).

In their study, Ng and Chung proposed a wireless VLC-based medical healthcare information system as a practical and harmless alternative to RF wireless technology (Ng and Chung, 2012). Several other studies regarding monitoring vital signals based on VLC have been published, an uplink data transmission was proposed and a wavelength division multiplexing (WDM) based bio-medical signal transmission system was introduced in order to increase data transmission rate (Cahyadi, et al. 2015), (Lim et al., 2015), (An and Chung, 2016). An indoor system based on a hybrid Power Line Communication (PLC) with VLC system were proposed for hospital applications (Song et al., 2015), (Ding et al., 2015). A remote health-monitoring system with a highly efficient optical receiver is implemented using VLC as proposed by Al-Qahtani et.al in 2015 (Al-Qahtanie et al, 2015).

An extended study focused on the architectural concepts of the information system for healthcare administrations to deliver personal or public data service using the medical centres illumination network has been proposed by Hong (Hong et al., 2018).

3. VLC Based Prototype Development for Medical Use

3.1. Prototype's Quality Requirements According to ISO 13485 and EN 60601

The internationally approved standard that draws out all the requirements for a quality management system applied for the medical devices industry is ISO 13485:2016. This standard has been defined in order to be used by specific medical organizations during the life cycle of a medical device, starting with the initial idea to production and post-production, till the final neutralize and disposal. It has been designed to cover aspects like storage guidelines, distribution rules, installation conditions and servicing, as well as the provision of associated services.

The medical device term - according to ISO 13485 - is a product associated with any medical machine, instrument, tool, apparatus, in vitro reagent along with any other similar item intended to be used during the diagnosis process or prevention of illness as well as treatment of disease or any other medical conditions. Today, on the market there are many types of medical devices starting with basic hand tools till sophisticated high-tech machines.

We refer in our paper to the medical resilient devices like:

- wheelchairs (as well as dentist chairs);
- implantable devices like cardiac pacemakers and monitors;
- prosthetic limbs and prosthetic joints;
- life-supporting devices like respirators and lung ventilators;
- sophisticated, software-controlled devices like Computer Tomography (CT) scanners or Magnetic resonance imaging (MRI) machines.

European ISO 13485, as a Quality Management System (QMS) sets the procedures, policies and processes that support an organization in meeting the requirements expected in medical area. It is centered on the Plan-Do-Check-Act cycle, a management method consisting of four steps that are used in business for the control and repeated enhancement of processes and products. In most countries, a QMS is required by regulators in the medical devices industry and qualifies an organization to reliably provide harmless and actual medical devices and achieve specific requirements. Since regulations are quite different from one country to another, ISO 13485 sets general requirements, but requests a medical devices organization to identify those regulatory requirements which are relevant to its individual situation and integrate them into its QMS. Moreover, the standard is compatible with organization's other management systems and allow effectively management of risk, improves processes and efficiency as necessary and gain a competitive advantage.

For the first time, the U.S DHHS received reports (and therefore updated their recommendations) of RF adverse effects on the following electronic medical devices:

- Insulin pumps;
- Electronic devices as cardiac implants (pacemakers and implantable cardioverter defibrillators);
- Neuro-stimulators.

The European standard EN 60601-1:2006 for medical electrical devices suggest general requirements of the many standards for basic safety and critical performance and is widely accepted reference for medical electrical devices and compliance with U.S. IEC60601-1. It has also become a requirement for any electrical medical device launched on the market. This standard defines that all the devices related to vital assistance (critical device) must support a 10 V/m electrical field and that the rest of the devices (non-critical) accept a value of 3 V/m at a frequency from 80 MHz to 2.5 GHz. Furthermore, the standard rules that the medical device must support a magnetic field of 37.8 mG at the industrial frequency (60 Hz). The lowest value set by the standard at high frequencies, is considered 3 V/m, equivalent to 129.5 dB μ V/m due to the simultaneous presence of critical and non-critical devices (Gutiérrez et al., 2014).

3.2. VLC System Embedded in a Medical Device

VLC uses LEDs with white light in the visible spectrum that is not harmful for human eyes and do not affect human’s health at all. According to EN 62471:2008 standard for photobiological safety regulation of lamps and lamp systems, incoherent diffuse continuous-wave-modulated LEDs carry no photobiological hazard for the human eye when the irradiance does not exceed 100 W/m² at a distance of 0.2 m from the optical source in the direction of maximal directivity within 1000 s (Dimitrov and Haas, 2015). On the other hand, optical wireless communication based on infrared IrDA sources is subject of strict regulations (European Directive 2002/95/EC) regarding the long exposer at high heat loads that can interfere with the temperature balance of the body and can cause tissue damage or accelerate skin aging. Chronic exposure to heat can lead to eye disease (e.g. cataract).

The VLC system proposed is according to the general diagram shown in figure 1. LED allows to be modulated at a high frequency to send binary data (0 and 1). Therefore, for an efficient VLC system, the choice of LED type is important. There are two types of LEDs: white LEDs and a single-colour LEDs (e.g., red, green or blue). White light visible by human eye is generated using one of the two techniques:

- the first technique uses a blue LED coated with a phosphor layer that emits yellow light. An amount of a short wavelength light emitted by the blue LED is absorbed by the phosphor layer, so the emitted light from the absorber results in wavelength shift to a longer wavelength of yellow light. This is the best choice due to the lower complexity and cost. However, the slow response of phosphor limits the modulation bandwidth of the phosphorescent white LEDs to a few MHz (Gfeller et al., 1979).
- combining red ($\lambda \sim 625$ nm), green ($\lambda = 525$ nm) and blue ($\lambda = 470$ nm) (RGB) in a correct proportion (like in a colour television), the white light (or any other colour) can be generated. These triplet devices consist of a single package with three emitters and combining optics, and they are often used in applications where variable color emission is required. These devices are suitable for VLC as they offer the possibility of Wavelength Division Multiplexing (WDM).

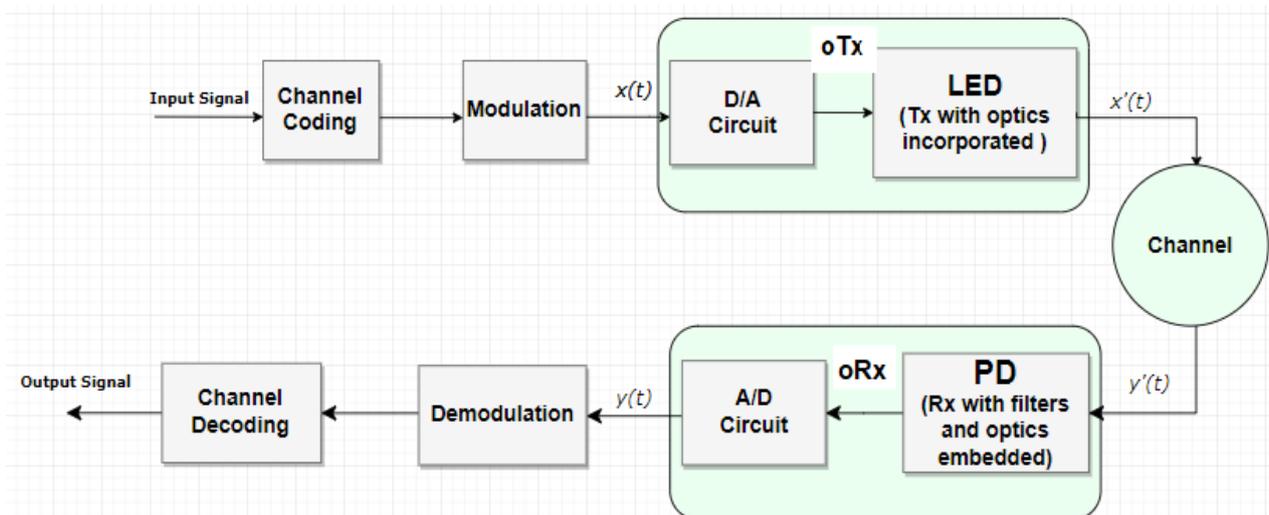

Fig. 1. General Diagram of the VLC system

There are two types of photodiodes (PD) used for VLC: Positive Intrinsic Negative (PIN) and Avalanche Photodiode (APD). APD has higher optical sensitivity (usually 10 dB) than PIN but is also very sensitive to temperature fluctuation. The choice of a detector is made considering its spectral response, area, capacitance and transit-time limited bandwidth effects. The most of the significant signal is carried in the blue range emission, therefore a filter is recommended to be used with the PD. When used with blue filtering, the transmission rate can reach hundreds of Mbps. As shown in figure 1, D/A stands for converting digital signals to analogic, and A/D converts analogic signals into digital signals.

3.3. Optical Channel Gain Simulation Conducted Indoor

The indoor position of the optical transmitter (oTx) and optical receiver (oRx) are important, their radiation/detection characteristics as well as the reflection properties of the objects in the environment, therefore we consider a Line of Sight (LoS) scenario as shown in figure 2. As practical experiments showed, in nature, most reflections are diffuse, therefore we can appropriately use the Lambertian model (Gfeller and Bapst, 1979). In order to obtain the Channel Impulse Response (CIR), we took into consideration in the square room of 3x3x2 m (L x l x h) multiple surfaces as different modules of a system with all having the same reflecting elements (plaster walls with 0.8 reflectivity index) and sum the reflected light at the receiver.

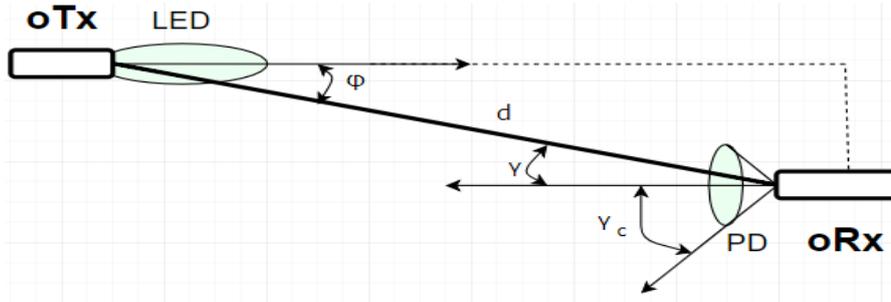

Fig. 2. Geometrical model of the direct NLoS light propagation scenario

The most important characteristics of a LED and a PD as parts of a VLC system are radiation pattern, optical spectral response, electrical modulation bandwidth and the electrical to optical (E/O) conversion. The receiving PD must have a fast response speed in order to properly interpret the transmitted optical signal. We used in our system the two types of LED shown in figure 3.a and PDs shown in 3. b.

We used for our first prototype a 1-Watt cold white LED with (3 chips) from TDS as oTx and 3 Vishay silicon PIN photodiode (fig 3.b left) as oRx. The second prototype has a 1-Watt cold white LED SG-1W as oTx and a BPW PD (fig 3.b right) as oRx.

3. a.

3.b.

Fig. 3. LEDs (3.a.) and PDs (3.b.) used in our prototypes

The first prototype consists of a P001L4Z11 LED made of InGaN/Sapphire, with power dissipation 1365 mW, DC forward current 350 mA, pulsed forward current ($t_p \leq 100\mu s$, Duty Cycle = 0.005) 700 mA, luminous flux 120 lm, forward voltage 3.3V, view angle (ϕ) 130° . Considering spectral sensitivity and response, BPV10 PIN photodiode is our first choice for oRx. This PD (fig 2 b. left) has a radiant sensitive area of 0.78mm^2 , angle of sensitivity $\gamma = \pm 40^\circ$, range of spectral bandwidth $\lambda_{0.1}$ from 380 to 1100 nm and absolute spectral sensitivity $s(\lambda)$ 0.55 A/W at VR = 5 V, $\lambda = 950$ nm. The PD's spectral response is important to coincide with the visible light range of the LED transmitted signal.

The second prototype uses a 1 Watt cold white LED 1WCW3K1A1 with a forward current of 350 mA, power dissipation 1.15 W, forward voltage between 3 and 3.8 V, wavelength Tc (nm) (K) between 8000 and 30000, luminous flux (LM) between 80 and 130, view angle (ϕ) $120^\circ \pm 5^\circ$, peak pulsed forward current 800 (mA) 1/10s and a planar Silicon PIN photodiode BPW20R in a (hermetically sealed) short TO-5 case, designed especially for high precision linear applications. The short circuit photocurrent is linear over seven decades of illumination level, due to its extremely high dark resistance. Then again, there is a strictly logarithmic correlation between illumination and open circuit voltage over the same range. Equipped with a clear, flat glass window, the spectral responsivity reaches from blue to near infrared. It has radiant sensitive area $A = 7.5\text{mm}^2$, the viewing angle of sensitivity $\gamma = \pm 50^\circ$, range of spectral bandwidth $\lambda_{0.5}$ from 550...1040 nm, relative spectral sensitivity $s(\lambda)_{\text{rel}}$ 0.22 A/W at VR = 5 V, $\lambda = 410$ nm and $s(\lambda)$ 0.5 A/W at VR = 5 V, $\lambda = 550$ nm.

The optical LoS link (see figure 2) considered is non-frequency selective with the length relatively short, therefore both attenuation due to the absorption and scattering are very low and we did not consider in this simulation.

The angular distribution of the radiation intensity pattern is modelled using a generalized Lambertian radiant intensity (Carruthers and Kannan, 2002) with the following distribution:

$$R_0(\varphi) = \begin{cases} \alpha \frac{(m_1 + 1)}{2\pi} \cos^{m_1}(\varphi), & \varphi \in [-\frac{\pi}{2}, \frac{\pi}{2}] \\ 0, & \varphi \geq \pi/2 \end{cases} \quad (1)$$

where m_1 is the Lambert’s mode number expressing directivity of the source beam, $\varphi = 0$ is the angle of maximum radiated power.

The order of Lambertian emission m_1 is related to the LED semi-angle at half-power $\varphi_{1/2}$ by:

$$m_1 = \frac{-\ln 2}{\ln(\cos\varphi_{1/2})} \quad (2)$$

The oRx (with the PD area A_{PD}) has an optical band-pass filter of transmission $T_s(\gamma)$ (considered here 1) and a non-imaging concentrator of gain $g(\gamma)$, the DC gain for the Rx located at a distance of d and angle φ with respect to oTx (see figure 2) can be approximated as:

$$H_{LoS} = \begin{cases} \frac{A_{PD}(m_1 + 1)}{2\pi d^2} \cos^m(\varphi) T_s(\gamma) g(\gamma) \cos\gamma, & 0 \leq \gamma \leq \gamma_c \\ 0, & \text{elsewhere} \end{cases} \quad (3)$$

The Lambertian order m is 1 and the optical gain $g(\gamma)$ of an ideal non-imaging concentrator having internal refractive

$$h_{LoS} = \frac{A_{PD}(m_1 + 1)}{2\pi d^2} \cos(\varphi) T_s(\gamma) g(\gamma) \cos(\gamma) \delta(t - \frac{d}{c}) \quad (4)$$

$$g(\gamma) = \begin{cases} \frac{n^2}{\sin^2\gamma_c}, & 0 \leq \gamma \leq \gamma_c \\ 0, & \gamma > \gamma_c \end{cases} \quad (5)$$

index n (considered here 1.5) is (Tanaka, 2003), where $\gamma_c \leq \pi/2$ is the Field of View (FoV).

When $\varphi < 90^\circ$ and $\gamma < \text{FoV}$ and $d > (A_{PD})^{1/2}$ the path loss depends on the square of distance between the oTx and oRx, and CIR is expressed as:

where c is the speed of the light in free space ($3 \cdot 10^8 \text{m/s}$), $\delta(\cdot)$ is the Dirac function and $\delta(t - d/c)$ represents the signal propagation delay.

Using the above-mentioned equation for our first prototype with the distance of 1 meter between oTx and oRx, the channel gain is shown in figure 4.a and for the second prototype channel gain is shown in figure 4.b.

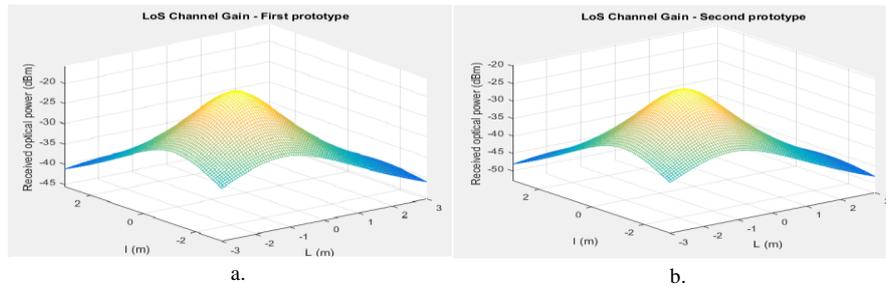

Fig. 4. LoS Channel Gain for the first and second prototype considered

Simulation completed in MatLab (Ghassemlooy et al., 2013) for both prototypes has been done taking into account conditions of the same room (plaster walls with 0.8 reflectivity index, dimensions $l \times L \times h = 3 \times 3 \times 2$ meters), with the same distance between oTx and oRx (1 m), in the same position with the same non-imaging concentrator and the same optical band-pass filter.

As it can be seen from the simulation above (figures 4 a. and 4 b.) the first prototype (figure 4. a) has a better channel gain - between 41 and 30 dBm than the second one (figure 4. b) with a channel gain between 48 and 36 dBm, due to the technical characteristics of LED and PD used. On the other hand, the second prototype is smaller, cheaper and achieves a better channel gain when the distance between oTx and oRx is shorter (0.5 m for example), so it can be used for simplex, fast data communication between small medical devices placed closed to each other.

4. Conclusions

The VLC prototypes we propose in this paper are intended to be used in a LOS scenario for a simplex data wireless communication between two medical device situated in a medical facility at a distance of 1 meter to each other, fast data wireless communication, in order to avoid any interferences occurring from using multiple devices based on RF communication.

Results show that a LoS visible light simplex data communication between two medical equipment is achievable with low cost on-the-shelf optical devices, thus a very convenient replacement for data communication based on RF which is limited or forbidden in many areas of medical facilities. Both prototypes satisfy the quality requirements of ISO 13485 and EN 60601. The first and most important quality of our prototypes stands in their ubiquitous availability in medical RF forbidden environments (both facilities and medical devices) and indoor fast data communication.

Machine learning application detecting potent illicit central nervous system stimulants

Mirela Praisler^{a*}, Stefanut Ciochina^a, Marian Coman^a

^a“Dunarea de Jos” University of Galati, 47 Domneasca Str., Galati 800008, Romania

Abstract

We are presenting a machine learning application built for the automatic recognition of the class membership of the main types of illicit synthetic drugs that are abused for their stimulant and / or hallucinogenic biological activity, as well of their main precursors. The detection is based on spectra recorded between 1550 and 1330 cm^{-1} with a portable laser infrared spectrometer. A w_{TE} feature weight was determined in order to identify and enhance the most discriminant absorptions. The effect of spectra preprocessing is presented in detail for all the modeled classes of compounds. Principal Component Analysis (PCA) was then performed in order to evaluate the obtained clusters. The discrimination power of each of the main principal components and the potential overlap of the clusters was assessed by using statistical box plots. The bidimensional score plot obtained for the main principal components have been analyzed in conjunction with the corresponding loading plot in order to identify the absorption bands that are contributing to the formation of each cluster. The results recommend the application as an efficient forensic tool.

Keywords: drugs of abuse; precursors; machine learning.

1. Introduction

We are presenting a machine learning application designed to operate a portable laser infrared spectrometer screening for illicit synthetic drugs that are abused for their stimulant and / or hallucinogenic pharmacological activity, as well as their main precursors (Mengali et al., 2013), (Herbst et al., 2012). More specifically, the system is designed to perform the automatic recognition of the class membership of the following class of designer drugs: amphetamine (α -methylphenethylamine, AMP) and its analogues, tenamphetamine (3,4-methylenedioxyamphetamine, MDA) and its analogues, and ephedrine (*rel*-(*R,S*)-2-(methylamino)-1-phenylpropan-1-ol, EPH) isomers and analogues.

AMP and most of its analogues are stimulants of the central nervous system (CNS). These drugs, especially methamphetamine (MAMP), are often abused for recreational purposes (Karch, 2007). Besides their (moderate) psychological dependence liability and addiction liability, these stimulants may have very severe side effects. Hence, they are controlled in most of the countries (UNODC, 2017).

MDA and its analogues are even more dangerous. Besides their CNS stimulant effect, they also have an important hallucinogenic and euphoriant effect (Laing, 2003). For example, the most frequently abused analogue, midomamphetamine (3,4-methylenedioxymethamphetamine, MDMA), sold on the black market under the name of *Ecstasy*, often leads to paranoia, insomnia and rapid heartbeat. This class of substituted amphetamines may lead to death due to increased body temperature and dehydration. Hence, they have no approved medical uses.

EPH and many of its analogues and isomers (e.g. pseudoephedrine, norephedrine) are often abused by athletes and participants to rave parties (Momaya et al., 2015). They are abused as performance enhancers, as they seem to delay significantly the sensation of fatigue. Although these compounds have a milder CNS stimulant activity and do have some medical uses, they are controlled substances and as closely monitored worldwide as the other two classes of amphetamines mentioned above, because they are the main precursors of stimulant amphetamines (UNODC, 2017).

During the last decade, a true proliferation of clandestine laboratories has been noticed worldwide. This trend has prompted governments to fund the development of new portable instruments, designed to assist the law enforcement officers during field operations, as well as for border protection (EMCDDA, 2017). Such a prototype has been developed within the DIRAC project, funded by the European Union. This instrument is a portable infrared laser spectrometer designed to perform a fast *in situ* analysis of amphetamines and of their main precursors.

The artificial intelligence application presented in this paper is designed to automatically process the vibrational spectra of the samples and to detect reliably any compound having a molecular structure similar to the targeted parent compounds (AMP, MDA and EPH). The challenge is related to the fact that the class identity assignment is based only on the absorptions recorded in the limited infrared domain (1550 and 1330 cm^{-1}) specific to the laser source of radiation of the spectrometer, i.e. the UT7 quantum cascade laser (QCL). This paper describes the computational architecture of the application and the studies performed in order to assess to what extent the system reaches the detection accuracy obtained when the full infrared spectra are available for analysis.

2. Experimental part

A spectral database was formed by including the spectra of AMP and six of its analogues (MAMP, EAMP, PAMP, APEA, MAPEA and BPEA), MDA and five of its analogues (MDMA, MDEA, N-OH-MDEA, BDB and MBDB), EPH and five of its isomers and analogues (pseudoephedrine, norephedrine, norpseudoephedrine, N-methylephedrine and benzylephedrine), as well as seventeen negatives, i.e. randomly selected compounds of forensic interest (Praisler et al., 2017). We will further refer to these four classes of compounds as M, T, E and N respectively. The absorptions have been recorded, with a 5 cm^{-1} resolution, between 1550 and 1330 cm^{-1} . Hence, the database represents a matrix with 36 x 45 entries.

This database has been used in order to determine a w_{TE} feature weight (Praisler et al., 2017), based on the Fisher function (see Fig.1). For this purpose, the spectra of T and E compounds have been included in class I, and those of the M and N substances in class II. In order to enhance the cohesion of the clusters, a new database has been obtained by processing the 36 spectra with the w_{TE} feature weight (Ciochina et al., 2017).

The latter database has been subjected to Principal Component Analysis (PCA) (Jolliffe, 2002). The score plots have been used to assess to what extent the modeled classes of drugs of abuse are clustering and how well-defined (distinguishable one from another) these clusters are. The potential cluster overlap was estimated based on statistical box plots. The score plots, corroborated with the corresponding loading plots, have also indicated the absorption bands (and associated chemical groups) that are contributing to the formation of each cluster. The clustering quality has been compared with that obtained with the full infrared spectra (Praisler and Ciochina, 2014).

3. Results and discussion

The w_{TE} feature weight enhances the absorptions ($w_{TE} \geq 1$) according to their modeling and discrimination power. The intensity of the bands found to be irrelevant for distinguishing between the targeted classes of compounds is left unchanged ($w_{TE} = 1$). Fig. 1 indicates that the most important absorptions are those around 1480, 1445 and 1430 cm^{-1} .

The effect of spectra processing on the mean spectra of the targeted classes of compounds is illustrated in Fig. 2. The latter indicates that the 1480 cm^{-1} corresponds to the absorptions specific to the stimulant phenethylamines (M and E) and the absorptions found between 1445 and 1430 cm^{-1} distinguishes the positives (M, T, E) from the negatives (N).

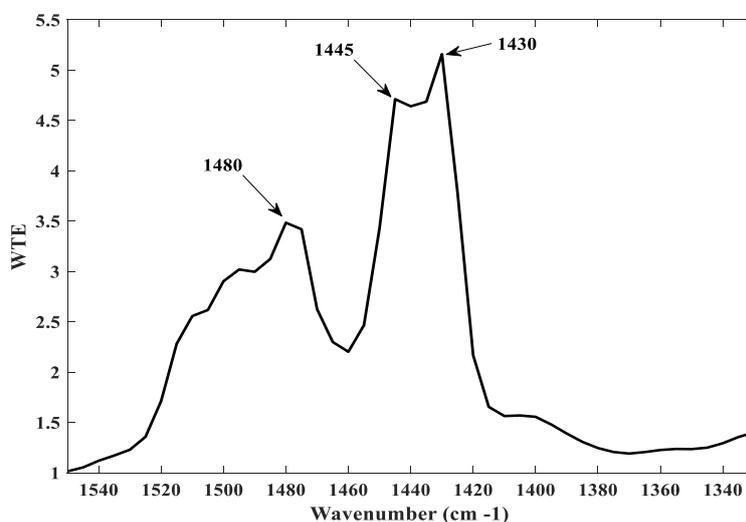

Fig. 1. w_{TE} feature weight used to process the original spectra in order to obtain the final database

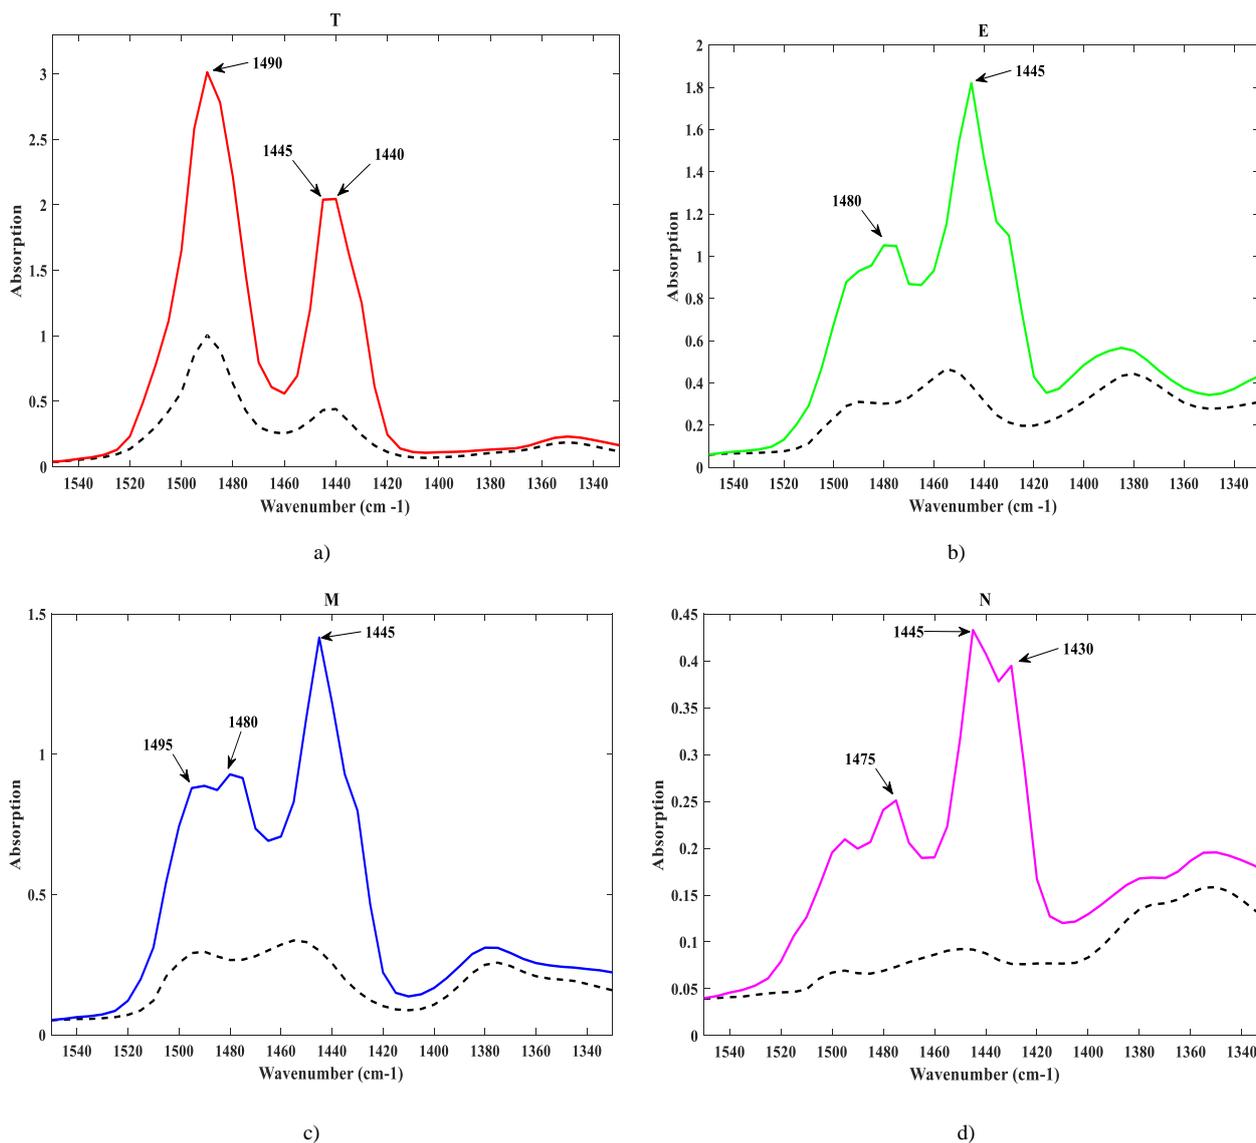

Fig. 2. Mean spectra of: a) hallucinogenic amphetamines (class code T); b) ephedrines (class code E); c) stimulant amphetamines (class code M); d) non-amphetamines (class code N). - - - - - initial spectrum; ——— spectrum preprocessed with the w_{TE} selective amplifier.

The database formed with the processed spectra has been subjected to PCA, in order to perform an exploratory analysis. The number of principal components (PCs) needed to model the targeted classes of drugs of abuse has been established based on the dynamics of the cumulated explained variance, which indicates that the first two PCs are enough for this purpose (see Fig. 3).

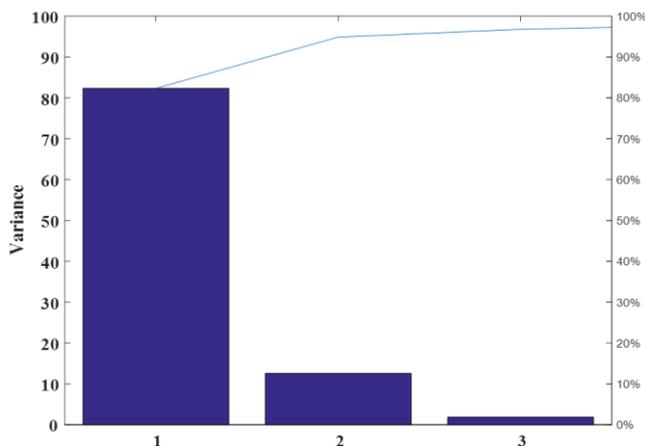

Fig. 3. Explained variance obtained for the spectra recorded between 1550 and 1330 cm⁻¹ and processed with the w_{TE} feature weight.

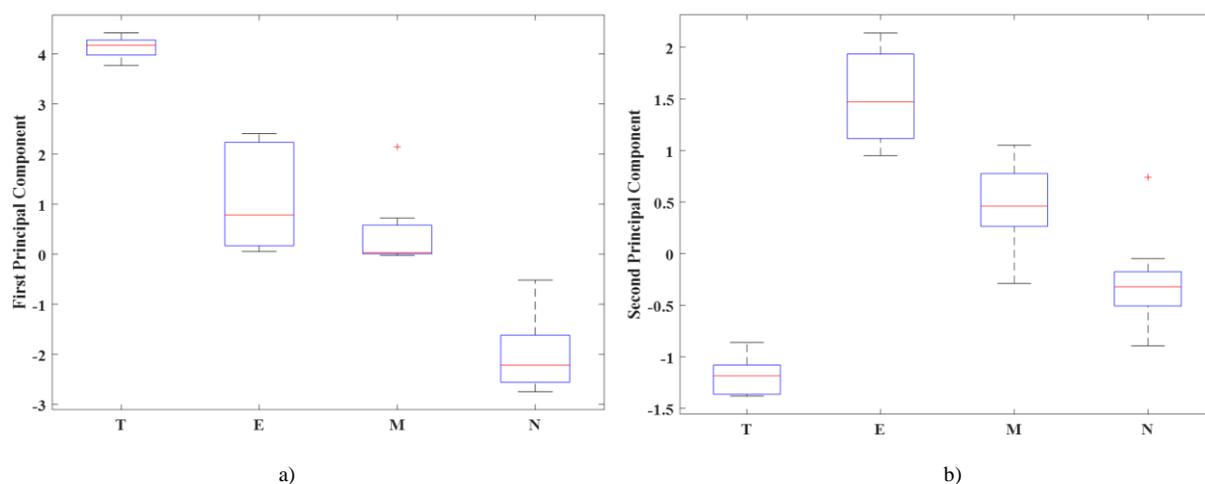

Fig. 4. Statistical analysis of the PCA scores of hallucinogenic amphetamines (T), ephedrines (E), stimulant amphetamines (M) and negatives (N): a) PC1 scores; b) PC2 scores.

The scores specific to each modeled class of compounds have been assessed by using statistical box plots, which are presented in Fig. 4. They indicate that PC1 is mainly discriminating the hallucinogens (T) and the negatives (N) from the stimulant phenethylamines (M and E). However, the PC1 scores of AMP and EPH analogues are relatively similar. On the other hand, the PC2 scores are clearly distinguishing between the latter two groups of synthetic drugs.

These aspects may also be observed in the PC1 vs. PC2 score plot presented in Fig. 5. The MDA analogues (T) are forming a very well-defined and dense cluster found in quadrant IV. They are the only compounds characterized by large positive PC1 and negative PC2 scores. With the exception of N33 (dextromoramide), the cluster formed by the negatives is located in quadrant III, these substances being characterized by large negative PC1 and PC2 scores. On the other hand, the points associated to the stimulant amphetamines (M), as well as those specific to the ephedrines (E) are quite scattered. The cluster formed by the ephedrines is found in quadrant I and may be distinguished from the M cluster based on the PC2 scores. All EPH isomers and analogues have positive PC2 scores that are typically larger than those of the stimulant amphetamines (M). With the exception of M17 (β -phenylethylamine), all the AMP analogues have small positive PC1 and PC2 scores.

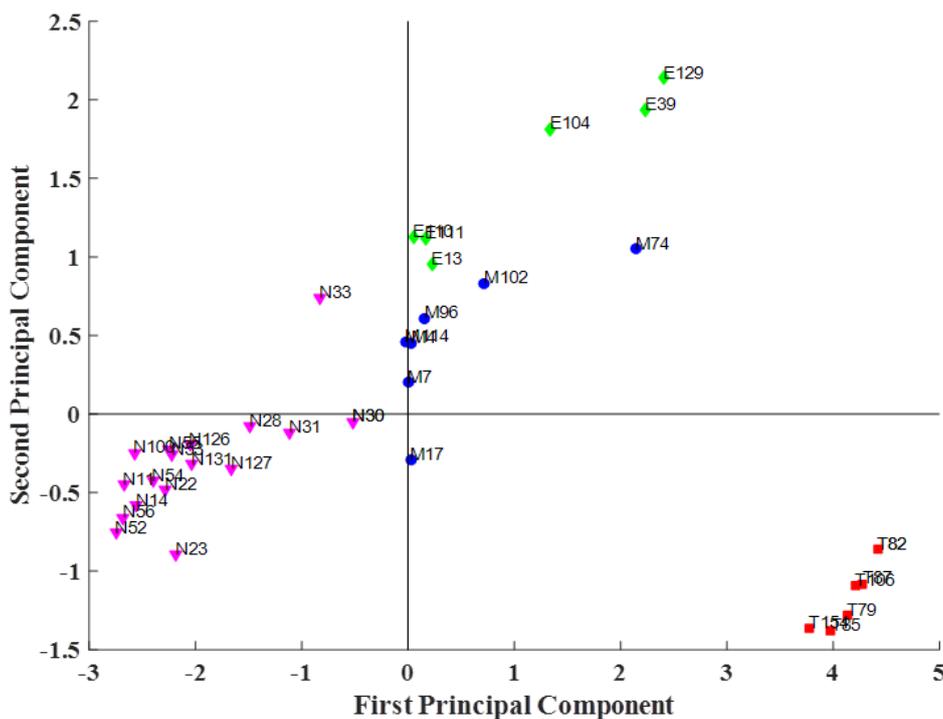

Fig. 5. PC1 vs. PC2 score plot obtained for the w_{TE} processed spectra of hallucinogenic amphetamines (T), ephedrines (E), stimulant amphetamines (M) and negatives (N).

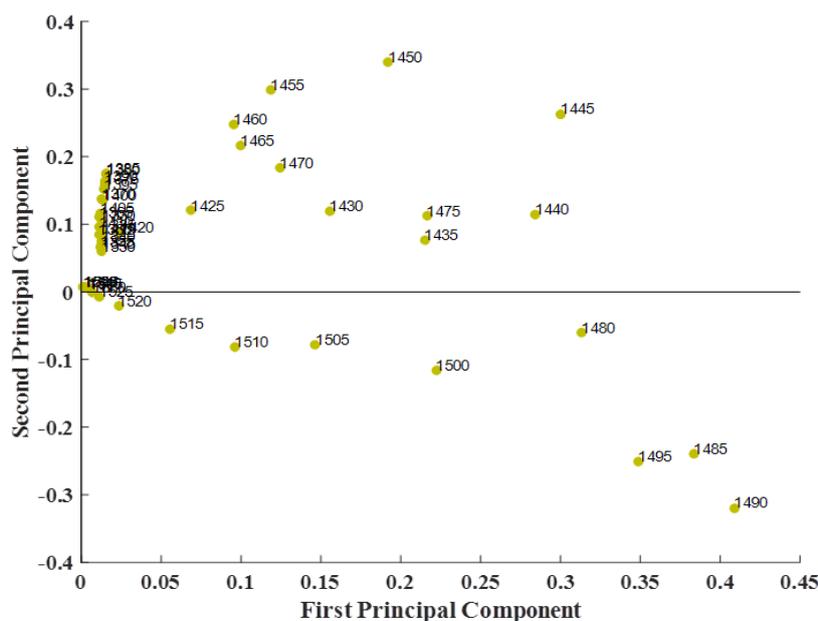

Fig. 6. PC1 vs. PC2 loading plot obtained for the w_{TE} processed spectra of hallucinogenic amphetamines (T), ephedrines (E), stimulant amphetamines (M) and negatives (N).

The associated loading plot, presented in Fig. 6, may help us identify the main absorptions that are responsible for the formation of each of the four clusters. The larger the weight of a variable (wavenumber), the more important it is for clustering a given class of modeled compounds. The plot indicates that the hallucinogens (T) form such a well-defined cluster due to their strong and very stable absorption band found at 1490 cm^{-1} (see also Fig. 2a) (Praisler et al., 2000a), (Praisler et al., 2000b). As all the variables between 1520 and 1480 cm^{-1} are also contributing to the formation of this dense cluster, we may conclude that the shape of the left wing of the 1490 cm^{-1} band is also a spectral feature used for the recognition of MDA analogues.

The absorptions between 1425 and 1475 cm^{-1} are contributing to the formation of the M and E clusters, being responsible of the large positive PC1 and PC2 scores of these compounds. The absorptions around 1380 cm^{-1} are mainly responsible for distinguishing ephedrines from AMP and its analogues. Both classes of drugs have a specific absorption band at this wavenumber (Praisler et al., 2002). Fig. 6 corroborated with Fig. 2b and 2c indicate that the discrimination relies on the intensity of this band. We may conclude that the ephedrines (E) have larger positive PC2 scores because, in their case, the 1380 cm^{-1} absorption band is typically stronger than in the case of stimulant amphetamines (M).

4. Conclusions

The application was designed to operate a new portable spectrometer, which is equipped with a QCL that emits between 1550 and 1330 cm^{-1} (UT7). The results indicate that the system is a fast and efficient forensic tool, as it detects automatically all the substances having a molecular structure similar (not only identical) to the modeled classes of compounds, i.e. hallucinogenic amphetamines, stimulant amphetamines and their main precursors, the ephedrines.

The main challenge in building this application was to obtain, despite the narrowness of the spectral domain specific to the UT7 laser source, a correct classification rate similar to that obtained with the full infrared GC-FTIR spectra, which are recorded between 4000 and 600 cm^{-1} . The results indicate that although the balance between the number of variables (absorbances) and the number of objects (compounds) is better in the case of the laser spectrometer than in the case of the GC-FTIR instruments providing the full infrared spectrum, the overall accuracy of the system is slightly lower in the former than in the latter case (Praisler et al., 2000), (Praisler et al., 2002).

More specifically, the closeness of the clusters formed by the stimulant amphetamines (M) and ephedrines (E) revealed by the PCA score plot indicates that some misclassifications between these two classes of compounds are to be expected. This behavior is due to the extreme similarity of the molecular structures (and hence of the infrared spectra) of these two classes of compounds. For example, EPH has the MAMP molecular structure with a $-\text{OH}$ group at the β position. This similarity also explains the fact that both classes of drugs share the same pharmacological activity, i.e. they are all CNS stimulants (Karch, 2007).

Nevertheless, this weakness is not essential: the laser spectrometer is designed to scan the suspect samples for controlled substances, i.e. to assign the class identity of all the compounds similar to the modeled ones. Once a sample is found as a T, M or E positive, it is sent to the laboratory for individual identification, based on its full GC-FTIR and GC-MS spectra. Hence, as long as the potential misclassifications may appear only between classes of controlled substances, the system is perfectly acceptable from a forensic point of view.

What is essential is that no positive (T, M or E) is misclassified as a negative (N). From this point of view, the accuracy of the system is similar to that of the applications processing the full infrared spectra.

The score and loading plots confirm that processing the spectra with the feature weight w_{TE} is crucial. This function manages to identify and to emphasize the most relevant absorptions. These are characterized by the best stability, not only from the point of view of their position and intensity, but also of their shape. Interestingly, the absorptions bands found by the w_{TE} feature weight to have the most important modeling and discrimination power are not necessarily the strongest ones. Medium or weak absorption bands may very well be the most relevant for distinguishing among the modeled classes of compounds, if they are relatively stable and specific to one or more of these classes.

In conclusion, the exploratory analysis performed in this study encourages further studies aiming to the development of intelligent systems based on more complex classification techniques.

Scanning for illicit psychoactive drugs based on pattern recognition

Stefanut Ciochina^a, Mirela Praisler^{a*}, Marian Coman^a

^a“Dunarea de Jos” University of Galati, 47 Domneasca Str., Galati 800008, Romania

Abstract

We are presenting an artificial intelligence application able to perform, *in-situ*, the automatic recognition of illicit phenethylamines. Official statistics indicate that these drugs are increasingly abused worldwide as recreational drugs, for their stimulant or hallucinogenic effect on the central nervous system. The spectra of a series of known illicit amphetamines have been recorded, with a resolution of 5 cm⁻¹, with a portable spectrometer equipped with a quantum cascade laser operating in the 1550 - 1330 cm⁻¹ infrared spectral domain. The spectra have been pre-processed by using a *wTE* Fisher function, which was defined based on structure - activity relationships. As the number of available compounds is relatively small, a data dimensionality reduction was performed by using Principal Component Analysis (PCA). The cluster overlap was estimated based on confidence intervals determined for each of the main principal components. The 3D score plot and associated loading plots have been analyzed in order to assess the quality of the identifiable clusters. Then, a new database, consisting of the PCA scores, was subjected to Hierarchical Cluster Analysis (HCA). The recommended number of clusters (as measured by the Silhouette index), the clustering tree built by using agglomerative clustering and the corresponding cophenetic correlation coefficient have been analyzed for an increasing number of principal components. The best correct classification rates have been obtained for four clusters, i.e. stimulant amphetamines, hallucinogenic amphetamines, ephedrine and negatives. Hence, combining these two pattern recognition methods (PCA and HCA) leads to an efficient forensic tool scanning for illicit psychoactive drugs. The system may successfully reveal not only the class identity of unknowns, but also their most likely pharmacological effect.

Keywords: psychoactive drugs; pattern recognition; infrared laser spectrometry.

1. Introduction

During the last decade, an alarming increase of the number of clandestine laboratories producing synthetic drugs of abuse, especially amphetamine analogues, have been noticed worldwide, especially in Eastern Europe (UNODC, 2017a), (UNODC, 2017b). This finding has emphasized the urgent need for capacity-building and better forensic technical assistance. Consequently, the European Union (EU) has decided to fund the development of new and more accurate instruments that might help the police and customs officers to detect illicit substances more efficiently (EMCDDA, 2017). The prototype of such an instrument, i.e. a portable Gas Chromatography – Infrared Absorption Spectrometer (GC-IRAS) that uses a quantum cascade laser (QCL) as source of radiation, has been developed within the EU funded DIRAC project. This instrument was expected to be able to perform a fast *in situ* detection of amphetamine-type stimulants (ATS) and of their main precursors (Herbst et al., 2012), (Mengali et al., 2013), (Praisler et al., 2014a).

We should underline that the instrument is capable to analyze mixtures, the GC module ensuring the separation of their components. This means that, in the case of illicit tablets, besides the major active ingredients and adulterants, the excipients (diluents, binders, disintegrators, lubricants, damping agents, drying agents) and other products such as dyes, aromas and sweeteners may also be identified. This aspect is very important, because the ingredients used in formulations vary considerably from one manufacturer to another and thus the origin of the illicit tablets can be traced (Karch, 2007). Another important feature of the portable spectrometer is that it can analyze not only tablets and powders, but also liquids. Hence, it may be also used by the authorities for monitoring real-time data on geographical and temporal trends in illicit drug use based on wastewater analysis (EMCDDA, 2018).

In this paper we are presenting an artificial intelligence application that was built to operate this GC-IRAS portable spectrometer. The application assigns the class identity of hallucinogenic and stimulant amphetamines, as well as of ephedrine, which are their main precursors (Karch, 2007), (Laing, 2003), (Momaya et al., 2015).

The class membership is established subjecting the spectra to Principal Component Analysis (PCA) and then to Hierarchical Cluster Analysis (HCA). The results indicate that the system is characterized by correct classification rates similar to those obtained with the full infrared spectra (recorded between 4000 and 600 cm^{-1}).

2. Experimental part

A former study has indicated that the best results may be obtained with the spectra recorded with a quantum cascade laser (QCL) emitting in the 1550 - 1330 cm^{-1} spectral window (UT7) (Praisler and Ciochina, 2013). Hence, a first spectral database has been built with the spectra recorded in this spectral domain, with a 5 cm^{-1} resolution. This database consists of the vibrational spectra of seven stimulant amphetamines, six hallucinogenic amphetamines and six ephedrine. The class of stimulant amphetamines, further referred to as class M, includes amphetamine (AMP) and its main analogues MAMP, EAMP, PAMP, APEA, MAPEA and BPEA (Karch, 2007), (UNODC, 2017b). The class of hallucinogenic amphetamines (class T) contains the spectra of 3,4-methylenedioxyamphetamine (MDA) and of its main analogues MDMA, MDEA, N-OH-MDEA, BDB and MBDB (Laing, 2003), (UNODC, 2017b). The ephedrines are represented by ephedrine (EPH) and its main isomers and analogues, i.e. pseudoephedrine, norephedrine, norpseudoephedrine, N-methylephedrine and benzylephedrine (Karch, 2007), (Momaya et al., 2015). The database also contains the spectra of seventeen negatives, representing a large variety of toxicological concern (Praisler et al., 2014a). The natural coherence and the global quality of the clusters are often enhanced significantly by spectra processing (Praisler and Ciochina, 2014b). Former tests have indicated that this is especially true in the case when only a limited part of the full infrared spectrum is taken into account (Ciochina et al., 2017). Hence, the spectra included in the database have been processed with a w_{TE} feature weight, which was obtained by using the Fisher function. To define and compute w_{TE} , the spectra of T and E compounds have been included in class I, and those of the M and N compounds in class II.

The dimensionality of the data was then reduced by subjecting the w_{TE} processed spectra to Principal Component Analysis (PCA) (Jolliffe, 2002). The cluster overlap was estimated based on confidence intervals determined for each of the main principal components. The 3D score plot and associated loading plots have been analyzed in order to assess the quality of the identifiable clusters. Then, a new database, consisting of the PCA scores, was subjected to Hierarchical Cluster Analysis (HCA) L. (Kaufman and P.J. Rousseeuw, 2005). More specifically, clustering trees have been built based on the scores computed for an increasing number of principal components (PCs) and hierarchical agglomerative clustering algorithm. The number of clusters that may be best distinguished has been identified quantitatively, by using the average Silhouette index (Starczewski and Krzyżak, 2015). The cophenetic correlation coefficient has been used in order to assess which of these dendrograms preserves best the distances between the original unmodeled objects.

The correct classification rates have been compared, in order to identify the most efficient computational architecture. The efficiency of the best performing system has also been compared with that obtained for systems designed to assign the same class identities based on the full infrared spectrum and pattern recognition methods (Praisler et al., 2002), (Praisler et al., 2000a).

3. Results and discussion

The w_{TE} processed spectra have been explored by using PCA. In order to determine the number of PCs needed to model the targeted classes of drugs of abuse, the eigenvalues and the explained variance have been calculated. The results presented in Table 1 indicate that the first three PCs are enough for this purpose, as they are cumulating an explained variance of 96.77% (see Fig. 3).

Table 1. Eigenvalues and explained variance determined with the w_{TE} processed spectra of stimulant and hallucinogenic amphetamines and of ephedrines

Eigenvalue	Explained variance (%)	Cumulated explained variance (%)
5,6222	82.3366	82.3366
0,8571	12.5527	94.8893
0,1287	1.8844	96.7737

The mean scores and the confidence intervals calculated for PC1 indicates that this PC, which is associated with most of the explained variance (82.34 % out of 96.77%), is mainly discriminating the hallucinogenic amphetamines (T) and the negatives (N) from the other two classes of modeled compounds, i.e. stimulant amphetamines (M) and ephedrines (E) (see Fig.1). The PC2 scores are strengthening this discrimination. In addition, although PC2 accounts for only 12.55% of the explained variance, it distinguishes between the latter two modeled classes of controlled drugs. This behavior is remarkable, as the compounds belonging to these two classes of stimulant phenethylamines (M and E) have a very similar molecular structure (see Fig. 2). The PC3 scores do not seem to have a specific role.

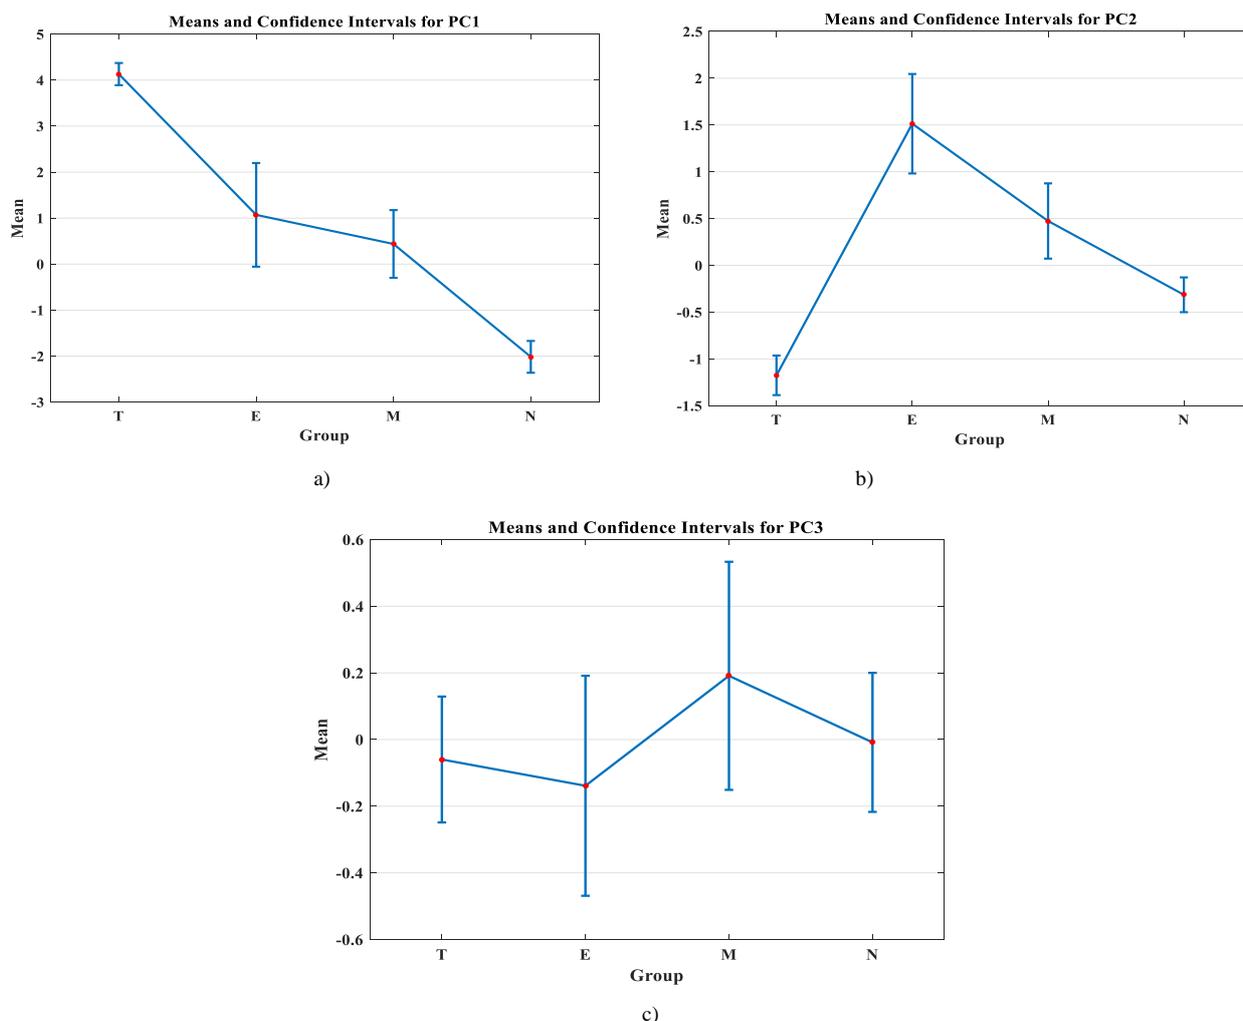

Fig. 1. Confidence intervals associated to the PCA scores determined based on the w_{TE} processed spectra of hallucinogenic amphetamines (class code T), ephedrines (E), stimulant amphetamines (M) and negatives (N); a) PC1; b) PC2; c) PC3

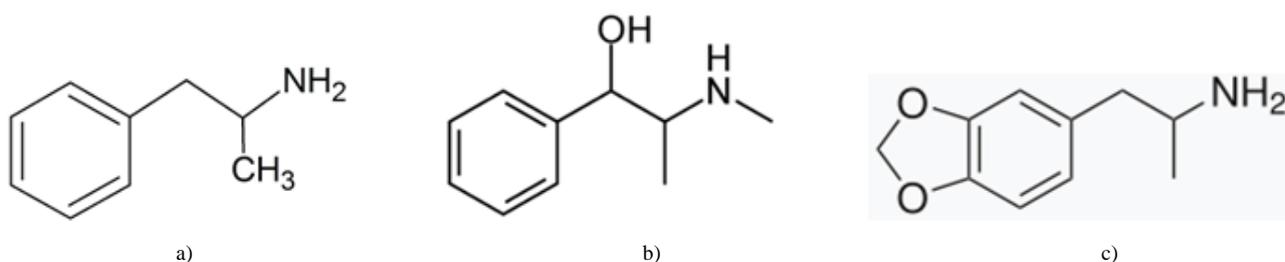

Fig. 2. Molecular structure of the parent compounds of the modeled classes of illicit drugs: a) amphetamine (AMP); b) ephedrine (EPH); c) 3,4-methylenedioxyamphetamine (MDA)

The 3D score plot and the associated loading plots are presented in Fig. 3 and Fig. 4. The most important absorptions, which are characterized by the largest (positive) PC1 loadings, leading to the most specific discriminations ensured by the PC1 scores (the T and N clusters from the M and E clusters) are found around 1490 and 1445 cm^{-1} . They are highly specific to the hallucinogenic amphetamines, which are displaying very strong and stable absorption bands at these wavenumbers (Praisler et al., 2000b).

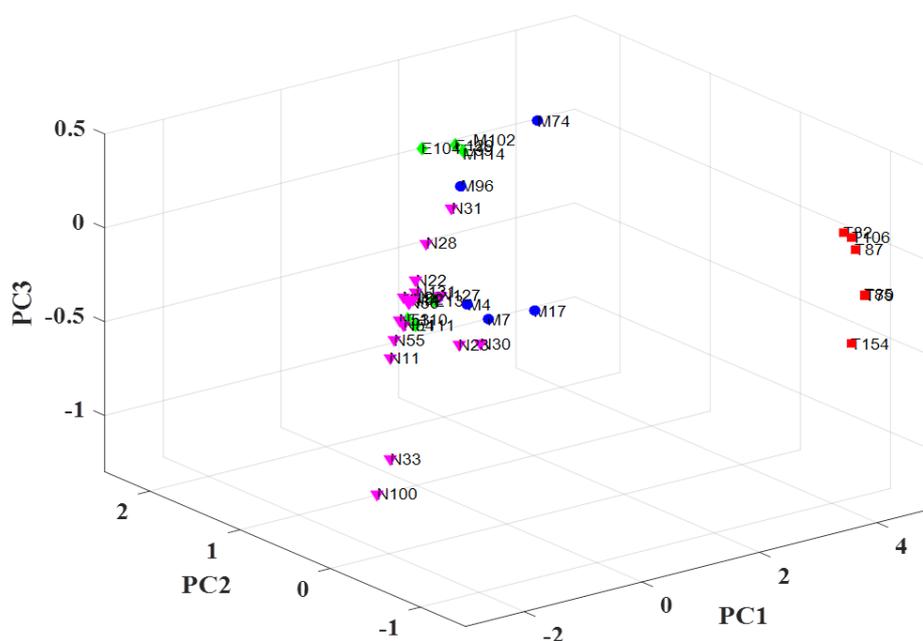

Fig. 3. 3D score plot discriminating the targeted psychoactive substances: stimulant amphetamines (M, blue dots), hallucinogenic amphetamines (T, red dots), ephedrines (E, green dots) and negatives (N – purple dots).

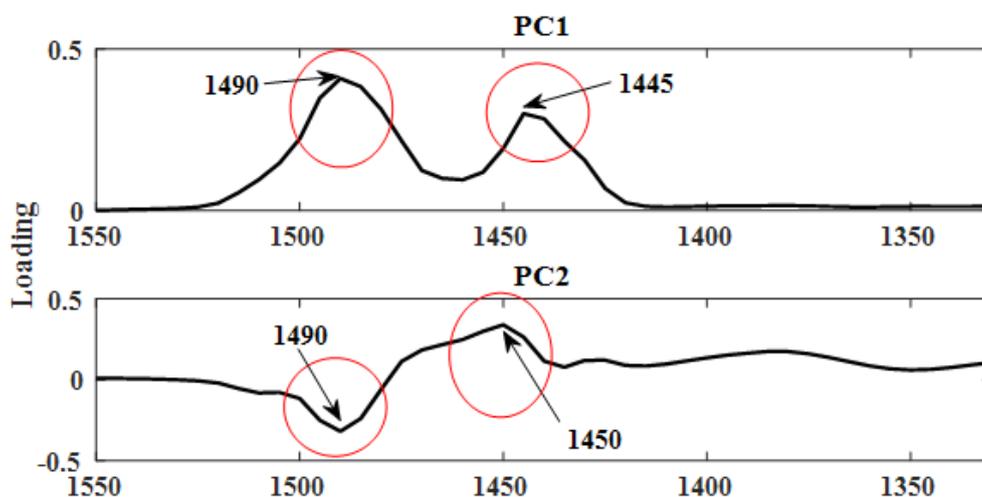

Fig. 4. PCA loading plots obtained for the w_{TE} processed spectra of stimulant amphetamines, hallucinogenic amphetamines, ephedrines and negatives

These absorptions are also characterized by large (negative or positive) PC2 loadings, which is consistent with the important role played by the PC2 scores in distinguishing the T and N clusters from the M and E clusters. Besides these absorptions, the other absorptions between 1475 and 1425 cm^{-1} have also significant positive loadings. These variables are contributing to the discrimination between stimulant amphetamines (M) and ephedrines (E) (Praisler et al., 2000b).

A first quantitative assessment of the number of clusters that may be best distinguished in the score plots has been made from the point of view of the consistency within the clusters of data, based on the average Silhouette index. This assessment has been performed for an increasing number of PCs, i.e. for the clusters identifiable based on the scores of PC1, then by using the PC1 and PC2 scores, and finally based on the (PC1, PC2, PC3) scores. In all cases, the index values have indicated that the best results may be obtained with four clusters, i.e. stimulant amphetamines (M), hallucinogenic amphetamines (T), ephedrines (E) and negatives (N). The highest (and very similar) values have been obtained for the average Silhouette index in the case of one (PC1) and of two (PC1 and PC2) PCs (see Fig. 5), i.e. 0.8779 and 0.8671 respectively.

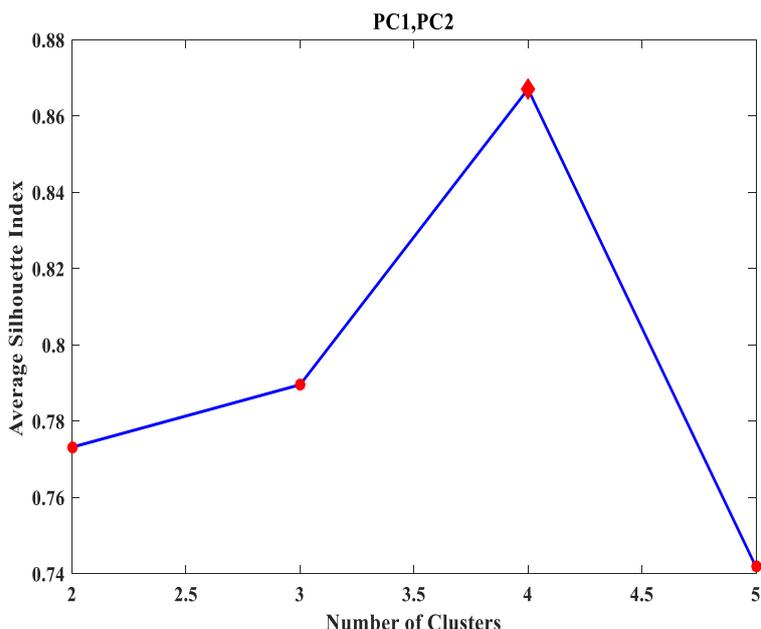

Fig. 4. Average Silhouette index obtained based on the PC1 and PC2 scores obtained for the w_{TE} processed spectra of the targeted compounds

Hence, clustering trees have been built for these two cases, by using HCA based on the agglomerative clustering algorithm. They have been evaluated based on the cophenetic correlation coefficient c , which assesses how well a dendrogram maintains the distances between the unmodeled objects. The best (and very similar) values have been obtained for the clustering trees built with the (PC1, PC2) scores and with the (PC1, PC2, PC3) scores, i.e. $c = 0.8755$ and $c = 0.8759$ respectively. Taking into account these results and the correct classification rates, we have concluded that the best computational approach is to combine HCA with PCA, the input for the hierarchical agglomerative clustering algorithm being the PC1 and PC2 scores.

The dendrogram obtained in this case is presented in Fig. 6. It indicates that the main characteristics of this class identity assignment system are the remarkable sensitivity and selectivity in detecting the class formed by the amphetamines with the highest toxicity, i.e. the hallucinogens (T). Another very important characteristic is the selectivity of the system from the point of view of the negatives: no positive compound (T, M, E) is (mis)classified as a negative. A lower but quite acceptable accuracy is obtained in the case of the M and E compounds, due to the extremely high similarity between the molecular structures, and consequently of their infrared spectra, of these two classes of stimulant phenethylamines.

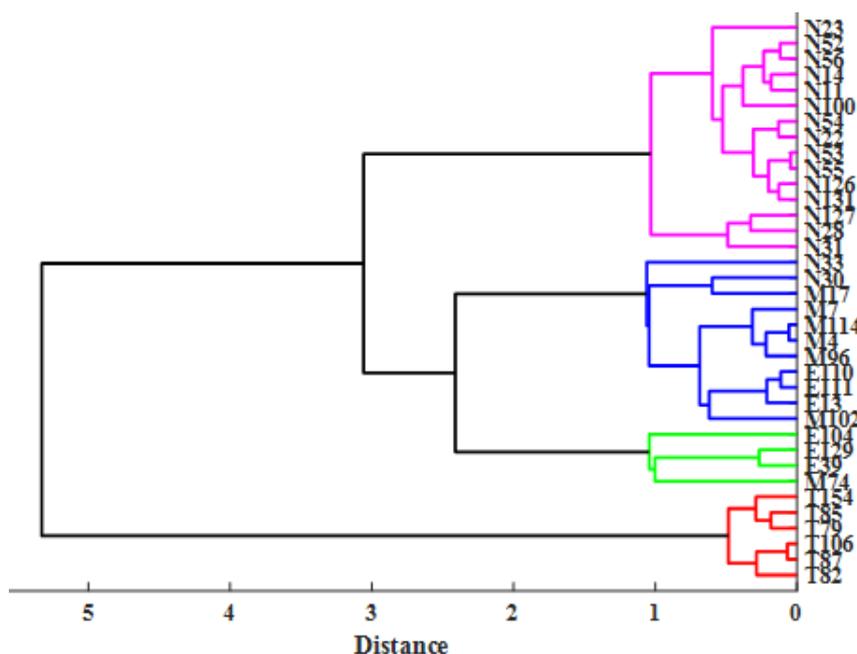

Fig. 5. HCA clustering tree built with the PC1 and PC2 scores specific to the w_{TE} processed spectra of the modeled illicit drugs

4. Conclusions

The results indicate that combining PCA and HCA leads to an efficient forensic artificial intelligence application. Although its accuracy in distinguishing stimulant amphetamines from ephedrine, which are their main precursors, is lower than in the case of the systems assigning the class identity based on the full infrared spectrum (4000 – 600 cm⁻¹), the system meets the mandatory requirements of a screening tool. This is a compromise that must be made in order to decrease the size of the portable spectrometer by replacing the traditional IR source of radiation, which is quite voluminous, with a QCL.

This compromise is quite acceptable, if we keep in mind that the system is only expected to screen for the modeled classes of drugs of abuse, and not to identify their individual nature. What is essential is that no positive is misclassified as a negative, meaning that all the illicit samples will be detected *in situ* as positives. Hence, the suspect substance will be taken into custody and sent for individual identification in laboratory conditions (based on several analytical methods, such as the full vibrational spectra).

Live car traffic monitoring with Raspberry Pi hardware

Cosmin Rus^{a*}, Monica Leba^a

^aUniversity of Petrosani, University Street 20, Petrosani 332006, Romania

Abstract

This paper presents traffic management and road monitoring applications using the latest generation of IT and mobile telecommunication systems. An intelligent system with self-learning function is proposed for urban traffic junctions. This system allows automatic adjustment of green times depending on intersection traffic as well as traffic at upstream and downstream intersections. A remote road monitoring system is also introduced. This system uses modern communications equipment for periodically reading and transmitting parameters such as road temperature, humidity, wind intensity and vehicle weight. In this IoT project, we use a Raspberry Pi, a webcam and ThingSpeak to analyze traffic on a busy highway. With Simulink we design and deploy a traffic monitoring algorithm to the Raspberry Pi, and we analyze and visualize the traffic patterns using ThingSpeak, an IoT analytics platform, and MATLAB.

Keywords: matlab; simulink; thingspeak; urban traffic.

1. Introduction

The result of the increase in vehicle traffic has caused many problems. For example, traffic accidents, traffic congestion, air pollution caused by traffic and so on. Traffic congestion has been a significant problem. It has been widely noticed that the growth of preliminary transport infrastructure, several sidewalks and extensive roads have failed to reduce congestion in cities. As a result, many researchers have turned their attention to the Intelligent Transport System (ITS), which can use traffic flow data based on traffic monitoring at traffic junctions for congestion detection. In order to process the information and to monitor the results, in order to better understand the flow of traffic, an increasing dependence on traffic surveillance requires better detection of vehicles in an extended area. Automated detection of vehicles in video surveillance data is a very difficult issue in the eyes of computers with important practical applications such as traffic analysis and security. (Mallikarjun et al., 2017)

Vehicle detection and counting are important in calculating traffic congestion on highways. The main purpose of vehicle detection and counting in the traffic video project is to develop the methodology for automatic vehicle detection and counting on motorways. A system for efficient detection and counting of dynamic vehicles has been developed. Intelligent visual surveillance for road vehicles is a key component for the development of intelligent transport systems. The entropy masking method does not require prior knowledge of extracting road features on static images. Vehicle detection and tracking in video surveillance using segmentation with initial background decline using a morphological operator to determine the visible regions in a video frame sequence. Edges are counted showing how many areas are of a certain size, especially in the areas where the cars are located are the points and the vehicle counting in the field of traffic monitoring on highways. (Arulselvi et al., 2017)

Automated detection and tracking of video surveillance data is a very difficult issue in computer vision with important practical applications such as traffic analysis and security. Cameras are a relatively inexpensive surveillance tool. Manual review of the large amount of data it generates is often impossible. Thus, video analysis algorithms that require little or no human involvement is a good solution. Video surveillance systems focus on background modeling, vehicle classification and tracking. Increasing availability of video sensors and high-performance video processing hardware offers great possibilities to address many issues of video understanding, among which vehicle highlighting and target classification are very important. A vehicle tracking and classification system is described as one that can classify moving vehicles and further classifies vehicles in different classes. (Uke et al., 2013)

2. Proposed system architecture

The structure of the system presented in this paper is computationally efficient and can work in real time, while maintaining very respectable detection rates. However, these types of systems contain some inevitable problems caused by obstruction of the object if a larger vehicle with a smaller, partially closed vehicle is usually considered an object, since the first plane detection methods are not projected in inherent way to segregate multiple vehicles. In another case, the appearance of a larger vehicle or a shadow of the vehicle that bypasses adjacent bands is also known to trigger false detection. Consequently, the merit of using computer vision as a surveillance tool has been limited, focusing strictly on building reliable systems over time.

The system uses an existing video sequence. The first frame is considered to be the reference framework. Subsequent frames are taken as input frames. They are compared and the background is removed. If a vehicle is present in the entry frame, it will be retained. The detected vehicle is thus tracked by various techniques, namely the adaptive base method and the block analysis method.

Fig.1 Video processing algorithm for vehicle counting

3. Internal detection

Open CV is an open source project, an important part of the library that implements those wrong data structures and algorithms that you can find in your open CV. Therefore, source tutorials are part of the library.

Computer vision is a rapidly growing field, partly due to both cheaper and most capable cameras, largely due to affordable processing power and partly due to the fact that vision algorithms begin to mature. Opening up the resume itself has played a role in increasing computer vision, allowing thousands of people to do more productive work in vision. Focusing on real-time vision, Open CV helps students and professionals effectively implement projects and initiate research, giving them a computer vision and a machine learning infrastructure that was previously available in just a few labs mature research. (Mallikarjun et al., 2017)

A general detection approach is to extract the characteristic regions from the video clip using a background modeling technique learned. This involves subtracting each image from the background scene. The first frame is considered the initial background and the threshold of the resultant difference image to determine the foreground image. A vehicle is a group of pixels that move in a coherent manner, either as a lighter region on a darker background or vice versa. Often, the vehicle may have the same color as the background, or may be part of it may be aging with the background, because of which vehicle detection becomes difficult. This leads to a wrong number of vehicles. (Shinde, 2015)

Detection of information can be used to refine the vehicle type and also to correct errors caused by occlusions. Once the static vehicles are recorded, the background image is low in the video frames to get the dynamic vehicles in the foreground. Post-processing is performed on top-of-the-line dynamic vehicles to reduce noise interference. (Uke, 2013)

Image segmentation is done as follows:

- Segmentation of vehicle interest regions. At this stage, regions that may contain an unknown object must be detected.
- The next step focuses on extracting appropriate features and then extracting vehicles. The primary purpose of feature extraction is to reduce data by measuring certain features that distinguish input patterns.
- Final classification. He assigns a label to a vehicle based on the information provided by his descriptors. The analysis is performed on mathematical morphology operators for segmentation of a gray image.

a. Detection of vehicles

The adapted background surface uses the current frame and the reference image. The difference between the current frame and the reference frame exceeds the threshold is considered to be the moving vehicle. The optical flow method can detect the moving vehicle even when the camera moves, but it takes more time for its computational complexity and is very sensitive to noise. The motion area usually appears rather noisy in real images, and the optical flow estimate involves only local computing. Thus, the optical flow method can't detect the exact contour of the moving vehicle.

a. Tracking of vehicles

Vehicle tracking involves the continuous identification of the vehicle detected in the video sequence and is achieved by specifically tracking the limit around the detected vehicle. Tracking vehicles is a difficult problem. Difficulties related to vehicle tracking can occur due to steep vehicle movement, changing vehicle and scene layouts, rigid vehicle structures, vehicle and vehicle scenes, and camera shake. (Mallikarjun et al., 2017)

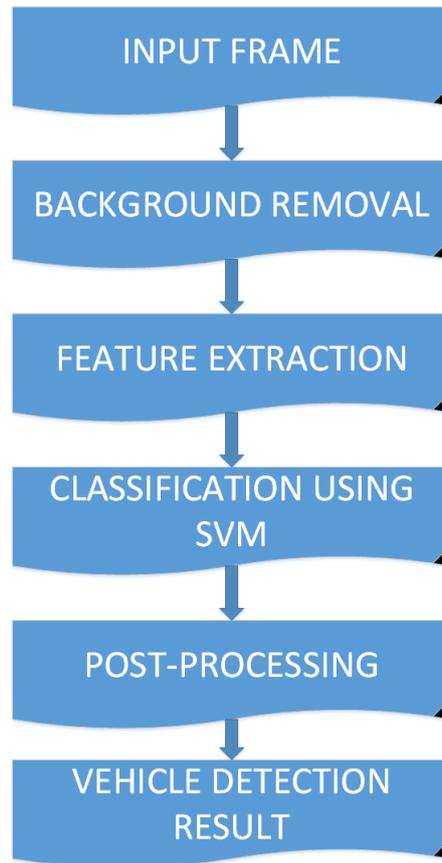

Fig. 2 The algorithm of a vehicle detection process

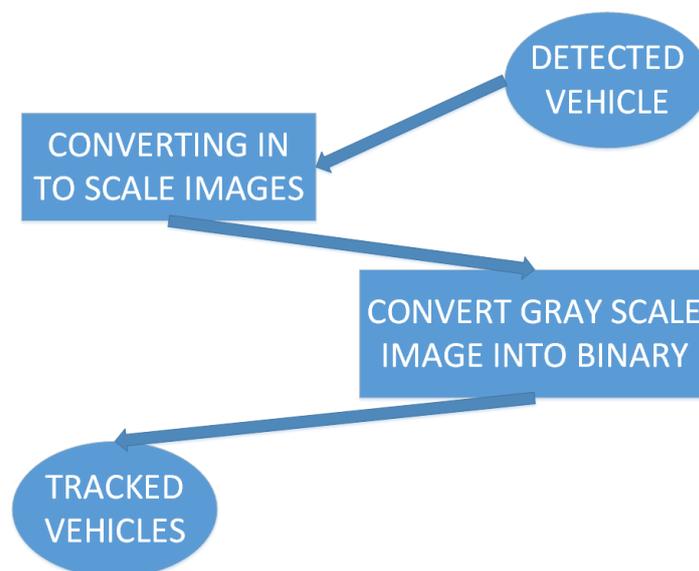

Fig. 3 The algorithm of a tracking vehicle process

b. Counting of vehicles

This system captures the webcam gestures that are connected to the microcontroller via the USB host and the image is processed by image processing technique. Here we use the Open CV library to detect a frontal image image using the Haar-Cascade hand detector, which will enhance interaction with the human computer. If any gesture is recognized by the camera, a rectangular box will appear on the monitor. The identified gestures are sent to Raspberry PI and we can perform TV-related functions. In this way, we implement a one-room TV control system using a gesture drawing.

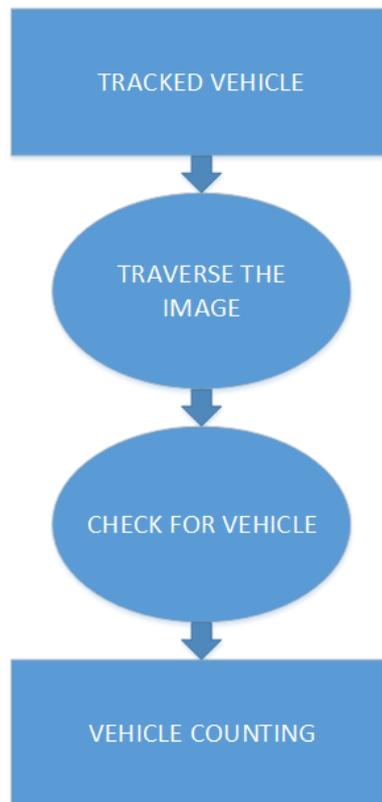

Fig. 4 The entire vehicle counting algorithm using image processing

Due to the high processing power of the data acquisition elements, this whole process of counting vehicles on a road can be done in about 0.01 seconds.

4. System implementation and data analysis

In this IoT project, we use a Raspberry Pi, a webcam and ThingSpeak to analyze traffic on a busy highway. We deploy a traffic monitoring algorithm to the Raspberry Pi device, and we analyze and visualize the traffic patterns with ThingSpeak, a cloud data aggregator. This project stores data in channel 48629 on ThingSpeak.

For this project, we show how to develop analytics for the edge device and how to perform exploratory analysis on data collected on the cloud. We also illustrate a simple example of how to perform automated online analysis in the cloud. The example uses ThingSpeak and MATLAB to perform the analyses. We constructed the traffic monitor using a Raspberry Pi 3, and a USB webcam. The webcam, a Tracer HD Pro, was mounted on a flexible mini tripod. We placed the camera near a window on the 2th floor of our university building that overlooks the street. We angled the camera to have a clear view of both sides of the street. The camera was connected to one USB port of the Raspberry Pi. We then connected the Raspberry Pi to the wireless network in the building. The complete parts list is shown below.

- Raspberry Pi 3 Model B ARM v7 with 1 GB RAM
- 5 V 3 A switching Power Supply with MicroUSB cable
- Tracer HD Pro
- Monoprice flexible mini tripod
- WiFi for internet connectivity

Fig. 5 Raspberry Pi 3 connection and the webcam used

Because we did not want to send high-bandwidth video images to the cloud, we chose to detect the vehicles at the edge using the processor on the Raspberry Pi 3. We then send the count value to the data aggregator at an update rate of once every 15 seconds, the maximum data rate allowed by ThingSpeak. To develop the traffic monitoring algorithm, we used Simulink, Image Processing Toolbox, Computer Vision System Toolbox and the Simulink Support Package for Raspberry Pi Hardware. Simulink is a modeling environment that can to automatically generate code that can run on an embedded controller. In this example, Simulink generates code that runs on the Raspberry Pi 3. The Simulink model for the traffic monitoring algorithm is shown below.

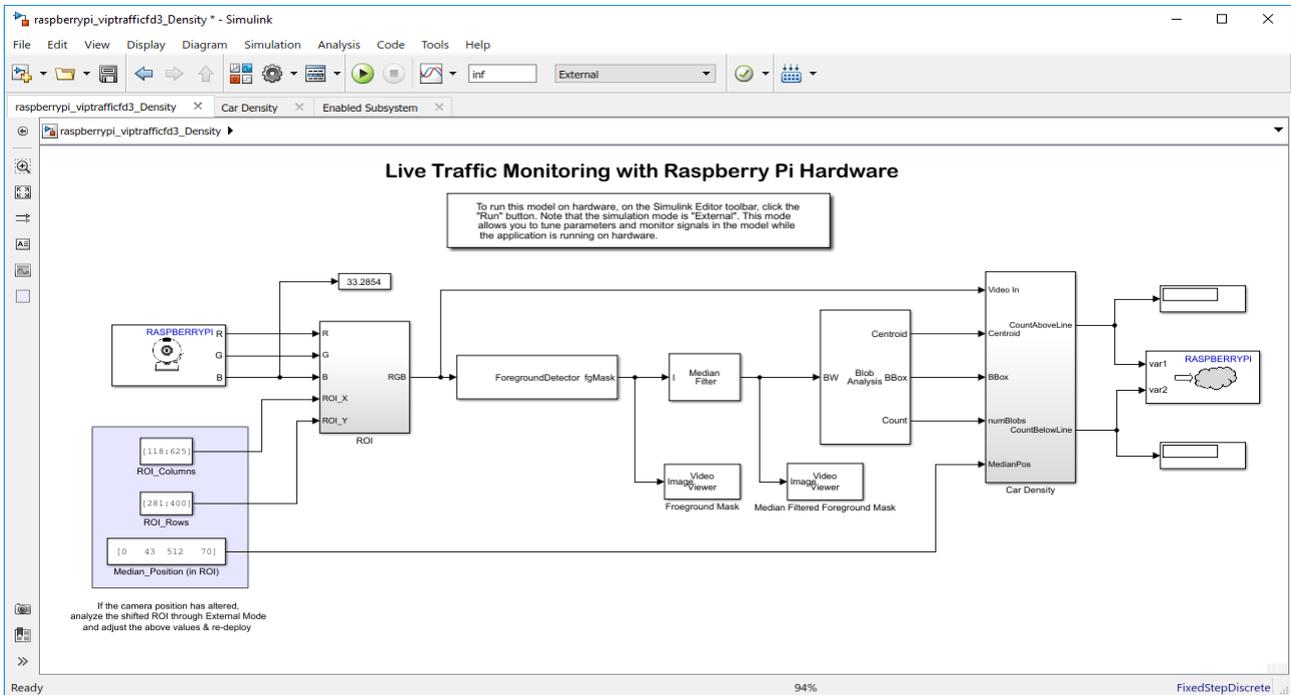

Fig. 6 Simulink traffic monitoring algorithm

To develop the algorithm, we used the external mode capability of Simulink. In this mode, Simulink gathers the video stream from the Raspberry Pi, and the user can view the video on an external monitor using the SDL Video Display block while the algorithm is running. Figure 7 shows the entire vehicle counting system using the alternative energy (solar energy in this case) as the power source of the Raspberry Pi system.

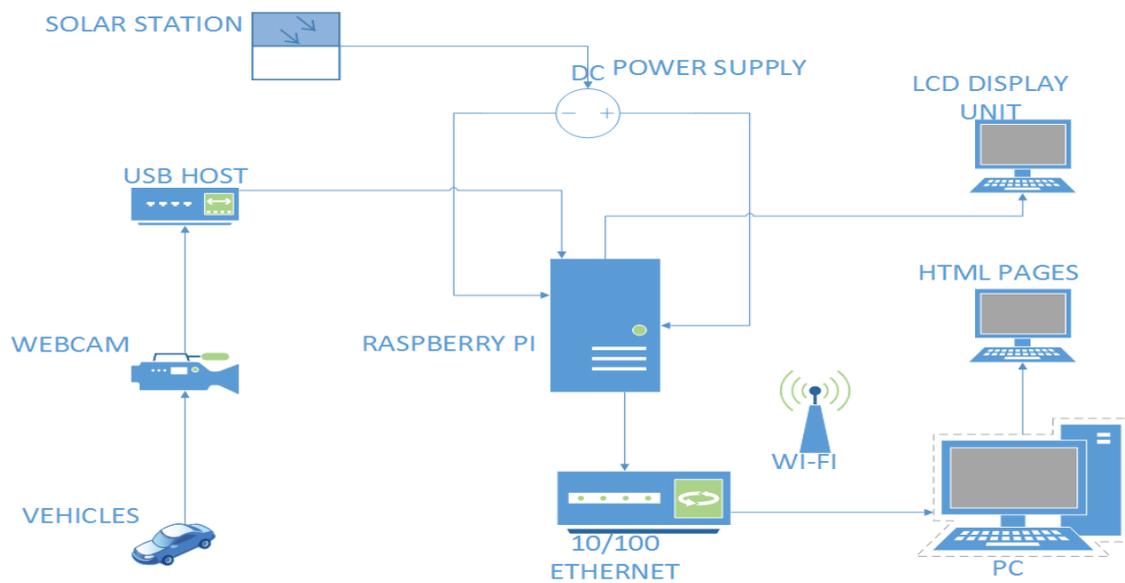

Fig. 7 Block diagram of the entire system prototype

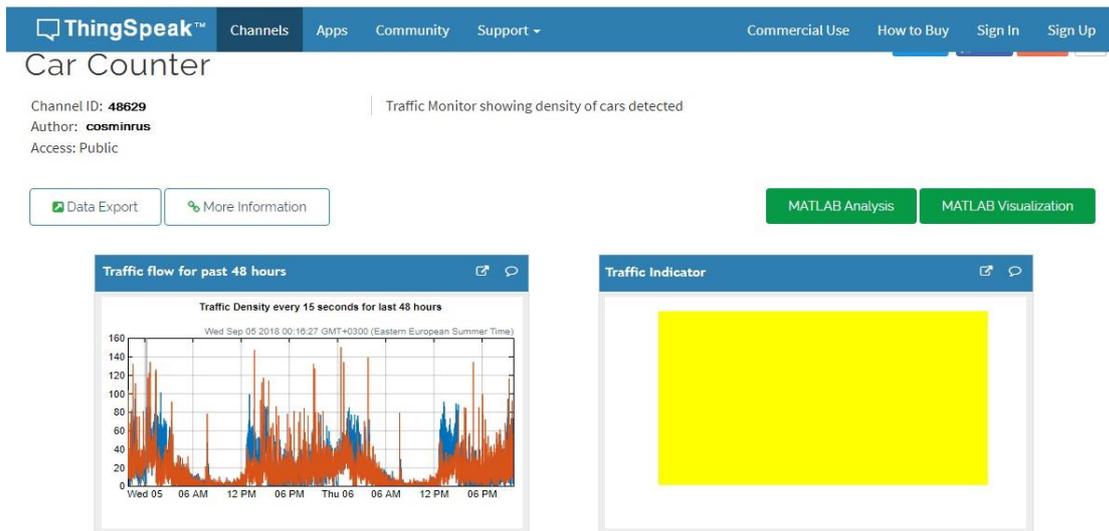

Fig. 8 ThingSpeak vehicle counter diagram

In this paper, we try to demonstrate how to develop a traffic monitoring that can be deployed onto Raspberry Pi edge node and sends data to ThingSpeak. We showed how to use MATLAB for offline analysis by retrieving data from ThingSpeak and analyzing and visualizing daily and weekly traffic patterns. And we also showed how to perform custom online visualizations inside the ThingSpeak web service by using the MATLAB Visualizations App to create a color-coded live traffic indicator that updates continuously as traffic data arrives.

5. CONCLUSION

A Raspberry Pi system and USB camera is used to detect, track and count real-time vehicles. The density of vehicles circulating on a particular road is determined in real time. The results of the proposed method with regard to the accuracy and time required are better compared to other methods. Due to the static IP address attributed to the Raspberry system, we can communicate with other remote computers. The performance of the proposed system is superior to 5% to 10% compared to other methods or systems used. It has been found that the cost of the proposed system is much lower than the existing systems. Vehicle detection and tracking by the system are reliable. The proposed method only considered the color characteristics of the vehicle and made it replace existing systems. The number of vehicles present in the video is calculated in real time. The experimental results demonstrated on a preexisting set of data considered at different camera angles, rear view of the vehicles and different camera heights show flexibility and good precision of the proposed method. A vehicle classification method is also being pursued. The classification method will improve the performance of the system detection.

Quality management and Web 2.0 tools embedded in the agile approach for education

Raluca Dovleac^{a*}, Ahmad Sad^a, Andreea Ionica^a, Monica Leba^a

^aUniversity of Petrosani, Strada Universitatii nr. 20, Petrosani 332006, Romania

Abstract

Throughout time, quality has gained popularity and has been implemented in various occupational fields, leading to debates and discussions about the role of quality and quality management in the education sector. The necessity of ensuring quality is, however, not the only thing that has made an impact on the educational process, it being a cumulative effort of more forces, with ICT (Information and Communication technologies) and web technologies being some of them. Using ICT in education was always a challenge to enhance learning, especially when it comes to using web 2.0 elements that include blogging. The paper explores the following aspects: (1) Combining gamification elements in class blogs, adding extra enhancements to learning which can be reflected in the student's blogs posts and can be measured using Google analytics and (2) Using quality management tools and creativity techniques to ensure quality for each stage of teacher/student blogging cycle. The purpose of the research is to emphasize an original path to ensure quality in education by integrating quality management tools and web 2.0 tools and using highly effective development approaches such as the ones embodied by the Agile approach.

Keywords: quality; quality management; Agile; education; gamification.

1. Introduction

There is a need in general to motivate students more in learning. An example here are Computers Maintenance students labeled as students at risk in a vocational school. They tend to have low motivation for learning and have many problems concerning education like poor attention, high dropout rate, behavior problems. The term student “At-Risk” is used to describe students who are in danger of not meeting educational goals such as graduating from high school or acquiring the skills necessary to become contributing members of society, some of them exhibit disruptive behavior that interferes with their learning. These students' background characteristics may place them at or below the poverty level. Other characteristics include low grades and tests scores, abundant absences from school, and low motivation. At-risk students usually feel that they are overwhelmed by the content covered in regular high school. They may have different learning disabilities that make reading and writing difficult for them.

The required approach should be based on using technology in education because as previous studies show, technology can be used to motivate these students (Madrazo, 2011), (Barley, 2002), research revealing how feelings of autonomy, extrinsic and intrinsic goal orientation, and task value are related to increased motivation among at-risk students (Madrazo, 2011). Information and Communications Technologies (ICT) have been widely perceived as the lever that would lead to significant educational and pedagogical outcomes and support students' development on the knowledge and skills needed to succeed in the 21st century society, where the graduates of secondary school needed to have for the digital literacy requirements (i.e. ICT skills, Critical thinking skills, and ethical skills). So the required model needs to be simple to use, easy to apply and easy to deploy. It shouldn't require powerful PC not available in all areas. It should be free to use and continues to stay free and shouldn't require any installation fees. Web 2.0 applications including blogs, wikis, social networking, social bookmarking, RSS, podcasting, media sharing etc., have enabled students to master many parts of the digital literacy requirements.

E-mail address: raluca.dovleac@yahoo.com

Academics, researchers, educators and policymakers have advocated that the emerged Web 2.0 applications have the potential to offer enhanced learning opportunities for both students and educators and support lifelong competence development (Jimoyiannis and Angelaina, 2012). Using blogs in the classroom can help increase student learning using student’s preferred learning style, personal interest, and engagement. It also encourages self-reflection for the student and critical thinking. Blogs allow collaboration that promotes a constructive environment. And for low-achieving students blogging can give the "silent student" a voice by allowing them the opportunity to write on topics of interest (Sawmiller, 2010). Figure 1 shows a teacher blog with all the assignments for the year 2018 for the Computer Studies class of students.

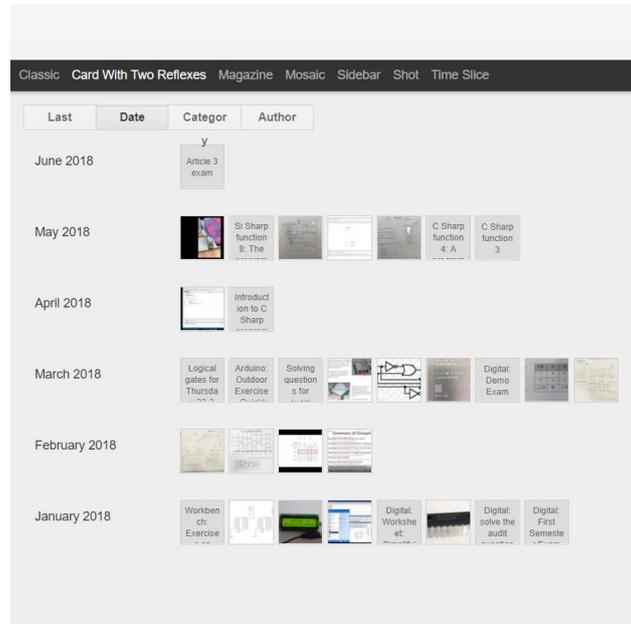

Fig. 1 Teacher blog with assignments divided per months

Figures 2 and 3 show some of the metrics displayed by Google Analytics and available for the teacher’s blog to help him understand the behavior of his students and get more insight into what interests them. The teacher can learn valuable information about the students and their behavior such as: what time of the day they are more likely to be working on their assignment, how much time they spend on average on the webpage, what type of device they are logged in from, which pages (assignments) have the most visits and so on.

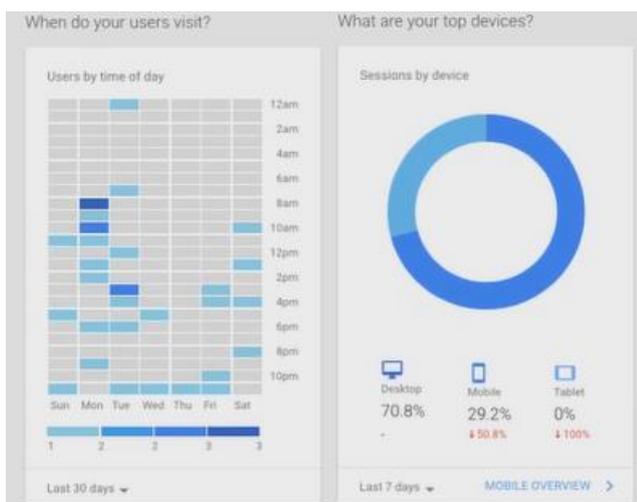

Fig. 2 Metrics from Google Analytics

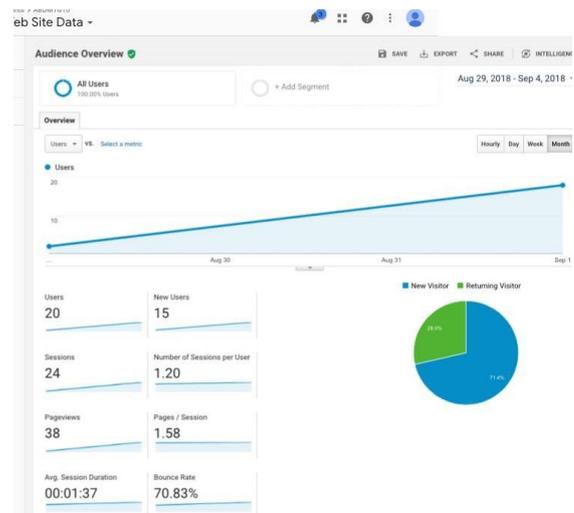

Fig. 3 Audience Overview dashboard

The usage of blogs in the teaching process has been noted also in the case of the Agile Teaching/Learning Methodology (ATLM) which is an approach to the teaching/learning process based on principles of the Agile Manifesto. The application of ATLM has been proven to be successful for increasing student individual study, motivation and results. This approach is based on the Agile software development approach and it advocates that software development is very similar to the teaching process in the sense that it involves multiple parties with different

objectives, limited resources, tight schedules and fixed deadlines and a lot of both expected and unexpected changes. The main focus of this approach is to take the teacher out of the learning loop and give the students the possibility of becoming more autonomous and involved in their learning endeavours (Hon and Chun, 2004).

The similarities between the Agile approach and the Teaching process can be best observed in Figure 4 where on one column the four Agile core values are written while the other column shown the correspondence between these and the teaching process.

Agile core values	Teaching process correspondence
Individuals and interactions over processes and tools	Putting an emphasis on the interaction with the student rather than the medium of interaction.
Working software over comprehensive documentation	Quantifiable results obtained through Google analytics rather than basing decisions on the result of a test paper
Customer collaboration over contract negotiation	Active listening to what the students understand and what they are interested in. Being able to quickly resolve issues and misunderstandings.
Responding to change over following a plan	Adapting the lessons according to the results observed by the teacher in regard to the efforts of his students and the results

Fig. 4 Correspondence between Agile and teaching

The two main concerns that arise from this approach relate to the possibility of integrating gamification tools and techniques in the educational process for the case of Agile ATLM and any other approach focused on blog related teaching activities on one hand, and the means of ensuring quality of the educational process for the case of the Agile ATLM. In the next sections of the paper we look at these problems and provide tools to help solve them.

2. Materials and methods

The paper proposes the integration of quality management tools and gamification tools and techniques in order to both help ensure quality within the Agile approach used in the case of the educational process as well as help students become even more engaged and motivated.

An important aspect to be considered given the fact that the Agile approach to teaching is used, is of course the necessity of integrating quality assurance practices and activities in the Agile approach to teaching. As it has been noticed by Bhasin in his paper, the best approach regarding the integration of these practices is within the development team’s daily activities while making sure that important aspects such as transparency, team collaboration and flexibility are covered. It has also been debated that Agile methodologies can include quality assurance practices within their activities but they must be shaped according to the Agile principles so that they can adapt to the iterative practices of Agile with the purpose of ensuring quality and stability for each iteration of the development process (Bhasin, 2012).

With this in mind, the authors have identified quality management tools that can help ensure quality and stability for each stage of the teaching process. In order to apply these tools and techniques the authors have chosen to guide themselves through the help of the Agile System Development Life Cycle (SDLC) and have used a simplified version of the SDLC as shown in Figure 5. Based on this approach, the authors will create a model that will incorporate quality management tools and gamification tools for every stage of the development lifecycle.

The proposed model was designed for the case of startups looking to implement the Agile approach in their activity, even if they are not software development based startups and it maintains the base idea behind the Agile SDLC (Dovleac and Ionica, 2017).

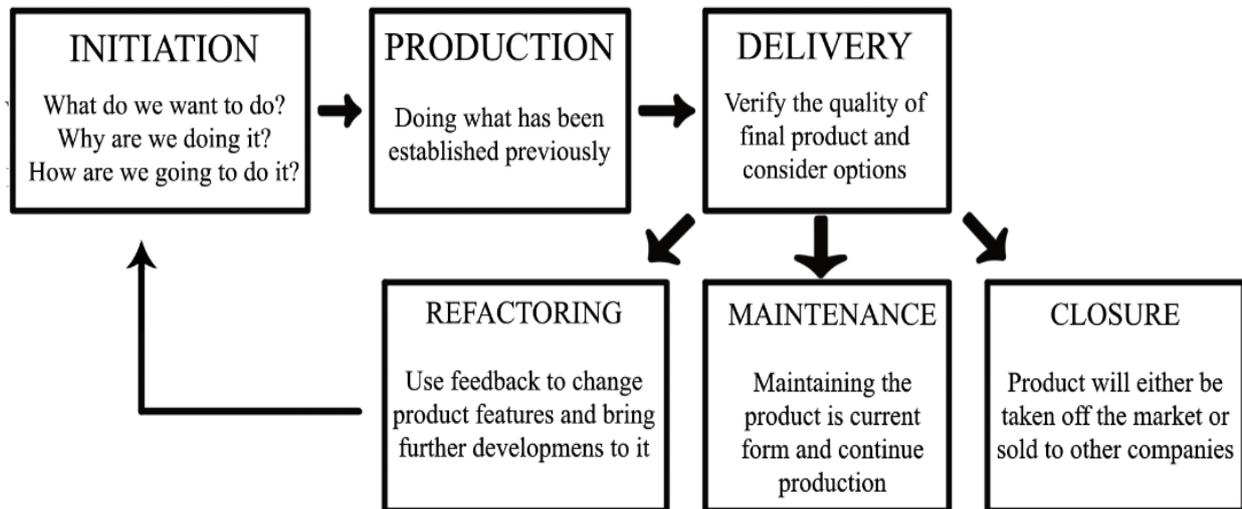

Fig. 5 Simplified Agile SDLC (Dovleac & Ionica, 2017)

The model, applied in the case of the educational process would involve the following activities in each of its development phases:

- **Initiation phase:** During this phase the teacher studies the curriculum and, if possible, gathers info about the students and their environment. He then divides the lessons into small chunks of information that are easy to understand and intractable enough to capture the attention of the students. At this stage, the teacher can also develop exercises with different degrees of difficulty for the first lessons in order to make sure that everybody is engaged. Furthermore, the integration of gamification tools can begin with this stage, where the teacher can plan how the students will remain engaged and rewarded through the help of gamification tools such as: achievement points and badges. Still in this stage, the teacher creates a class blog and furthermore guides the students into creating their own blogs and gmail accounts if necessary. Furthermore, in this stage, the teacher makes sure that the whole class understands the way the lessons will be taught and is familiarized with the Agile principles.
- **Production phase:** During this phase the teacher releases new assignments and lessons every week while gathering feedback from students. In this phase, the students complete their assignments, ask questions and require clarifications.
- **Delivery phase:** This phase takes place after each delivered assignment has been completed by the students and feedback from both Google analytics as well as students has been gathered. In this stage the teacher must decide the impact that the lesson had on the students and take actions accordingly. The available actions are:
 - **Closure:** the students failed to understand the lesson and upon closer examination the teacher can see that the lessons might not have been appropriate for the level of knowledge of the students or was not interactive enough, explanatory enough. The lesson is left behind as it is and the teacher focuses on delivering the same lesson differently.
 - **Maintenance:** the teacher evaluates the results as being according to the established goals and furthermore the students agree, therefore the template for the next lesson will remain similar.
 - **Refactoring:** the students understood the lesson but they had major difficulties and so the future lessons must be improved, refactored.

Given the fact that the Agile approach is focused on delivering iteratively small chunks of product rather than the whole product at once, the cycle will repeat in the sense that after the teacher completes one of the three alternatives following the Delivery phase, he must return to the Initiation phase in order to design and deliver the next lesson/assignment to the students.

The integration of quality management tools for each stage of the development process in the case of the Agile teaching approach proves to be therefore useful in order to guarantee that quality assurance best practices are met. Figure 6 shows how quality management tools can be integrated for each stage of the process, while Figure 7 shows how gamification tools and techniques can be implemented in order to obtain the best results.

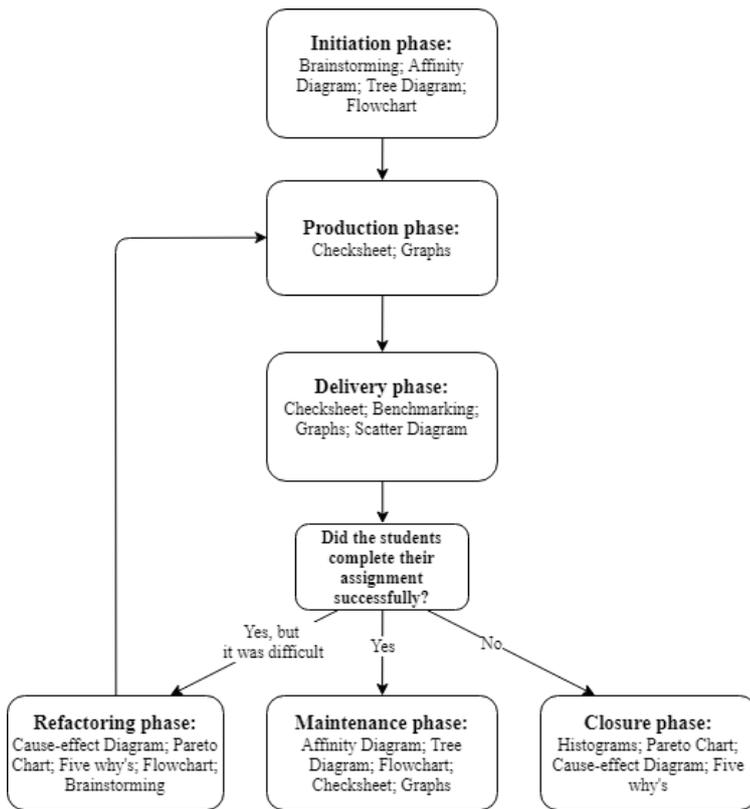

Fig. 6 Quality management tools integrated in Agile teaching approach

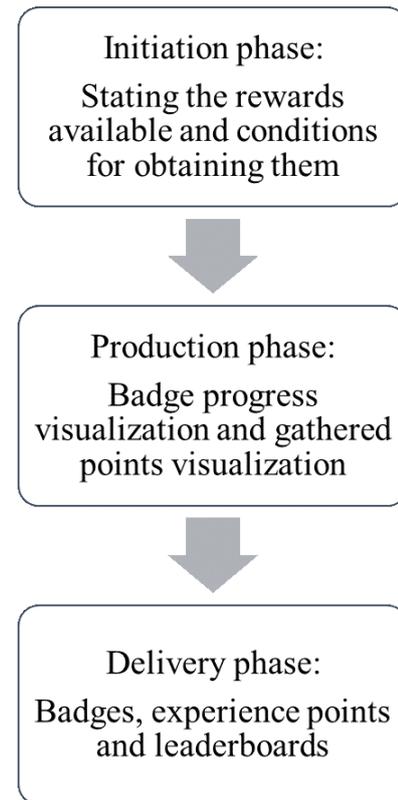

Fig. 7 Gamifications tools used in Agile teaching approach

As it can be seen from Figure 6, some of the quality management tools used in one stage of the development process may be used later for other stages if necessary. Furthermore, in the paper the authors considered just the most quality management tools but the implementation of other, newer quality management tools is possible. Figure 7 shows some of the most basic gamification tools and techniques that can be used in the main phases of the development process in the case of applying Agile approach principles to the teaching process in order to both help ensure the quality of the educational act as well as help improve the motivation for study among students.

3. Results

Information and Communications Technologies (ICT) have been widely perceived as the lever that would lead to significant educational and pedagogical outcomes and support students' development on the knowledge and skills needed to succeed in the 21st century society, where the graduates of secondary school needed to have for the digital literacy requirements (i.e. ICT skills, Critical thinking skills, and ethical skills).

Web 2.0 applications including blogs, wikis, social networking, social bookmarking, RSS, podcasting, media sharing etc., have enabled students to master many parts of the digital literacy requirements. Academics, researchers, educators and policymakers have advocated that the emerged Web 2.0 applications have the potential to offer enhanced learning opportunities for both students and educators and support lifelong competence development (Jimoyiannis and Angelaina, 2012).

Based on the blog implementation in the educational process, approaches meant to help improve it have emerged such as that of Hon and Chun, who both proposed and demonstrated the utility of implementing an Agile approach to the teaching and learning process (Hon and Chun, 2004).

The original contribution of the authors of the paper regarding this subject is the implementation of quality management tools to help ensure quality of the educational process for the case of teachers using the Agile development style as well as including gamification tools and techniques to help raise student interest and motivation. The proposed model can be further improved by integrating more or newer quality management and gamification tools.

Quality in Web Design – Trends and responsiveness techniques

Luminița Giurgiu^{a*}, Dănuț Moșteanu^a

^a“Nicolae Bălcescu” Land Forces Academy, Revoluției Street no.3-5, Sibiu, Romania

Abstract

Offering the same support to a variety of devices for a single website became an unquestionable common issue of quality in the web design area. The ability of a website to adjust and fit to different devices and resolutions on which is displayed without undergoing degradation is nowadays a matter of both interest and normality.

Because a responsive website can provide an optimal viewing experience - without resizing, zooming or scrolling across most devices, web designers have addressed this challenge with many and different solutions. To keep up with the changes in web design, this article intends to discuss some trends, techniques and solutions with specific references to the Land Forces Academy site.

Keywords: responsive techniques, web design trends.

1. Introduction

Generally speaking, trends in web design can have several roles: from a more appealing and more functional webpage to traffic and subsequent conversions. Why does a website need to keep up-to-date appearance and functionality? Considering the evolution of technology, many websites have experience a few frequent changes so visitors can enjoy pleasant experiences no matter how they access them.

The concept of responsive web design is not something new; it has existed for a few years, more precisely since the transition to CSS3 and HTML5. A responsive web site responds correctly and displays the items on the page as best as possible, depending on the resolution of the detected screen. We cannot talk about a separate version of the site, compatible with mobile devices, but we have only one version that is displayed correctly regardless of the device. It must display information and graphic theme correctly regardless of the browser used, screen resolution, or operating system.

2. Some trends in short

The main focus for any company, institution or private person is, or at least should be, the customer experience, while aesthetics and functionality remain basic principles. Because most of the traffic comes from the mobile area - for the 2018 web design - the adaptation to the mobile phone remains a priority. The following trends, each of them is user-centered and based on the relation between experience and website.

2.1. Responsive design

Web responsive design - as it has become a necessity, it is a little exaggerated to call it a trend in 2018, but still in this category. Flexibility of design is therefore a requirement of the market before it is an advantage over competitors. More than that, a good result on search engine results pages will be obtained if the site benefits from a responsive web design because search engines will index the pages much easier and recommend it to users.

* Corresponding author. Tel.: 0744387557
E-mail address: luminita.giurgiu.a@gmail.com

2.2. Flat design interface

The flat design interface - remains a trend this year. That means minimalism, full colors, simple elements and a design that let information be the first. Beyond that, it is important that the mobile version can perform through its relevance, simplicity and airy spaces. So nothing new about this trend, but it is already known that flat web design websites are easy to access and use, they have friendly and colorful interfaces. In fact, the simplicity of this design concept and the lack of loading pages with all sorts of unnecessary elements are very much appreciated. This design airflow helps users to navigate content more easily without distracting them. So, the content is leading.

2.3. Images at high resolutions

Using images at high resolutions - because of a narrowband bandwidth, the images were loaded at low resolutions not long ago. However, with the improvement of Internet connections and the increase of Internet speed, this constraint is no longer valid.

That is why the sharp and large images that, because of the new techniques, can be used as wallpaper, being resized and optimized so as to considerably reduce the loading time of the page, is preferred. Large images, especially those used as a backdrop of a website, have a double utility: on the one hand, they make the site more attractive and simplified and, on the other hand, manage to communicate the message clearly and effectively size.

2.4. Scrolling

The scroll option - regardless of the new techniques that web designers adopt, the scroll option is and will continue to be one of the most used, as it is closely related to the responsive design. This is highly sought after and appreciated by mobile device users. Scrolling considerably reduces the additional time it takes to load a page and simplifies browsing of users by giving them fluency.

2.5. Irregular grid layout

Irregular grid layout – using the CSS grid technique that allows web developers to create complex responsive web design layouts more easily and consistently across browsers, any content in the same width and thickness can be resized, displaying it in columns of any height.

Among the advantages is the fact that it is attractive to the eye regardless of the loading elements: news, event pages, press releases, photo galleries.

2.6. Artificial intelligence

Artificial intelligence and reinvent the homepage - artificial intelligence is already part of the website structure in the form of personalization of messages by user or computer chat support. It is expected to be present more and more on sites and will revolutionize the way we communicate. It is also closed related to the reinvent of the homepage. In 2018 it is expected that the structure of the homepage will have the most changes. New websites, as well as already consolidated brands with great openness to innovation, move further away from the traditional homepage, meaning that one of the company's priorities will be to create a personalized experience for each individual user depending on the location, history, or data they know about him. Thus, the content he sees and interacts with will change according to the specificity of each user.

2.7. Sticky menu

Sticky menu - it is located in a fixed space on the page where it does not disappear, even browsing the page, so it is accessible to all users without having to scroll. Web site designers have begun to introduce this kind of fixed menus at the bottom of the site that allow to go back without having to navigate back to the top. Modern functionality is a need that remains mandatory and the bottom of the screen seems to be more functional in 2018.

3. Responsive design

As a concept, responsive design, it is based on three fundamental elements: media queries, flexible images that change their size and fluid grids that take screen resolution into account.

3.1. Media Queries (@media)

Introduced in CSS3, Media Query is a CSS technique providing an effective way to load different CSS styles for different resolutions. By imposing CSS style conditions depending on screen resolution, @media includes a CSS property block only if a certain condition is true (Frain, 2013). Let's see an example where the browser window is less than 600px, the background color will change to blue and the edge of the menu's div will be eliminated:

```
@media only screen and (max-width: 600px) {  
  body {background-color: blue;}  
  .menu {margin:0px;} }
```

By the use of a series of similar queries, different conditions could be created for different resolutions: 320px, 480px, 600px, 768px, 900px, 1200px. More than that, any number of conditions can be used, if necessary.

3.2. Flexible, fluid images

Another key element is the flexible image. Flexible, fluid images particularity consists in changing their width and height according to the resolution and size of the grid. For this purpose, images are saved on the server in a certain number of dimensional sets, of which the corresponding image will be loaded, depending on the size of the screen. Among the techniques used to resize images proportionally, the most popular is the maximum width:

```
img {max-width: 100%; height: auto}
```

This way, the maximum image width will be 100% and if it decreases, the same will happen with the image. So, flexible or fluid images cause the adjustment of the size to the parent block. The consequence is that if the parent block is smaller than the image size, then the image is reduced proportionally. The same technique applies for the flexible embedded videos.

3.3. Fluid grids

The use of fluid grids is a very important step in responsive web design. Considering the large number of resolutions today, the fluid grids' benefits cannot be ignored. Fluid grids are based on percentage sizes, being very well calculated. The layout's elements are all scaled to each other and the measurements are not made in pixel dimensions, but in percentages and relative units. Thus, when the website is scaled to a very low resolution, all its elements shrink and perfectly align with each other. In order to obtain such a result, the best way is to realize a high resolution design, to take each item measures and to do the division of the element width by the design width.

4. Some responsiveness techniques used in the Land Forces Academy official web site

The responsive version of the academy official website has considered the three elements described above, and involved the use of several techniques, of which only three would be discussed:

4.1. The breakpoints setting

Breakpoints have to be set in places where it is needed so that the page elements move suitably to display well on screen. For setting the breakpoints where the content starts to look bad as the screen shrinks, the dimensions of the page's elements need to be measured in pixels. Using Google Chrome, activating "Inspect element" mode, and then tracing the edge of the appeared section until the page starts not looking well could be the way of establishing these dimensions. Next, breakpoints are set using Media Queries in CSS (Marcotte, 2015). So, a breakpoint could be added where certain parts of the design will behave differently on each side of the breakpoint. For example, a media query was used to add a breakpoint at 768px; when the screen gets smaller than 768px, each column should have a width of 100%.

The example in figure 1 shows that the difference between the classes is only the name and it gives the possibility to determine how the breakpoints affect the columns:

- Case of extra small devices Phones (<768px) it would be considered the class prefix col-xs-*. Because the place is very limited the arrangement of the elements must be well thought-out so clarity is preserved. In most cases, the menu from the navigation area will become an icon. The menu adapts itself to the small space by line breaks and the selection boxes for the target group selection disappear. The options of the selection boxes are moved to a different level and sublevel in the menu.

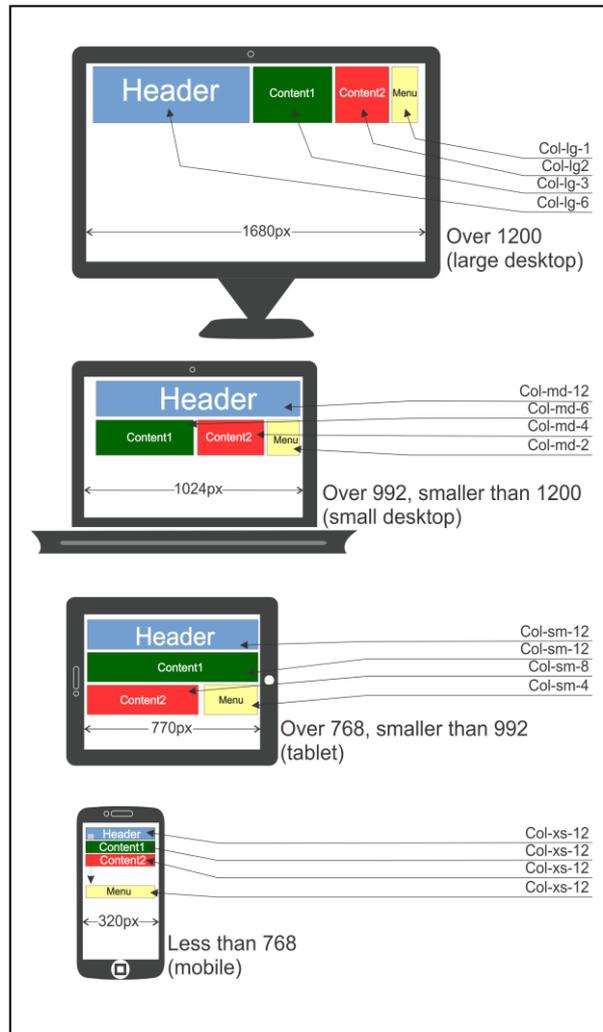

Fig. 1. Responsive design technique – setting the breakpoints

- Case of small devices Tablets ($\geq 768px$) it would be considered the class prefix `col-sm-*`.
 - Case of medium devices Desktops ($\geq 992px$ and $< 1200px$) – it would be considered the class prefix `col-md-*`.
 - Case of large devices Desktops ($\geq 1200px$) - it would be considered the class prefix `col-lg-*`.
- The symbol “*” signifies a number: `.col-md-3` creates a column three times the size of a `.col-md-1` column; `.col-xs-10` creates a column ten times the size of `.col-xs-1`, etc.

4.2. Graceful degradation and progressive enhancement

Given the existing content, the new construction of the website had to consider the two approaches represented in Figure 2:

- First - if the website already exists, it is possible just a redesign. It is called *graceful degradation*, where the detailed site for large screen has to gradually stretch down. The smaller the screen, the more elements of the page need to be omitted, condensed or remapped to keep the site clear and easy to use.
- Second - for a fresh new start, the concept is mobile first and it is called *progressive enhancement*. It means that first is created a page for the smallest screen and finally for the large screen, because the better a page is essentialised to the substance, the more evident and useful it is on small end devices. Then, the mobile-focused view of the site is progressively enhanced to the more refined tablet view and finally to the large desktop version with all the images, details, animations and information that appear on the smaller display also.

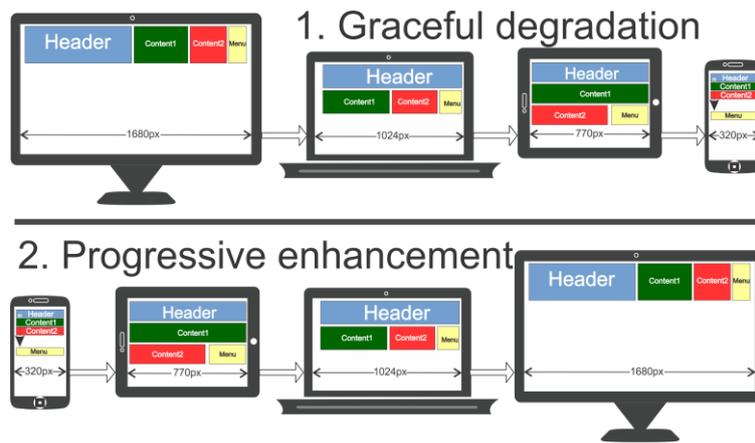

Fig.2. Approaches in the redesign of the site

The effort was done in the second direction and the official website of the academy respects the same approach in both English and Romanian versions. By actually working on the redesign of the site, I came to the conclusion, which was originally planned from the beginning that the natural, real trend in web design is to create the site starting from the screen of mobile devices and not from the desktop screens.

The justification of the importance of the presentation level is given by getting in user interaction. The presentation level is what the end user sees after all the app processing, so it must be up to the required complexity. Being simple and intuitive, no matter how elaborated its structure is and how complicate the system, the website fulfills the user's desire to navigate quickly, clear and agreeable.

4.3. Responsive layout and responsive classes

Responsive layout refers to the use of columns. By default, Bootstrap uses the 12-column system. A graphic representation is shown in figure 3. The calculation of column sizes was done using formula $12/x$, where x is the desired number of columns.

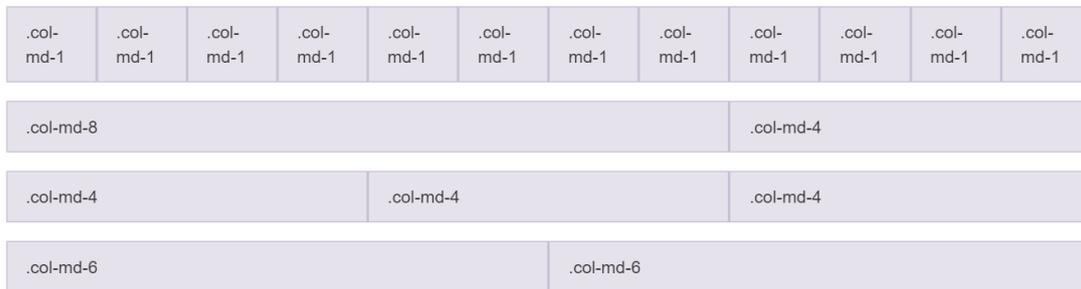

Fig.3. Bootstrap 12 columns system

For a response to different devices, bootstrap classes were also used in the site code. With the help of the responsive utility classes, the content is hidden or displayed, depending on the device. Figure 4 shows a table of correspondence between the available classes and their effect on a given media query aspect.

	Extra small devices Phones (<768px)	Small devices Tablets (=768px)	Medium devices Desktops (=992px)	Large devices Desktops (=1200px)
<code>.visible-xs*</code>	Visible	Hidden	Hidden	Hidden
<code>.visible-sm*</code>	Hidden	Visible	Hidden	Hidden
<code>.visible-md*</code>	Hidden	Hidden	Visible	Hidden
<code>.visible-lg*</code>	Hidden	Hidden	Hidden	Visible

Exoskeleton for improving quality of life for low mobility persons

Marius Risteiu^{a*}, Monica Leba^a, Andrei Arad^a

^aUniversity of Petrosani, Str.Universitatii, no.20, 332006, Petrosani, Romania

Abstract

Exoskeletons were originally created for military applications to help soldiers lift or carry extra weight. From that point the scope has been moved to other applications, among others to help the people who have suffered a stroke and therefore have reduced mobility. This paper proposes a model of an exoskeleton to help move the upper limbs of a patient, the control of the exoskeleton being achieved based on signals acquired from EMG sensors.

Keywords: EMG; modeling; simulation; robot.

1. Introduction

The development of the exoskeleton robot technology has started just like many others in the military field. First application of the exoskeleton robot was to give more power to a soldier so he could carry extra weight. Since then, this technology has focused on developing systems for assisting and improving human power. Later, this technology has been used in other applications, such as limb rehabilitation and tele-operations. The research in exoskeleton domain is still a growing area and requires multidisciplinary approaches for solving complex technical problems (Gopura et al. 2015).

This kind of devices were designed with varying degrees of mobility depending on the area which they are rehabilitating. The vast majority of these types of devices are made for upper limb rehabilitation, but there are designs made for the lower limbs as well. The ARMin device, for example, is based on a haptic unit with two-degrees of freedom and the mechanical part is constructed to allow the upper limbs to be rehabilitated in two ways. ARM mode makes flat movements on shoulder and elbow, and WRIST mode performs tasks that move the forearm and wrist.

Hand with the problem is attached to the guide bar that is positioned depending on which mode the device is set to work. Starting from this model, another device named ARMin III has been developed, that is equipped with 6 engines, making the shoulder movements with 3 degrees of freedom, elbow joint, a supination of the arm, and a flexion/extension for the wrist. One of the advantages for this device is the symmetrical construction that can be used for both arms, and control algorithms allow not only device control but also interaction forces between user and exoskeleton (Nef et al. 2009).

Another exoskeleton device is SUEFUL 7 which is capable of assisting in horizontal and vertical movements, shoulder flexion / extension, internal / external shoulder rotation, flexion / elbow extension, forearm supination / pronation, flexion / extension wrist, radial / ulnar deviation of the palpation wrist. SUEFUL 7 has been designed to be worn on the upper limb but since many patients use the wheelchair it has been adapted to fit the seat so that the user is not affected by its weight (Gopura et al. 2009).

In the literature, there are several exoskeleton robots among we mention MIT-MANUS, GENTLE/S, Pneu-WREX and NEREBOT are specifically designed to help arm stretching exercises but lack the ability to assist in wrist and forearm movements. On the other side CRAMER, RICE WRIST, HAND MENTOR and HVAR are robotic devices specially designed to perform exercises for the movement of the forearm and wrist but do not allow the arm to exert other movements. In this field of exoskeleton robots, devices can still be developed because in many cases the devices need to be customized according to the needs of the user because we cannot talk about a standard model in case of people who have difficulty in moving their arms (Kiguchi et al. 2009).

2. Exoskeleton design

In this paper we have proposed, model and test a device for improving the quality of life for persons with reduced mobility of upper limbs as shown in figure 1.

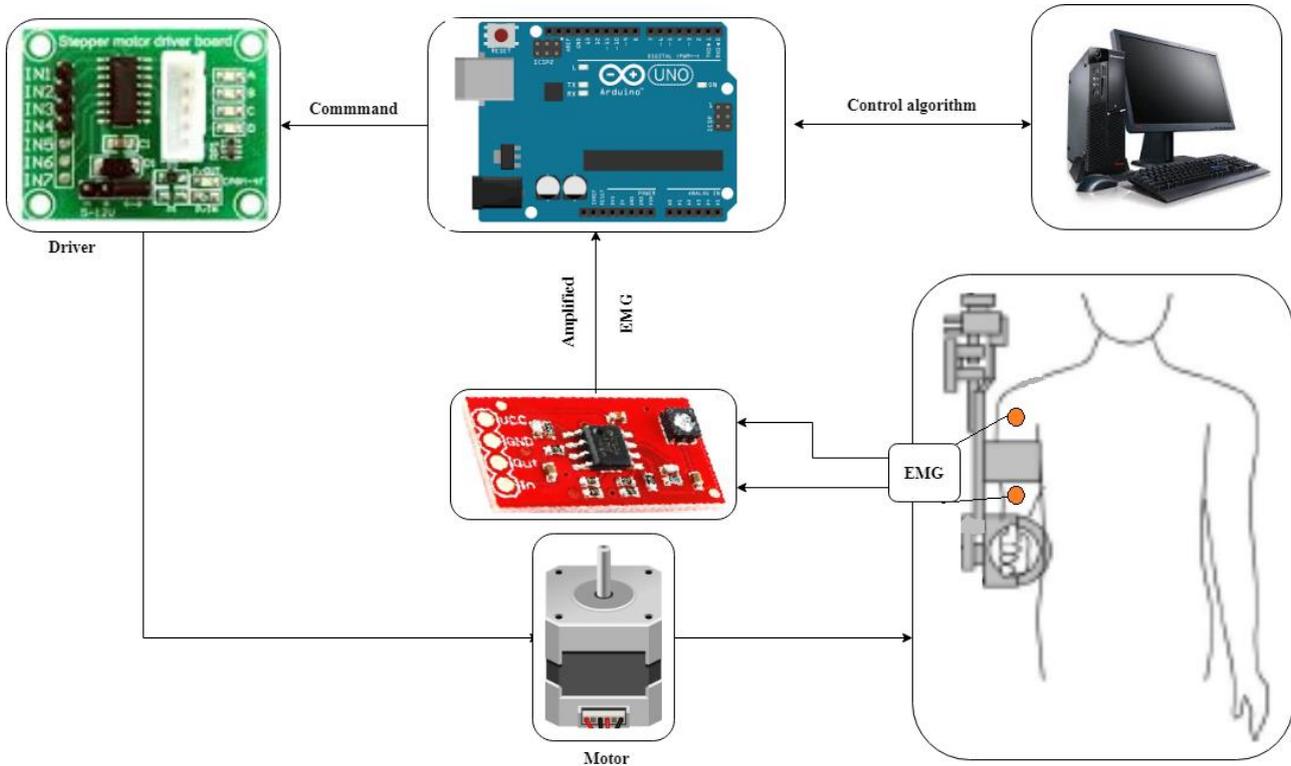

Fig. 1. Block diagram of exoskeleton device

Figure 1 shows the block diagram together with the operating algorithm of the exoskeleton. First, the exoskeleton must be fixed on the right arm of the user and EMG sensor electrodes must be positioned on the muscle groups so that a better signal can be taken. As seen in the above figure after the signal is taken over by the electrodes it passes through the amplifier so the signal to be filtered and amplified. After filtering and amplification, the signal goes further into the Arduino UNO interface board that communicates further with the computer to can use the kinematic models. Once a motion decision is established, the control signal is transmitted to the motor driver by forwarding the signal to the execution element. For the realization of this device it was necessary in the first phase to make a mathematical model of the human arm and a mathematical model for exoskeleton (Kiguchi et al. 2004). After determining the direct kinematical model of the arm, the inverse kinematic model of the exoskeleton was determined to perform the movements according to the user's intentions of movement. Through the kinematic inverse model, we determine the movements each joint must achieve in order to reach the imposed position, meaning the linear translation d_1 and the rotation angles θ_2, θ_3 . The matrix of the direct model is:

$$T_{0,3} = \begin{bmatrix} -s_{2+3} & -c_{2+3} & 0 & -d_4 \cdot s_{2+3} - d_3 \cdot s_2 \\ c_{2+3} & -s_{2+3} & 0 & d_4 \cdot c_{2+3} + d_3 \cdot c_2 + d_2 \\ 0 & 0 & 1 & -d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Based on the Denavit-Hartenberg direct kinematic model previously developed, there was designed the simulation model in MatLab-Simulink-SimMechanics, as presented in figure 2.

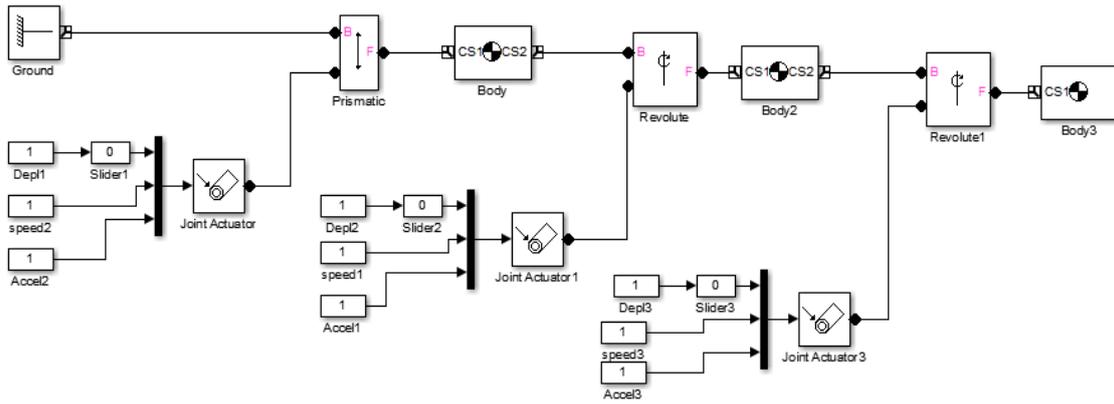

Fig. 2. Matlab Simulink SimMechanics exoskeleton model

There was implemented the direct model, as can be seen from the sliders in figure 3 representing each joint actuation, first joint in a prismatic joint and the other two are revolute joints.

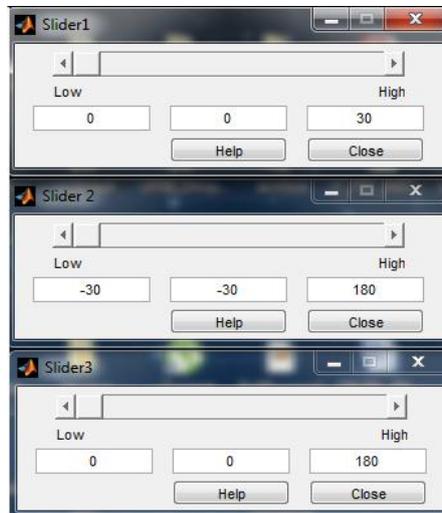

Fig. 3 Direct model

In figure 4 is presented a position of the exoskeleton that corresponds to the position presented in the sliders from the same figure.

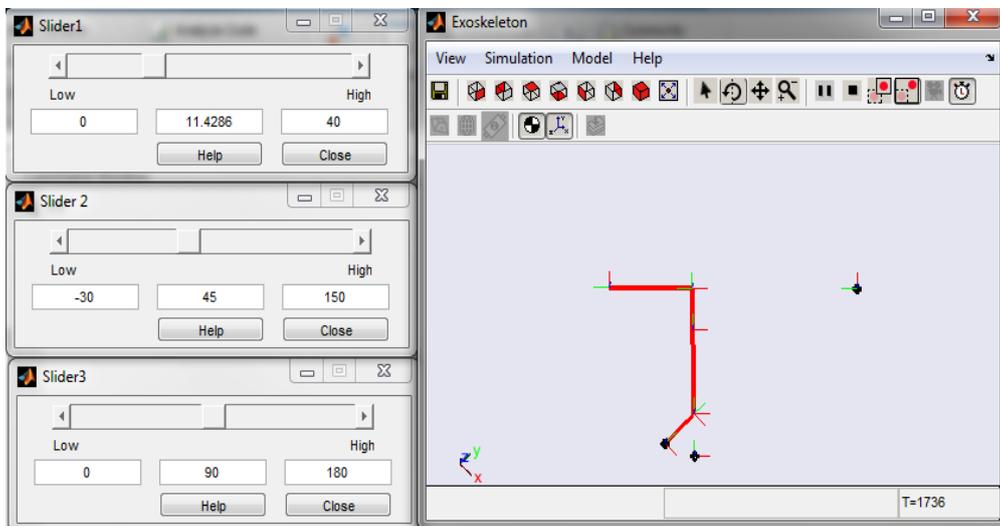

Fig. 4. Simulation results

3. EMG based controller

The electromyography (EMG) sensors take the value of electrical voltage that occurs at the level of the muscular endings. Electrodes used for EMG sensors can be two types:

- invasive – are intramuscular electrodes, with a needle inserted into the muscles to retrieve the signal
- noninvasive – are surface electrodes that have a conductive gel placed over them and stick to the surface of the skin (Norali et al. 2009).

Due to the fact that the non-invasive ones are easier to use without causing any discomfort to the person monitored in this project we have chosen to use them. With the help of the signals received from non-invasive EMG sensors, the left/right control circuit of a servomotor was designed as shown in figure 5. This represents a testing prototype for the control system of the exoskeleton.

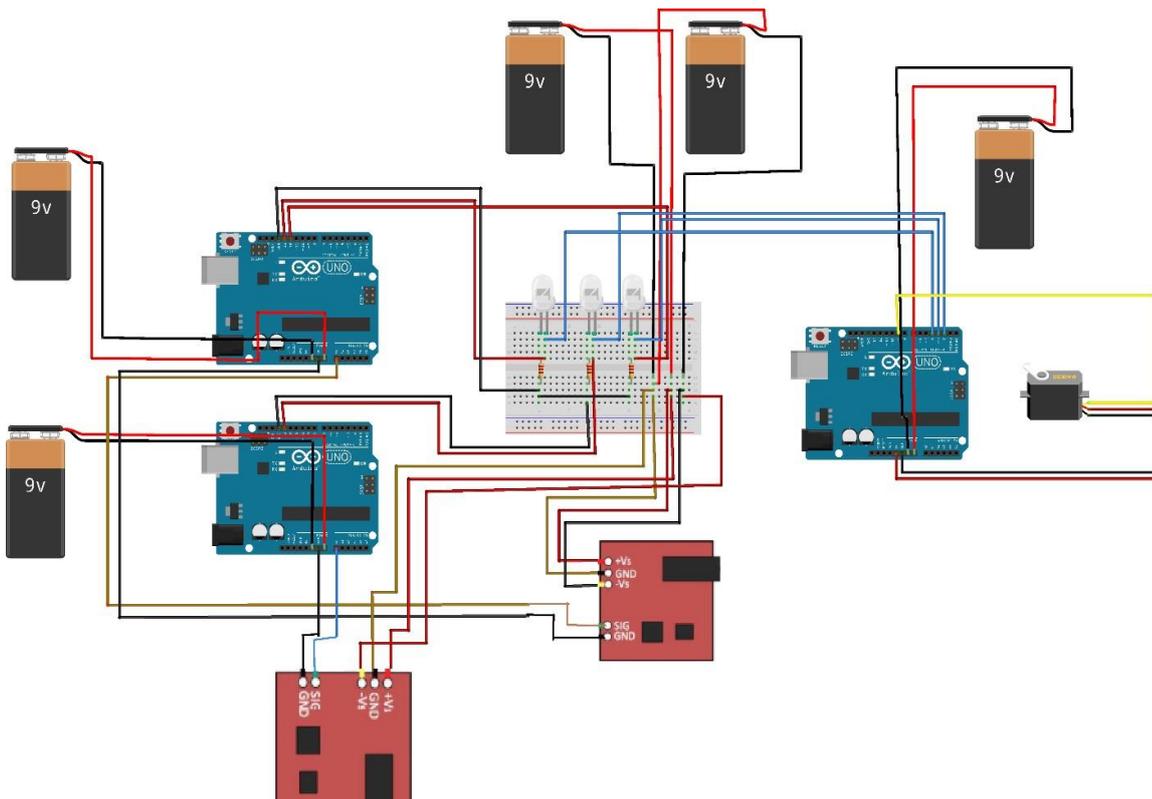

Fig. 5. EMG based control diagram

Three Arduino UNO development boards and two MioWare V3 EMG sensors were used to implement this assembly. The two EMG sensors are connected to 2 Arduino boards that deal with data acquisition. The two boards are designed to monitor the signals received from the sensors, but also to interpret these signals according to the muscles that are observed. Depending on the signal amplitude, the microcontroller interprets what we call the intention of flexion or extension of the muscle.

At first, the implementation of the system was attempted on a single Arduino board but due to the fact that sensor readings take a sufficient period of time to be able to affect the operation of the engine and that there were interferences between the sensors reads on the same development board so we decided to implement these components on 3 different boards.

The two data acquisition boards are programmed to emit a digital signal depending on the intent of the monitored muscles. The third board is used to interpret these digital signals. Depending on the intentions of the muscles, it will make the decision to move the servomotor.

The system presented can be used to simultaneously monitor 2 muscles, and to make decisions based on these intentions.

At the time of implementation, the muscles we considered were biceps and triceps. The studied movement as well as the one for which the system was implemented is the flexion or extension of the elbow. Depending on how the person who wears the sensors moving the elbow the device moves also, it is possible to determine with these sensors the intention as well as the direction of movement.

In fact, the whole system is based on these two variables that take values according to the signals received from the muscles. There must be an intention to move the arm in a certain direction in order to achieve a valid interpretation.

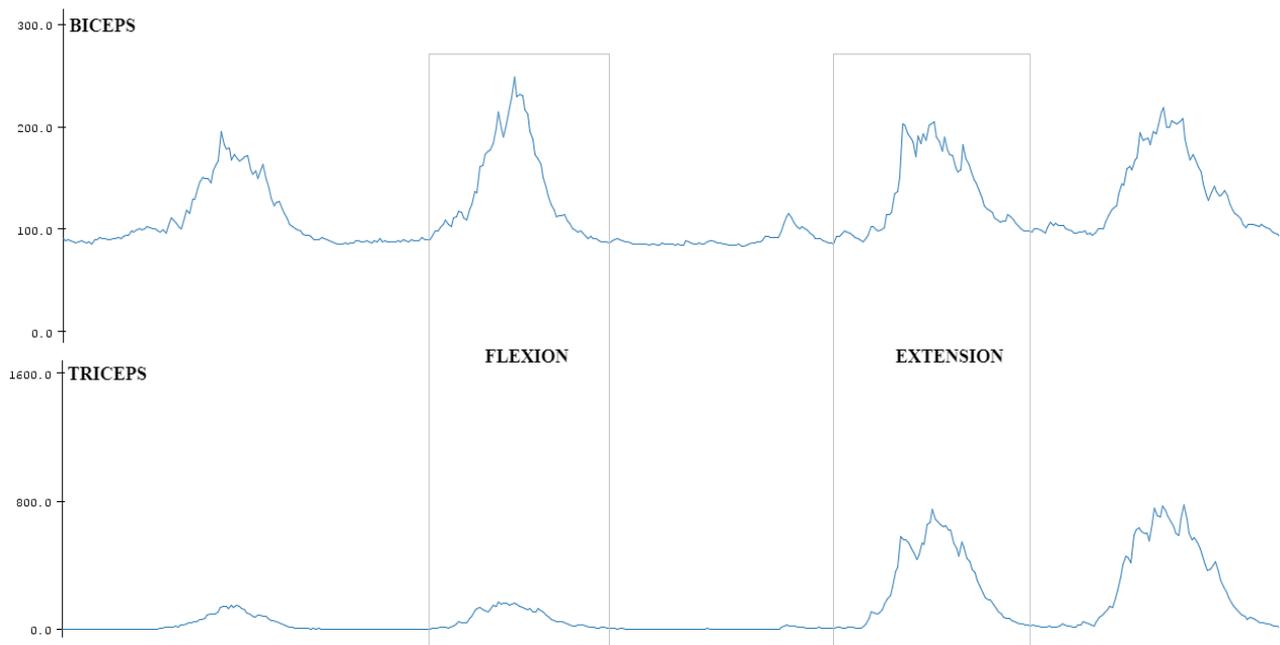

Fig. 6. Signals from EMG sensors and identified movement

Figure 6 shows the signals taken from the biceps and triceps during the flexion or extension elbow movement. Depending on the signal amplitude, the two boards responsible with the data acquisition decide whether there is a motion intention and the direction in which the motion is desired. Forced arm strain without moving it in a certain direction will only produce a motion signal, not a specific direction.

The program written on the acquisition boards microcontroller checks whether the analogue value exceeds the minimum value from which the signal may be interpreted. If this condition is met, the program performs a series of 50 readings that must be greater than the minimum declared value in order to consider the signal as a moving intent. If second condition is also met, the program changes the state of a digital pin to indicate that it has detected a motion intention. This algorithm is implemented on both Arduino boards, the difference being that the board on which the direction is implemented has two constant values defined, and depending on these two values, it decides the direction of motion. If the signal is too weak, it is ignored because it may represent noise from imperfect contact between electrodes and skin or there exist an electromagnetic field.

Also, in order to avoid delays in the coupling movement, the program also has a condition that once the engine starts to move, it is necessary to eliminate the intention to move equivalent to another 50 readings to stop the engine. Of course, due to the short time between readings, it can be approximated that 50 readings are performed in approximately 500ms. The condition that dictates that the engine will only stop after 50 readings from the disappearance of the intent has been implemented because erroneous readings can occur that are far below reality and without this condition would stop the engine for other 500ms.

These constants that were previously spoken as the minimum values over which the signal is considered are threshold values, and are obtained by studying a user's muscular activity and are valid only if the device is used by that user.

Also due to imperfect contact between sensor electrodes and skin and various types of electrodes, these values are only valid for one use. Removing electrodes and sticking to others even if this is done in exactly the same place can have major influences on how the electrode reads muscle tensions, and as a result they will lead to interpretation mistakes.

The disadvantage of using non-invasive electrodes is that they are imprecise because they depend on how they are bonded to the skin as well as on the level of contamination of the contact gel. From this point of view, invasive electrodes, even if they cause major discomfort in practice, are much more useful and the data taken from this type of sensors can often be repeated easily if the electrodes are placed in the same places.

4. Conclusions

Exoskeleton robots are a combination of human intelligence and the machine power. Due to the fact that the world population is in an ever-aging and more and more people get limb movement deficiencies, exoskeletons are needed in rehabilitation operations and for improving the quality of life.

Exoskeletons based on an electromyographic controller are, from our point of view, some of the easiest to implement as long as there is muscle activity. Where very high precision is not required, it is much easier to use non-invasive electrodes because the invasive ones need a more sterile environment and can cause infections if inappropriately used.

The proposed exoskeleton, modeled and tested in this paper, is based on an EMG controller with non-invasive electrodes and was designed to assist the movement of the upper limb of a person with partial motion disability.

Increase the quality of temperature measurements using virtual instrumentation

Nicolae Patrascoiu^{a*} Cosmin Rus^a

^aUniversity of Petrosani, Str.Universitatii, no.20, 332006, Petrosani, Romania

Abstract

For temperature monitoring, there are many options that are determined either by the type of sensor used or the method of acquisition and processing data from it. In this paper, we propose such a temperature monitoring system by using semiconductor integrated sensors and an open source platform based acquisition module. The proposed system allows the selection of available several sensor static characteristics used and their treatment by means of interpolation methods to process the data thus obtained.

Keywords: integrated sensor; LM 9402x; Arduino Uno; spline interpolation; LabView.

1. Introduction

Obtaining temperature information allows either adjusting it in a process or system, or collecting data about other physical variables whose values can be temperature dependent. As is known in the temperature measurement, different types of sensors are used according to the functional principle. Thus, resistance temperature detectors (RTD), thermistor, thermocouple, or p-n junction can be used.

It is known that the temperature sensitivity of the p-n junction is part of the transistor's defining equations and is quite predictable over the typical semiconductor operating the range of -55°C to $+150^{\circ}\text{C}$. Starting from this observation, the semiconductor temperature sensors are made and used.

Most semiconductor junction temperature sensors use a diode-connected bipolar transistor (by short-circuited the collector-base junction). A constant current passed through the base-emitter junction produces a junction voltage between the base and emitter (V_{BE}) that is a linear function ($V_{BE} = f(T)$) of the absolute temperature (T). The overall forward voltage drop has a temperature coefficient of approximately $2 \text{ mV}/^{\circ}\text{C}$

When compared to a thermocouple or a resistive temperature device (RTD), the temperature coefficient of a semiconductor sensor is larger but still quite small. Also, the semiconductor sensor's forward voltage has an offset that varies significantly from unit to unit. However, the semiconductor junction voltage vs. temperature is much more linear than that of a thermocouple or RTD. In addition to the temperature-sensing element, circuitry is easily integrated to produce a monolithic temperature sensor with an output that can be easily interfaced to a microcontroller and to provide features that are useful in specific applications. For example, by using an embedded temperature sensor with additional circuitry, protection features can be added to integrated circuits (ICs) (Fraden, 2014).

Electronic platforms open – source offer users the possibility to create its own hardware structure based on a core developed around a microcontroller. Their usefulness is essential in the realization phase, and especially in prototyping phase of the technical systems requiring a central processing unit like microcontroller type (Oxer and Hugh, 2010).

In order to achieve the virtual instrument that we propose in this paper we used the Arduino platform. This is a development board achieved in various configurations, every of these using various microcontrollers ATmega and can be used for building digital devices and interactive objects that can sense and control physical devices. The software component of the platform is integrated into a graphical user interface (GUI), IDE type, which is based on programming language named Processing (Durfee, 2008).

2. Integrated temperature sensors LM 9402x

The integrated circuits LM9402x, (LM94021, LM94022, LM94023) built in CMOS technology, integrates a temperature sensor and signal processing circuitry to provide an analog precision output signal that is dependent on the temperature of the capsule.

For temperature monitoring, this application uses the LM94021 sensor manufactured by Texas Instruments and is available on the LM9402xEVM Evaluation Module (EVM) with the same manufacturer. It is usable for a wide range of temperatures between -50 °C and + 150 °C, providing an output voltage that is inversely proportional to the measured temperature. It operates with a single-pole supply voltage starting from 1.5V and the low current required for the LM94021 circuitry makes it ideal for battery-powered systems as well as for general temperature sensing applications.

With two logic inputs, Gain Select 1 (GS1) and Gain Select 0 (GS0), it is possible to select the slope, i.e. the value of the output size according to the input voltage, i.e. the voltage-temperature ratio (Texas Instruments Inc., 2013).

The slope selection inputs can be directly connected to the source potential (V_{DD}) or to the ground (GND) without the need for pull-up or pull-down resistance, thus reducing the number of components. These selection entries can also be controlled by TTL-compliant logical signals that allow the system to optimize gain during operation or system diagnostics.

For the correct use of the temperature sensor in Fig.1, the pins configuration, the graphical presentation of the transfer characteristics and the slopes corresponding to each of these characteristics are presented. The slopes are chosen via the GS1 and GS0 pins (Texas Instruments Inc., 2013).

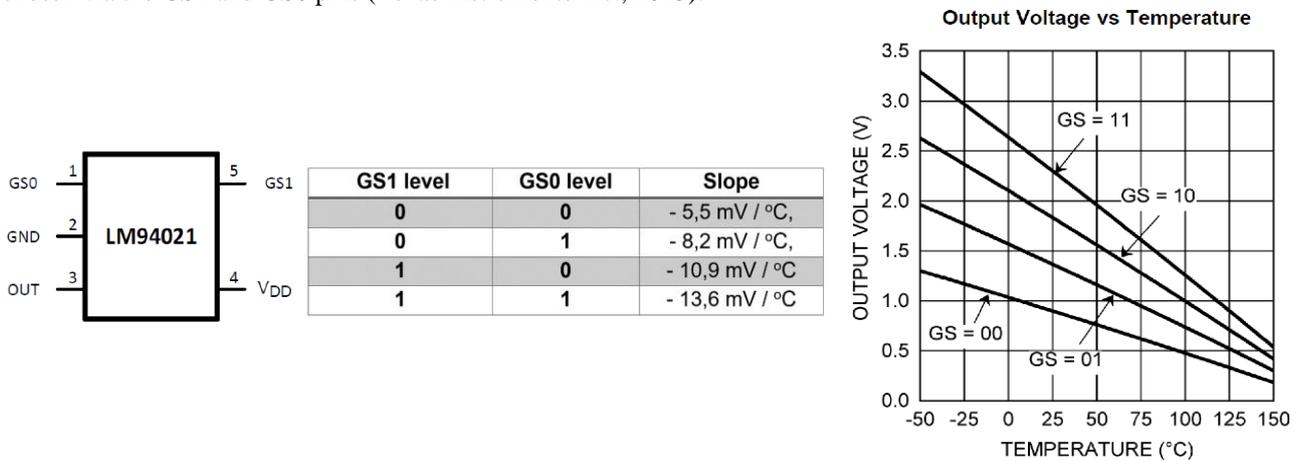

Fig.1. Typical transfer characteristics of the LM 94021 sensor

Although the LM94021 sensor response has a very good linearity is not perfectly linear, the response is slightly parabolic. The shape of the operating characteristics presented in Fig.1. is approximately linear.

The actual operating features are tabulated and can be used in applications built with this sensor by the "look-up table" method. Output voltage values expressed in mV for all 4 selectable sensitivities and for the full range are available to download at http://www.ti.com/lscs/ti/analog/temperature_sensor.page.

The static characteristics can be expressed and analytically based on the next parabolic equations defined for the 4 slopes as follows:

$$\text{For } GS1 = 0 / GS0 = 0 \quad V_{\text{TEMP}} [\text{mV}] = 870,6\text{mV} - 5,506 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C}) - 0,00176 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C})^2 \quad (1)$$

$$\text{For } GS1 = 0 / GS0 = 1 \quad V_{\text{TEMP}} [\text{mV}] = 1324,0\text{mV} - 8,194 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C}) - 0,00262 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C})^2 \quad (2)$$

$$\text{For } GS1 = 1 / GS0 = 0 \quad V_{\text{TEMP}} [\text{mV}] = 1777,3\text{mV} - 10,888 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C}) - 0,00347 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C})^2 \quad (3)$$

$$\text{For } GS1 = 1 / GS0 = 1 \quad V_{\text{TEMP}} [\text{mV}] = 2230,8\text{mV} - 13,582 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C}) - 0,00433 \frac{\text{mV}}{^{\circ}\text{C}} \cdot (T - 30^{\circ}\text{C})^2 \quad (4)$$

3. Hardware structure

An Arduino Uno open source platform is used to acquisition and primary process of the signal from the sensor. In Fig.2 the block diagram of the monitoring system is presented.

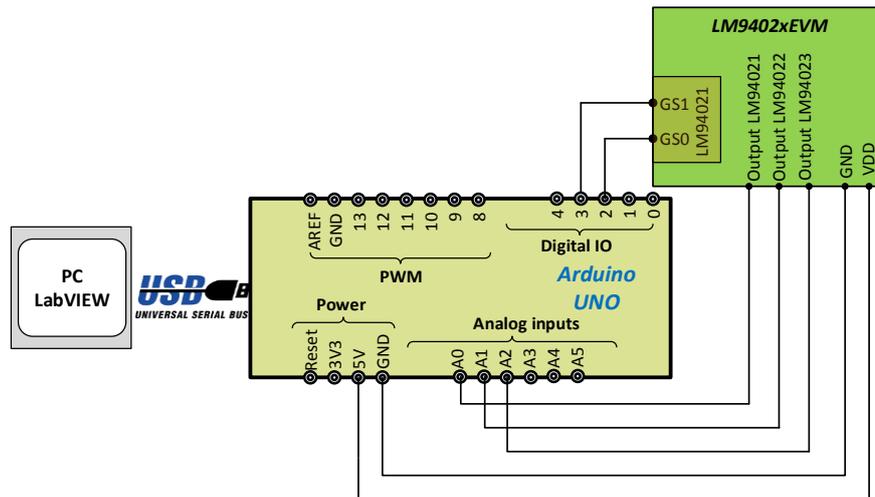

Fig.2. Hardware structure

Information about the temperature value represented by the voltage at the sensor output is taken over by the Arduino Uno module respectively from the analog channel AI0 to which the signal from the sensor is connected. For other analog values, the other analog channels can also be used through a suitable selection.

With the Arduino Uno module, a first signal processing is made, namely its analog-to-digital conversion, for which the integrated microcontroller ATmega328 structure on the Arduino Uno module is used (Evans, 2014).

Through the USB serial interface is obtained a link between a computer and the Arduino Uno module so that the data can be retrieved and processed by means of an application written in LabVIEW. This application provides to the user the data in a synthetic form via an appropriate interface. Also through the same interface user will be able to generate certain commands to the monitored technical system.

The sensor slope control is achieved through two digital channels that allow the user to select any of the four slope values through the application.

3.1. LM9402xEVM Evaluation Module (EVM)

The Texas Instruments LM9402xEVM (EVM) evaluation module, Fig.3 is designed to evaluate the operation mode and performance of the LM94021, LM94022 and LM94023 sensors (Texas Instruments Inc, 2018).

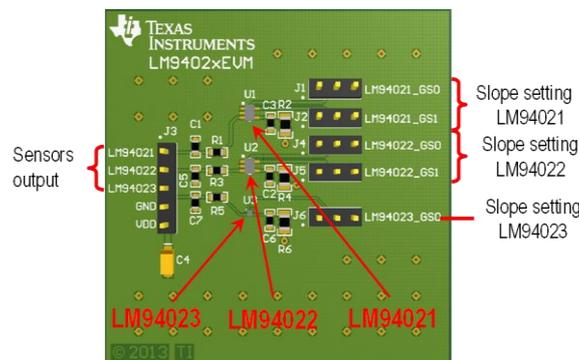

Fig.3. The LM9402xEVM Evaluation Module (EVM)

The Texas Instruments LM9402xEVM (EVM) evaluation module contains all three temperature analogue sensors and all jumpers for setting the slope either by connecting to the V_{DD} supply voltage ($GSx = 1$) or by connecting to the GND table ($GSx = 0$). Slope control can also be accomplished by appropriate logic levels taken from the digital channels of the Arduino Uno module and applied on the same jumper. Are used for this the digital IO2 and IO3 pins.

The analog output of the sensor is connected to the analog input AN0 of the Arduino module.

4. Virtual instrument

The virtual instrument is the application and represents the program written in LabVIEW, with which the communication with the Arduino Uno module is managed, and the processing of the data received from the sensors via the Arduino module is performed.

4.1. Front panel

On the front panel there are user interface elements that can be used to:

- entering data or commands (input elements) called controls;
- displaying the results obtained by processing data called indicators.

In Fig.4 there are shown the snapshots of the front panel of the virtual instrument corresponding to its operation.

In the realization of this application, three windows of the front panel are used, the user having the choice of any at any time of them. The three windows named **Grafic**, **Tabel** and **Statistica** can be selected using the Tab command.

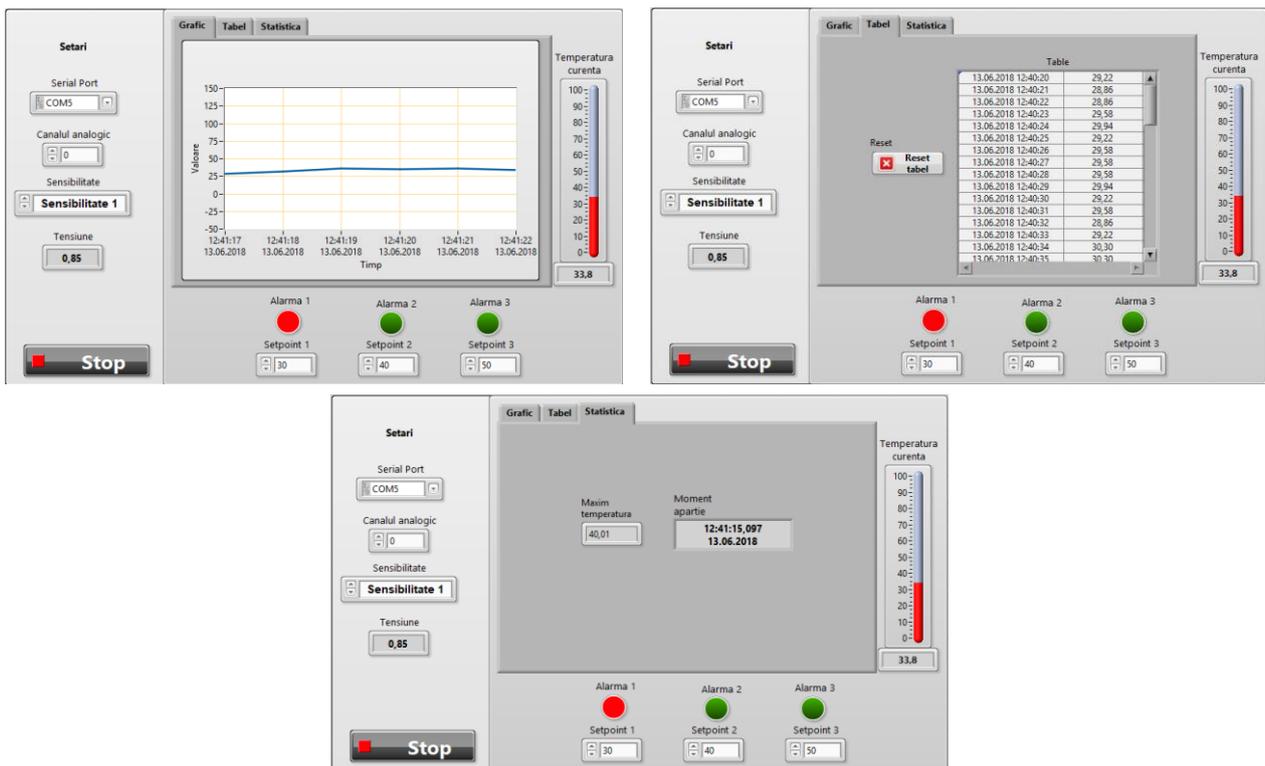

Fig.4. Snapshots of the front panel

The **Grafic** window is used to display the time evolution of the monitored temperature values. The time units on the abscissa are the real-time units, represented by the date, time, minute, and second corresponding to the reading of the respective temperature value by the sensor.

The **Tabel** window is a table representation of these temperature readings and their reading times

The **Statistica** window shows the maximum value found throughout the temperature acquisition as well as the time of its identification.

Also on the front panel are the following indicators:

- **Tensiune** - a numeric type indicator showing the volt value of the voltage read from the sensor;
- **Temperatura curenta** - slide indicator showing the value of the current temperature in degrees;
- **Alarma 1, Alarma 2, Alarma 3** - Boolean indicators indicating that the set alarm thresholds have been exceeded

The controls on the front panel with their defined functions are:

- **Portul Serial** - ring control used to select the USB port to which the Arduino Uno module is connected;
- **Canalul analogic** - numerical control used to select the analog input to which the sensor to be read is connected;
- **Sensibilitate** - ring-type control used to select one of the 4 slopes of the sensor.
- **Setpoint 1, Setpoint 2, Setpoint 3** - numerical controls used to set alarm thresholds.
- **STOP** - boolean control used to stop the program running

4.2. Diagram block

The block diagram is the proper program and consists of operations, functions and programming structures arranged according to the data flow necessary to execute the program (Sumathi and Surekha, 2007).

Running the program is done as long as the **STOP** button on the front panel is not actuated, and this operation is given by including all operations and functions in a While structure. Between two consecutive cycles of this structure, a delay of 1 sec is set by using the *Wait Until Next ms.vi* function so that the acquired temperature values with one read per second. Is used the *Open Serial.vi* function that open a serial communication with the LINX-controlled module, in this case the Arduino Uno module, and *Close.vi* function, respectively, that shut down communication with the LINX-controlled module and release the computer's connection resources. The activation of the two functions takes place when the program starts running after the **STOP** button is activated.

The general block diagram of the virtual instrument is presented in Fig. 5.

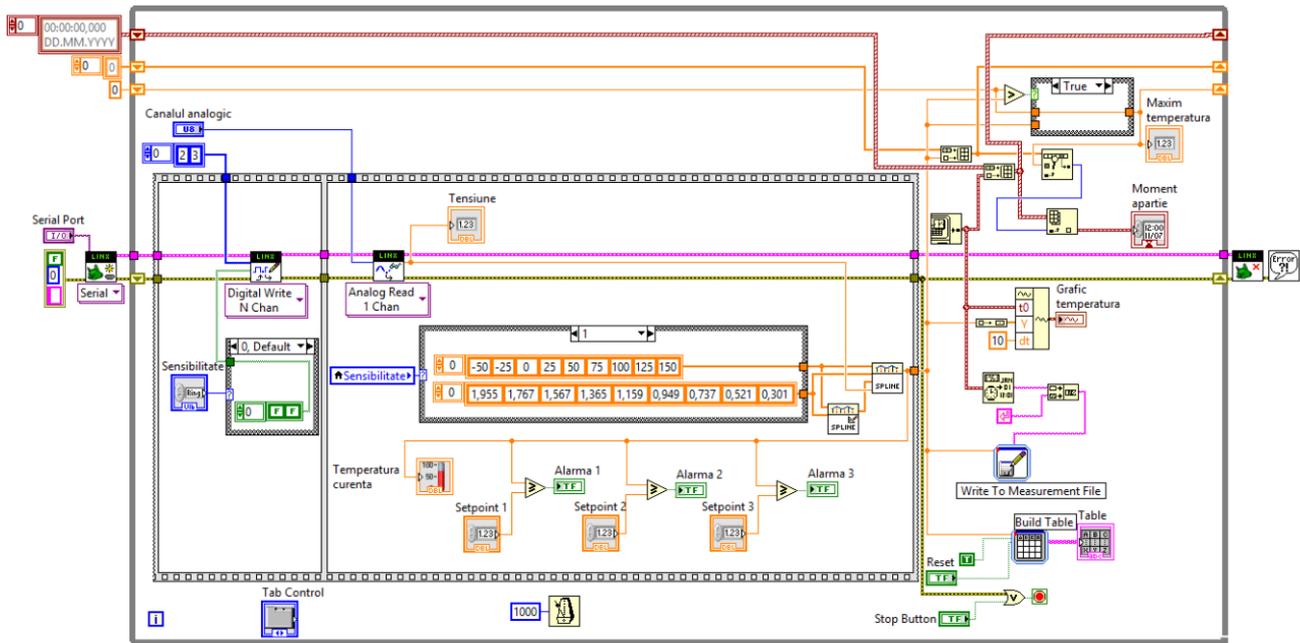

Fig.5. Block diagram of the virtual instrument

By using the *Sequence* structure, data acquisition and processing takes place in two sequences, as follows:

1. The slope value is selected by using the *Digital Write.vi* function that sent through selected digital outputs the proper code to the selection pins GS0 and GS1;
2. The voltage value is read from the sensor by using the *Analog Read.vi* function and the voltage-temperature conversion is made after that.

With the values of the voltage read from the AN0 analog input for the voltage-temperature conversion, the relations (1) ... (4) or the "look-up table" can be used.

In this application, for the conversion voltage-temperature was chosen a method that does not involve significant memory allocation and is valid across the entire range of the transducer. An interpolation method has been chosen for only a few of the voltage-temperature pairs from the sensor catalog.

The *Spline Interpolant.vi* and *Spline Interpolation.vi* functions are used for a small set of value pairs from the sensor catalog for each slope, as shown in Fig 6.

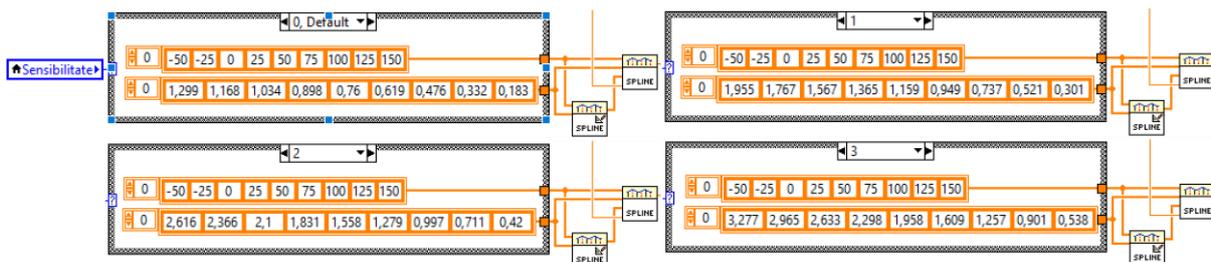

Fig.6. Voltage – temperature conversion for all four slopes

The *Spline Interpolation.vi* function returns a temperature value by the spline interpolation. The current temperature corresponds to the values of the read tension and the values obtained at the output of the *Spline Interpolant.vi* function that return an array with the length of the number of values and containing the second derivative of the spline $g(x)$ at the tabs of the read tension.

During the acquisition, the maximum value of the temperature and the moment of its occurrence are identified in each reading cycle by using the *Shift Register* operation. With this transfer operation between consecutive cycles, the maximum value identified in a cycle with the new read value is compared and the maximum between them is kept.

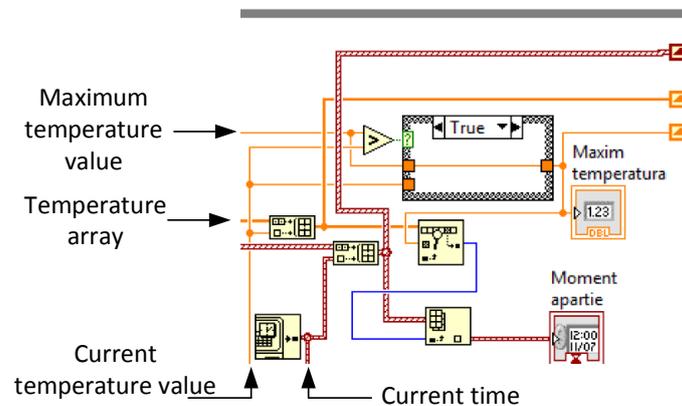

Fig.7. Identifying the maximum temperature

At the same time, the values read in each cycle are grouped and indexed into a vector so that for each maximum of the temperature values its vector index is also identified. Simultaneously with the temperature values are indexed and their time moments and using the index of the maximum temperature can be found and the time of reading this value.

The readings values of the temperature can be exported in a *.lvm* format to a file that can be later opened in an Excel spreadsheet and used to keep a history of the measured sizes. For this, *Write To Measurement File Express VI* function is used. This function performs the data entry in text-based measurement files (*.lvm*), binary measurement files (*.tdm* or *.tdms*) or Microsoft Excel files (*.xlsx*).

5. Conclusions

Following the obtained results, it can conclude that this virtual instrument can be used to acquire the temperature values with high measurement speed and precision selected through selected slopes.

The fastest of the tested sensors is the LM 94021, with the linearity being very good, the other sensors being slower but the conclusions being valid for them as well in terms of precision.

Data is stored in an external Excel file and further processing is possible.

Similarly, implementation can be done on other sensors with low time response (humidity sensor, atmospheric pressure sensor, etc.)

A mobile system based on LiDAR technology used for data acquisition in traffic management

Cosmin Rus^{a*}, Nicolae Pătrășcoiu^a

^aUniversity of Petrosani, University Street 20, Petrosani 332006, Romania

Abstract

This paper we propose a solution to realize of a mobile system for traffic management by counting the number of vehicles on a road with one or two lanes. The traffic intensity is measured using the transducers based on LiDAR principle. The acquired data are local stored into a local data logger and simultaneous are transmitted via radio communication to a dedicated server. The novelty of this system is represented by the communication facility provided by the new LoRa technology. LoRa is a long-range wireless telecommunication system with low power and low data rates promoted as an Internet-based object (IoT) infrastructure solution. End devices (end-nodes connected to various sensors) use LoRa on a single wireless network to communicate with Internet-connected gateways that act as transparent links and allow messages to be sent between these end devices and a network server central. This paper also provides an overview of the LoRa wireless telecommunication system and an analysis of its functional components. System performance is evaluated by field tests and simulations. Based on the analyzes and evaluations, some solutions for monitoring and controlling processes are proposed using this communications infrastructure. Also, it is highlights that this system is mobile and it is not invasive on the road structure.

Keywords: LoRa; data acquisition; non-invasive technology; urban traffic management; LabView.

1. Introduction

In recent decades there has been a steady increase in the number of private cars in traffic, while public transport is steadily declining. The current road infrastructure no longer meets the demands. Accidents and congestion caused by traffic have an important impact on life, reduce productivity and reduce energy. Traffic congestion, which causes environmental problems and accidents, is becoming increasingly acute. The benefits of transport are diminished by the increasing number of negative impacts (air pollution and accidents, increased stress on road users), resulting in a vicious circle in urban transport. The spectacular increase in road traffic can't be met in the short term by a corresponding increase in road space. For this reason, in all developed economic environments, two-directional solutions were dealt with: improving the design of road space to increase utilization and improving the parameters of the traffic through control and monitoring. Developing an intelligent transport system requires the collection of high-quality and real-time information about the traffic flow. Increasing pressure to improve the traffic management, the collection of traffic data methods has evolved considerably, and the access to real-time traffic information becomes usual (Steinset, 2004).

For planning the road development or the management of traffic it is very important to collect the traffic data and use them in anticipation of traffic volume. The traffic flow can be considered as a function having a random distribution because it differs from many parameters including the time of day for measurement, season, geographical position, environmental conditions. It follows that the data collected is a methodological statistic and, despite such complexities, it follows some well-defined models that can be classified and analyzed. Thus, the collection of traffic data can be done in different ways and plays an important role in the evaluation and management of road networks (Massa et al., 2008). Generally, the traffic flow consists of vehicle count on the road and the technologies used for this can be split into two categories: the intrusive and non-intrusive.

The intrusive methods consist of transducers which are placing on or in the road and a data recorder. The most usual transducer used in intrusive methods are: pneumatic road tubes, piezoelectric and almost inductive loops. For all of them, it is necessary to bury in the construction layers of the road, becoming fixed or permanent installation.

E-mail address: cosminrus@upet.ro.

The non-intrusive techniques are based on the remote data recording. Eliminating the manual counting that is often used, new technologies use transducers based on passive and active infrared, microwave radar, ultrasonic and passive acoustic, or video image detection.

2. Lidar sensors

To achieve the system, Lidar sensors have been selected due to their some features, such as influence reduced of the dust or ambient light, the operation is not influenced by the color or optical transparency of the reflective surface.

Small dimensions and low power consumption make this sensor ideal for projects where energy sources are batteries and energy consumption should be as low as possible. The sensor can be used for drones, robotics, 3D image scanning, collision avoidance, fluid / solid level measurement, medical imaging and more. This device measures the distance by calculating the delay between transmitting an infrared laser signal and receiving it after reflecting at a target meeting. This delay translates away using the known lightning speed. The sensor transmits through the laser beam a coded signature and searches for that signature in the reflection of the signal, allowing for an extremely efficient detection. Signal processing techniques are used to achieve high sensitivity, speed and accuracy using a low power source and a low-cost system.

To perform a measurement, this sensor first performs a receiver polarity correction, correcting the change of ambient light level and allowing maximum sensitivity.

Then the device sends a reference signal directly from the transmitter to the receiver. Store the transmission signature, set the delay for the "zero" distance and recalculate this delay periodically after several measurements.

Then the device initiates a measurement by making a series of data acquisitions. Each acquisition is a transmission of the main laser signal while recording the return signal to the receiver. If there is a signal match, the result is stored in memory as a correlation record. The next purchase is summed up with the previous result. When an object at a certain distance reflects the laser signal back to the device, these repeated acquisitions cause a peak of signal coming out of the "noise" area at the corresponding location of the distance from the correlation record.

The device integrates purchases until the peak of the correlation record signal reaches a maximum value. If the returned signal is not strong enough for this to occur, the device stops from making purchases.

The signal strength is calculated from the magnitude of the signal recording peak and from a valid signal, the reference threshold is calculated from the noise level. If the tip is above this threshold, the measurement is considered valid and the device will calculate the distance, otherwise it will report 1 cm. From the next measurement, the sequence is resumed.

At startup or reset, the device performs a self-test sequence and initializes all registers with the default values. Approximately 22 ms the distance can be taken with the I2C interface.

This device has a serial interface compatible with I2C. It can be connected to an I2C bus as a slave device under the control of an I2C master.

The I2C circuit works internally at 3.3 V. An internal level switch allows the device to run at a maximum of 5 V. The 3k ohm pullup internal resistances provide this functionality and allow easy use and easy connection to the I2C host.

The device has a 7-bit slave address with a default value of 0x62. The 8 bit write address I2C is 0xC4 and 0xC5 for reading.

After initializing the system, the most significant bit of the I2C address byte is set to automatically increment the register address with successive reads or writes in a transfer data block. This is commonly used to read the two bytes of a 16-bit value in a single transfer and is used in the following example.

3. Local data acquisition

The hardware structure of the mobile system is represented in Fig. 1 and consists of the following:

- Arduino Uno/Nano development board;
- Lidar Lite v3 sensor connected to Arduino digital inputs;
- ESP32 a low-power system on a chip (SoC) with Wi-Fi and dual mode Bluetooth capabilities, that is connected to the Arduino between a serial communication bus;
- A simple local LCD display also connected to the Arduino between a serial communication bus;

The LiDAR sensor will be connected according to the technical specifications to the Arduino module either using an I2C connection or using a PWM connection. The ESP32 will connect to Arduino using a serial connection and will allow the retrieved information to another module or to a LoRa gateway. The LCD display allows you to display information on the number of vehicles on a traffic arc, thus testing the entire system to the specified parameters. The entire system will be powered either from the power grid where it is possible or from an external battery in case of necessity. In the future, it is also desirable to create a power system using other types of renewable energy. ESP32 module allows communication using wireless communication protocol LoRa and so these modules can be integrated simply in any equipment regardless of its physical size tends to be minimized and a more reliable all components.

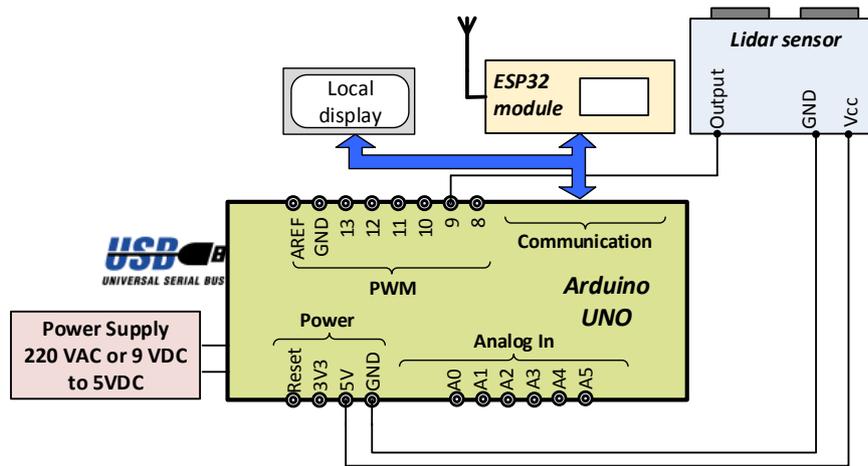

Fig. 1 Hardware structure diagram

For this system the supply voltage is provided from an alternative voltage source or from a battery through the 5 VDC controller on the Arduino board. In this way, the autonomy of the system can be assured. The monitoring system using a Lidar sensor, in addition to allowing for special portability, also ensures a fast and secure acquisition of data in traffic management (the number of machines crossing an intersection, their speed, distance measurements). Laser scanning of the Lidar type has other applications in many areas of activity. LiDAR laser scanning provides an interactive topographic map with a height accuracy of up to 20 cm. Current data has an accuracy of up to 1.5 m. As a complement to topographic measurements, technology can be used to build roads, other construction sites, etc. It can also be used to evaluate different alternatives in the field of construction, education and research, engineering.

Since LiDAR is based on air scanning, the system is able to scan large areas of land in a relatively short time. An aircraft / helicopter mounted LiDAR system can scan a 300 km² area with a precision of 0.15 m over a 4-hour flight. Unlike photogrammetry involving manual, time-consuming work, LiDAR processing is largely automatic, with the possibility of obtaining the land model within weeks and not months after obtaining the data.

LiDAR is an automated system and does not involve a prior objective visit. Topographic maps can be obtained even in less accessible areas with reduced visibility and complexity at ground level.

Fast and automatic data collection for LiDAR allows designers to consider a multitude of options and alternatives in the design that will be performed. It also allows them to study alternative routes to suggest to the beneficiary. Normally, only 3-4 flights will be required to get a precise representation of the land and buildings, respectively alternate routes in an area with increased complexity. The optimal option will then be selected to meet the expectations of the beneficiary.

LiDAR is able to penetrate dense vegetation, which means that the team of designers can get information from hard-to-reach areas much faster and more accurately.

The experimental model setup is shown in Fig.2.

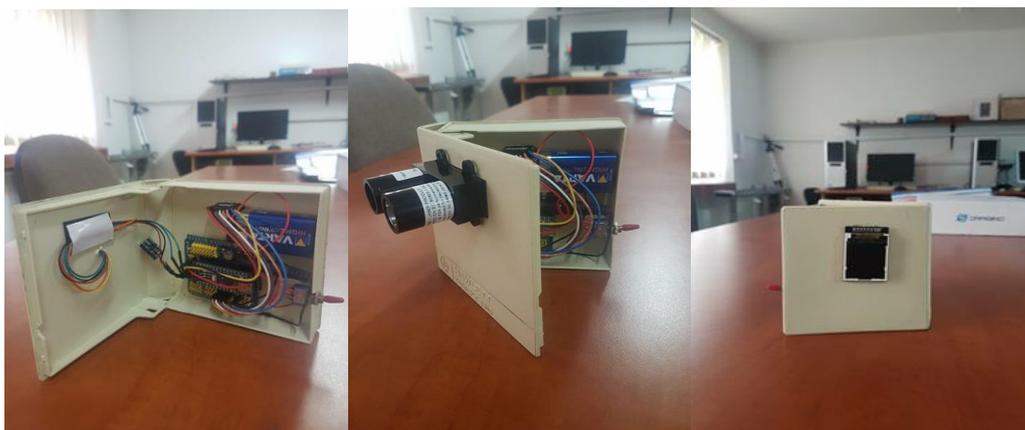

Fig. 2 Experimental model setup

The sensor is used to count vehicles on a lane at a time. Calculate the distance from the sensor to a particular reference point between it and the sidewalk, or consider the maximum distance that can be measured with this type of sensor when another value is found count a vehicle. The resulting number of counting vehicles on lane is locally displayed through a local LCD display and also are sent to the ESP32 radio module. Through this module, the information can be sent by radio transmission in 2.4 GHz band to long distance till a LoRa (Long Range Wireless Network) gateway connected to a network server from where it can be taken through internet network.

4. LoRa network

The term LoRa (or LoRa technology) refers to a category of high-power low power long range radio communications. Unlike conventional digital radio transmission technologies, LoRa technologies have the capability of communicating data over miles of miles or even tens of kilometers, with extraordinary applicability in wireless sensor networks, the Internet of Things (IoT), and networking of smart devices. Behind the term LoRa is actually a multitude of proprietary or open technologies, similar to functionality but totally incompatible as implementation - the field of long distance radio communications is currently in a pioneering phase in which standardization stability and technological interconnection methods are a far-reaching goal. Other terms used to refer to high-bandwidth digital radio networks are LoRaWAN (Low Range Power Network), LPWAN (Low Power Wide Area Network), Low Power Network (LPN). Some of these terms are registered as brands belonging to certain companies or consortia being used to identify a particular LoRa technology (even the term LoRa is a registered trademark of Semtech). LoRaWAN is a radio transmission protocol capable of forms a smart grid. The setup network uses a star-of-stars topology, with gateways serving as transparent bridges that transmit information between sensors and the central server. Gateways connect to the network through traditional IP connections, and sensor devices use single-pass wireless communications for one or more gateways (Dongare et al., 2017).

The structure of LoRa network is similar to one cellular network, but instead of having a single interconnected network, LoRa allows the deployment of more independent networks over the same infrastructure (Sanchez-Iborra et al., 2016).

LoRa can covers 15-20 kilometers. The compromise for such a distance is a reduced power and a lower bit rate, about 0.3 to 50 kbps.

The elements components of the system structure in "end-to-end" way of LoRaWAN are shown in Fig.3 and these are:

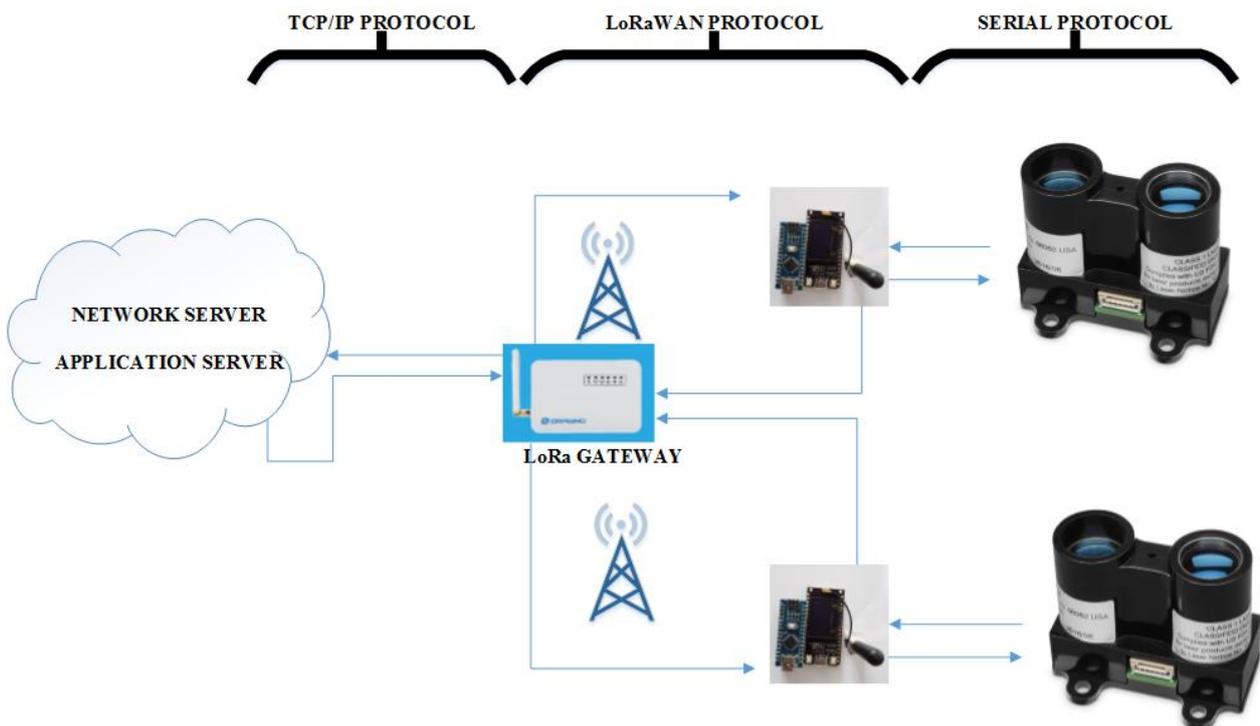

Fig. 3 The architecture of LoRa system

Nodes

Represents the elements of the LoRa network that monitors and controls the infrastructure devices which are usually located at distance, the ESP32 - LoRa - OLED (Fig. 4) which transmit the data taken from the LiDAR sensors via an Arduino Nano development board in this case. The ESP32 - LoRa - OLED has a 0.96 inch blue OLED display for displaying local information and a Lora transceiver, the SX1276 transceiver for the 868 MHz band. It has a high sensitivity over -148dBm, + 20dBm output power, high reliability and long transmission distance. The onboard Wi-Fi antenna, lithium battery charging circuit, CP2102 interface and USB serial chip, make it the perfect support for Arduino development environment (Espressif Systems, 2015).

Operating voltage is from 3.3V to 7V. It have support for Sniffer software protocol analysis, Station, SoftAP, and Wi-Fi Direct modes. Data rates are comprised between: 11 Mbps and 150 Mbps and the transmit power is between 15.5 dBm and 19.5 dBm. This development board has a receiver sensitivity up to -98 dBm.

Fig. 4 ESP32 - LoRa – OLED development module

LoRa Gateway

This is the device that receives data from network nodes (ESP32) through the LoRaWAN protocol and then is transferred over the Internet to the main application server. The connection to the application server may be Ethernet, GSM data, or any other cable or wireless telecommunications connection that provides an Internet connection. In fact this base stations (LoRa Gateway) are connected to the network server using standard IP connections. In this way, the data uses a standard protocol that can be connected to any public or private telecommunications network. Given the resemblance of a LoRa network with a mobile network, the LoRa base stations can often be integrated into a cellular base station. In this way, the unused capacity of the cellular station can be used to transmit the data to the network server (Sornin et al., 2017).

Fig. 5 Dragino LoRa gateway used for system

Network server

The network server manages entire LoRa network. The network server acts to remove duplicate packets, recognition programs, and control the data transmission speed. Given the way it can be deployed and connected, the complexity of implementing a LoRa network is very low.

Application server

From the application server that is installed on the network server, we can access applications that retrieve data from network nodes through the gateway and display them to provide the most relevant information for the client. In addition, LoRa allows bidirectional communication between nodes and the network server, remote commands can be sent to the nodes, these commands can be related to node management (remote software update) and control of elements in a system (change of green time of traffic lights).

5. Conclusion

The realization of this mobile system of counting the number of vehicles crossing a road artery from an urban center is the first step in the direction of developing a traffic management system. The most important feature of this system is that it does not use invasive techniques on vehicle runways and can easily be moved from one location to another location. Through the LoRa network, real-time data can be obtained on the car traffic characteristics of the monitoring points, thus obtaining sufficient data to formulate new directions for the development of the automotive infrastructure plans. LoRa is a long-range telecommunication and low-power telecommunication system for the "Internet of Things". The physical layer of the entire system uses the LoRa module, a proprietary technology with a MAC protocol. LoRaWAN is an open standard with the specifications available for free. This paper provides an analysis of the bidirectional operation of the LoRa protocol on an experimental platform specifically designed to study the performance of the network, documented in this paper. The results obtained during the preparation of this paper show that LoRa modulation, due to modulation of spectrum dispersion and high sensitivity of the receiver, offers good interference resistance. Field trials demonstrate that LoRa can provide satisfactory network coverage of up to 3 km on a network in a suburban area with not very dense residential dwellings. LoRa is therefore suitable for low power, low speed and long range. The experimental results also show that the protocol is reliable and very simple to implement.

Abstract

The Computer Brain Interface (BCIs) is a new type of user interface designed to recognize real-time user-specific intentions based on user brain mapping. Gradual advancing technology behind the BCI interface has made it possible to develop gaming applications that use directly brain input instead of well-known traditional control methods. This paper presents the Mental Pool Game, a brain-controlled computer game powered by Unity3D, which uses a commercial BCI device based on a network of electroencephalography (EEG) sensors placed on the scalp capable of creating brain patterns only by capturing conscious thoughts from a user that can be easily reproduced as mental actions to control strength and speed on which the user can project on the white ball to hit any of the eight balls on the pool table.

Keywords: BCI; EEG; video games

1. Introduction

Over the past decades, there was an exponential improvement in imaging technologies that allow researchers to assess cognitive workload, short-term memory and space / navigational behavior in humans. Using new experimental paradigms and brain imaging devices, researchers get a deeper insight into neural correlations of emotion, knowledge and engine control.

Brain-Computer Interface (BCI) combines two fundamental research areas: Neuroscience and Human-Computer Interaction (HCI) that serve as a link bridge that allows users to interact with the computer based on commands transmitted directly from the brain to the standard input of the computer (Vasiljevic et. al., 2018).

BCI systems use different neuroimaging sensors to retrieve evoked brain signals through a specific thinking process that corresponds to a certain mental state of the user at a time that can be converted into a computer command. In order to provide a general overview of sensory, motor and cognitive processes, the BCI system uses the electroencephalogram (EEG) principle to measure electrical activity of the brain, which is diffusely distributed across the scalp and that corresponding to brainwave: alpha, beta and theta (Galway et. al., 2015).

2. BCI related to games

Nowadays the increase in the accessibility of computer systems among the population and also the advancement in computing technology that is able to offer computers with more computing power and with an advanced 3d computing graphics has pushed the video game industry to become a major industry that engage specialists from many sub-disciplines to be able to provide an improved user experience in game play that become a new way of life able to improve task management, simulation and learning activities.

* Corresponding author. Ph.D. Student Eng., Sebastian-Daniel Rosca
E-mail address: sebastianrosca91@yahoo.com.

As far as brain-controlled video game technology is concerned, it can be used for both medical and non-medical purposes: to recover limb motricity in case of brain level trauma or in case of suffering by a neurologic disease such as stroke or severe neurodegenerative disease using generation of motor imagery based on BCI commands; as assistive technology for person with mobility impairment such as spinal cord injuries who otherwise are not able to perform game controls; for relaxation and entertainment using in many case to measure the concentration level of a player (Rosca and Leba, 2018, Anwar et. al., 2018 and Belkacem et. al., 2015).

The main concern in developing video games based on the BCI interface is to achieve a natural user interaction with the game environment capable to motivate the user both by implementing of some intuitive controls and by transmitting some entertaining and challenging experiences because the result of implementing a BCI system is dependent of user engagement.

Research in the field of video games, even in the case of BCI technology, has shown that rational playing of video games brings a benefit in the life of the player by acquiring new knowledge, experience and skill improvement given by certain cognitive processes that it involves during playing games such as: problem solving, remembering and training sessions (Vourvopoulos et.al., 2017).

Continuous growth of the video game industry driven by the development of Virtual Reality (VR) and the development of rapid game prototyping tools allowed the integration of the BCI interface into games development that can help the research environment like: Games as stimulus developed for studying human behavior; Games as means of training; Games able to evaluate performance metric of users (Kerous et.al., 2018).

A BCI interface uses electroencephalography (EEG) as an access point to detect and record the activity of neurons by creating a pattern of brainwaves that is generated by conscious thoughts that can then be analyzed by a computer and converted into brain-controlled commands applicable as inputs for a game.

Using the electroencephalogram principle in games designed to evaluate metric performances as a result of analyzing the data acquired for a particular user can be obtained measurements of his performance indices like: cognitive workload, level of stress, arousal, task engagement and level of relaxation (McMahan et.al., 2015).

With regard to the processing of EEG segments, this is not an easy task. A major common problem is that mental imaging operation used as entry for game control varies from one person to another on the one hand because the brainwave pattern obtained from the mental drive training session is unique for each person, requiring a training session for each user and on the other hand due to variables such as: attention, emotion, focusing on thought and hand grasping imagination (Diamal et. al., 2017).

In terms of brain activity analysis during video game play using the BCI interface, the major brainwave frequencies that present interest are: Alpha brainwave (7.5 -12 Hz) that reflects the relaxation level of the user and Beta brainwave (12 – 30 Hz) that corresponds to the level of attention, concentration and vigilance of the player during play games. The research in gaming domain based on BCI interfaces has demonstrated that Beta rhythm magnitude it growing in amplitude when the player needs to navigate into game environment, because this activity it based on extra level of concentration from user. The same things are observed in the situation in which the player must avoid hazard moments or when it must focus to survive from enemy attacks (McMahan et. al., 2015, Diamal et. al., 2017 and Bakaoukas et. al., 2016).

3. Software

3.1. Unity3D Gaming Engine

Unity is an open source cross-platform game engine developed by Unity Technologies. It is a developer-oriented platform that allows: the development of 2-dimensional and 3-dimensional desktop applications for both Windows and Linux operating systems; mobile app development for Android OS and iOS operating system; development of console games (Posen, 2018).

The three-dimensional version of the Unity platform known as Unity3D includes a number of complex components useful to game developers such as: component mesh, component physics, rendering component, audio component and script component etc.

Unity3D also offers a wealth of resources from common ground scripts to common scripts to useful collision detection tools to create realistic games. As far as the implementation of scripting functions is concerned, Unity3d supports both the C# programming language and the JavaScript programming language both designed to develop high performance multimedia applications and games (Yang et.al., 2015).

3.2. Mental Pool Game design

In this paper we developed a 3D Mental Pool Game based on Unity3D game engine powered by C# programming language which has been designed for several target user groups, from healthy people to people with disabilities, so they will no longer have to use classical commands that depend on the use of well-known peripheral input devices present on any PC such as a keyboard, mouse or joystick to control the movement of an object on a virtual environment,

in our case to control the strength and speed that the user can project, using only his own brain, on a white ball in order to hit any of the eight balls placed on the pool table using a system based on a BCI interface as presented below:

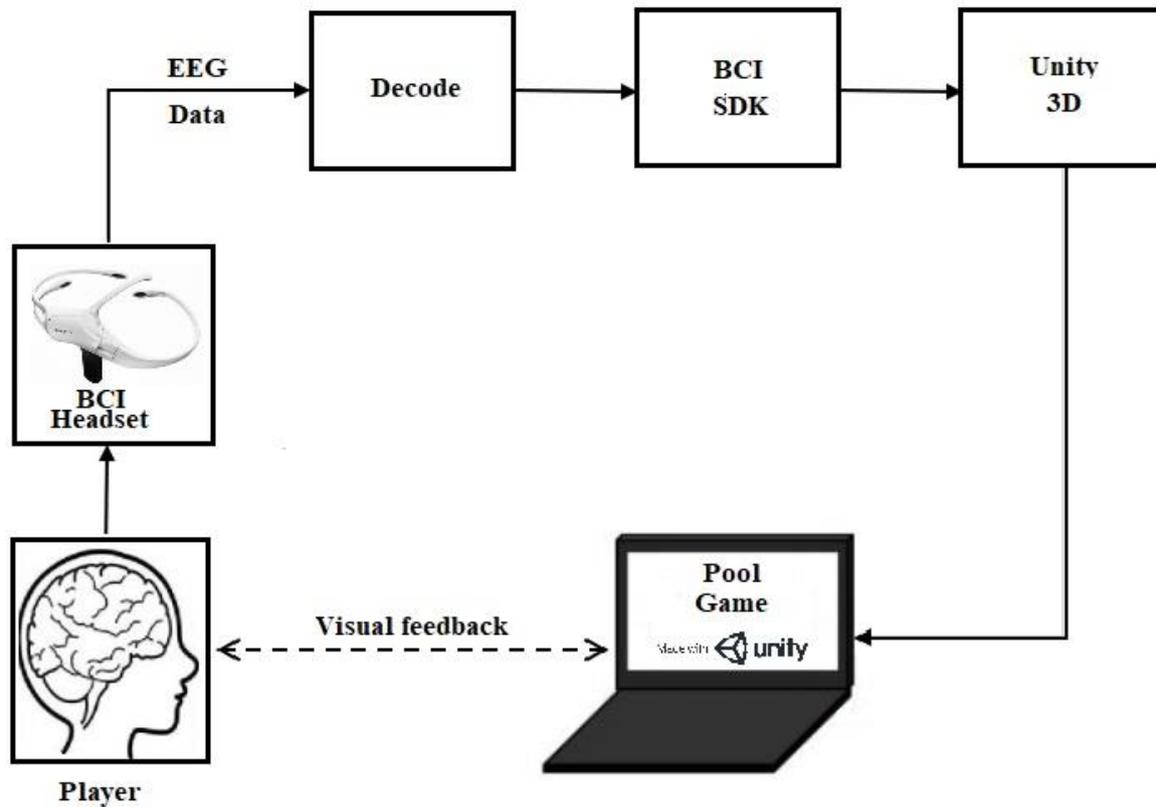

Fig. 1 Block diagram of BCI system design

In fig.1 is shown the functional diagram of the BCI system along with the algorithm for acquisition and analysis of the electroencephalogram signals from the subject and conversion of these signals into mental commands that can be used as inputs to send in the game control commands directly from the brain.

The BCI headset used for acquiring EEG signals from the brain is a commercial version that provides five semi-dry EEG electrodes placed on the scalp level of user and that can detect the activity of the whole region of the brain. Also, the BCI helmet has a 3-axis gyroscope that is used to update the white ball position on the pool table within the game scene according to the user's position by changing the direction of the head movement.

In order to decode the EEG signals from the user of the game, the BCI headset uses a series of analog to digital (ADC) converters to translate the electrical activity of the neurons into a binary form that can be recognized by any computers.

The EMOTIV BCI software development kit (SDK) is used to analyze and detect the user-generated binary commands generated by the game user using the BCI headset and based on a script written in C # programming it can convert them into keypress used as input to give white ball a specific movement speed on the table.

The following is a BCI system operating logic scheme used to control the game in which steps are considered during the design stage.

As can be seen in fig.2 the video game user must first check whether there is a connection between the BCI headset and the computer and in the opposed case the user must act to apply some of saline solution to rehydrate EEG sensors to improve their contact with the scalp that otherwise represents a common problem for non-invasive BCI systems based on semi-dry EEG electrodes.

Also to be able to play Mental Pool Game an user it must to start training session of two distinguish mental commands: Neutral mental command that correspond to neutral state it is used as a reference to distinguish between the conscious thoughts that form the brain pattern that corresponds to a particular action and the signals generated by noise sources such as head movement or due to bad contact of EEG electrode with scalp; Push mental command allows the game user to record the brain pattern on which he focus on an action imagining the forward movement of the white ball on the billiard table. The moment speed of the white ball is variable depending on the cognitive power that the user allocates at certain moment to performing the mental task.

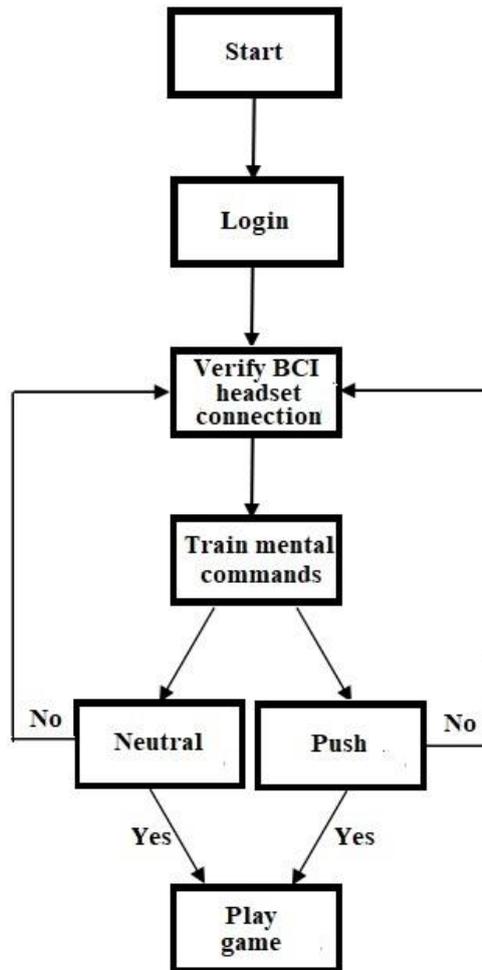

Fig. 2 Logic bloc diagram for BCI system design

The following is the graphical user interface (GUI) of the Mental Pool Game developed by us in the Unity3D platform game engine (fig.3):

Fig. 3 Mental Pool Game GUI

4. Results & Discussions

Three healthy subjects were first familiarized with BCI headset on how mental patterns were formed based on the acquisition of electroencephalogram (EEG) signals during a training session that involved a training of Neutral and Push mental commands within the software development kit (SDK) Emotiv Xavier Control Panel developed by EMOTIV Inc. They had 30 seconds to train each mental command within the graphical user interface and in case of training of the Push mental command during their training session, they were asked to visualize the forward movement of a virtual cube, either directly or following a predefined animation and were able to track on top of the interface via a gauge indicator the own cognitive power that was dependent on the level of focus with which they performed the mental task. After all of the subjects played one round of each game until the exhaustion of the balls on the pool table.

During the experiment, it was found that the force with which the white ball was pushed onto the pool table to strike other balls is directly influenced by the level of attention and concentration that must be maintained throughout the mental load, with the power to concentrate depending on the fatigue of the subjects, the stress conditions, their emotional state, and the level of interest represented by the degree of attractiveness of the game in order to capture their attention.

5. Conclusions

This paper proposed a 3-dimensional game developed in the Unity3D game engine which has been implemented in accordance with physics laws to reproduce a true copy of the real game and whose controls can be driven directly by brain using the EEG signal caption from the user through the BCI interface that is able to convert electrical stimuli in binary form based on a script written in C# programming language that used a series of functions designed for mapping mental commands that are provided by Emotiv BCI software development kit (SDK) to convert binary form of signals into keystroke sequences used as control inputs for game play.

The Mental Pool Game has been designed so that it can be used both for purely recreational purposes by healthy people and for medical purposes especially in the case of people with permanent disabilities such as: severe neurodegenerative disease that cannot have cure, spinal cord injuries or superior limbs amputation in which case the game based on BCI interface is used as assistive technology. Also, for medical purposes the game proposed by us can be used by people with temporary medical problems mainly for the purpose of faster recovery, such as stroke, people who have suffered brain damage or for treating children that suffer from Attention-Deficit Hyperactivity Disorder (ADHD).

Based on simple user-driven mental commands, the game developed by us aims to improve the player's concentration power and level of attention by stimulating the brain to produce beta brainwave.

As a future development we propose: to adapt the game for mobile devices such as those running on the Android operating system as the Unity3D game development engine allows this, and commercial BCI systems now offer applications that provide the BCI interface for smartphones, smart devices especially for controlling other devices; to adapt the pool game in a manner that can be played in multiplayer mode by two player at the same time just like in the case of real pool game that should be in benefit of both player because the level of attention and concentration power increases when the two players are in direct competition to win the game; to export in cloud or save on computer the EEG data from gaming sessions for every player in part based on login data to be able to analyze them in offline mode using specialized software such as: BCI2000 that offers support for MatLab-Simulink development environment, EEGLAB a toolbox for MatLab or in Emotiv Xavier Test Bench, data that can be useful later in the medical field for diagnosis of brain disease or in patient recovery process.

Methodology for determining the replacement period for lifter bars

Teodora Hristova^a

^aUniversity of Mining and Geology “St. Ivan Rilski”, Sofia, BULGARIA

Abstract

The timely replacement of the drum mill liners brings about an increase in the quality of the milled product and reduces the milling costs. Therefore, an approach has been chosen to determine the replacement period for semi-autogenous mill liners in view of minimizing costs. A methodology has been developed to determine the service life of the milling lifter bars, whereby factors such as energy consumption, yield of the calculated class, productivity, price of liners, replacement costs and downtime loss are included. Costs are determined in terms of the type and quantity of the processed ore, balls, and backwater consumption that feed the mill. In the case under consideration, it has been found that it is economically most advantageous to replace the liners of the mill drum approximately every 4 months.

Keywords: lifter bar; liner; replacement period; energy cost;

1. Introduction

The individual components of the processing machines vary in terms of service lifetime. The faultless operation of machines and the extension of their service life is achieved through the timely replacement of the worn-out parts. These measures lead to a decrease in production costs but sometimes they result in a deteriorating production quality. In order to optimize production costs while maintaining the production quality, it is necessary to develop a methodology for determining the replacement period for some of the components that includes various factors, such as production safety, productivity, unit price, energy consumption, and others.

2. Subject of study

An object considered in the article is the mill liners which are changed in accordance with the wear of the lifter bars. This is a major component that yields a relatively large share in the formation of the production cost of the mineral processing plants.

3. Models to determine the duration of work of liners

In the case of mills, much of the decisions for capital replacement are taken in accordance with the engineering (Minin and Hainov, 2013 and Djordjevic, N. et al., 2004) and the economic safety requirements (Liao et al., 2006). In order to obtain higher economic benefits, deterministic economic models are recommended to use so as to determine the lifespan of the individual components of each machine (Kalala et al., 2008, Cleary, 2001, Yahyaei et al., 2009, Bearman and Briggs, 1998). These models are based on the depreciation term, on the estimate of the downtime costs, as well as on the consequences of failures and are applied by different authors. The disadvantage of the models described is the lack of information about the production quality, i.e. the reduction in particle size according to the wear of lifter bars.

Other researchers (Santarisi and Almomany, 2005) offer linear substitution strategies based on mathematical models of the wear of cement mill cladding. Their conclusions mainly concern the fact that the optimum replacement interval increases productivity (tons/hour) with reduced specific energy consumption and with a reduction in the price per unit of the cement produced.

The review shows that it is necessary to develop a determinate model of liner replacement based on a broad perspective that includes the economic decision to influence maintenance in terms of quality and quantity of the mill production. For this purpose, it is necessary to perform an LCP (life cycle profit) or loss analysis based on the technological parameters. The maximum profits, the minimum losses, or maximizing the profitability of the mill can serve as criteria.

A model has been developed for maximizing gross profit (Dandotiya, 2011). However, profit depends not only on the technical parameters of production, but also on the market situation; therefore, this is not a suitable criteria for a longer period considered. The current research uses the model by Yun and Choi (Yun, Y.W, C.H. Choi, 2000), who suggest optimum replacement intervals in a repair system via the introduction of a random time horizon. They model a system according to a pre-determined period, wherein the optimum replacement interval is related to the minimizing of the expected costs. In this case, repairs are not carried out between two replacements. Also, their methodology does not include factors such as production efficiency, energy consumption, and metal recovery.

4. Methodology for determining the period of lifter replacement

The present study offers the methodology and the subsequent data simulation that aim to minimize the life cycle cost by determining the optimum replacement interval. The life cycle model is based on a detailed analysis of the mill efficiency, the liner wear, and maintenance statistics. Practical data was used without taking into account the measurement of wear between two successive replacements.

4.1. Output modeling data

4.1.1. Factors influencing the model

The mathematical model is associated with determining the time for liner replacement and includes the following factors: product quality related to tons of ore produced; price for liner maintenance; ore density (the ratio of tons of balls, ore and water); and the amount of electricity consumed. For all these elements to be compatible, they are referred to the price per ton of ore produced. It has been established that the efficiency of the grinding process for each type of ore depends on the size of the lifter bars; therefore, in the model, their height is a basic parameter that leads to more efficient decision-making.

Quality of the output product and percentage of metal recovery. The quality of recovery decreases at a reduced size of the lifter bars because the mill revolutions are increased, the material is kept for a shorter period, and the pulp produced is with a larger grain size (Yahyaei et al., 2009, Schena et al., 1996). The purpose of determining the replacement period is to increase the percentage of metal extraction (recovery is achieved at a later stage - floatation), which leads to an increase in profitability and to lowering of price per unit produced.

Changes in the mill volume due to wear. In this case, the automatic control of the material feed rate is based on the instantaneous mill load. Liner wear leads to an increase of mill volume by up to 17%, which raises the throughput or capacity of the mill. As a result, the amount of the milled product is reduced.

Variations in the energy consumption. According to Djordjevic et al. (2004), Minin and Hainov, (2013) the relatively high lifter bars consume less power than outworn lifter bars under identical conditions (process parameters, such as: angular speed; mill filling with ore, water, balls; type of ore).

Density of the ore (pulp). According to the multivariate analysis, it is established that the most important parameter causing wear of lifter bars is the ore density (Wijaya, 2010). Ore density changes inversely with wear, which indicates to a directly proportional relationship between the density and life of the lifter bars.

Maintenance of the liner. Repair, inspection and accident downtime lead to high costs due to unproduced production.

The percentage of ore extraction is not included as a factor because it also depends on the floatation process.

Several assumptions are made in the techno-economic model to ensure that there are no variations in the life cycle due to changes in productivity levels. They are:

- 1) the total time with a lower level of pulp in mill is much shorter than the service life of the liner;
- 2) the wear of the liner itself is not measured as, in relation to the lifter bars, it is very insignificant in terms of percentage;
- 3) the wear of the liner was studied for a single kind of ore containing gold and copper;
- 4) the profile of the liner and the design of the lifter bars are not taken into account in the model.

4.1.2. Model parameters.

This section briefly describes the parameters employed in the mathematical model.

Suitability of the liners. The technical suitability of the liner bars shall be tested throughout the lifetime at regular intervals. In this case, the data is taken on a daily basis.

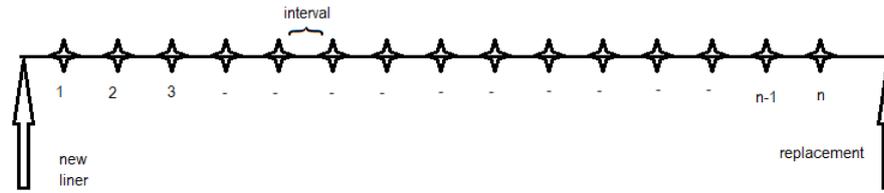

Fig.1. Measurement period

Costs. Costs are calculated for the entire exploitation period of the liner.

Total costs = [operating costs (energy costs) + replacement costs + costs for consumables], where

$$\sum_{i=1}^n E_i \cdot C_{energy} \tag{1}$$

where: E_i is the number of intervals, n is the duration of one cycle, and C_{energy} is the electricity costs [in BGN].

Replacement costs. Replacement costs of liners include the price of liners and the installation of a new inner liner, with each I^{th} interval being:

$$\frac{C_{rep}}{T_{cycle+T_{rep}}} t \tag{2}$$

where: T_{cycle} is the time for one cycle, T_{rep} is the repair time (interruption and replacement), and t is the duration of sampling intervals [measured in days], C_{rep} is the replacement cost.

In the case of an SAG mill, the cost of the liner is 37% of the total milling costs, see Catalog Manual (2002). Since interruptions happen only during repair operations, then in the case $T_{cycle} = 0$:

Costs for consumables, balls, etc. during the life cycle.

$$\sum_{i=1}^n E_i \cdot C_{cons} \tag{3}$$

where C_{cons} - is consumables per ton of ore [in BGN].

Costs of stay. The costs of stay or loss of production cannot be compensated and can lead to a breach of standard operations and to inefficiency. Downtime costs (or the so called production loss) are the most critical parameter in the decision-making model; i.e. the duration of the milling stops regardless of whether they are for liner inspection or replacement. Depending on the duration of the shutdown, the energy costs and the production efficiency costs vary, too. Therefore, in the particular case, the cost per hour is assumed to be constant for each cycle of time, with the downtime cost for each I^{th} sampling interval being as follows:

$$\frac{C_{DR}}{T_{cycle+T_{rep}}} t \tag{4}$$

where C_{DR} - is the stay costs [in BGN].

In the model, it is assumed that downtime losses for the planning horizon are reduced to the price of unprocessed gold and copper:

$$C_{DR} = (T_{rep} \cdot C_{Cu} + T_{rep} \cdot C_{Au}) \frac{T_{max}}{T_{cycle+T_{rep}}} = (T_{rep} \cdot Q_r \cdot I_z \cdot C_{Cu1} + T_{rep} \cdot Q_r \cdot I_z \cdot C_{Au1}) \frac{T_{max}}{T_{cycle+T_{rep}}} \tag{5}$$

where T_{max} is the maximum time for 10 years which is equal to the days of work and stay; C_{Cu1} and C_{Au1} are the prices of copper and gold per kilogram; I_z is the percentage of gold or copper content in the ore; Q_r is the amount of ore per day.

As production losses, liner prices, metal prices on the stock exchange, etc. may vary over the years, to reduce the prediction error for a longer period of time, the expression is simplified and reduced to a loss minimization model:

$$C = \sum_{i=1}^n E_i \cdot C_{energy} + \sum_{i=1}^n E_i \cdot C_{cons} + \frac{C_{rep}}{T_{cycle+T_{rep}}} t + \frac{C_{DR}}{T_{cycle+T_{rep}}} t \tag{6}$$

The optimization approach is based on a comparison of gross costs at different replacement intervals.

To justify the model, the horizon concept is introduced for a planned period (days, months): The lifetime of the liner from its installation to its removal. This is employed to calculate the LCC. The optimization used in this case is based on two scenarios L (long) and S (short) with a data interval for one liner cycle. The S scenario contains fewer days T_s , whereas the L scenario contains more days T_l ; consequently $T_l > T_s$. A longer time T_{max} , including time is selected that comprises several L or S scenarios.

The comparison is performed over a given time horizon of T_{max} in order to determine the best interval for loss minimization. T_{max} is at the threshold of the lifespan of the liners and includes the installation time and the operation time. To determine the number of cycles N , the dependence is used:

$$N = \frac{T_{max}}{T_{cycle} + T_{rep}} \tag{7}$$

where T_{max} is the maximum study period; T_{cycle} is the mill operation time; T_{rep} is the shutdown time for liner replacement.

In order to optimize the life cycle, as well as to reduce the cost of staying, it is advisable to make a diagram of cost minimizing, including downtime loss, per production unit. For this purpose, time intervals have been introduced for a period of 10 years or 120 months, both of which are close to the L scenario. The L interval is assumed to be 150 days and the S interval is 135 days. To compare two L and S scenarios, the gross loss is calculated for T_{max} days.

Results

For the verification of the techno-economic model, data was obtained from a semi-autogenous mill for processing ore with gold and copper content, but due to the confidentiality of the data used those have been scaled. Based on these, models were developed to determine the correlation between the liner wear and the process parameters for the entire lifetime of the liners. Through variations in the liner life cycle over a longer period of time, a decision was made related to the optimum replacement period.

All costs per ton of ore produced are visualized by the graphs in Fig. 2 with their variation in days within a period of 150 days, of which 147 days are the operation of the mill and 3 are for the liner replacement. In the graph, R_b are the costs of balls, R are the total costs (including water), R_{liner} are liner costs, and R_e are the electricity costs.

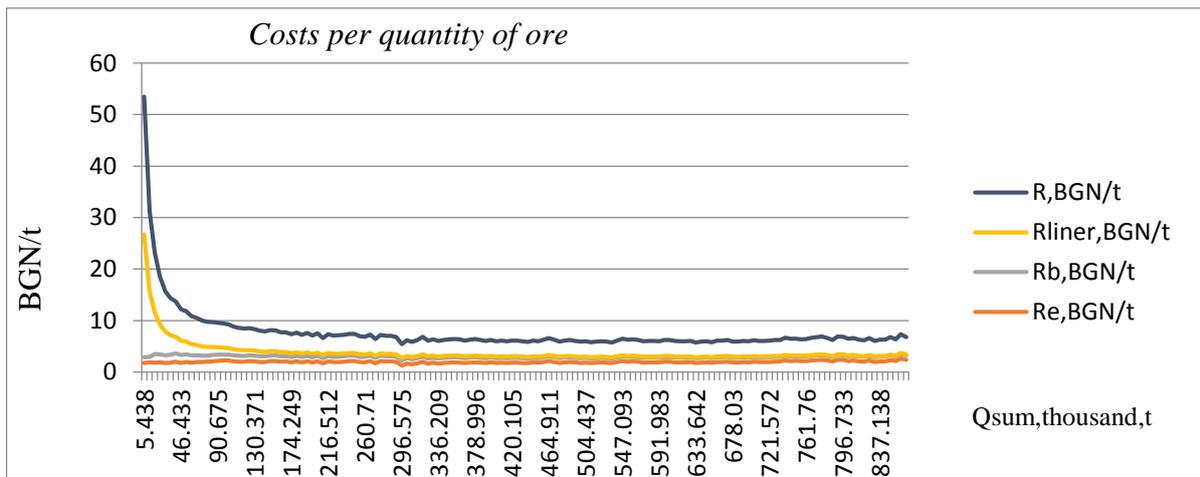

Fig. 2. Costs versus amount of ore

It is clear from the graph that for the amount of ore of 128,439 thousand tons the price of liner becomes lower than the price of electricity per ton of ore. At the end of the period, the energy cost and total cost increase. It is economically more profitable to replace the liner before the cost rises. Fig. 3a) shows these costs and for better visibility Fig.3.b) gives the costs for the end of the period.

The graph shows that the costs that are on the increase are those for electricity and the total costs. For the sake of clarity, they are outlined against the entire period of liner operation.

The calculations show that costs are on the rise after 120 days. To clarify the moment to replacement, the optimization approach is applied. For this, we assume that $T_{max} = 120$ months, and we choose the horizon periods: 150 days for the first variant and 135 days for the second variant. It is estimated that $120/5 = 24$ liners are replaced within 10 years in the first variant. The second variant is two weeks shorter and the number of liners replaced within the same period will be 26.6. Costs are calculated after the dependence (6) or for variant one - BGN 13383,0864 thousand over a period of 10 years, with the duration of liner operation of nearly 5 months. For a period of operation of 4.5 months, the amount is BGN 12254,4033 thousand.

For the entire period of operation, the T_{max} costs are calculated on the basis of the following dependence:

$$C_{zag} = \left(\sum_{i=1}^n E_i \cdot C_{energy} + \sum_{i=1}^n E_i \cdot C_{cons} + C_{rep} + C_{DR} \right) \frac{T_{max}}{T_{cycle} + T_{rep}} = \left(\sum_{i=1}^n E_i \cdot C_{energy} + \sum_{i=1}^n E_i \cdot C_{cons} + C_{rep} + C_{Cu} + C_{Au} \right) N \tag{8}$$

The variation in gross cost is determined by a simulation program for ($n = 1, 2, 3 \dots$ Trisk), where Trisk represents the maximum number of days in operation of the liners before their thickness is reduced to the hazardous zone, i.e. one which implies a risk of damaging the mill. Also, the discounted rate is not taken into account due to the short technical life cycle of the liner as compared to the lifespan of the whole mill.

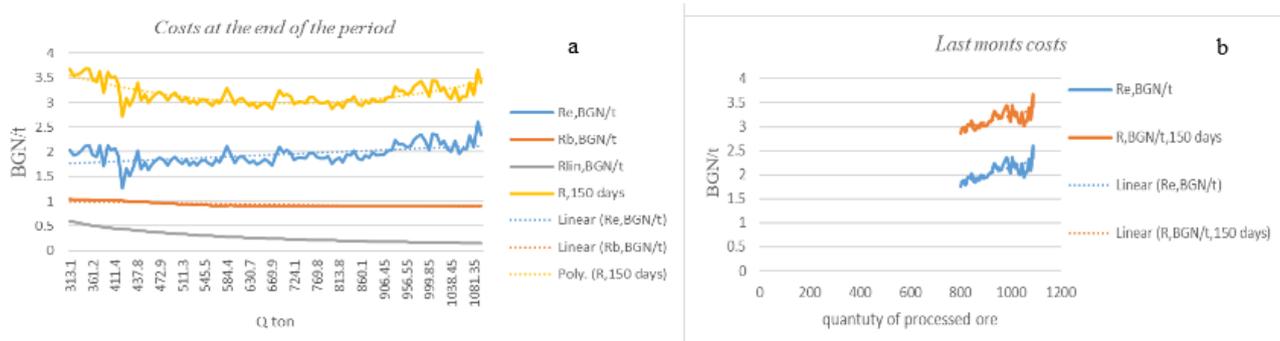

Fig. 3a). Costs for the last month and 3b) Total costs and electricity costs at the end of the period

The cumulative cost curve for a horizon of 150 days looks like this (Figure 4). It is obvious that the minimum is approximately on day120 and it is economically more profitable to replace the liner during this period. At minimum costs for variants of 2 to 150 days, the last days of the cycle are shown in Fig. 5.

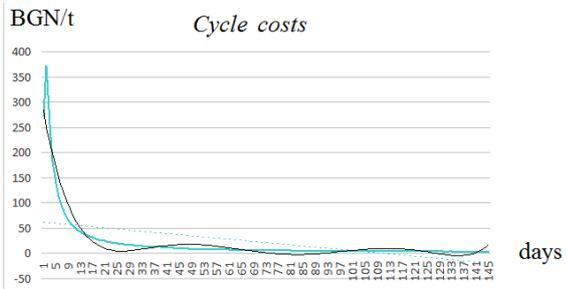

Fig. 4. Cost curve for a 150-day period

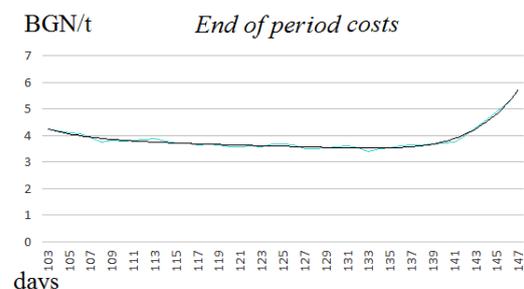

Fig. 5. Total costs to end of the period for the first variant of a 150-day cycle

With 120-month planning T_{max} , which is consistent with the proposed Optimization Maintenance Policy, the results of this study show (see Fig. 5) that around day 141, the cost curve reaches a minimum, and then rises. This indicates that it is appropriate to replace the liner after 138 days or after 8,000,000 tons of processed ore. If a 10% error is included due to the replacement of the type of liner, or to ore characteristics, or to the change in the price of metals on the exchange, etc., then it is normal to change the liner after 140 days. Despite the long horizon, the sensitivity of the model results ranges from 1-2% for the various optimum scenarios.

Fig. 6 compares to two variants with cycles of 150 and 120 days, respectively. There are shown two L and S scenarios with the corresponding curves. The total area of the loss curves in the S scenario is less than the total area of the curves in the L scenario. This is due to better process efficiency and to the lower power consumption in the initial phases of the life cycle of the liner bars. At the same time, the S scenario has more substitute times than the L scenario, which leads to more downtime costs, but despite everything, the total costs over a 10-year period remain lower. Therefore, the life cycle is optimised based on the minimisation of the loss curve for a given time horizon.

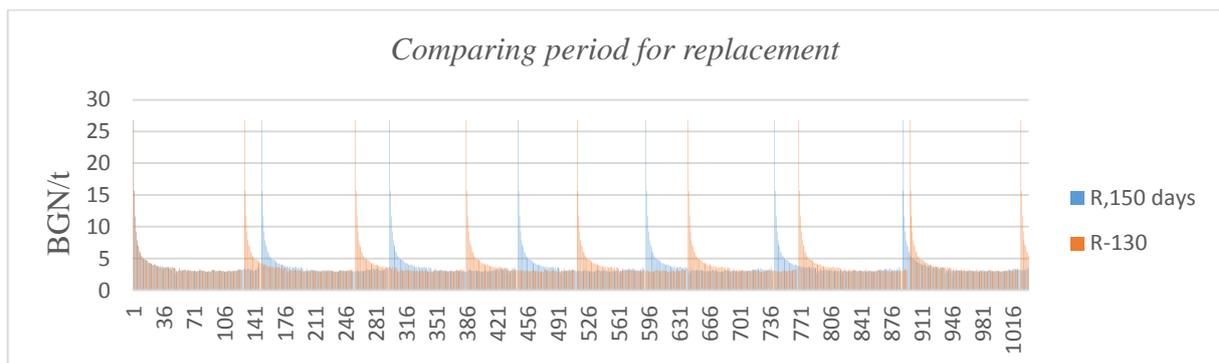

Fig. 6. Location of the cycles for both variants

Conclusion

In conclusion, the following inferences can be drawn:

1. The timely replacement of lifter bars will not only reduce the costs per ton of ore but will increase the quality of the milled product.
2. By economic criteria, this should be done earlier, around day 136 or, in this case, after 800,000 tons of processed ore with these liner bars.
3. For greater precision of measurements, it is necessary to monitor the liner wear with a laser scanner that also measures the shape of the lifter bars at least twice a month.
4. When replacing the liner manufacturer or the liner configuration, the study hereby should be repeated.
5. The results of this study are valid for the type of processed ore during the specified period.

When establishing the boundary wear by economic criteria, all metal, electricity, and liner prices used in the model, along with the liner replacement, were determined at the beginning of 2015.

Abstract

The paper addresses the problem of determining the coefficients of use over time to the theoretical level and at the level applied in reference to extraction complexes used in open-pit lignite exploitation. In this sense, for the first time in our country we achieved a mathematical statistical analysis of how the elements of the system for extracting from a database by means of empirical processed malfunctions of the highest topical. There were significant correlations between obtained a set of parameters that influence the performance of the operation. Conclusions were useful to split off significant elements affecting the time coefficients respectively capacitive indicators.

Keywords: statistics, mathematical methods, reliability, maintenance

1. General conditions

The problem of determining the coefficients of use over time to the theoretical level and at the level applied in reference to extraction complexes used in open-pit lignite exploitation is extremely important. That is why the process must work efficiently, which means that it must be reliable and on the other hand it must have the highest excavation capacity at specific energy consumption as low possible.

Increasing efficiency in work is subject of choice in accordance with actual operating conditions and all equipment on extraction technological lines of lignite and sterile from the roof of lignite layers to be in correlation. It should also be ensured reasonable exploitation in terms of intensive and extensive, and the adoption of a modern and efficient system for carrying out maintenance, being necessary the rehabilitation processes completion and modernization in order to maintain the level of their technical status.

The entire scope of paper considers the extraction complexes used in Oltenia open-pit coal field, especially Jilt Mining. Such theoretical aspects are tackled classic which allows qualitative and quantitative appreciation of the use of in time for excavation, transport and storage equipment of the extraction system.

Is analysed the evolution of usability for equipment on the technological lines. To do this, it is uses well-organized database of operation time for equipment from extracting complex machinery. Using the mathematical statistics methods was conducted a detailed analysis of influence for each parameter on use over time an extraction system.

2. Theoretical issues concerning the study of the use of machinery, excavation, transport and storage

The study of use time and capacity of technological systems with complex configuration is an issue of great importance and involves levels and different "angles" approach. This study allows for quantification of intensive and extensively uses, both at the level of each component, as well as at the level of the system as a whole. Applying this methodology presupposes the existence of a database "radiography" item or operation studied system. The downside of this methodology derives from the fact that captures quantitative aspects, but the use of another method based on statistical analysis and calculation software gentle this impediment.

This new approach represents an effective means for studying the functioning of extracting technological systems but the full resolution this presupposes the existence of a monitoring system and a database that will provide the knowledge real time operation the technological capacity of the system.

The efficiency of the use of equipment for excavation, transport and dumping within the exploitation of lignite is synthesized through three indicators. They are determined by collecting and processing statistical data relating to operating and stationary times, for machinery from technological flow. With the help of these operating and stationary times use indices are calculated:

- extensive use coefficient;
- intensive use coefficient;
- global use coefficient.

Extensive use coefficient, I_E , is an indicator that is calculated on the basis of the operation hours reported of calendar time:

$$I_E = \frac{t_f}{t_c} \quad (1)$$

where: t_f – represent operating time, h and t_c – is calendar time, h .

Intensive use coefficient is given by the relationship:

$$I_i = \frac{Q_R}{Q_T} \quad (2)$$

where: Q_R – made hourly capacity, m^3/h or t/h și Q_T – theoretical hourly capacity, m^3/h or t/h .

Made hourly capacity represents the ratio of the excavated mass (sterile and/or coal) and operating time:

$$Q_R = \frac{M_E}{t_f}, [m^3/h] \text{ or } [t/h] \quad (3)$$

where: M_E – excavated mass, m^3 or t

Global use coefficient (I_G) is calculated by multiplying the extensive use coefficient whit intensive use coefficient:

$$I_G = I_i \cdot I_E \quad (4)$$

3. Research on the evolution over time of use for equipment from technological lines

The use degree of technological machinery may be expressed by determining the coefficients of extensive use, intensive use and global. Based on the recorded data and considering the time period 2001 ... 2015, histograms were constructed on the utilization degree. Thus is shown in Figure 1, the histogram for the coefficient of use extensively, intensively and histogram for global use coefficient, all for the Jilt Mining.

It is noted that extensive use coefficient has a general trend of increase in the period under review. Thus in the year 2001 the value of this indicator was 0.16, in the year 2015 has reached the value of 0.40. There is some time between the years 2007 and 2010 found a slight decrease. Intensive use coefficient has a slightly increasing trend to rise 0.29 in the year 2001, the amount of 0.41 in the year 2013. In the year 2015 this coefficient reaches the value of 0.36.

Global use coefficient has a general trend of increase in the amount of 0.05 in the year 2001 and the value of 0.15 in the year 2015.

The growth use coefficients are explained by the completion of some phases of restructuring and modernization, and this increase is due to mentality changes and thanks to the new realities of the market economy.

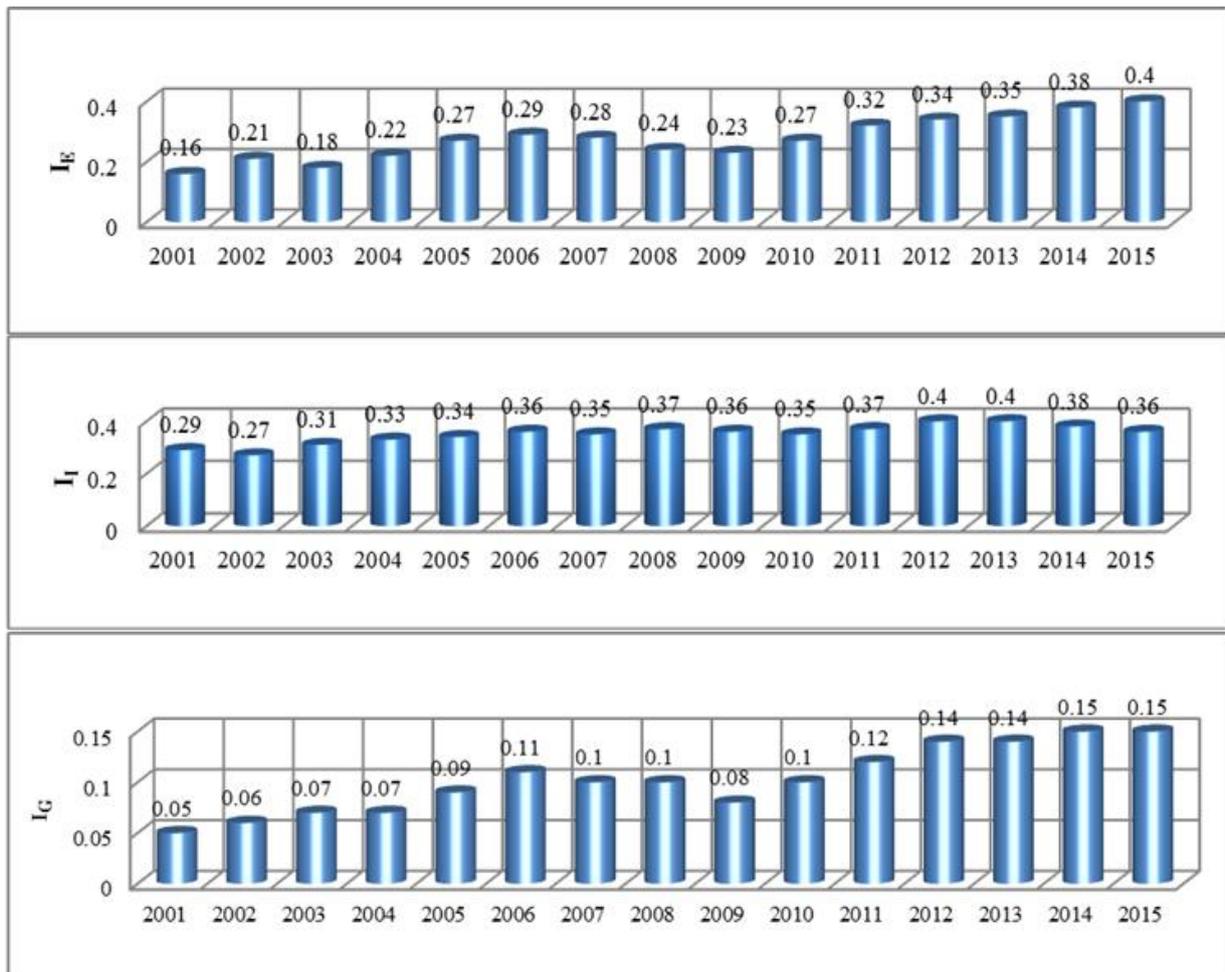

Fig. 1. The evolution over time of the extensive, intensive and global use coefficient for the Open-Pit Jilț Mining

4. The study of utilization in time a extraction complexes using mathematics statistical methods

Calculation methods for determining the capacity of extracting systems differ and depending on the system type. In the present paper considering only continuously extraction systems, in this sense, we consider their use over time, respectively theirs real production capacity.

There are problems of great difficulty, derived from the complexity of system, the number of influence parameters their time variation, geological conditions and geographical conditions. Other factors of influence are weather conditions, social aspects, energy market, etc.

For determination of extraction capacity, transport and storage it must be calculated from to beginning for a longer period (month, year), this objective involves defining of transported volume determined by every extracting element in part. The production capacity of the system is the sum of production capacity of extracting elements.

The paper approaches operating time evaluation of extraction system and their use coefficient in time. By this magnitude the behaviour of the system is manifested, respectively the mutual interaction between its elements. Using SP SS - SELF - SERVICE DATA ANALYTICS software, a detailed statistical study has been developed that takes into account dependent and independent variables that define, from a perspective use time, the components of the complex extraction system.

Normality tests were performed, mathematical fireworks were applied in less informative areas, and multiple regression methods were developed for statistical motivation of dependent variables versus independent variables, and useful correlations were established between these.

It follows that from a capacitive point of view the system is influenced by the actual operating time of the extraction elements. In turn, the running time determines value of the working time and the planned stop times, and the sum of the working time and stop time is the calendar time.

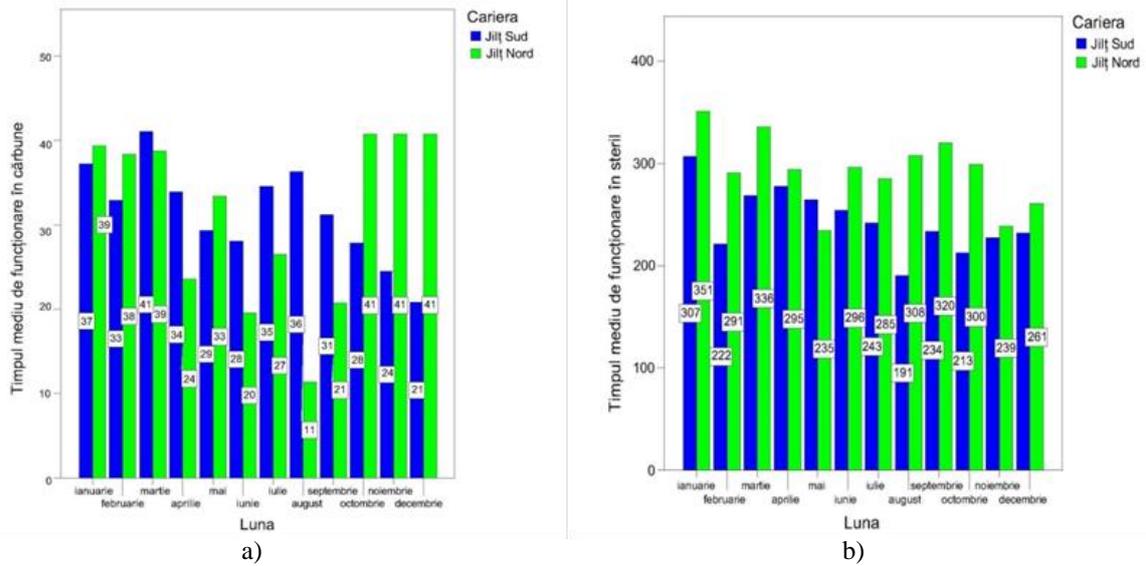

Fig. 2. The average operating time chart a) in coal; b) in sterile

We will approach from the point of view of statistical data resulting from monitoring over time of the extraction system in the year 2011 Open-Pit Jilt Mining. It was chosen this year as the basis of a careful analysis it was observed for this period, the relative dates are complete and well structured.

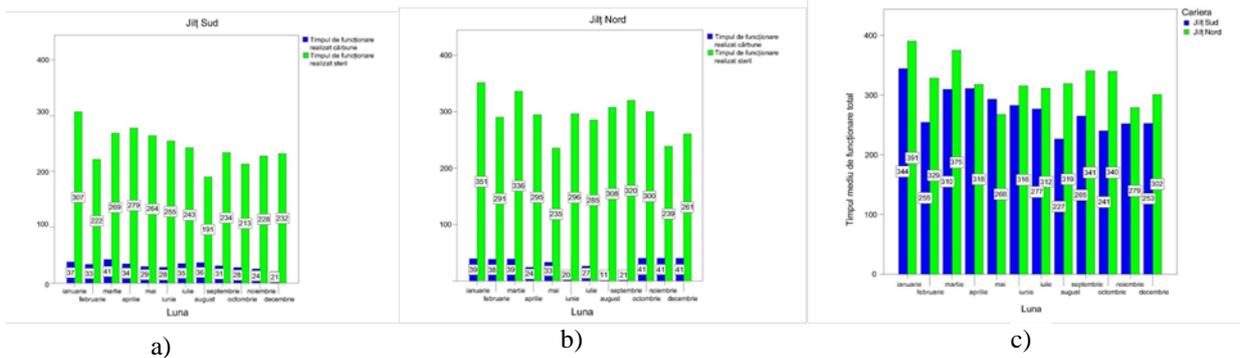

Fig. 3. The operating time chart in open-pit mining a) Jilt South; b) Jilt North and c) total

Based on these data have been presented graphically and analysed the main elements of influence in the use of extraction systems.

In Figure 2, it is observed that during the operation of the extraction system in the coal has a fairly large variation. It is a minimum of 10 hours per month in the Jilt North open-pit mining and 42 hours per month in the Jilt South open-pit mining. Consistency in operation occurs in the Jilt North, where in 3 consecutive months (October, November and December) operating time is 40 hours.

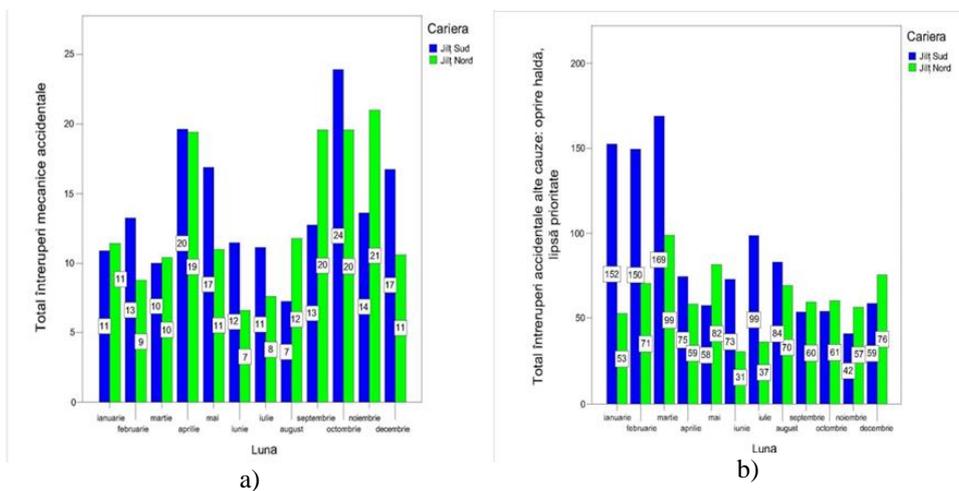

Fig. 4. Interruption times chart a) accidental mechanical; b) other accidental causes

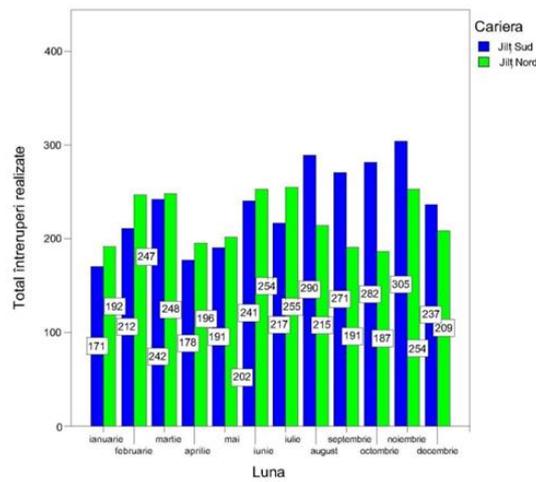

Fig. 5. Realized interrupt chart

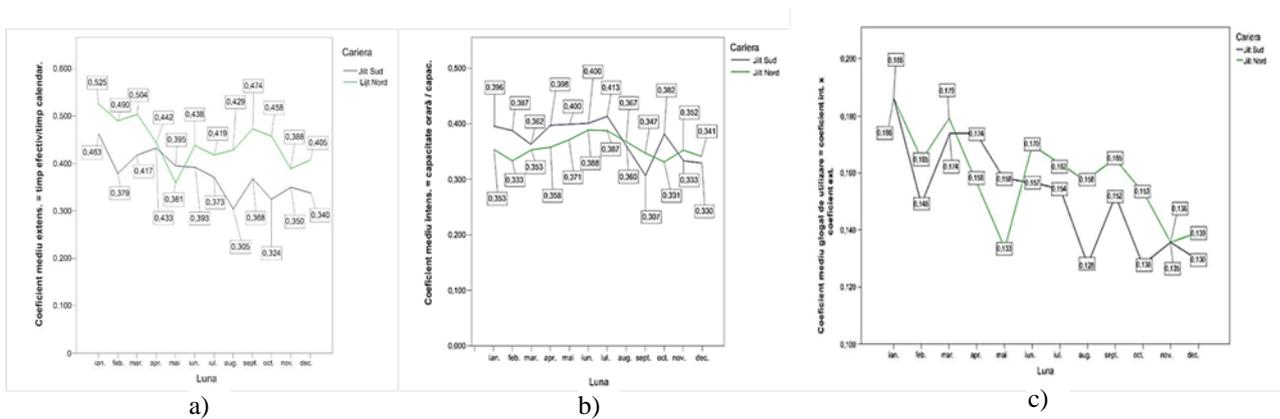

Fig. 6. a) The extensive use average coefficient chart; b) The intensive use average coefficient chart; c) The global use average coefficient chart.

5. Conclusion

From this approach we can see that there are important reserves for increasing use of extraction systems over time, so effort of knowledge will focus on scientific discovery of causes and measures to be taken to improve situation, thereby increasing production capacity will reduce costs, and lignite extraction will become more and more competitive.

This approach allows a profound understanding over time functioning of the extraction system components through the mutual influence light.

A fairly complex picture is provided, which implies a certain level of readiness, but can lead to well-grounded decisions, decisions must be followed by actions leading to an increase in use of the system subject to analysis.

The adoption of modern maintenance systems and modernization processes completion ensures increased lifetime for extraction system from open-pit Jilt Mining, even though some are approaching the maximum exploitation time and others have exceeded this limit. Adoption of this strategy is valid because it and other countries with developed mining industry was extended the life of the equipment of high complexity (as bucket wheel excavator) by monitoring the operation, data processing and modernization measures aimed at ensuring the success of the approach to be used in the operation of such equipment.

Abstract

The aim of the research is to optimize the production of small volume dimension stone products – mainly in limestone quarries - with the re-thinking of the use of production and transport equipment. The tool to be developed for both production and transport can reduce the number of mining machines to be used in the mine. It is planned to reduce the expenses of running mining businesses, which include mining operations, costs of maintenance. This paper shows the initial steps to develop a dimension stone mining adapter for a Construction Loadall base machine.

Keywords: prototype, development, mining, limestone, adapter

1. Introduction

The Institute of Mining and Geotechnical Engineering of University of Miskolc started the development of a small volume mining production and transport adapter suitable for limestone in the MIOCÉN project with the project managements of FÉMGER Kft. and HOBAGÉP Bt.

The aim of the research is to optimize the production of small volume dimension stone products – mainly in limestone quarries - with the re-thinking of the use of production and transport equipment. The tool to be developed for both production and transport can reduce the number of mining machines to be used in the mine. It is planned to reduce the expenses of running mining businesses, which include mining operations, costs of maintenance. The goal is to be cheaper on the market and to be more competitive with the companies in the market (Fülöp et al., 2017).

2. Limestone Leitha

For the design of the adapter to be developed and the selected technology, the determination of the mined rock environment was essential. The rock selected from the point of view of the project is the limestone Leitha in the Sopron Mountains, which is the main component of this area. The name of the stone was derived from the Leitha Mountain (or river), which separates the former Hungary from Austria.

Limestone in Fertőrákos and in Margitbánya (located in Austria) has been a popular building material for millennia: the Celts and the Romans living there used this stone as well. The nearby Carnuntum (near today Vienna) and the buildings and the protective walls of Scarbantia (Sopron) are made of this material.

From the 18th century it became a popular building material. They were easy to mine and transport, massive amounts of blocks were transported to the buildings of nearby big cities. Much of the houses in Vienna and Bratislava were made of this material, but in almost every village around Sopron we find buildings built from "Rákosi" stone. At first only the temples were built out of it (e.g. the Saint Michael church in Sopron, Stephansdom in Vienna), but soon it was the basic material of the residential buildings. We could mention the Esterhazy Castle in Fertőd (Fig. 1.) or the Castle of Festetics in Keszthely. In addition to the building work, it also served as a base for many tombs, memorials and sculptures.

* Corresponding author. Tel.: +36-46-565-111/18-08

E-mail address: gtbvir@uni-miskolc.hu

Fig. 1. Esterházy Castle in Fertőd (Wikipedia)

Rákosi stone is moderately resistant to weather, so it is best to use in plaster finished structures. The example of the Trinity of Kőszeg has been a good example of the relatively poor resistance, which was set up in 1713, but since it has been restored 3 times (1813, 1869 and 1974). The pedestals of the Buda Castle buildings were made of this stone (the stones which were recently removed from Margitbánya, unfortunately they are also destroyed by the salting of roads and pavements). These future reconstruction needs have justified our choice of cooperation with “Fertőrákosi II” limestone quarry.

The Rákosi limestone is 100 - 150 m thick, large-grained shallow-sea sediment. Its material is made up of reddish algae, snails, shells, sea-urchins and bryozoas. The color of the rock is yellowish-white. Its density is between 1750 kg/m^3 and 2500 kg/m^3 in the air-dry state. Its compressive strength is typically around 10 MPa. (Mednyánszky, 2017, Török, 2008).

3. Methods of production of dimensional stones

To develop the rock winning technology, it is imperative to know the geological knowledge of the site and the use of the extracted material. Based on these, we must choose which way to start optimally in the development.

There are several versions of the dimensional stone production, which are:

- a) Block production with a large borehole blasting technology, in which we create oversize blocks, which require further cutting or shaping.
- b) Cleavage of stone blocks using chemical swelling energy. One way is to use water-swellable mixtures for rock fracturing purposes.
- c) Use of mechanical, hydraulic and combined rock setting wedges placed in small-diameter holes. Hydraulic units consist of a high-pressure hydraulic unit and a tensioning tool. Owing to the high-pressure hydraulic unit the wedge tensioning tools cause tension to the walls of the holes, thereby developing tensile stresses in the stones between the holes.
- d) Creating blocks by drilling when the boreholes are drilled densely along the contour of the block so that they are in contact or interconnected.
- e) Rock sawing, which can be done with disc, chain and rope. The gentlest block production method is the sawing of blocks. For the smooth operation of the rock saws it is necessary that the rock is free from cracks.

Fig. 2. An abandoned building stone mine (Molnár, 2012)

To mining blocks in a place where blocks are not sawed, a large number of boreholes are needed. The boreholes have to be spaced from 15 to 40 cm apart to allow the rock to be fractured along a certain plane.

Since the most gentle production method is rock sawing, and to reduce the number of machines, we plan to solve the production with a design that is capable of winning and transport.

4. The prototype adapter

The basic machine for the adapter is provided by a JCB Construction Loadall (Fig. 3.). Due to the large load capacity and design of the machine, it is used for different workflows in many areas. Its multifunctional applicability ensures that the hydraulic system of the requested machine has a pump capacity of 140 l/min and a working pressure of 260 bar.

Fig. 3. The basic machine of the project, a JCB Construction Loadall

Based on the new technology, the adapter can be disassembled into two main units. One of them is the cutting chain saw unit combined with a feed and rotation hydraulic system and a hydraulic rotary unit. This part of the adapter can cut from three sides perpendicular to the front face.

The structure of the rock chain saw contains individually manufactured elements, such as chain-shaped teeth, which are formed in a specific, unique order on the chain and form 7-8 teeth-repeating chains, specially developed for rock quality (Fig. 4.). The shape of the cutting device is very important because of the cutting forces and loads (Tomus, O. B., Rada, A. C., 2017). High loads can produce unwanted effects on mining system (Andras et al., 2016). During design the chain guide should be designed separately, which should consider the lubrication system to be used to reduce friction during operation.

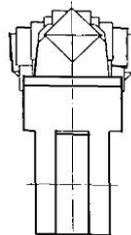

Fig. 4. Special chain saw elements (front-wise)

The other main machine unit serves to support and move the first main unit while cutting and performs stability and elevation of the block with an object table, which is subject to heavy wear and tear during the mining use.

Testing the prototype adapter (Fig. 5.) is unavoidable during the development period, which will be carried out at the manufacturing workshop and in the limestone quarry. During testing, the static and dynamic uses of the units in the adapter are studied, even in extreme cases, to determine the more accurate technical parameters.

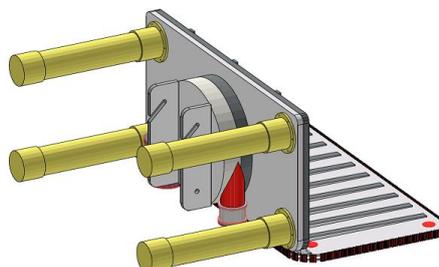

Fig. 5. An initial version of the prototype adapter

5. Conclusion

Future reconstructions of historic buildings, tombs, memorials and sculptures need good quality dimensional limestones. This is why we start a new project to design a mining adapter. To develop the rock winning technology, it is imperative to know the geological knowledge of the site and the use of the extracted material. Based on these, we must choose which way to start optimally in the development.

Since the most gentle production method is rock sawing, and to reduce the number of machines, we plan to solve the production with a design that is capable of winning and transport.

A two-stage macro based approach for developing aircraft engine components concessions based on surface morphing technologies

Rusu Robert^a, Alexandru Tudor – George^{a*}, Monica Manole^a

^aAssystem Technologies, 7 Iuliu maniu Blvd., 061072 Bucharest, Romania

Abstract

Computer Aided Engineering tools are widespread in the aerospace industry, being used in all the life cycle stages of an aircraft in order to numerically capture the behavior of parts and sub-assemblies subject to ground and flight loads. In the case of turbofan engines, apart from the design stage, simulation tools are found in a close relationship with physical geometry measurement test procedures, being used to support manufacturing changes from the baseline virtual prototypes. While such approaches are found at the maturity stage, being used in various configurations by teams geographically delimited around the world, the high degree of manual work involved together with the high level of repetitive task required lead to high amounts of time being spent on such projects with a low degree of knowledge based engineering being captured and re-used. The present paper addresses such issues by extending conventional simulation approaches with surface morphing capabilities that are embedded within computer aided engineering pre-processing software, as tools that can fill the gap between physical geometry measurements data and numerical simulation models. The given concepts are proved by means of a conceptual case study regarding manufacturing non-conformities occurring for a variable stator vane turbofan engine component.

Keywords: Jet engines, Computer Aided Engineering, Non-Destructive testing, Morphing

1. Introduction

The ongoing trends in the aerospace industry call for new airliners that can operate with lower noise levels and higher fuel efficiency across extended flight ranges (Graham et al., 2014). Apart from the structural aspects of a jet airliner, the engines represent a main concern in this sense, R&D efforts being focused on components that are lighter and stiffer. A wide range of alternative materials are currently in use in the design of stator and rotor components. Examples include (but are not limited to) metal matrix composites, hybrid-metallic materials and titanium alloys, yielding enhanced aerodynamic performances and high structural durability (Srinvas et al., 2018). To support integration of such materials in the design of aircraft engine components, virtual prototyping technologies benefit from the use of computer aided software (Ryazonov, 2016). Surface modeling capabilities embedded within Computer Aided Design (CAD) software assisted design engineers with the necessary tools for achieving innovative shapes for blade structures while the applicability of such design scenarios can be validated thanks to the wide scale use of Computer Aided Engineering software (CAE), based on numerical modeling and simulation methods (Boldă and Pupăză, 2018). The resulting design stage prototypes are subject to several manufacturing processes in order to achieve a compromise between the baseline and the physical structure, such that the efficiency, natural frequencies, strength and toughness requirements are met with respect to economical and manufacturability criteria (Amoo, 2012). From this point of view, conventional and non-conventional manufacturing processes are deployed (i.e. investment casting of a turbine blade, electrochemical machining of blade shrouds and electro discharge machining of groove face surfaces in axial compressor blades). The wide scale implementation of industrial robots together with the ongoing improvement of fault detection and diagnosis expert systems has significantly lowered manufacturing issues (Ivan et. al., 2015; Alexandru, 2001) Even so, the ever increasing complexity of aircraft engines, results in components that are prone to non-conformities (NC). For example, shrinkage of thin walled structures during casting can result in non-uniform wall thickness that can lead to stress redistributions (Dong et. al, 2017) while generating features by electro discharge machining can result in rim zones in the case materials with characteristics altered by mechanical or thermal effects are used.

E-mail address: talexandru@assystem.com

As a consequence, such non-conformities are susceptible crack initiation and propagation sites (Pramanik et. al., 2017). From an economical point of view, considering all out of tolerance components as scrapable parts, can result in low profit margins while from a technological point of view, performing rework (i.e. light machining and welding) does not guarantee on-time delivery of the final product. While some non-conformities cannot be acceptable without rework as they pose a threat to the structural integrity of the engines (i.e. internal cracks found in the proximity of stress concentration points), other non-conformities have no significant side effect as the impacted component can withstand damage throughout the life cycle of the engine (i.e. localized loss of thickness in low stress locations). Considering the high costs related to the manufacturing of aircraft engine components and the aerospace design philosophies, it is imperative to develop a concession approach, in order to prove that a component that is out of tolerance can be considered acceptable with or without further work performed. Physical geometry measurements supported by automated 3D scanning apparatus are well developed being used in wide scale for identifying geometrical tolerance deviations (Burghardt et al., 2017). Non-destructive testing (NDT) approaches are common for the inspection of internal (x-ray scan) and external manufacturing NC (penetrating liquids) (Bernoud and Mourad, 2011). Results from both inspection types are used for performing manufacturing flaws concessions based on analytical and numerical calculations. The first part of the work discusses about the concessions process workflow, describing a generalized approach adopted in the aerospace industry. The second part of the work presents the significance of CAE simulations in the concession processes, together with the most common methods used for developing concessions calculations. In the third part of the work, limitations of the existing methodologies are discussed, highlighting the need to tackle such issues by developing new approaches. The original contribution is illustrated in the last part of the work, consisting of a macro-based tool that performs a two-stage process for test reports data conversion and update of the baseline models. Automation of FEM editing is achieved by expanding the simulation models with surface morphing based on parametric surface definition capabilities and by combining FEM transformation commands found in most commercial pre-processing software. To prove the given concepts, a conceptual case study regarding the update of a baseline Variable Stator Vane (VSV) model is illustrated by the end of the work. LMS Samtech SAMCEF Solver suite is used due to its embedded geometric, FEM modeling, solving and post-processing capabilities.

2. Concessions workflow

The concession process is characterized by the use of inspection data in other to prove by analytical, numerical or design means that an out of tolerance component can withstand damage throughout the life cycle of the assembly it is part of. The method requires an identification of the applicable criteria and their relationship with the NC. For example, loss of thickness of a stator blade causes the mass of the component to change, developing a different dynamic behavior than that of the baseline. To verify the criteria, the dynamic calculations are updated to consider the thickness loss and the analysis is re-run in order to process the changes of the natural frequency and vibration mode shapes.

Major jet engines manufacturers successfully implemented and use concession approaches for components having a certain non-conformity threshold value. While the choice of tools, methods and guidelines is specific to each company, a general approach workflow is depicted in Fig 1. Test reports based on geometrical measurements or NDT are studied to identify if the manufactured component exceeds the tolerance values prescribed in the shop drawing. A certain threshold value is defined; such that aerodynamic criteria remain unchanged (pressure and temperature gradients are not impacted by the NC).

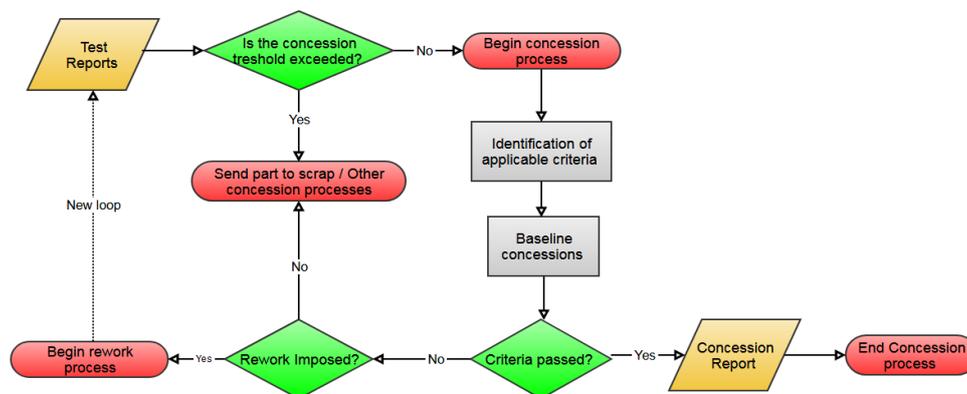

Fig. 1. A typical concession workflow structure applicable to aircraft engine components

If the manufactured parts exceed this value, either a different concession approach is used or the part is sent to scrap. The concession process represents a three-step approach:

- *Identification of applicable criteria*: based on the out of tolerance values, their location on the part and the type of NC, certain functional criteria are impacted. For example, a surface crack located on the trailing edge of an outlet guided vane significantly lowers the fatigue life of the impacted part;

- **Baseline concessions:** For each impacted criteria, an analysis is performed to determine if the NC can be acceptable as is (no rework is required), acceptable with further work performed or not acceptable (for parts that have NC or reworked NC that do not have the ability to maintain their structural reliability throughout the life cycle of the jet engine);
- **Concession report:** an overview of the calculations performed is presented in the concession report. This document serves as a basis for mounting the part as is or for performing further work.

3. Simulation models

CAE simulation models are widely in use in the complete life-cycle of a product in order to numerically capture the behavior of parts or assemblies subject to ground and flight load cases. To perform most common analysis types (i.e. static stress, modal, frequency response, eigenvalue buckling), a CAD geometric model is subdivided in elements (meshed structure). Each element consists of set of nodes that are linked together to close the computational model, where each node typically represents an integration point. Both simulation metadata and results stand at the core of the concession processes, being used as baseline references for developing justification calculations. Several concession approaches are available:

- **Analytical calculations:** changes from the baseline section result in the increase of the mechanical stresses if the section loss occurs or decrease of the stresses and/or load redistribution if the out of tolerance value is positive. In this case, results are extracted from the baseline simulation models and are multiplied by specific factors. Such factors are based on in-house knowledge (i.e. experimental assessment of mechanical stresses on out of tolerance parts) or on simplifying assumptions (i.e. stress increase factor are derived from the critical section area ratio) – see Fig 2. - a.
- **CAD/CAE based studies:** a reverse process can be performed to geometrically represent the area where the NC is localized. Various densities of mesh can be applied to refine the calculation model around the NC. Loading is applied under the form of displacements extracted from the baseline simulations that are applied to the boundaries of the model – see Fig 2 - b.
- **CAE simulations update:** each element consists of a set of nodes localized in the global model space by three coordinates (CX; CY and CZ). The free faces of an element (for 2D and 3D element types) define the boundaries of the outer skin for a solid body. To update the simulation models without performing a re-mesh of the structure, nodal coordinates should be updated to take in to account the NC. An example is illustrated in Fig 2 –c. The free faces of a 3 node 3D tetrahedron element are displaced such that the baseline mesh is translated to a modified mesh that captures a shape deviation.

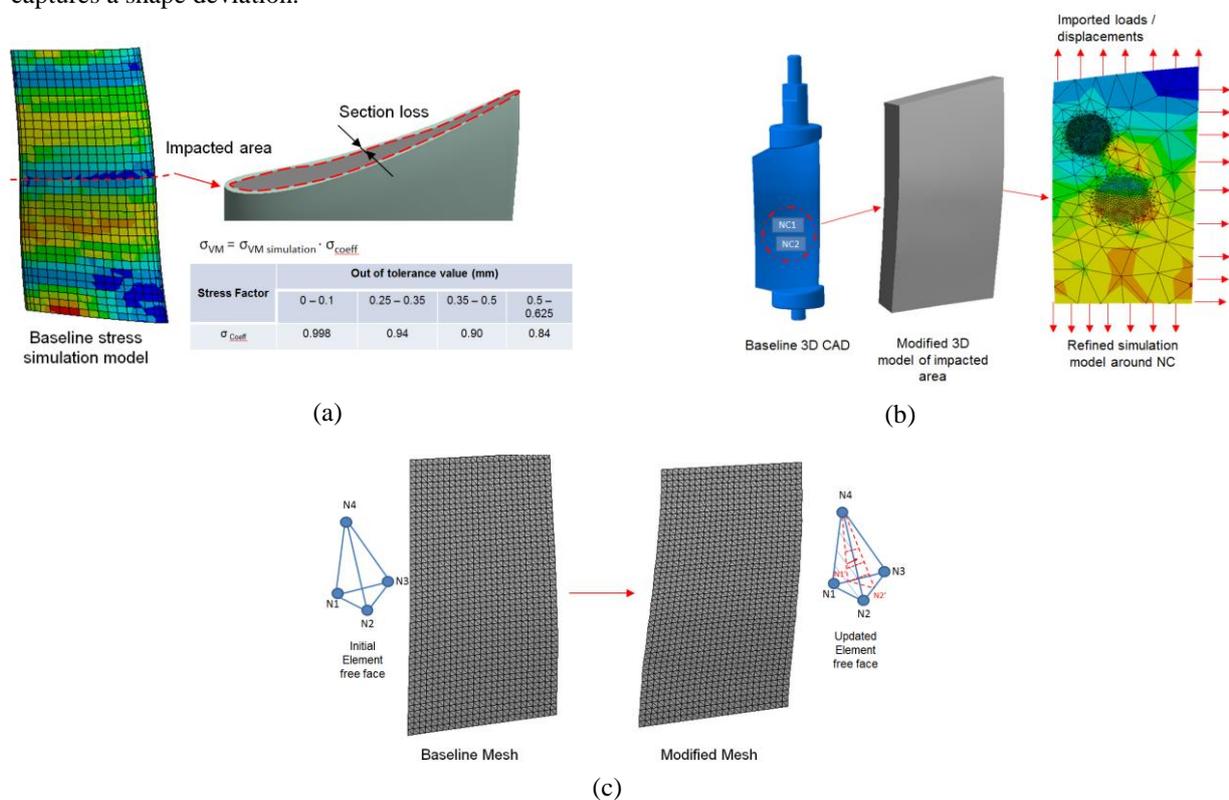

Fig. 2. Concession approaches (a) analytical solution approach; (b) CAD/CAE based studies; (c) CAE simulations update

4. Limiting aspects of concession approaches

All concession approaches can be considered valid for supporting both manufacturing and R&D activities in the field of aircraft engines. Even so, specific issues arise that require a closer observation:

- *High level of repetitive tasks* – All types of concession processes involve a high degree of manual work to be performed. Most of the times, the selection of the impacted area, extraction of results from the baseline and / or generation of the mesh involve a high degree of repetitive tasks to be performed. This results in a high probability of errors to occur, requiring extra check to be performed;
- *Low traceability* – The choice of extractions, selection of the impacted area together with the mesh methods applied are a result of the engineer’s judgment. Being hard to define a standard approach, the same NC can be interpreted differently by different engineering teams, leading to different results and consequently, low traceability;
- *Low level of knowledge based engineering* – concession processes represent a rich source of knowledge modeling and sourcing. Even so, not much attention is paid to the development of knowledge based engineering approaches oriented for concession processes. As a consequence, small amounts of knowledge are re-used in such projects.

5. Proposed approach

The proposed approach consists of a macro written in Microsoft Excel VBA application that performs a two stage process – see Fig 3. At first, test reports are read in .CSV file format. Considering that the test reports have a standard structure, data is read from specific lines. Each out of tolerance point is used to update a baseline script written for SAMCEF Bacon module that has the aim of generating a parameterized surface that recreates the physical shape of the exterior solid faces. In the next step, a baseline CAE simulation model input file is read and stored in the memory. A graphical user interface was developed for simple control and preview of working files – see Fig 4.

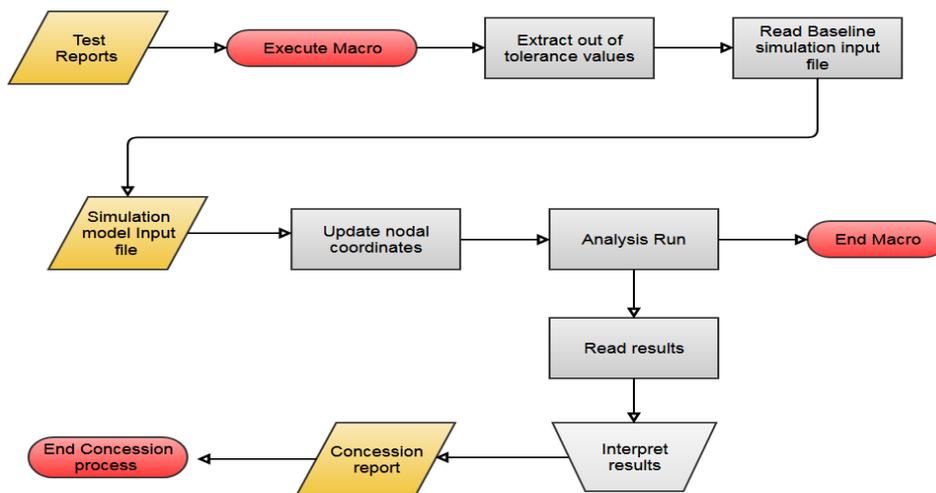

Fig. 3. Two-stage macro based approach

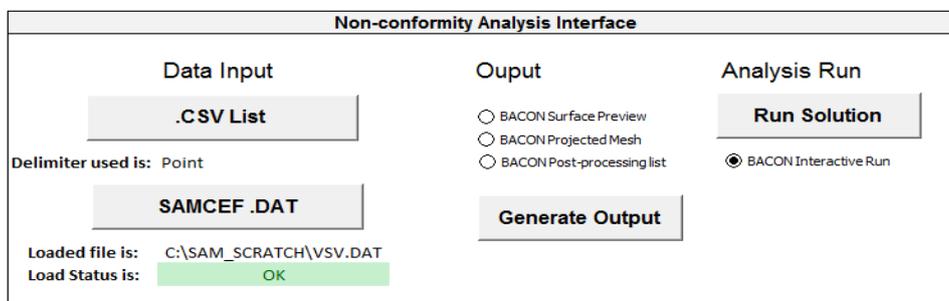

Fig. 4. Graphical user interface

In the next step, surface morphing is performed in order to map the exterior faces of the baseline mesh over the defined surface – see Fig 5. Note that exaggerated out of tolerance values were used for visualization purposes.

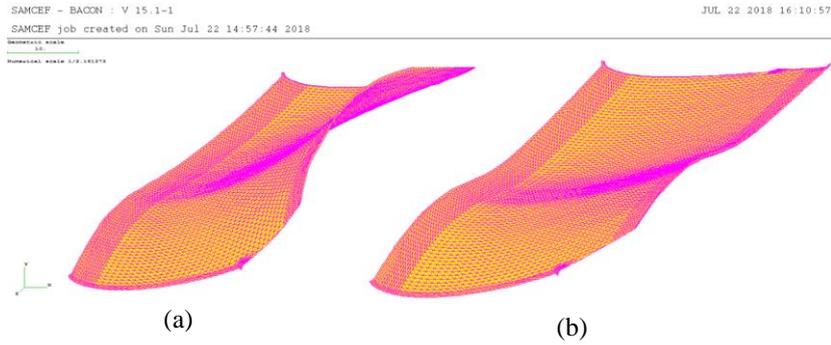

Fig. 5. Preview of Morphing operations performed for a VSV blade (a) Mesh after performing morphing operations; (b) Baseline mesh

The modified nodal coordinates recreate the physical shape of the out of tolerance components allowing for high-accuracy studies to be performed. Furthermore, resulting script files can be stored in databases to be re-used for similar cases. In the last step, a batch process takes place for running the analysis considering the new nodal coordinates.

6. Conceptual case study

A VSV component was subject to casting NC, resulting in a series of shape deviations occurring on the center section of the blade. Geometry inspection was carried out and results were saved to a standard .CSV extension file. The baseline mesh is presented in Fig 6. The workflow discussed in the previous chapter is applied. In this case, a static stress analysis is performed using SAMCEF ASEF module. High fidelity results are achieved by the end of the loop – see Fig 7. Compared to the baseline, the Von-Misses stress gradients and peak values have migrated, resulting in a new stress state that takes place due to the NC.

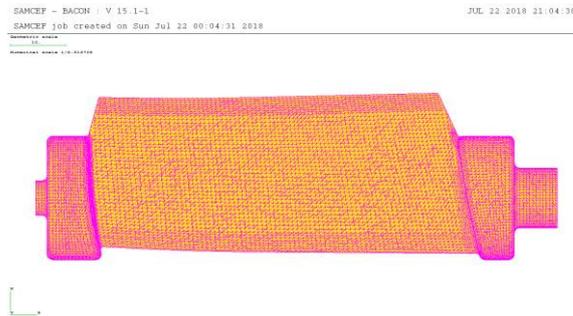

Fig. 6. Preview of the baseline 3D mesh

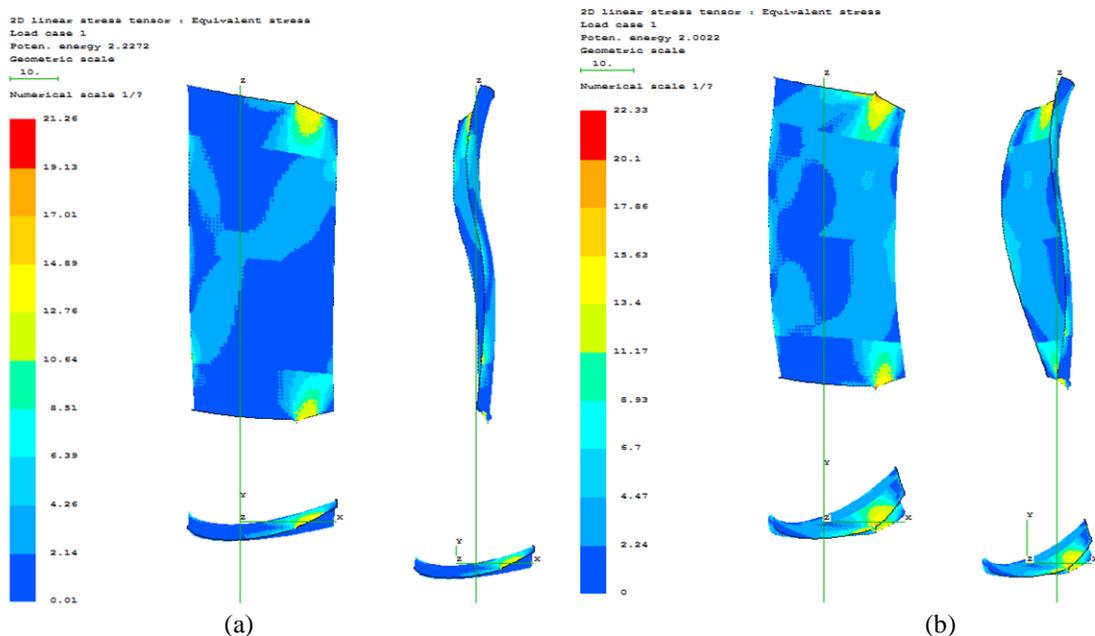

Fig. 7. Unaveraged Von-Mises stress criteria (a) Baseline simulation; (b) Updated simulation model

The baseline mesh and results of the analysis are further used as input data for 3rd party tools used for verifying specific functional criteria.

7. Conclusions

The present paper presents the workflow and approaches available for aircraft engine components concession processes. The identified issues are tackled by deploying a two stage macro based approach that automates the CAE simulation update process by reading data form test reports and generating a geometric surface that captures the real shape of the non-conformal product. Morphing technologies are used to map the baseline mesh over the resulting surface. The approach lowers the amount of repetitive tasks, while enhancing traceability and knowledge based engineering capabilities.

Abstract

Drilling is a highly demanding machining process due to complex variables like tool geometry, material failure and drilling fluid behaviour. In order to increase the quality of this process, a model was developed using SolidWorks, in order to simulate the behaviour of the drilling fluid flow for different speed and pressure values, from the point of view of the transport of debris out of the wellbore, prevention of external fluid influx, and the maintenance of wellbore stability. The results of the simulations demonstrate the effects of drilling fluid flow parameters on drilling and also confirms the capabilities and advantages of FEM simulation of the drilling process.

Keywords: Drilling, Drilling fluid, Simulation, FEM, Wellbore;

1. Foreword

Well drilling is a technology used from ancient times and is employed in many fields, such as:

- geological exploration;
- oil and gas extraction;
- underground water extraction;
- mining shaft sinking;
- geotechnical research.

The well is an excavation having a cylindrical shape. The wells can be vertical or inclined ones.

The well drilling is a complex operation which consists in rock removal and the transportation of detritus (debris) away from the well to the surface. The drilling is performed with the equipment called drilling rig.

The drilling rigs can be:

- heavy drilling rigs, with high actuating power, the drilling depth reaching thousands of meters and the well diameter ranges from hundreds of millimetres to 7000 mm;
- small depth drilling rigs (lightweight drilling rigs) with reduced actuating power, and drilling depth less than 1000 – 2000 m, with small well diameters.

The purpose of the drilling operation determines the kind of drill bit used, which differs in the manner in which the rock is removed on the bottom of the well, as follows:

- for the exploration wells, which aim to obtain samples of rocks, the rock cutting is performed in an annular cross section, using a bit named coring drill bit (Figure 1), the drilling is called coring drilling and the rock sample obtained is named core specimen, which is a cylindrical piece of rock, which is useful for the knowledge of the geological structure of the location's subsurface.
- for the wells drilled with the purpose of extraction (oil, gas, water) or mining infrastructure (transport or ventilation shafts) the rock removal on the bottom of the well is made on full circular cross section, and the corresponding tool is the conventional drill bit (Figure 2). In both cases the drill bit is actuated through the drill string by the rotating table which is located at the top of the well and is a component of the drilling rig. The detritus is transported away using the so-called drilling fluid or mud.

Fig.1 Coring drill bit

Fig.2 Conventional drill bit (tri-cone type)

The most frequently used drilling method is the rotary one, with debris transported to surface by fluid circulation. The drilling process is a continuous one, the rock removal and the detritus transportation being performed simultaneously. (Figure 3).

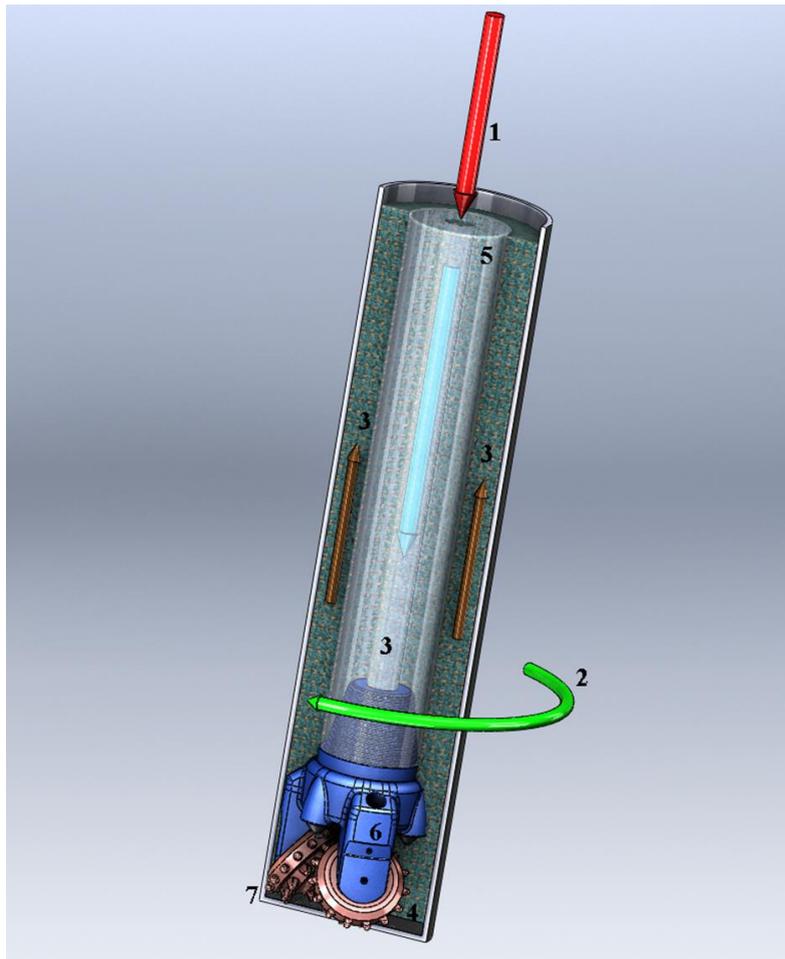

Fig.3 The principle of drill bit's operation (1 – thrust force, 2 – torque, 3 – fluid flow, 4 – detritus, 5 – drill string, 6 – drill bit, 7 – bottom of well)

2. The analysis of the drilling fluid behaviour by Flow Simulation tool of SolidWorks

We analysed the drilling fluid behaviour for a rig that has a three-cone drill bit with drilling fluid circulation channels. The analysis was done in SOLIDWORKS software, using the Flow Simulation tool. The assembly analysed is shown in Figure 4.

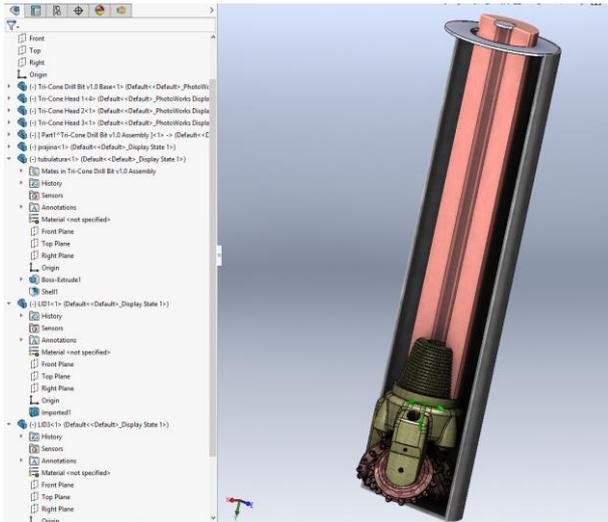

Fig.4 The assembly on which the analysis was conducted

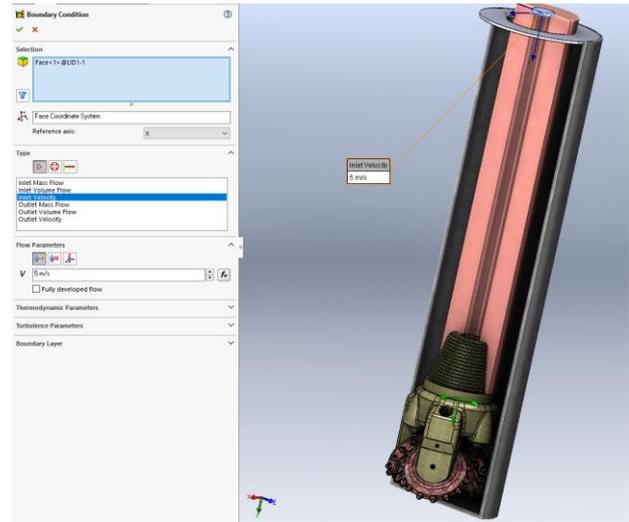

Fig.5 Set-up of the inlet velocity of the drilling fluid into the drill string

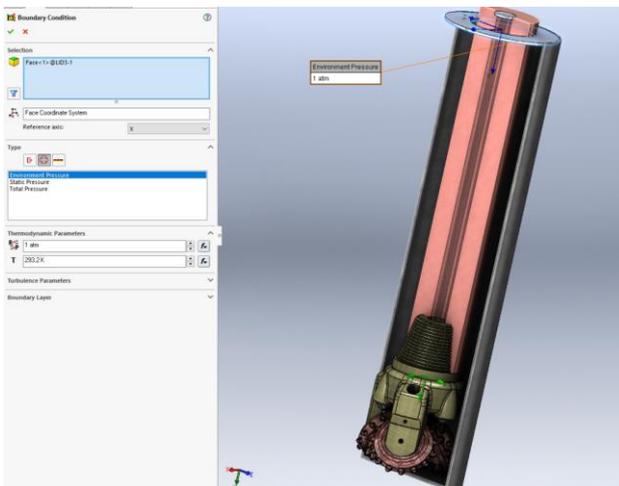

Fig.6 Set-up of the upper pipe pressure

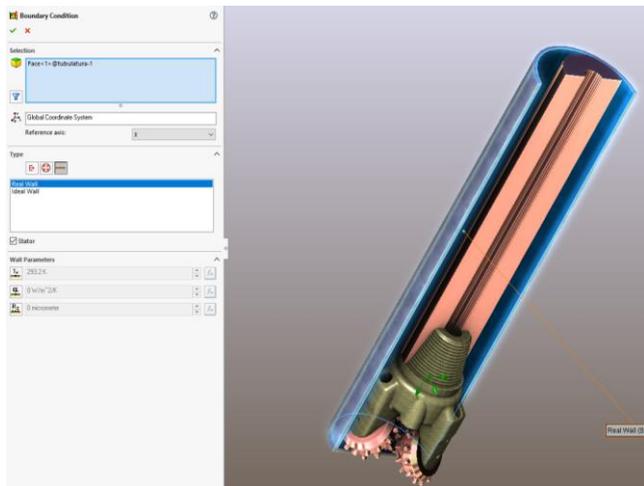

Fig.7 Set-up of the stator limit corresponding to the internal surface of the piping

Two parts named LID1 and LID3 were added in order to "close" the drilling fluid circuit at the top of the drill string and of the duct (casing) respectively. Their role is essential in case of an internal analysis because they determine the limits of the scope of analysis. Water was considered as drilling fluid.

We have imposed three conditions at the separation limit of the analysed field: the inlet velocity into the string (Figure 5), the upper pipe pressure (Figure 6) and a stator limit corresponding to the internal surface of the piping (Figure 7).

The rotating movement of the drill-bit and of the drill-string was simulated by defining into the assembly of two areas of rotation, to "encompass" the drill-bit and the drill-string respectively. In Figure 8, these rotation areas are set to transparent while in the final presentation of the results their attribute was changed to "hidden".

To these two areas we imposed an angular velocity of $105 \frac{rad}{s}$ or $1000 \frac{rot}{min}$ (figure 9).

Figure 10 shows a screenshot of the drilling-fluid behaviour in the defined conditions. It can be seen that its speed increases considerably at the exit of the three nozzles. This result highlights the hydrodynamic role of the drilling fluid.

By analysing the trajectory lines of the drilling fluid it can be concluded that in the annulus (space between the drill-string and the tubing) the fluid has a helical motion from the bottom to the top of the bore-hole. This helical trajectory is generated by the rotation movement of the drill-string and bit, which act as rotors for fluid pumped into the well.

Figure 11 shows the pressure variation of the drilling fluid. Similar to figure 10 it can be seen that the pressure rises at the bottom of the well, which also highlights the hydrodynamic role of the drilling fluid.

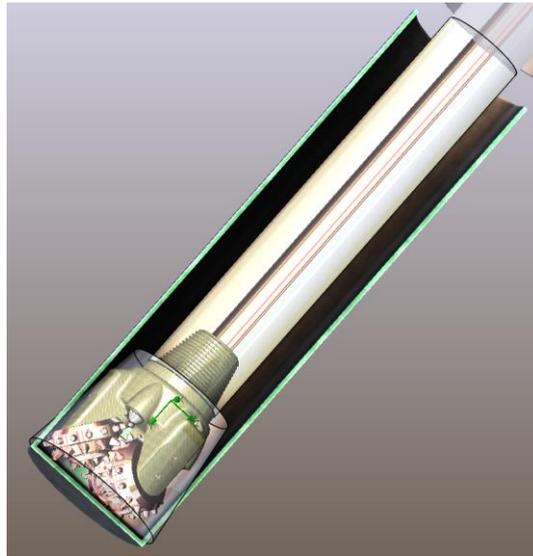

Fig.8 The defined areas of rotation

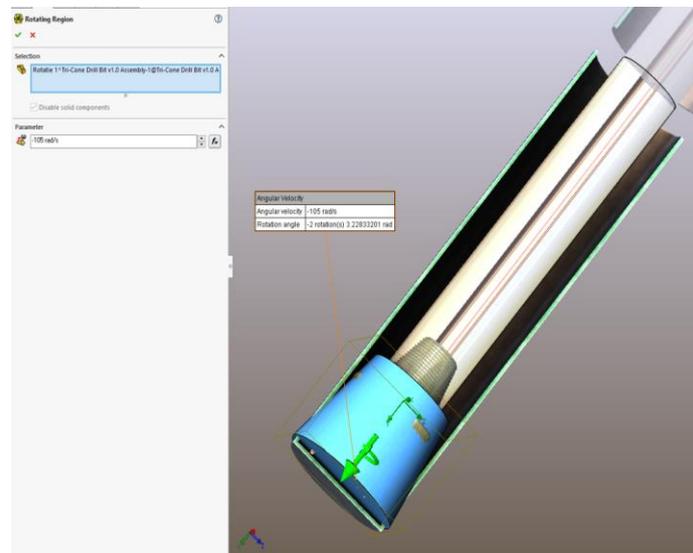

Fig.9 Defining the angular velocity of the areas of rotation

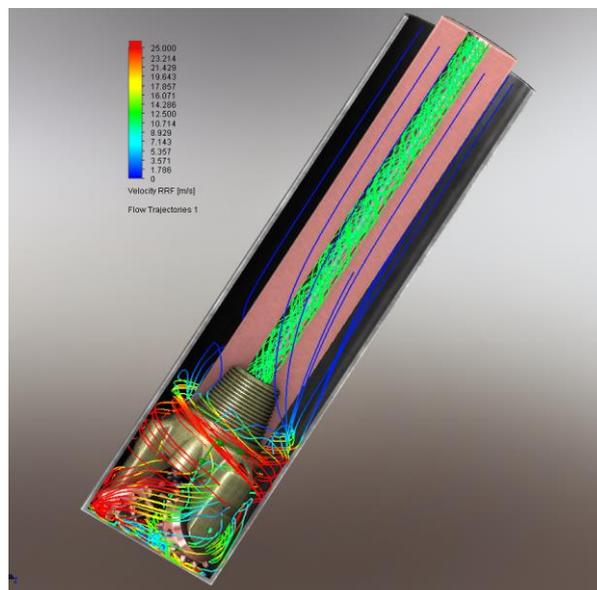

Fig.10 Speed of the drilling fluid

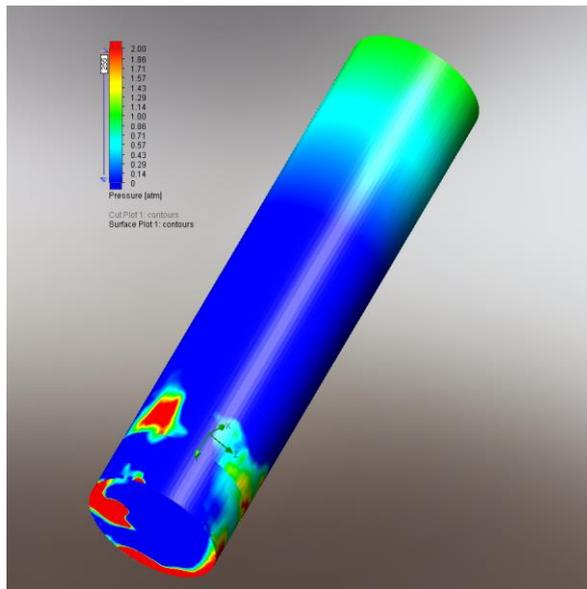

Fig.11 Pressure of the drilling fluid

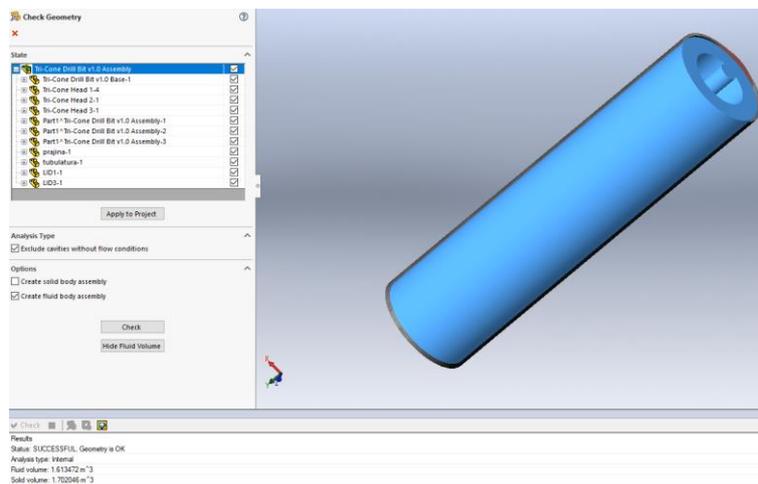

Fig.12 Determination of the drill-fluid volume

Fig.13 Sections through the drill-fluid “part”

SOLIDWORKS software allows the determination of the fluid volume that is used in the conducted analysis. Figure 12 shows this option. For the example considered a volume of the drill-fluid in amount of aprox. 1.61 cubic meters was considered. In figure 13 the drill-fluid volume was considered as a SolidWorks part that was sectioned by two planes.

3. Conclusions

The study of the behaviour of the drilling fluid using FEA shows that:

- The hydrodynamic role of the drilling fluid, which, because of the increase of velocity and pressure at the exit nozzles dislocates the debris from the bottom of the borehole
- The hydrostatic role of the drilling fluid, because the pressure of it on the walls of the well prevents the collapse of loose formation of rocks as well penetration of the borehole by external fluids.
- The power conducting and informative role of the drilling fluid, which acts as an energy transmitter towards the drill-bit and also permit the analysis and information gathering from the evacuated debris.

Results of present and future research can be used in the design of drill strings, by replacing the standard cycle of designing → prototyping → testing into a simpler and more cost-effective process of prototyping only for the validation of the final design. Obviously, the final goal is the building of improved drill strings and drill bits in order to increase the quality of the well drilling process.

Abstract

BWEs used in open pit coal mining are subjected to excessive loads during cutting because of the interaction between the working face and the bucket wheel's components. High loads and unexpected shocks produce downtimes, increased wear, or severe damage of the BWE components or operational subsystems, leading to increased energy consumption, lower production rate and, finally, increased mining costs. A study of the forces acting on the shaft of the bucket wheel was conducted, using computerised modelling and simulation, in order to reduce the mentioned issues and improve the quality of the excavation process.

Keywords: BWE, Rotor shaft, Cutting process, Simulation, Forces;

1. Introduction

The bucket wheel excavator (BWE) is a machine with continuous operation which cuts the rock with the help of the buckets installed on the rotor, performing at the same time the transfer of the excavated material to the main conveyor, with the help of the conveyor belts installed on its boom. The operating equipment is the rotor (bucket wheel) which performs a rotation movement in vertical plane and, with the help of the boom, a horizontal pivoting movement and a vertical ascendant – descendent movement. In this paper we present a modality of determining the operation power of an excavator rotor using numerical methods. The aim of approaching some virtual models which allow the analysis of the operation of some components of the rotor excavator resides in the improvement of the cutting – loading system, the reduction of the specific energy consumption during the cutting operations while maintaining the installed power for the operation of the rotor and the increase in the excavation capacity, respectively the degree of intensive use of the excavator.

2. Definition and calculus of the excavation parameters

The method proposed for the calculus of the operation power of the rotor has been applied to a model EsRc 1400 excavator. This type of excavator is used in the lignite mine pits in the coal fields in Oltenia.

The geometric characteristics regarding the positioning of the rotor and the rotation mechanism are presented in figure 1 where the notations employed carry the following significance:

- H_s – the height of the rotation axis of the boom as against the operating level of the excavator;
- L_{sp} – the distance between the rotation axis of the boom and the rotation axis of the upper platform;
- L_p – the pivot length of the boom;
- H_{sp} – the distance between the rotation center of the rotor and the lower surface of the boom;
- H_{sp} – the distance between the rotation center of the rotor and the symmetry vertical plan of the boom;
- δ – the angle between the longitudinal axis of the rotor and the pivoting axis of the boom.

* Corresponding author. Tel.: +40-722366653,
E-mail address: andrei.andras@gmail.com

The arm of the excavator performs in vertical plane an ascendant and descendent movement around the rotation axis of the boom (figure 1). Horizontally, the rotation movement occurs around the rotation axis of the upper platform with the pivoting speed V_p (figure 2). From a technological and also energetic point of view, the plans in which the two rotations appear (ascendance – descendance and pivoting) must be vertical, respectively, horizontal. The vertical and horizontal deviation must not exceed 3,50 – 4,50.

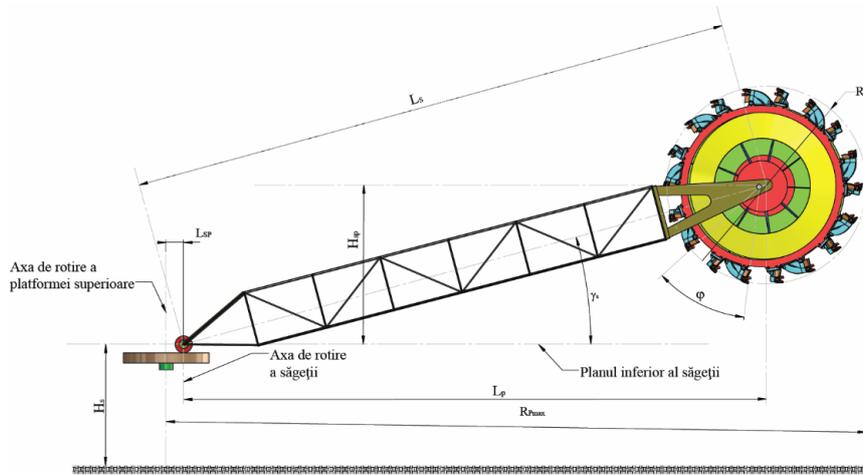

Fig.1 The geometric characteristics of the arm - rotor system, side view

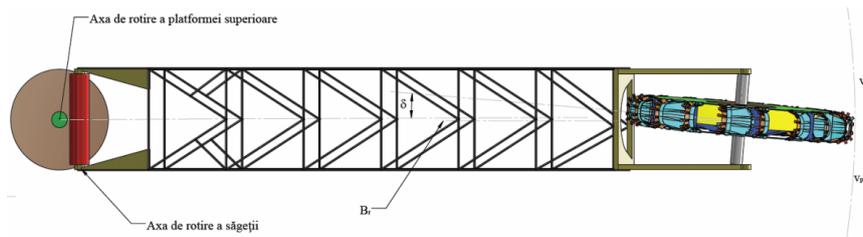

Fig.2 The geometric characteristics of the arm - rotor system, view from above

Figure 3 illustrates the case of the excavation of four slices, numbered 1, 2, 3 and 4. For each of these slices, the pivoting radius is modified. For this reason, it is necessary to correlate the pivoting speed with the position of the rotor.

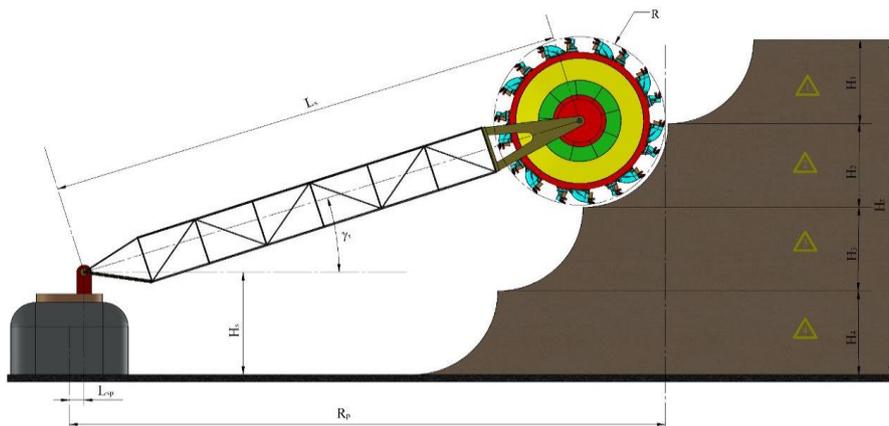

Fig.3 Excavation of slices

3. Calculus of the force and energetic characteristics

During the excavation process, the energy consumption at the level of the bucket wheel has two major components:

- the energy necessary for cutting the material to be excavated;
- the energy necessary for lifting the loose material resulted from cutting with the help of the buckets.

Between the two of the components presented above, the energy necessary for cutting the material is predominant, representing 60 ... 90% of the energy necessary for operating the bucket wheel.

Determining the energy and power necessary for operating the bucket wheel under certain functioning circumstances is essential for:

- the selection of excavators from an existent lot;
- the design of new excavators;
- the design of the new cutting – loading systems for the existent excavators.

The calculus of the power necessary for cutting with rotor excavators can aim at:

- determining the dependence of the power on the parameters of the operating regime for a given excavator;
- optimizing the energetic regime by accomplishing a cutting capacity at minimum energy consumption;
- determining the dependence of the power absorbed by the cutting – loading system on the cutting capacity, respectively the pivoting speed in the working front.

For the BWEs the force characteristics refer to:

- the forces which act on the bucket represented by:
 - the cutting force F_x which operates according to a direction tangent to the trajectory of the bucket;
 - the penetration force F_y which operates according to a normal direction to the trajectory of the bucket;
 - the lateral force F_z which operates according to a binormal direction to the trajectory of the bucket.
- the forces which act on the rotor are represented by:
 - the resultant cutting force F_{xR} ;
 - the resultant penetration force F_{yR} ;
 - the resultant lateral force F_{zR} .

The energetic characteristics refer to:

- the power necessary for excavation P_{ex} ;
- the power necessary for lifting the material P_r ;
- the power necessary to pivot the upper platform of the excavator, the boom and the rotor P_p .

The force and energy parameters depend on time and the characteristics of the dislocated chip. In practice, average values are employed so that we have:

According to the above information, the power necessary to drive the rotor will display the expression:

$$P = \frac{P_{ex} + P_r}{\eta_t} \quad (1)$$

where η_t represents the efficiency of the engine – bucket wheel transmission.

Thus, the following results:

$$P = \frac{1}{\Delta t \cdot \eta_t} Q_T \left[\frac{k_{uz} \cdot K_e}{k_a} + \frac{1}{\eta_r} \left(D - \frac{H}{2} - \frac{2}{3} h_c \right) \rho_a \cdot g \right] \quad (2)$$

where:

- Q_T - the theoretical excavation capacity (3280 m³/h);
- D - the cutting diameter of the rotor (11,5 m);
- H - the height of the bench (7,5 m);
- k_{uz} - the wear degree of the teeth (1,2);
- K_e - the specific cutting resistance (60 N/cm²);
- k_a - loosening coefficient (1,35);
- η_t - transmission efficiency (0,85);
- h_c - the active height of the bucket (0,84 m);
- ρ_a - loose rock density (1,3 – 2 t/m³).

After applying the relation (2), results a value of the operation power of the excavator rotor of 314 kW.

4. Proposing a method of determining the operation power of the rotor of a bwe through modelling and simulation

The method presented in the previous section, based on mathematical relations and approximations is susceptible of errors leading to results which are not in accordance with reality. The development of the methods of modelling and simulation accomplished with packages of specialized integrated programs recorded lately offers the possibility of a holistic approach of the mechanical systems of the type presented in this paper, in which, the mechanical phenomena are solved intrinsically, without resorting to simplifying hypotheses which can affect the accuracy of the results.

In order to avoid the problems described previously, we have created the model of an excavator rotor using the SOLIDWORKS package. The analysed rotor is equipped with 9 cutting – loading buckets and 9 cutting buckets. A screenshot of the created model and the points of application of the resultant forces which operate the bucket are presented in figure 4. We considered the resultant forces produced by the cutting strength of the rock (for the buckets which are in the cutting process at a certain moment), the forces resulted from the weight of the material in the buckets and the inertia forces which appear when the buckets are discarded (these are determined directly by the application we have used).

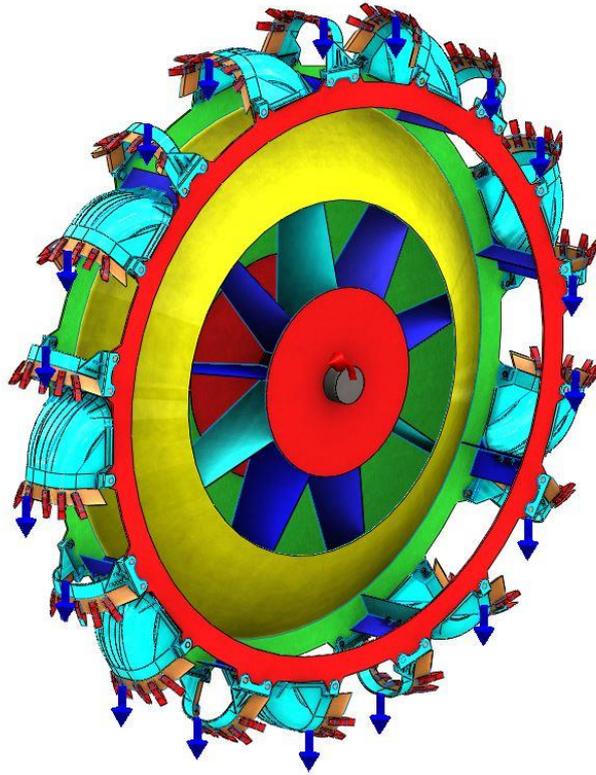

Fig.4 Screenshot of the bucket wheel

Figure 5 illustrates the diagram of time variation of the forces which drive the cutting – loading bucket.

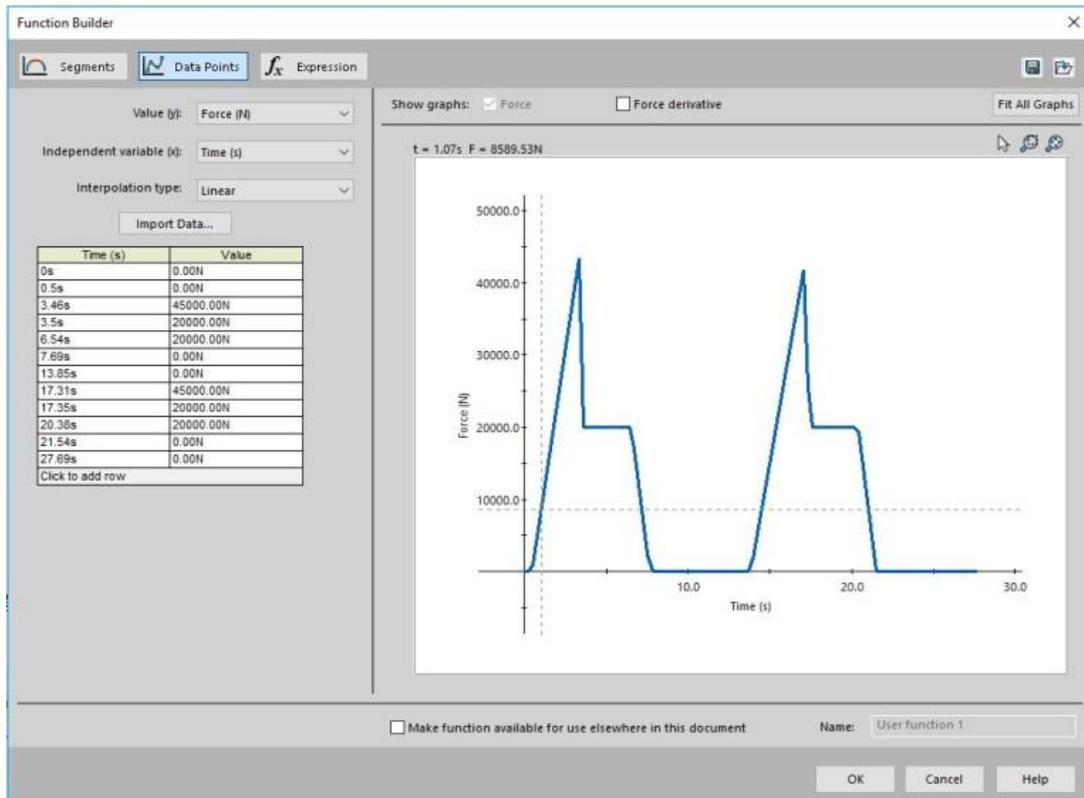

Fig.5 Diagram of time variation of the forces driving the cutting – loading bucket

Figure 6 presents the diagram of time variation of the forces which drive the cutting bucket. It can be noted that in the diagram in figure 6 the stages of lifting and discarding the bucket.

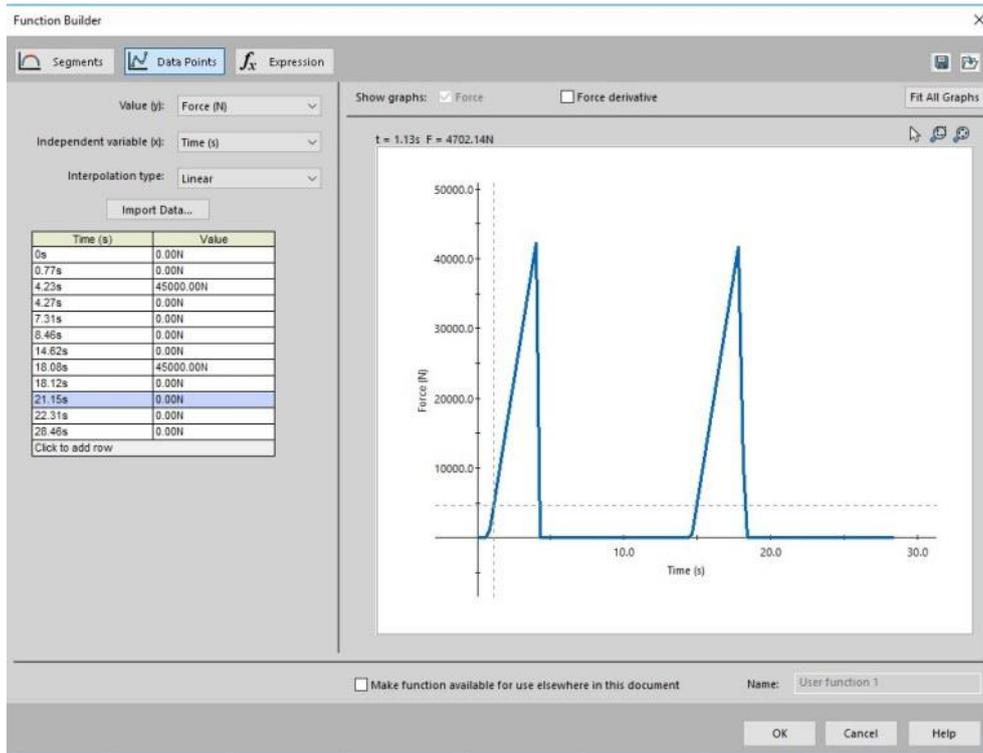

Fig.6 Diagram of time variation of the forces which drive a cutting bucket

The forces which drive the buckets are gapped with a short time interval of 1,54s, and the revolution of the rotor is 4,33 rot/min. Overlapping the forces which are gapped, we obtain for the duration of two complete rotations (27,69 s), the time variation of the operation power presented in figure 7.

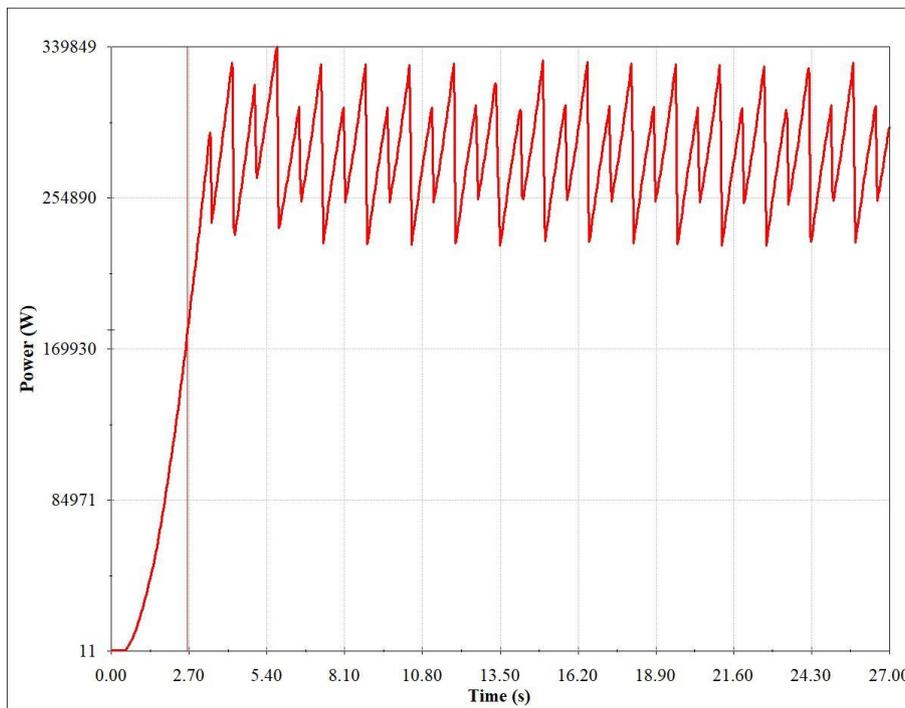

Fig.7 Time variation of the operating power

This figure shows that the power fluctuates between the limits of 240 kW and 340 kW, the average value being of 290 kW. The fact that this value is close to the value obtained through the classic calculus method presented in the previous section is not surprising, as we have considered the same characteristics of the tool and the excavated rock. Unlike the classic method, the presented method displays, besides the high accuracy, the advantage of illustrating the time variation of the power which can be useful in the dynamic analysis of the support structure of the excavator.

5. Conclusions

In this paper we propose a modality of determining the operation power of the rotor of an excavator through numerical methods.

The method is based on virtual models which allow the analysis of the functionality of the components of rotor excavators in order to improve the cutting – loading system, to reduce the specific energy consumption during cutting while maintaining the minimum installed power of operation of the rotor and to increase the excavation capacity.

We have presented a model of a rotor created with the SOLIDWORKS package with 9 cutting – loading buckets and 9 cutting buckets.

We have considered the resultant forces produced by the rock cutting strength (for the buckets which are in the cutting process at a certain moment), the forces determined by the weight of the material in the buckets and the inertia forces which occur when the buckets are discarded (these have been determined directly by the application employed).

The power calculated with the presented method fluctuates between the limits of 240 kW and 340 kW, the average value being of 290 kW, close to the value of 314 kW obtained with the classic method, the difference being reasonable as it refers to the same characteristics of the tool and the excavated rock.

Unlike the classic method, the presented method displays, besides the higher accuracy, the advantage of illustrating the time variation of the power which can be useful in the dynamic analysis of the support structure of the excavator.

As the presented method is based on numerical calculus methods, it displays a feature of generality, being applicable to any type of rotor excavator and rock characteristics.

Acknowledgements

This research was (partially) carried out in the framework of European Union Research Found for Coal and Steel research project RFCR-CT-2015-00003-BEWEXMIN “Bucket wheel excavators operating under difficult mining conditions including unmineable inclusions and geological structures with excessive mining resistance”.

Study on improvement of a manufacturing system using Lean Manufacturing

Ana Gavriluță*

Manufacturing and Industrial Management Department, University of Pitești, Târgul din Vale Street No. 1, Pitești Romania

Abstract

Lean Manufacturing is today one of the most successful business strategies used to improve the organization competitiveness. It is based on the philosophy, concepts and instruments of Toyota Production System. Starting from this aspect, the main goal of this paper is to analyze and improve a production system using Lean Manufacturing tool, Value Stream Mapping – VSM. To achieve this target were followed the activities: analysis of the initial production flow and mapping of it, using VSM; identifying the improvement solutions and applying them in the studied production system. After the implementation of the improvement solutions, it was obtained an optimization of the manufacturing planning process and a considerable reduction of WIP.

Keywords: Lean Manufacturing, VSM, WIP

1. Introduction

Lean manufacturing is an approach to organizational management, which aims to improve the quality of work by reducing lost. This approach is extended to all aspect of activities – from design and manufacturing to the commercialization of products. The core principles were developed by the Japanese companies at the end of the ‘80s beginning of ‘90s. The Lean approach is to reduce actions that don’t bring added value to the product, an all his making cycle.

Garner, 2007 states that lean manufacturing approaches are adopted in an automotive parts manufacturer in order to remain competitive in an increasingly global market. The focus of lean manufacturing approach is on reducing the non-value added (NVA) waste that pollutes the flow of the product as it is being transformed in the value chain.

The usage of Lean tools depends on the nature of industry, the plant size and the technological capabilities of the country. Womack tell us in 2005 that most of the industries tend to implement 5S and other visual management tools. US industries use six-sigma somewhat heavily than the other countries. United States of America (USA) and Canadian industries use Value Stream Mapping (VSM) more than the small scale Indian industries.

2. Value stream mapping – lean manufacturing tools

Lean philosophy is based on the representation of the enterprise on the stream of flow of value for the client. The totality of actions passed by a product, with added value and without any, creates a flow. According to Lean, the tendency is to increase the speed of the flow of value, ensuring a continuity and uniformity by eliminating the loss caused by the activities with no added value.

To organize the map of flow and to identify where this must be improved, are used lean manufacturing tools. The Value Stream Map – VSM is the main tool to represent a flow of value, this allowing the analysis of present situation and the identification of loss that leads to delays in product making. Concluding there are two types of maps: the present one and the future one. The first reflects the model of the process at the start of the analysis and leads to its diagnosis (detection of loss), the second is the projection of the future situation – an optimized state. The second VSM is the base of the design of the new process.

* Corresponding author. Tel.: +4-074-610-1580
E-mail address: ana.gavriluta@upit.ro.

The value stream map is a schematic description of process by which a product passes from the supplier to the final client. The VSM reflects all the steps by which the product evolves, from the generation of ideas to development, to production and ending with the delivery to the client, after market and recycling, re-usage of materials and treatment of waste.

Because of the need to show the activities involved in making of a product, these are represented as the following symbols, fig.1.

Symbols	Description	Symbols	Description	Symbols	Description
	Customer/ Supplier Start or end point for material flow		Kaizen Blitz Area for improvement		External Shipment Shipments to or from suppliers
	Process Machine, operation or department through which material flows		Supermarket Small inventory for immediate production		FIFO First in, First out lane
	Data Box		Buffer Safety Stock		In Box Information Queues
	Inventory		Pull Symbols Replenish stock in supermarket		Internal Movement
	Work Cell		Kanban Card Replenish stock in supermarket		People, phones, operators, etc.
	Push Arrow		Load Leveling		
	NVA Delay		Go and See When there is a problem, go and see what's wrong.		Scheduling

Fig. 1. VSM symbol

An important factor to create a correct VSM, is to make a very close to reality description of the actual situation, what is really happening on the field in the analyzed process. For that, the first step in building a VSM consists in the identification of product or of the family of products that would be the focus of the map. The next step is to establish the targets for the improvement of the process of product making, with a detailed description. A simple description, lacking in details of the process will lead to a wrong result, to loss of time and other resources.

The targets can be in the domain of safety, quality, supply chain, productivity, transport, flexibility, handling, ergonomics, cost, stock etc. To analyze this process, is recommended to establish a minimum of 1-2 objectives that allow the focus of team resources and a clear definition of priorities for the implementation of tasks. For this KPIs, will be defined the current situation and the targeted values.

After establishing the objectives, can be represented the flow of value starting from the client to the suppliers. The flow of materials is the most important part of logistic. It can be it, which can drive the improvement in the logistic processes and mainly in the improvement of the three main objectives of logistic: increase in quality level, reduction of the delay to make the products and reduction of costs.

In the literature, it is recommended to not split each analyzed product in its components, because this is mostly specific to other techniques of process mapping, as flow charting, that is a more correct tool for flow analysis with a more detailed level of representation. This flow map can have the following elements:

- The client at the end of process;
- The operations on a table format with details about: cycle time, change over time, number of people, uptime, available time, scrap rate, product diversities etc.;
- Stocks;
- Flow of materials;
- Assembly of components depending on the flow;
- The suppliers at the beginning of process.

After the flow of material is drawn, the next is represented on the map, the information flow. One of the details that differentiate a VSM from other lean charting instruments, is the inclusion of the flow of information. It contains details referring to: the way in which the clients order the product, frequency of orders, method and way of transfer of information back to the supplier, information referring to the method of panning and production programing etc.

The last step in making a VSM is to create the future flow of value in which are applied all the opportunities of improvement identified on the current state map (targeting a superior level of performance) and the development of the plan to transform the future map of value in a current state. In some cases, is better to develop an ideal map, which will highlight all the ways to improve by introducing all the possible action plan.

3. Description of the initial production system

In this paper is presented an example that intends to improve the performance of a manufacturing system. The system is split in two buildings. In the first section the products are machined and partially assembled. The sub-assembly is transferred to the second section, where are assembled on the final product. In the first building are two different production lines: the first is a manufacturing line and the second is an assembly of the sub-assembly. The storage area is in the first section. The link between the storage area and the manufacturing area is made through a tunnel. The supply of the line from section 1 is made with an electrical tractor. In fig.2 is represented the layout of this system with the areas of work and storage showed.

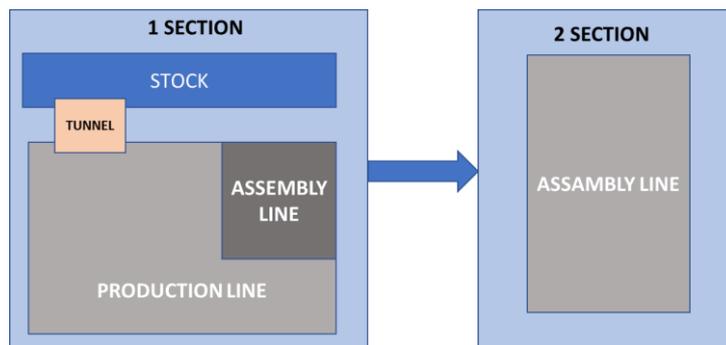

Fig. 2. Layout production system

The raw material is received by the logistic operator in the RM (raw material) truck station. From there the containers are moved with a forklift in the logistic warehouse, where are unloaded and stored on their designated place. In the storage area, the operator prepares the transport trolleys that will supply the workstations.

Now, the manufacturing line is supplied with components in the first operation, the launching point being in this workstation. The operator selects the manufacturing batch type and its quantity, loading the components on the entry of the line conveyer.

The transport between operations is done on a conveyer, using a transport adaptor (pallet) that allows the handing and positioning of these in the manufacturing centers, working in a closed loop. The assembly line is supplied in the first operation with machined components coming from the machining line. In the assembly line, the products are transported on similar adaptors (pallets). The last workstation of the assembly line is the unloading and production declaration. This is done with the help of an IT system, for each packaging the system printing labels that contain information as: reference, number of parts, weight of container etc. This label is attached to the container by the operator that works in this workstation.

The transport between the two lines is done manually. After the unloading of the parts from the manufacturing line and the production declaration, the transport trolleys are pushed manually by the operator to the assembly line, in a storage area for manufactured parts.

The operator that works in the first workstation of the assembly line takes the transport trolley and moves it at the entry of the assembly line. The surface designed for that is of 3.36 sq.m. The operator loads the assembly line manually, as seen in fig.3.

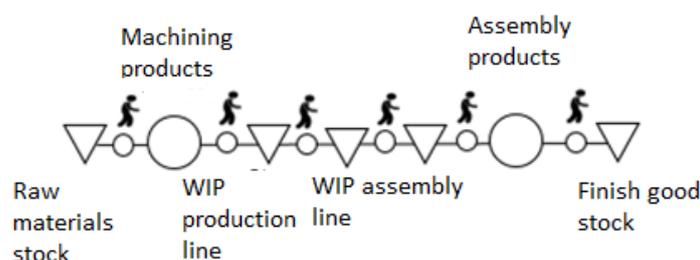

Fig. 3. Section 1

At the end of the assembly line, the operator places the sub-assemblies in the packaging. The operator pushes the full packaging in the storage area in the proximity of the assembly line end. From here, the packaging are taken by the logistic operator with the help of an electric tractor and are transported to the finished products warehouse. Here are around 3040 finished products that are stored on an area of 47.6 sq.m. From here the parts are transported to the second production section. The frequency of transport is of 2 hours.

To identify the areas with potential of improvement, the team made a VSM for the manufacturing system in its initial state, fig.4.

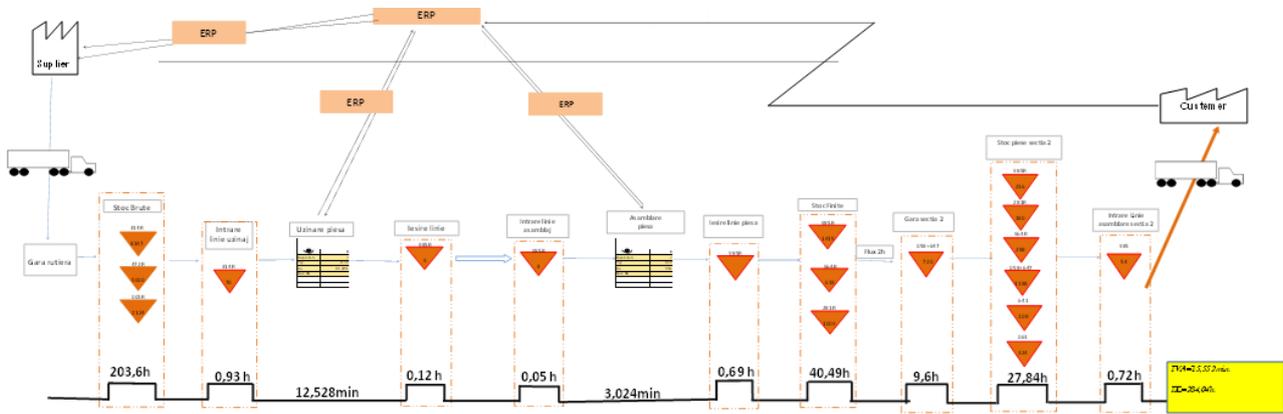

Fig. 4. VSM actual

After the analysis of the initial situation, the resulted KPIs chosen are represented in table 1.

Table 1. The initial results of the VSM analysis

KPI	Value
Number of handlings	18
Level of stock	21646 parts
Lead time	284,04 h
Storage area	278,6m ²
Process efficiency: (TVA/TE)	0,0009%

Considering that the stock represents a loss, it was proposed to increase the frequency of transport between the two sections, in order to create a synchronous flow between section 1 and section 2 where the main assembly line is situated. In the current situation, the supply flow between the sections, is done in batches, reason that asks for a series of changes, as the reduction of handlings and the increase of transport flow.

4. Amelioration of the production system

In order to make a direct flow of supply is needed that in the section 1, the manufacturing must be done synchronized with the assembly in section 2. In the initial situation, the operator does not have a fix number of packaging on the 2 hours flow, this differing depending on the request of the assembly line.

The reduction of stock level can be done by integrating an automated transport system between the manufacturing lines of section 1. For the automation of the transport between the manufacturing lines, are proposed two variants:

- Implementation of an AGV system;
- Implementation of conveyers system.

The first hypothesis includes the implementation of an AGV system including two conveyers and a robot, see fig.5. The use of AGV implies the design of a route for their circulation considering the crossing with other logistic flows and the space needed for maintenance access. The AGV is equipped with a support for transport pallets for the machined parts. The transfer of parts between the manufacturing line and the AGV is done by a robot at the end of line workstation and at the entry of the assembly line are two short conveyers that help the transfer between the AGV and the assembly line:

- A conveyor to unload the parts (pallets with parts);
- A conveyor to return the empty pallets.

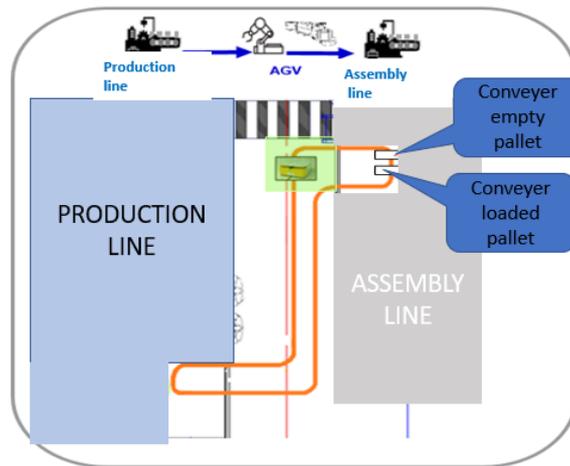

Fig. 5. Automation of transport using an AGV system

The second hypothesis: Implementation of a suspended conveyer with two elevators and a robot, fig.6. The loading of parts on the conveyer is done by a robot. At the operation of loading of the assembly line is designed an elevator system that takes the transfer pallet and transfers it to the upper conveyer system. The conveyer takes the pallet and transfers it to the assembly line. The upper conveyer has a return way for the transfer of empty pallets to the machining line where the robot makes the loading with the machined parts.

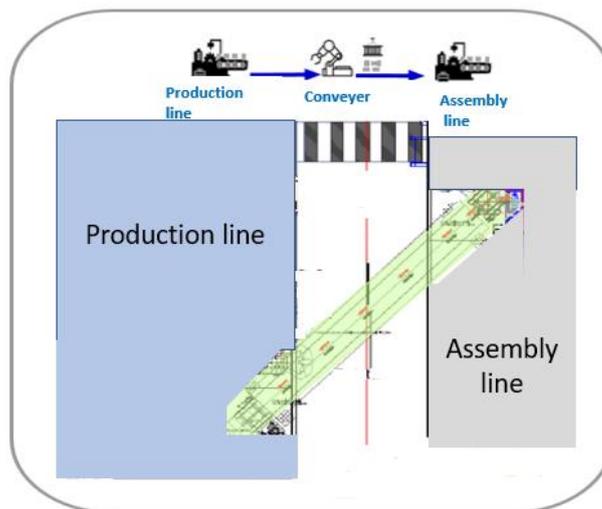

Fig. 6. Automation of transport using a conveyer system

Comparing the two hypothesis of improvement using the 4 KPI, are obtained the following values, show in table 2.

Table 2. Comparing between the transport systems hypothesis

KPI	Hypothesis 1	Hypothesis 2
Flexibility	+	-
Maintenance	+	-
Cost of implementation	55Keuro	300Keuro
Flow crossings	-	+

Using this KPI's it was chosen the improvement hypothesis 1, the automation of line supply with an AGV system. Also, the automation of transport allows to reduce the number of operators and the number of handlings of the overall industrial system.

5. Conclusions

Using the Lean Manufacturing tools, VSM, it was possible to identify the areas where manufacturing process can be improved aiming to synchronize the two manufacturing sections, leading to a reduction of stock level. The automation of supply process will be done by the implementation of an AGV system, considering that the implementation cost is lower and also the KPI's are better than the initial situation.

After the automation of the supply system, the following were reduced:

- The area of storage from section 1 and section 2, see fig.7;
- The level of stock from both sections, see fig.8;
- The number of handlings becomes 0, by eliminating the operators involved in the process.

Design of a learning platform for 5S method for using to improve a manufacturing system

Ana Gavriluță*

Manufacturing and Industrial Management Department, University of Pitești, Târgul din Vale Street No. 1, Pitești Romania

Abstract

For industry and science, the lean concept is a promising opportunity to realize a continuous quality while enhancing the effectiveness. Some industries, like the automobile industry, already reached a high lean status. The focus is on the methods of standardization and identification of problems, as 5S method. More the workplace is clean and organized, faster the problems are identified, because a clean working environment, is more predictive and a safer place. Starting from the principles of 5S method, the main objective of this paper is to develop a learning platform for this method, with the purpose to help increase the competences in Lean Manufacturing. The accuracy and usefulness of this platform is checked by using it in the improvement of a production system.

Keywords: 5S, factory learning, improvement, production

1. Introduction

Baena, 2017 tell us that the Learning Factory appear for the first time in an initiative of a group of universities from the United States in 1995 and since then was an official initiative for the education of engineers. Learning platforms constitute an indispensable tool for the deployment of online training courses. Not only do they provide significant benefits that have an impact on numerous areas of a company's presence, but they also showcase functional features which can take online training to the next level.

According to Veza, 2015, Lean Learning Factory appeared the first time in 2009 in the Faculty of Electric Engineering, Mechanical Engineering and Naval architecture, laboratory of industrial engineering of Split, Croatia. Its mission is to help bring the real-world into the classroom by giving practical experience for engineering students, to help transfer scientific research to industry through collaborative projects.

Lean Learning Factory was developed, firstly, to shorten the duration of implementation of this concept in an enterprise (usually the implementation of Lean Manufacturing concept in an enterprise is at least of 6 months). The second scope of this learning platform is to allow the teaching of Lean methods and tools, so the employees can apply them easily at their workplace.

Starting from this concept, in the laboratory of the University of Pitesti, it is developed a learning platform for the Lean Manufacturing concept. Part of this laboratory is the 5S platform that is developed and designed to ease the learning of this method.

2. 5S Methodology

5S Method was developed at the begging of the '80s by Hiroyuki Hirano in Japan and was first heard of as one of the techniques that enabled what was then termed "Just in Time Manufacturing".

An efficient and high quality work needs a clean environment, safety and rigor. The 5S principle, Seiri, Seiton, Seiso, Seiketsu, Shitsuke, allows the creation of a functional working environment, with simple, precise and efficient rules. The 5S is the foundation on which is it build the progress of Lean Manufacturing means and methods, acting as a stirring point in the management of change. In the same time, the 5S can be considered as basic rules of order, discipline, the starting kit for an improvement project.

Starting from the statement “the loss is a potential gain”, any liberation of loss means a gain. Important to notice is that no real improvement of productivity and quality will persist in the presence of waste. Concluding, we can state that 5S represents a generic term, “a mnemonic mean to see principle of spirit”. The 5S represents the first 5 letters of Japanese origin. In table 1, are shown translations of these in French, literary and usual, English and Romanian.

Table 1. 5S structure

Japanese	French		English	Romanian
	literară	Usual		
Seiri	ranger	s'organiser	sorting out	a rândui
Seiton	ordre, arrangement	situer(les choses)	systematic, arrangement	ordine
Seiso	nettoyage	scintiller	spic and span	curat
Seiketsu	propre, net	standardiser	standardizing	standard
Shitsuke	education	suivi	self-discipline	urmărire

The first S – Sort focuses on eliminating unnecessary items in the workplace. Focuses on eliminating unnecessary items from the workplace. Categorize equipment, furniture, tool in your working place into the following 3 categories:

- Necessary
- Unnecessary
- May not necessary

This step will also help with the “just in case” attitude.

All the unnecessary objects will have a red label and these will be recycled or stored in a special area of the warehouse.

The second S – Set in order implies to arrange and reduce the useless search. The principle of this set of actions can be resumed as:

- To arrange the useful object in a functional manner
- To replace in the designated area the used tools
- To make accessories and supports, that allow a fast identification
- To define rules of arrangement

This last step means also to:

- Paint the surfaces so the dirt can be seen
- To visually mark the limits of work areas
- To highlight the tools positions on panoplies etc.

The third S - Scrub, Sweep, Straighten implies to clean, the workspace will be freed of all the dirt, dust, unwanted scrap, creating a healthy environment, safer for humans and machines. In this step are targeted mostly:

- Storage areas – warehouse, shelves, tools and equipment storage
- Equipment: machines, logistic equipment, elevators etc.
- Surroundings: corridors, windows, conference rooms, wardrobes, cabinets etc.

During the cleaning a series of observations must be made: broken parts, and measuring tools, loose nuts and bolts cracked housings, lubricant levels.

The forth S –Standardize - includes activities which establish a regular and continuous practice of maintaining tidiness, orderliness, and cleanliness. Make rules and procedures to promote a good work environment until the first three S become everybody second nature. Thus, the following kinds of: development of Standard Operational Procedures, display marking of safety signs, garbage segregation system following the infection prevention and control, waste management policy, color cording for linen system, zoning for storing/parking equipment.

The fifth S – Sustain – includes activities of revision of standards. It must be put in place a survey system, for the 5S, making sure that it will be continued. Periodically the limits of workstations and other specifications are revised in a process of continuum improvement, a Kaizen.

Shitsuke or the following, assumes also the involvement, meaning the auto evaluation, to promote a team spirit, to impose rules of behavior, to put in place a good communication, to valorize the obtained results etc. All must step is a big win. After a first successful implementation, it can be continued the process of sorting, amelioration of ranging (cleaning process) and other places not considered before.

3. Design the 5S platform

In order for the 5S method to be successful, the most important factor is the commitment, participation and involvement of everyone and strong visible support from top management. To ensure the success of implementation is needed that the all the employees of the enterprise know the 5S practices. Generally, 5S method can be performed with the help of specialists which obligated the employees to execute the improvements with 5S. The resistance to change of

Analysis of micro-profile machining of the non-planar surfaces of injection molds for polymeric composites

Daniel Șerban^{a,*}, Constantin Gheorghe Opran^a

^aUniversity POLITEHNICA of Bucharest, 313 Splaiul Independentei, 060042, Bucharest, Romania

Abstract

Plastics are one of the 21st Century materials with an innovative development to meet the society's targets: resource efficiency, zero-energy buildings, saving water, reducing the gas emissions, waste as a resource, recycling closing the loop of “Circular Economy”, to name only few. Injection molding of polymeric composites products is one of the most used processes with low cost, good accuracy and high productivity. Mold surfaces are influencing the product quality, the ejection, the flow, and the aesthetic of the part. In this paper we analyze the micro profiling of the non-planar surfaces of an injection mold for a scaled model of a 15th Century stone church from Hațeg County, Romania. We present a study of milling the micro-profiles (details of bricks and stone in the range of 100 to 500 μm) directly into the mold cavities and milling the electrodes followed by electrical discharge machining. For the milling process two strategies were compared: milling the 3-dimension model and milling/engraving the vector pattern projected on the non-planar surfaces. The experiments consisted in building an aluminum mold and evidenced a good replication by injection molding the model parts in a composite of recycled polystyrene matrix, results being compared with the flow simulation.

Keywords: Injection molding; micro-profile; polymeric composites;

1. Introduction

This paper presents two methods for micro-profiling the injection mold surfaces of a scaled model of 15th century stone church. Estimating details in 3 dimensions for architecture from imagery presented interest to researchers and were proposed methods and software for obtaining surfaces patterns. Modeling in 3 dimensions is not only a creative activity but also a cognitive one as digital models which allow simulation, visualization. Modeling in 3 dimensions helps the manufacture of complex polymer composites injection moulds and to analyze the flow simulation. Micro-profile finishing the surfaces requires a lot of labor for available technologies: chemical etching, laser ablation, milling or electrical discharge machining. With the goal to find low-cost solutions, in our study we compare a method of combining 2D vector extraction from image of a brick and to 3D pattern onto mold surface with machining by generating the tool path on the surface projected vectors.

2. Related works

There are studies regarding the reconstruction of historical buildings and suggested methods for 3D digital modeling (Spallone, 2007), parsing architecture within plan drawings (Willis, 2009), who suggests a methodology in 7 steps: digitize the manuscript, pre-process the image, estimate a skeleton shape, vectorize, estimate a shape, each pixel in the binary image is assigned a semantic label and construct the 3D model; estimating details of Gothic architecture from imagery versus other methods which integrate the 3D measurements with texture data (Willis, 2010), or five-axis tool path generation for 3D curves created by projection on B-spline surfaces (Can and Unuvar, 2010), 3D reconstruction models for 3D engraving from 2D images by hybrid reverse engineering consisting in transforming an image to gray-scale and reducing the noise followed by cloud points extraction techniques for interactive design of brickworks by integrating two computational platforms – based on image and on parametric modeling (Afsari et al, 2014).

3. Experiments

We chose as model a 15th Century stone church from Hațeg County, Romania. This paper analyses the micro machining path generation of the 3D surfaces of an aluminum EN 7075 injection mould for a church scaled model, details of bricks and stone. One method consists in extracting vectors from a picture and project the 2D sketch onto the 3D surface and second method consists in 3D modeling the solid and milling with a pocket strategy followed by a parallel finishing.

Table 1. List of operations and time consumed for completion the micro profiling of mould surfaces

Operation	Method A [Hours]	Method B [Hours]
	North Wall	South Wall
Design CAD (3D modeling) the walls	1	1
Modeling The Mould Cavities	1	1
Extract vectors from picture, 2D sketch	1/2	-
Modeling 3D detail of wall texture	-	2
Milling the cavities (no texture)	3	3
Modeling and milling the electrode for North Wall	2	-
Micro Milling the electrode	1	-
Electrical Discharge Machining	1/2	-
Micro Milling The South Wall Surface	-	1
Total [hours]	9	8

For vector extraction was used an image of the North Wall apse and a raster resolution of 96 DPI (dots per inch), on a Stentiford Algorithm (Kumar and Teja, 2014). The vector extraction was exported in dxf format (Drawing Interchange Format) and then imported as a 2D sketch into the CAD/CAM software as presented in Fig.1 (b). The sketch was used to micro profile the electrode for the North mould cavity as a projection on the 3D surface tool paths. Then we investigated the milling and electrical discharge technologies of micro profiling the 3D surfaces and the replication by injection molding of a polymeric composite made of a high impact polystyrene matrix with ceramic powder 5%.

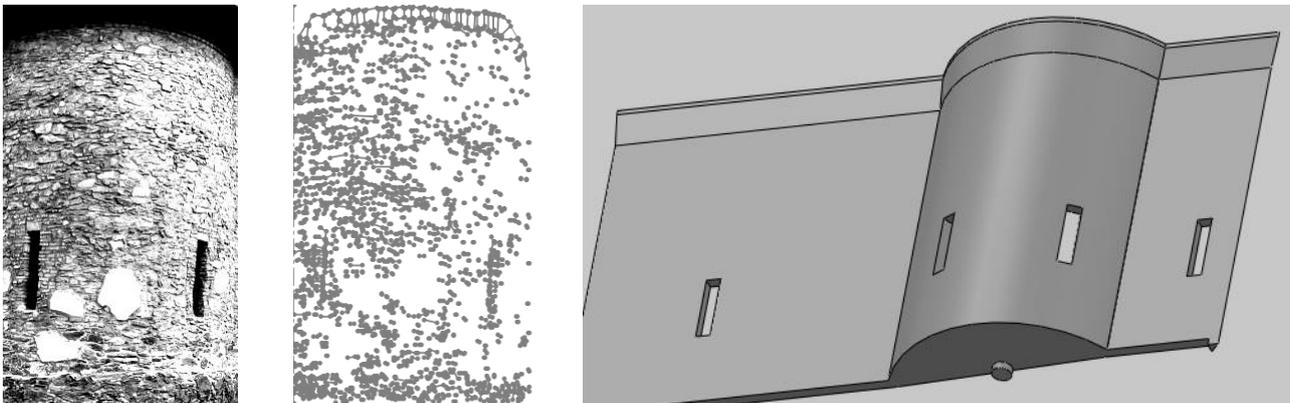

Fig. 1. (a) Church North Wall (Apse detail) ; (b) Vectors extraction; (c) 3D Model of Church replica 1:200 scale;

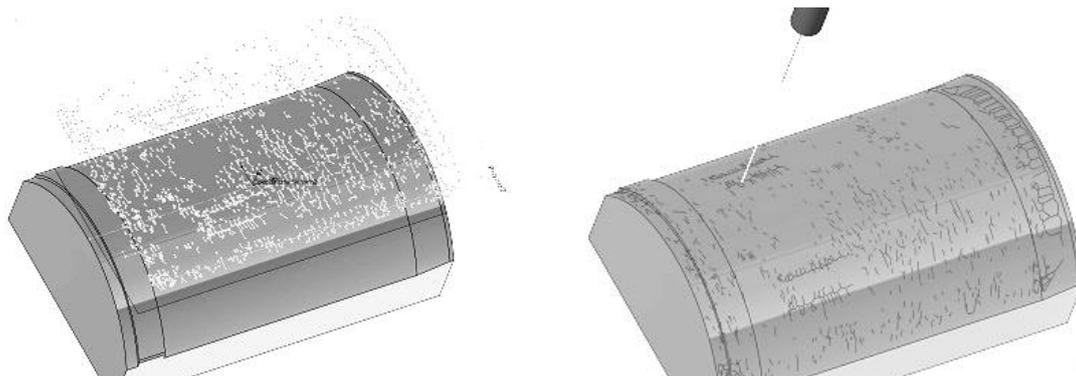

Fig. 2. (a) 2D sketch from picture extracted vectors ; (b) 3D Electrode with projected tool path on surface

Micro milling of the copper electrode and of the aluminum cavity was worked with a 0.1 mm pin point carbide tool on a milling machine with direct measurement system and a spindle of maximum 24.000 rpm. We used a projection a 2D sketch on a 3D surface strategy for micro profiling the electrode and a parallel technology for direct carving the South Wall apse cavity.

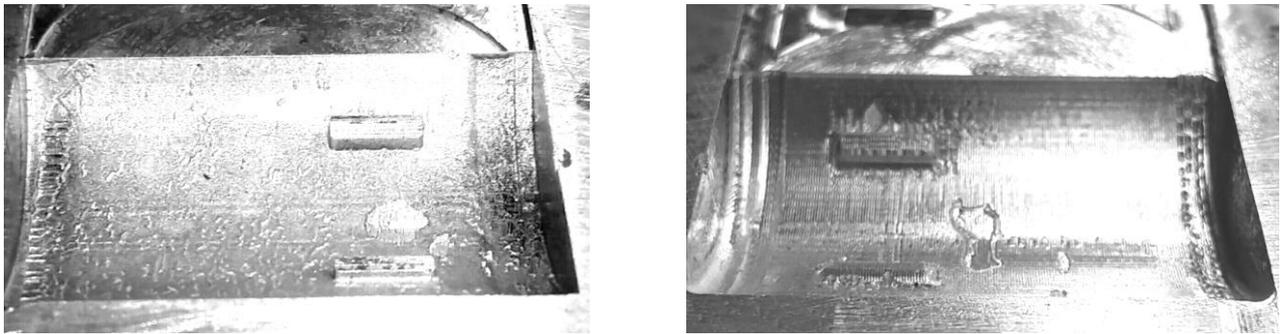

Fig. 3. (a) Electrical Discharge Machining North Wall Cavity; (b) Micro Profile Milling South Wall cavity;

Injection molding was performed on 1.000 KN clamping force machine with a 40 mm screw diameter. The pressure into the cavity was measured with a DME analog controller and a pressure sensor model 405C. For a good filling we adopted a strategy in two steps: finding out the injection pressure and the stroke to fill 95% the cavities and only second to pack to 100% the parts. On Table 2 we present a comparison between the flow simulation and measured ones of injection pressure and injection time.

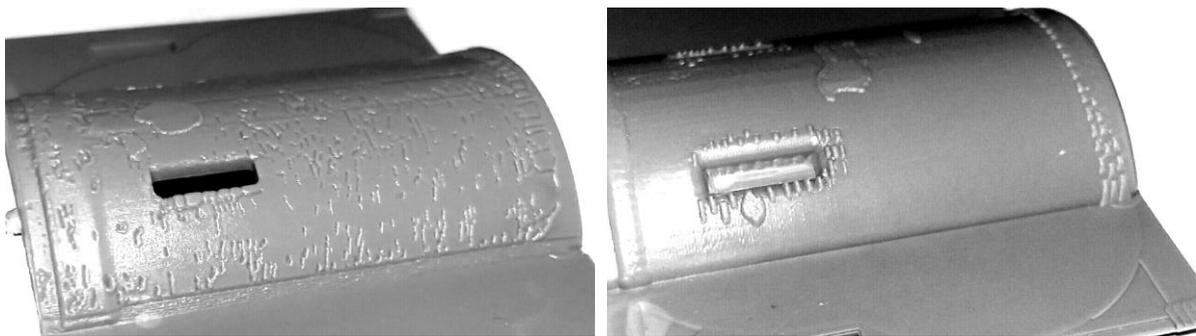

Fig. 4. (a) Detail of North Wall Apse Injection Moulding ; (b) Detail of South Wall Apse;

1. Table 2. Injection Moulding Parameters Comparison

Parameter	Measured Value	Flow Simulation Value
<i>Maximum Cavity Injection Pressure</i>	12.5 MPa	11.7 Mpa
<i>Filling Injection Time</i>	1.1 s	1.3 s

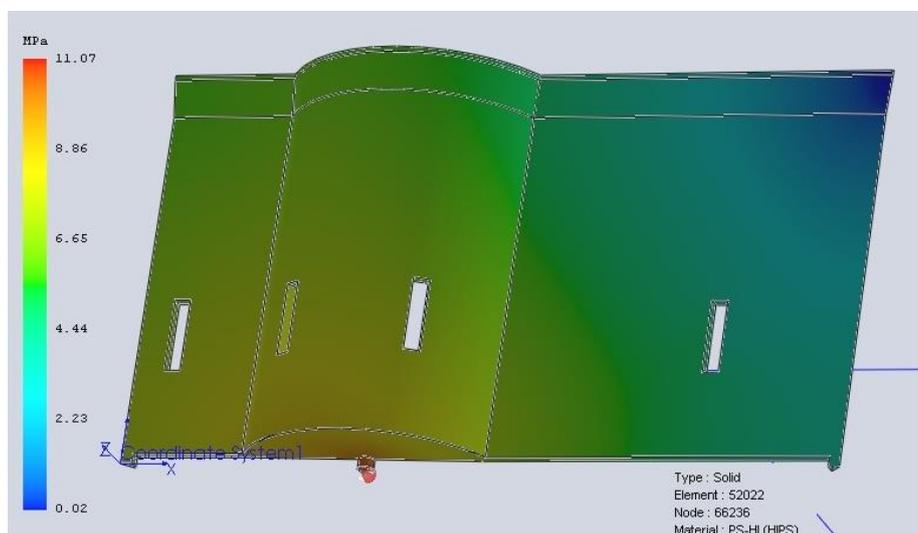

Fig. 4. Flow simulation of North Wall, Maximum Injection Pressure 11.07 MPa;

4. Conclusions

Vector extraction from image could offer the advantage of a reliable solution saving modeling time for replication of real models into products. It is a good method to obtain patterns for texturing, micro profiling injection moulds surfaces for polymeric composites. The experiments evidenced a good replication of the surface of the polymeric composite for both methods in machining the micro profiled cavities. 3D modeling helps designing complex assemblies, helps visualization and simulation.

Flow Analysis of the Pressure Distribution in the Experimental Chamber of the Differential Pumping

Pavla Hlavatá^a, Jiří Maxa^{a*}

^a Brno University of Technology, Technická 10, Brno 61600, Czech Republic

Abstract

The paper deals with the effect of the critical flow, which is reached during pumping of the differential pumping chamber of the Environmental Scanning Electron Microscope (ESEM). The study compares the state of the flow in the area of pumped chamber at pressure ratio on the apertures when the critical flow occurs and its advantages in design of the chambers versus the flow without the clogging the nozzle. The problem was solved using the finite volume method by the Ansys Fluent system.

Keywords: Differentially pumped chamber; ESEM; Ansys Fluent; The finite volume method; SolidWorks

1. Introduction

The article is based on a study of Dr. Danilatos, 2012, which deals with the pumping of the differentially pumped chamber in the environmental scanning electron microscope using the Monte Carlo statistic method. Based on these articles, a comparative study by Maxa, 2016 was produced, where comparable results were obtained by mechanism of continuum using the Ansys Fluent system which use the finite volume method, see Fig 1. and Maxa 2011 and 2012.

On this type of differentially pumped chamber, the analysis was made which monitor the impact of the shape of differentially pumped chamber on the flow path behind the aperture PLA 1 see Neděla 2010. This flow is interesting because of the critical flow created behind the aperture PLA 1, see Vyroubal 2013.

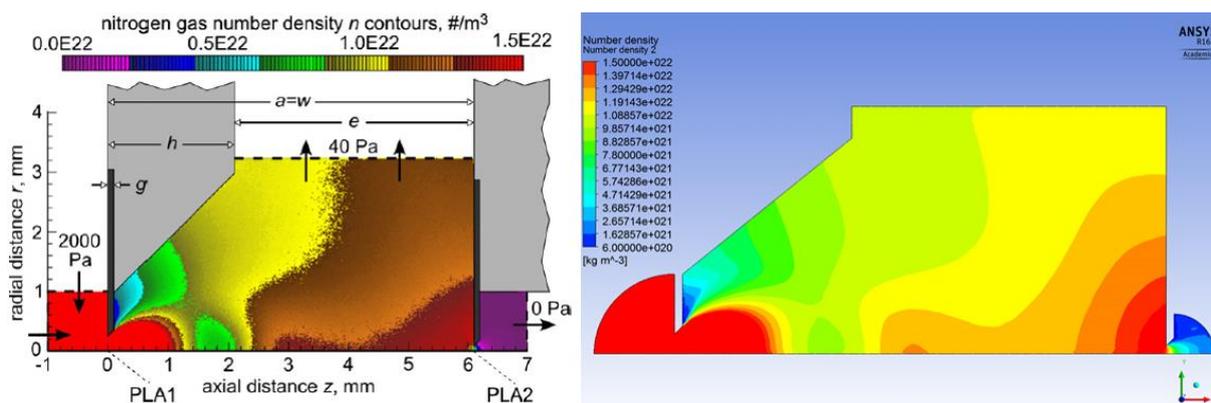

Fig. 1. Comparison of the analysis results obtained using Monte Carlo method and mechanism of continuum

On Institute of Scientific Instruments of Czech Academy of Sciences and Faculty of Electrical Engineering and Communication Technologies is preparing to base the theoretical studies with the experimental measurement of given physical conditions: supersonic flow in low pressures in the borderland of mechanism of continuum as a part of the Environmental scanning electron microscope parts development, see Neděla 2015, 2016, 2018.

* Corresponding author. Tel.: +420 54114 6129; fax: +420 54114 6147.
E-mail address: maxa@feec.vutbr.cz.

2. Experimental chamber

Prepared experimental chamber is constructed as a multicellular for the full scale of physical measurements. For example:

- Flow velocity above the aperture
- Pressure running in the flow axis above the aperture
- Pressure on the nozzle walls
- Pressure and temperature on chamber walls
- Optical method uses
- And etc.

The picture of the preparing experimental chamber is in the Fig.2

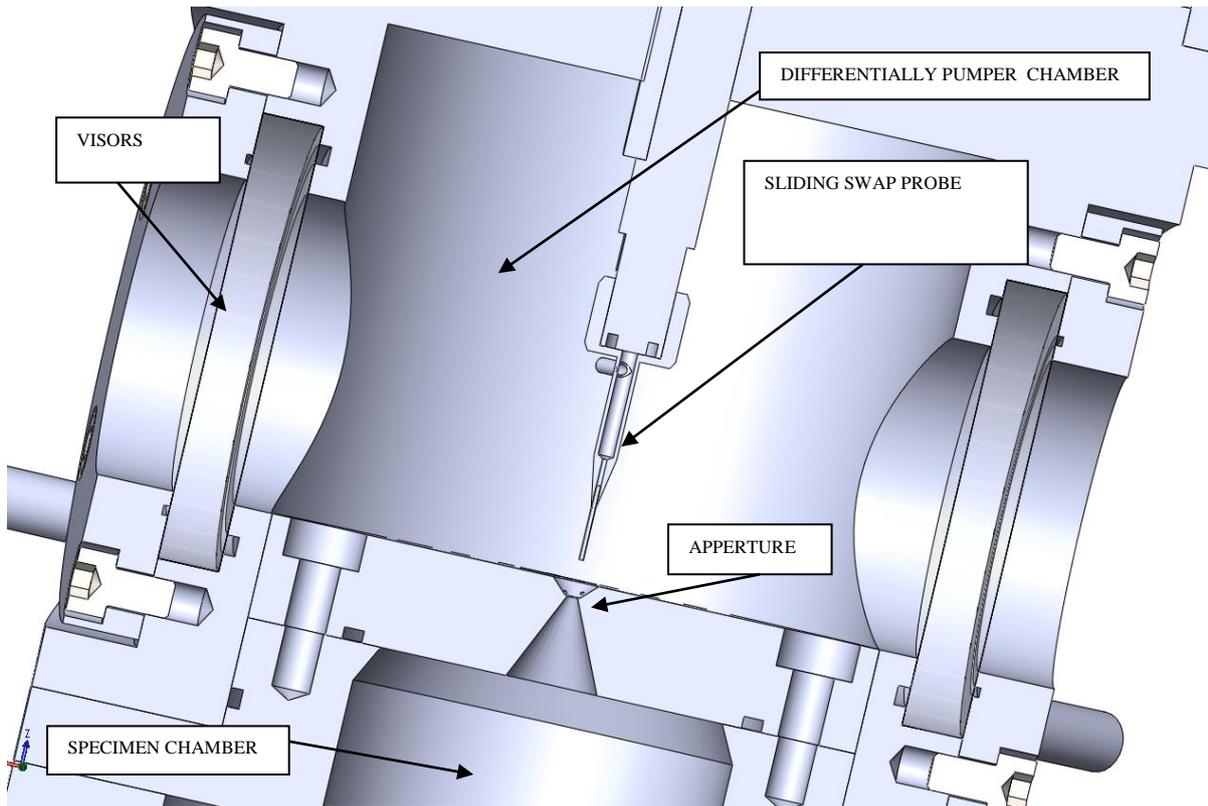

Fig. 2. Experimental chamber

Before the construction of given chamber took place many types of simulations to obtain presumed physics results, which will be compared with next experimental measurement. The construction of the chamber also came out from the series of mathematical- physics analysis.

In the Fig. 3 is pictured the 2D axisymmetric model of given chamber for the analysis in the Ansys Fluent system with the boundary conditions: in the specimen chamber is the area of 2000 Pa. The pressure is pumped through the aperture with the diameter of 0.5 mm to differentially pumped chamber and from here with appropriate feat to have 40 Pa in the differentially pumped chamber. It is about usual conditions in the environmental electron microscope.

Due to markedly different pressures in both sides of the aperture, the critical flow creates behind the aperture.

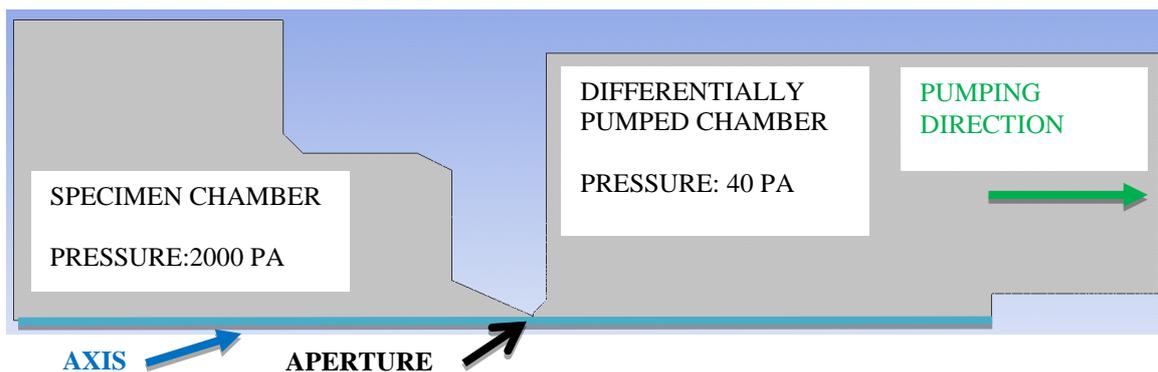

Fig. 3. Axisymmetric shape of the experimental chamber for simulations

3. Ansys Fluent system

To solve this problem, the Ansys Fluent was used, which uses the mechanism of continuum solving the equations by finite volume method. Due to the supersonic flow, the solver setting was chosen as Density based with the second order discretization. Density - Based solver solves the equations for momentum, continuity and energy at the same time, equations for other scalar quantities are solved separated after that. Also, in this case is the condition to determine number of iteration cycles to meet the convergence requirement. The Density – Based method solver offers two types of equation linearization method, explicit and implicit method [12]. In explicit method are the unknown values, in every cell, calculated using relationships which contain just existed values, known from the previous iteration. In this method can occur problems with numerical stability. In implicit method are the unknown values determined from existed and unknown values in near cells [12]. In our case, due to the difficulty of convergence, the implicit method was used.

4. Results

We evaluated the running of velocity, pressure and temperature in chosen lines see fig. 4 and also it was evaluated the total layout of given quantities in the chamber.

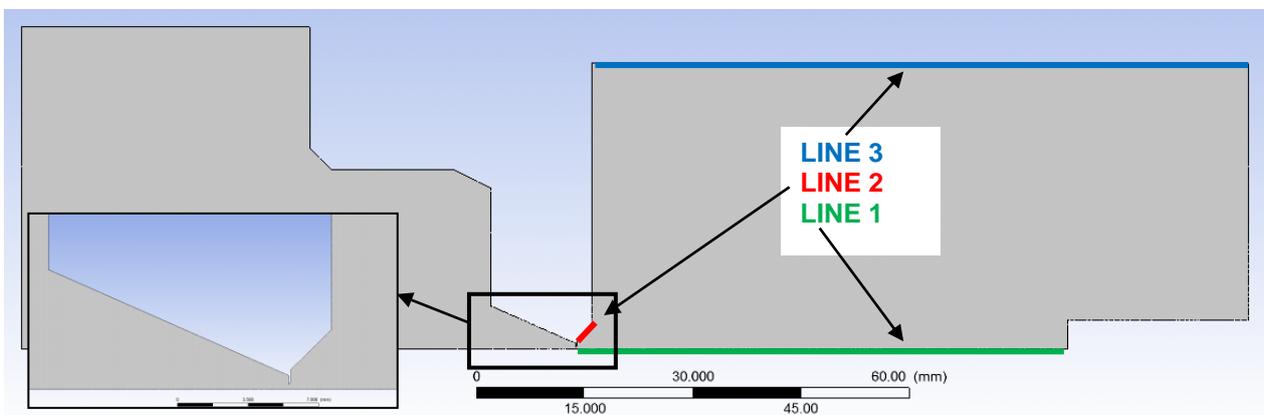

Fig. 4. Monitored paths

From the results comes out that above the aperture according to the pressure gradient occur the supersonic flow, when the velocity in the distance of 1.2 mm achieves almost values of 2 Mach. In this area the big pressure gradient occurs up to value of 16 Pa, see Fig.5 and 6. In the area, where the flow velocity drops below the velocity of 1 Mach, the pressure raises, and the shock wave is created, as is obvious in Fig 6 b.

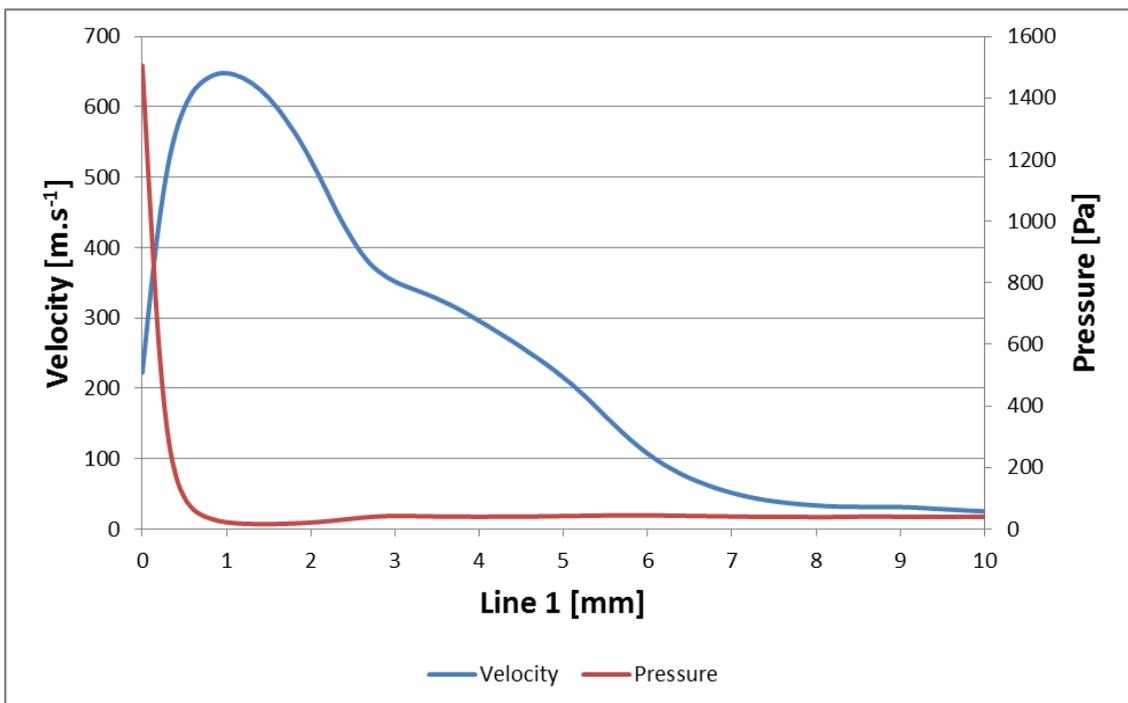

Fig. 5. Velocity and pressure running on line 1.

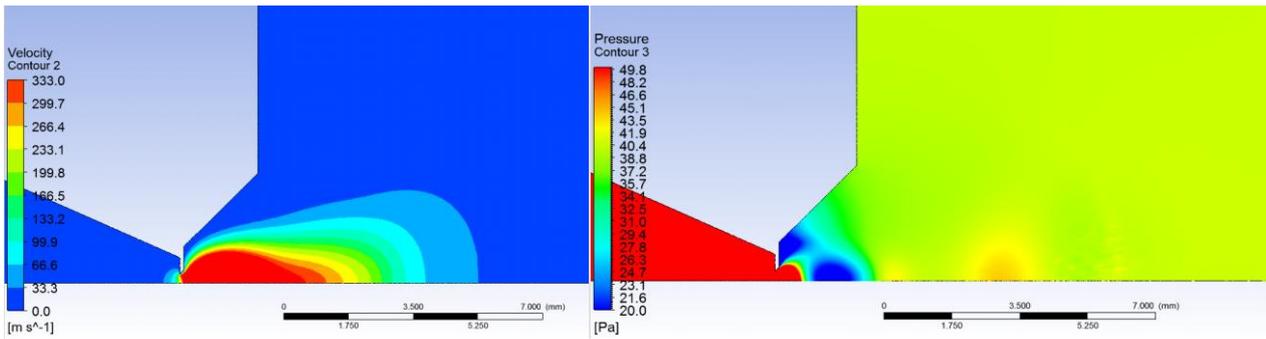

Fig. 6. (a) Velocity layout above the aperture – line 1; (b) Pressure layout above the aperture – line 1

In the Fig. 7 is pictured the temperature running with the dependence on the distance from the aperture on the line 1. The temperature behind the aperture drops up to value of $-183\text{ }^{\circ}\text{C}$. The reason of the quick temperature drop of the gas is supersonic flow state. After the minimum achievement because of the velocity drop below the value of 1 Mach, the temperature starts to rise and stabilize on the temperature of the differentially pumped chamber. The temperature will be scanned also from the walls of the differentially pumped chamber for the evaluation of the temperature layout in given chamber during its pumping- see line 3. The temperature running is evaluated in Fig. 8.

Another criterion will be pressure scanning using differentially pressure probes from the aperture walls – see line 2. Its running according to the mathematical – physics analysis is pictured in Fig. 9.

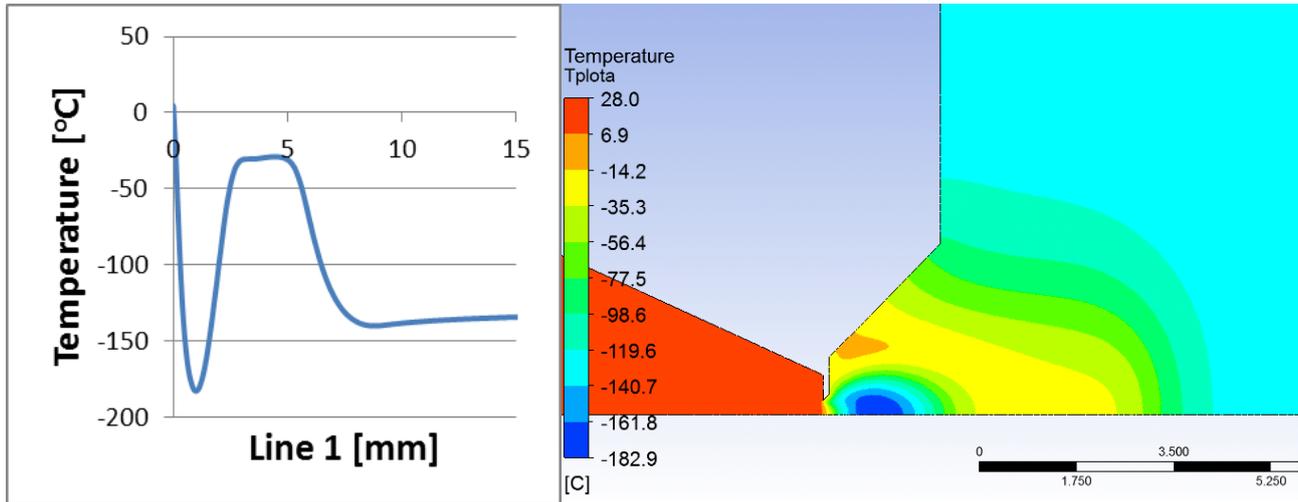

Fig. 7. Temperature layout above the aperture – line 1

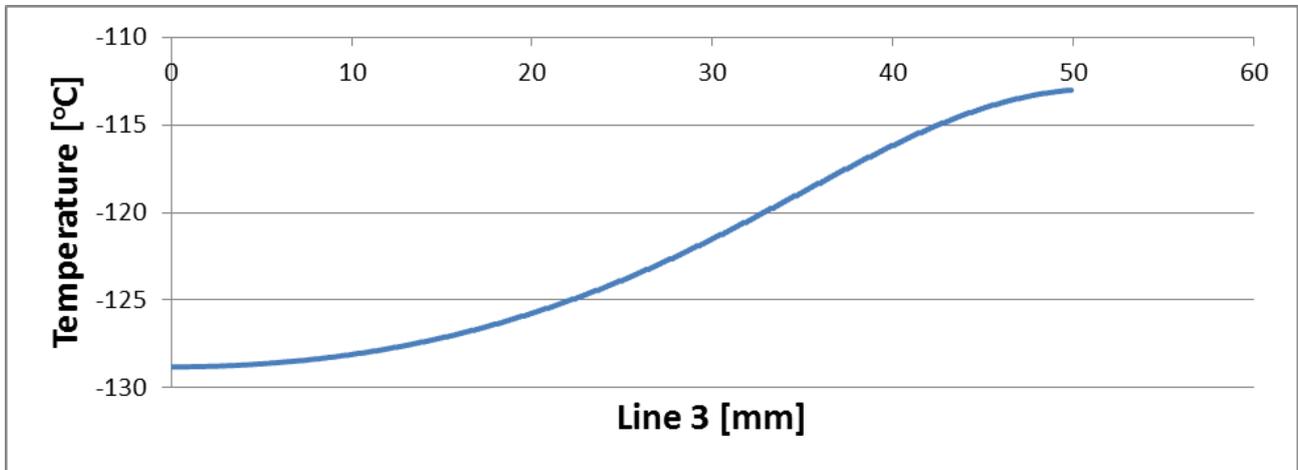

Fig. 8. Temperature layout on the chamber walls – line 3

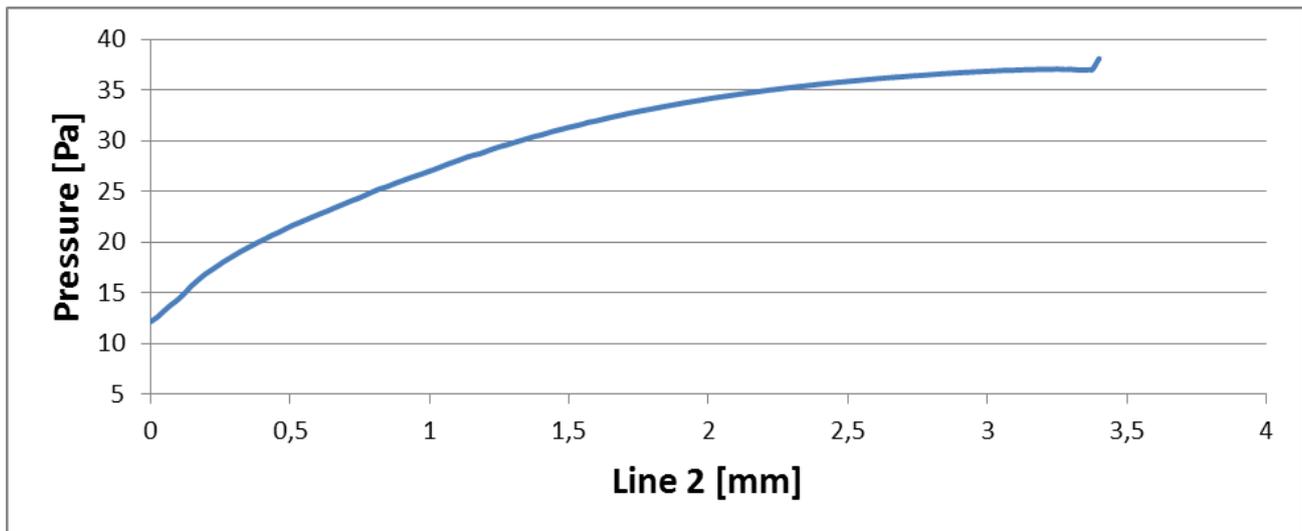

Fig. 9. Pressure layout on oblique aperture wall – line 2

5. Conclusion

It was made mathematical – physics analysis of the suggested experimental chamber. From the results comes out that for corresponding measurement is necessary to provide temperature probes able to capture the temperature up to – 183 °C, also the pressure probe used for capturing of the total and static pressure on the line 1 able to work in cryogen regime, where the very low temperatures are expected.

For pressure capturing from the conic aperture walls – see line 2 and Fig. 9 – is necessary for corresponding measurement to provide probes with the measurement error up to 1 Pa, because on this path will be expected, according to the analysis, the difference between the measured places approx. 5 Pa.

Frangible Coupling a Safety Element in Airports' Traffic

Iosif Dumitrescu ^a, Răzvan Bogdan Itu ^{a*}

^aUniversity of Petroșani, University Street, No 20, Petroșani 332006, Romania

Abstract

Any source of light from an airport area which is situated above the level of the runway must have a breaking section, which should give in the case of a collision with an airplane or any other vehicle. This breaking section is assured by a frangible coupling, which is an replacable part in the construction of the support. In this paper, we present the constructive solution of a frangible aluminium coupling, which must offer a breaking section at a height of maximum 38 milimetres above the level of the runway, for a height of the signal light of maximum 360 mm. The breaking section of the frangible coupling must resist at the air speeds behind a large plane, speeds that can go up to 480 km/h, and give in at a bending moment which is between 204 and 678 J. This frangible coupling was made by the firm ElectroMax Petroșani and was tested in the Strength of materials laboratory from the University of Petroșani.

Keywords: frangible support, signal light, panel, airport.

1. Introduction

Romanian civil aeronautical reglmentation RACR - AD – PETA ”The design and technical exploitation of airfields”, edition 2/2015 from 11.05.2015, chapter 5, defines signal lights as needing to be frangible. Those that are situated near a runway must be low enough to ensure the existence of the safety distance for the screw or for the propellers of the reaction engines. Sometimes anchors or chains are used, in order to avoid for the signal lights that are torn from their support to be carried away by the blow of the engines or by the wind.

The counselling material regarding the frangibility of signal lights is included in The Manual for the Designing of Airfields (ICAO Doc.9157), Part 6. The materials and configurations for the frangible structures must be appropriate for the desired use and must realize a structure as light as possible. The structures can be made of metallic or nonmetallic materials which are not affected by climatic conditions in the outdoors. The materials selected in order to fulfill the frangibility requirements must be strong, light and must have a reduced hardness module. Minimum weight is important, in order to ensure that the lowest quantity of energy is consumed in order to accelerate the signal lights' mass at the speed of the plane that hits it (The reference of the manual for designing the airfield ICAO, part 6, section 4.7.1.).

Nonmetallic materials can be especially conceived in order to offer excellent frangibility characteristics. However, their structural behavior can be difficult to analyze, because of the incertitude regarding their elasticity module or material isotropy. All the materials must be able to resist or be protected against climatic effects, including: temperature fluctuations, solar radiations, vibrations, bad weather (salt spray, wind, relative humidity) and corrosion (due to rain, snow, ice, sand, dirt or degradation materials) which are usually found in the air.

AC 150/5345 – 46 D regarding the plans of runway illumination offers guidance for light bodies situated along the runway. L-804 the elevated light bodies must have a frangibility point which is not larger than 1.5 inches (38 mm) above the runway.

For these devices, frangibility is attained by reducing the exterior diameter of the transversal section or by working on some holes or on other elements that reduce the effective resistance of the coupling at the height of 38 mm above the fixing foundation of the signal light (Fig. 1). Frangible coupling must work at temperatures of between -25° Celsius and +55° Celsius, at humidity between 0-100% and withstand wind speeds of up to 480 km/h. The coupling must break at a bending point situated between 204 and 678 J (Nm).

E-mail address: raz.van4u@yahoo.com

Fig. 1. Examples of frangible couplings

2. Establishing a constructive solution for the frangible signal light support

In figure 2, we show the general design of the signal light, which is made up of: 1 – signal light APP AL 008 02 WH; 2 – bracelet; 3 – M6x25 screw; 4 – aluminium tube $\Phi 40 \times 5$; 5 – frangible coupling G2^{1/2}; 6 – M6x16 screw; 7 – square base of 140x140.

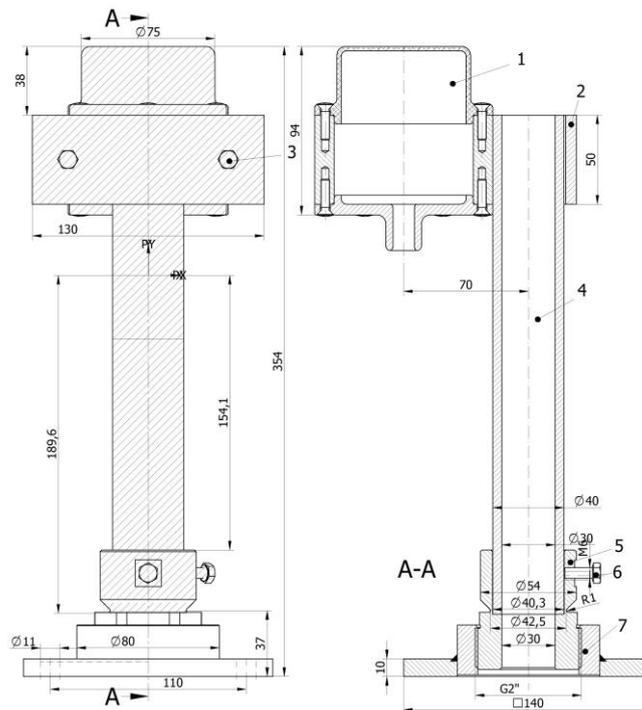

Fig. 2. The constructive solution for the support of the signal light APP AL 008 02 WH.

Based on these solutions, we drew a summary of calculus with the help of the software MathCAD, which allowed the checking of the bending of the tube in the area of its fixing in the coupling and of the breaking section of the frangible coupling for wind intensities situated between 240 and 480 km/h for an aluminium tube of $\Phi 35 \times 2$ mm and $\Phi 40 \times 5$ mm, which are shown in figure 3.a., curves 1 and 2. Also, we represented the bending tension in the tube of $\Phi 35 \times 2$ mm, for the minimum bending moment of 204 J, curve 3, and for the maximum value of 678 J, curve 6. The admissible tension for the tube made out of aluminium alloy EN WA 6082/ SR EN 755-2 was taken as equal to the flowing limit, which is of 250N/square mm, curve 5. We can observe that the bending tension of 432,8 N/mm², given by the maximum moment, curve 6, is much higher than the admissible tension, which imposes the choosing of the tube $\Phi 40 \times 5$ mm. Curve 5 represents the tension of maximum bending, of 153,05 N/square mm, from the tube $\Phi 40 \times 5$ mm, which is lower than the admissible tension.

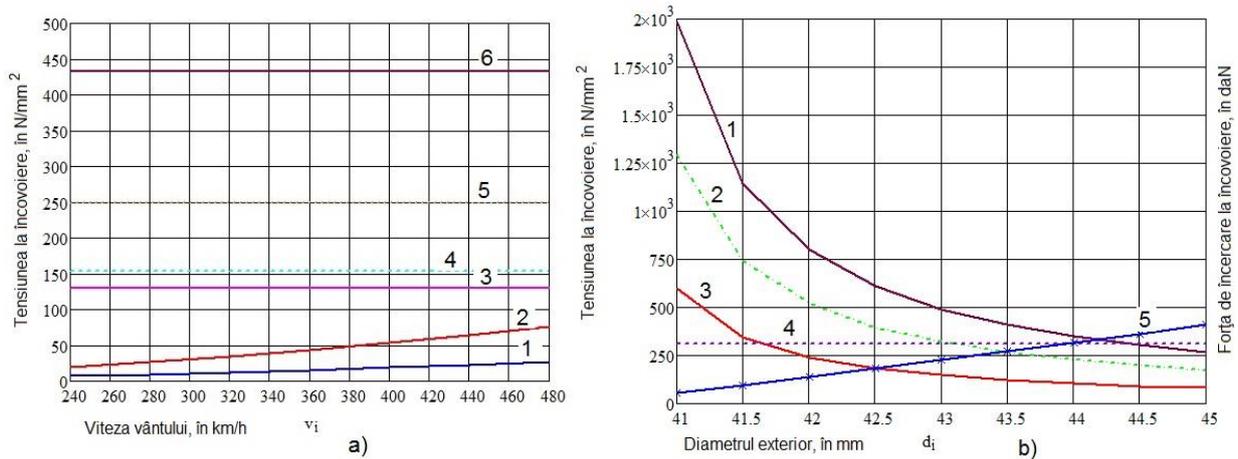

Fig. 3. The variation of the bending tension on the wind speed and exterior diameter of the frangible coupling

In figure 3.b we show the variation of bending tension in the coupling section, according to exterior diameter, curves 1,2 and 3 represent the variation of tension for the maximum, medium and minimum moments.

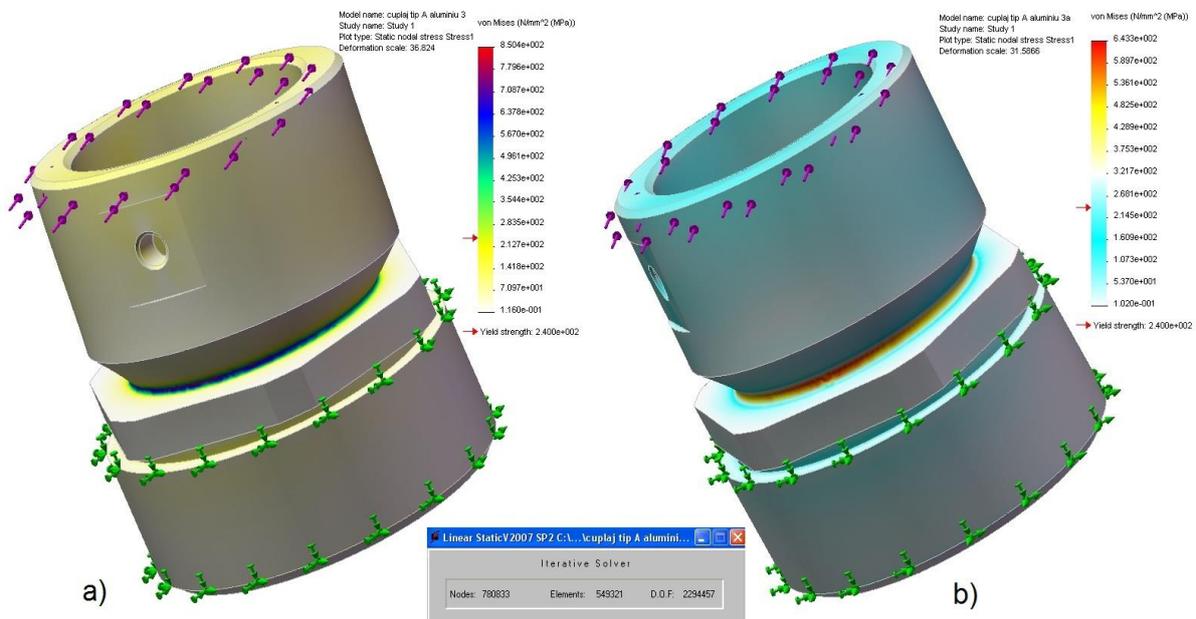

Fig. 4. The variation of the bending tension on the wind speed and the exterior diameter of the section of the frangible coupling

We can see that at a breaking resistance of 310 N/ square mm, the frangible coupling is made out of aluminium alloy EN WA 6082/SR EN 755-2, curve 4, intersects with the medium tension, curve 2, at an approximate diameter of 43 mm. Curve 5 represents the force of pressing for a force arm of 190 mm, which, for the 43 mm diameter, results in a breaking force of 240 daN.

A problem which was analyzed in the calculus program is the behavior of the critical section of the frangible coupling at the phenomenon of tiredness. For a number of 10⁶ cycles of pulsatory solicitation of the breaking section of the coupling, given by a wind speed of 240 km/h and a joining radius in the zone of the breaking of the coupling of 1 mm, we obtained a safety coefficient of 0.876, and for a radius of 0,5 mm, a safety coefficient of 0,561.

In order to show the influence of the joining radius from the zone of the breaking of the coupling, we undertook an analysis with a finite element of the frangible coupling at the static solicitation given by the maximum moment, in figure 4.a. for a radius of 0,5 mm and in the figure 4.b. for a radius of 1 mm. We can see that greater tensions have resulted than in the case of the classic formula, and the rapport between the two maximum tensions is 1.36 times smaller than the rapport between the coefficients of tiredness resistance of 1,56.

Next, the M10 screws were checked, group 6.8., for the fixing of the base of the signal light on the foundation, regarding the stretching solicitations, crushing of the fillet, and the result was the smallest coefficient of safety at crushing, of 2,2, for the case in which a single screw is at work. Also, the basis of the signal light's support was checked, which, for a sheet of 10 mm and a pap of 69 mm, did not verify at maximum solicitation, having a safety coefficient of 0,73, and the increaser of the pap's diameter at 79 mm was needed, and the coefficient grew at 1,33.

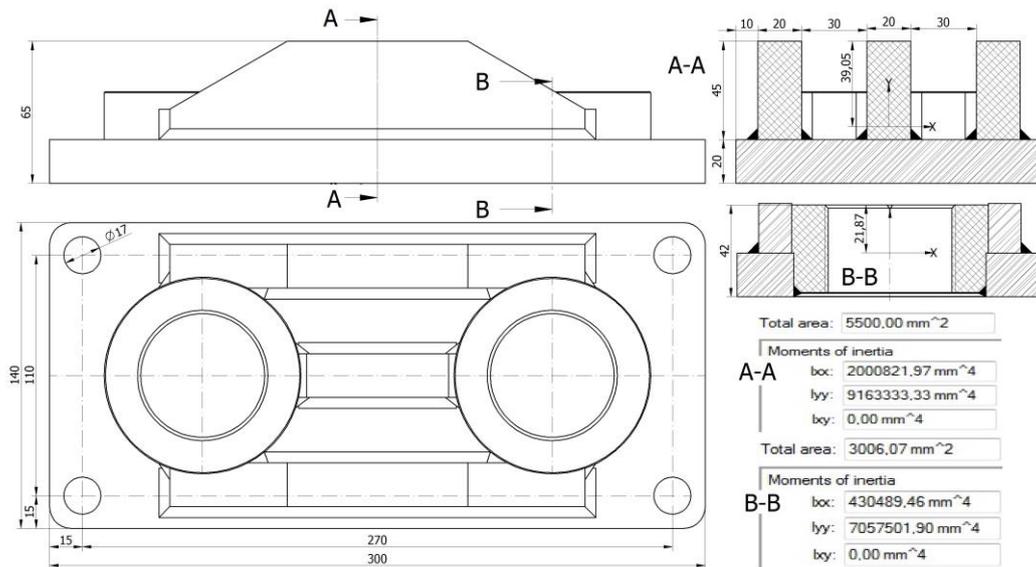

Fig. 7. The constructive form of the foot's basis and the geometrical characteristics of the two critical sections.

For the aluminium alloy EN WA 6082 in N/ square mm, SR EN 755-2, which has a minimum flowing limit of 260 N/square mm and the breaking resistance of 310 N/square mm, the resulting wind safety coefficients for the tube were pf 5,3 and for the moment of maximum breaking of 1,02. These safety coefficients were obtained by rapping to the flowing limit, which excludes the deformation of the tube.

For the zone of the breaking of the support through the frangible coupling, we have obtained wind safety coefficients of 15,8 and at the minimum breaking moment of 1,1 and at the maximum breaking moment of 1,9. These safety coefficients were obtained according to breaking resistance.

An important problem of the support foot of the light panel is the basis, which must resist to the very intense moment of breaking of the support of between 44 and 55 kJ, at half of the foot. In figure 7 we show the constructive solution of the foot's basis, with the geometrical characteristics of the critical sections, for which we obtained safety coefficients of over 1,8.

If the height of the light panel is lower than 1,2 m, we must only check at wind speed, which, through the constructive form of the panel, should not be higher than the bending moment of 240 Nm.

4. Conclusions

With the help of modern designing software, we were able to obtain a quality frangible coupling, which can be added to the portfolio of products of the firm ElectroMax Petroşani (fig. 8).

Fig. 8. Obtain a quality frangible coupling

Due to the construction of the signal light's support, we also modified its construction in comparison with figure 2, and we managed to power it with electrical energy through a cable inserted through the interior of the signal light' support.

In the case of light panels with a height lower than 1,2 m, we can use the support from the signal light, which satisfies the requirement that the device must resist at a bending moment of 204 Nm, but it should break before the bending moment reaches 678 Nm (see figure 1). In this case, we must check at wind speed, which, through the constructive form of the panel, should not be higher than 240 Nm, or, at the limit, the moment of the breaking of the frangible coupling.

For light panels higher than 1,2 m, we can use the constructive solution shown in this paper, with possibilities of improvement, constructively and technologically. Also, we can make a more detailed study of the variation of the distance between the two sustaining branches of the foot and of the support's foot basis.

The Influence of Humidity on Air Temperature in Underground Mines as a Factor of Air Quality Assessment

Racz Mihaela Dana^a, Petrilean Dan Codrut^{a*}

^a University of Petroșani, 20 University street, Petroșani, 332006, Romania

Abstract

Abstract. The relative temperature and humidity of air used in underground works represent its quality factors with predominant influences over the production process and the state of technical comfort. The quantity of condensate of the underground works which is obtained together with the cooling of moist air which goes through them creates major difficulties in the production process. The paper, thus, deals with the determination of the variation of temperature decrease on a meter of underground excavation depending on the inlet temperature and the quantity of condensate formed in underground works which exceed a depth of 200 m. it is useful to know the value for the decrease of the temperature for a meter of underground excavation while carrying out the works for opening a mine and for the preparation of wet galleries in order to dimension the drying installations and / or the pumps used to evacuate the condensate.

Keywords: moist air, temperature drop, humidity content, air quality.

1. Introduction

Due to a series of specific processes which occur on the wet land surfaces (rivers and seas waters, in certain industrial processes, etc.) the surrounding air contains a certain amount of water vapours. The existence of water vapour in the air makes it possible for the transformations of moist air to lead to the production of weather phenomena (rain, snow, glaze ice, white frost, fog, etc.). It is common knowledge that water vapours constitute the most important component of air. There is a constant process in nature of precipitations, water evaporation and transport with the help of the wind. In normal weather conditions the air is able to absorb to saturation either a small or a large quantity of water vapours. The percentage of vapours in air depends on the place and the season. Therefore, the air which enters the underground work is always moist.

The air humidity influences the heat exchange between the human body and the environment. Moreover, the humidity phase changes which occur inside the mine are accompanied by energy transfers which modify in one way or another the value of air temperature. Oniani and Lanchava, 1986 and Lanchava, 1982 have brought forward enlightening aspects concerning the influence the humidity of air has over the underground work, respectively the heat exchange and their weight.

In summer months the air temperature is higher than that on the walls therefore it cools down to the temperature of dew formation at the point when the process of excessive humidity condensation begins. As condensation occurs air heating, its temperature increases slightly and therefore the temperature drop underground in the vicinity of the ventilation shaft shall not be felt. The percentage of vapour content in the air increases in underground works and that is why the paper shall bring forward the cooling action they have on the air. Considering that the change in the humidity content as a function of ventilation way cannot be shown, the following hypotheses are still approved and brought forward by the speciality literature:

1. All the heat from the massif and other heat sources is used to change air temperature and humidity;
2. The relative humidity of the air passing through the mine changes linearly: while it enters the work, the value of the relative humidity of air is φ_1 , while in any point which is found at a distance l (m) from the entrance point it shall be:

* Corresponding author. Tel.: +4 0721373261
E-mail address: dcpetrilean@yahoo.com.

$$\varphi_2 = \varphi_1 + \frac{\varphi_2 - \varphi_1}{y_1} y = \varphi_1 + \xi y \quad (1)$$

where: φ_2 is the relative humidity when it exits the mine, in %;

y_1 – is the length of the underground work, in m;

ξ - the increase of relative humidity starting at 1 m from the ventilation way, in %/m.

The relative air humidity allows on its movement trajectory from the superior inlet ramp of the shaft to the longwall modify in the relative restricted limits (in average $\approx 10\%$) (Dosa, 2006).

The change of the underground air humidity is due to the evaporation of water from the open surfaces.

The Mollier diagram is quite useful for the determination of the characteristic parameters of moist air. As this diagram has been established for a 760 mmHg pressure it becomes redundant when it comes to study the changes of the air from underground works where barometric pressure varies with a significant value, rising with roughly 10 mmHg for every 100 m of depth. As the depth of the underground work considered for the study is not that high (approximately 100m) the Mollier diagram was used with oblique coordinates with a pressure of 760 mmHg, the error being therefore accepted.

Underground mines deal with the condensate issue which drips down on the walls of the underground work especially in summer months, the issue therefore substantially changing the comfort of the working conditions. There are, undoubtedly, other downsides which might appear make reference to the state of degradation of the walls of underground works, technical problems and respectively increased costs to remedy them. The usefulness of the study may be found in the documentation prepared for the opening and preparation works of moist galleries where the evaporation of water induces an important cooling of the walls, the dimensioning of the drying installations / the discharge pumps for the water resulted through condensation being of utmost importance.

2. Mathematical model

The upper layer of the water in open channels comes into direct contact with the air where a thin layer of air may be separated with the characteristic of having a temperature equal to the temperature of the surface of the water, while its relative humidity is $\varphi = 1$. Water evaporates if the molecular pressure of water vapours from the bordering layer exceeds the molecular pressure of water vapours from the air. The diffusion of water vapour from the bordering layer in the direction of a lower pressure is carried out through diffusion or due to convection phenomena. The faster the water vapours drip from the bordering layer the faster and more intense water vapours are formed in order to keep the bordering layer in a state of saturation.

This process enables a two type heat exchange between the water and the air it comes into contact: wither through convection or parallel to the change of weight, i.e. parallel o water evaporation or the condensation of water vapours in the air, when the air loses evaporation heat or receives the heat of the condensation of water vapours. The dimension of the heat exchange is so insignificant that it may be neglected (Lanchava, 1985).

In a horizontal gallery or in a gallery with a slight incline, the increase of the vapour content in the air is almost regular while the cooling of air per meter of gallery may be determined using the following elementary relation:

$$\frac{r}{c_p} \frac{dx}{dy}, \frac{K}{m} \quad (2)$$

where r is the latent evaporation heat and dx/dy is the balance of air humidity in relation to the length unit.

The change of the humidity content of the air in the mine occurs after the evaporation of the underground waters on one hand and through the influx of humidity in a gas state from the massif on the other hand (Cioca and Moraru, 2012).

Therefore, the balance of the humidity of air in the mine per meter may be expressed as follows:

$$\frac{dx}{dy} = \frac{W}{\dot{V} \cdot \rho} + \frac{S\sigma}{\dot{V} \cdot \rho} (x_s - x) \quad (3)$$

where: W is the humidity which exits the massif as gas through the walls of the mine work per length unit expressed in, kg/m s;

S – is the open water surface in the mine work for the entire length, in m^2/m ;

x_s – the humidity content in a saturation state kg/kg;

σ - the substance exchange coefficient in $kg/m^2 s$.

The saturated humidity content x in relation (3) may be determined using the following relation:

$$x_s = \frac{1}{\frac{\varphi}{x} + \frac{\varphi}{0,622} - 1,608}$$

which replaced in (1) results in:

$$\frac{dx}{dy} = \frac{W}{\dot{V} \cdot \rho} + \frac{S\sigma}{\dot{V} \cdot \rho} = \left(\frac{1}{\frac{\varphi}{x} + \frac{\varphi}{0,622} - 1,608} - x \right)$$

or

$$\frac{dx}{dy} = \frac{W}{\dot{V} \cdot \rho} + \frac{2\pi R_0 \sigma}{\dot{V} \cdot \rho} = \left(\frac{1}{\frac{\varphi}{x} + \frac{\varphi}{0,622} - 1,608} - x \right) \quad (4)$$

where R_0 represents the hydraulic radius of the mine work.

Starting from the definition of the degree of saturation:

$$\psi = \frac{x}{x_s} = \varphi \frac{B - p_s}{B - p_v} \cong \varphi \quad (5)$$

The following may be written $x = x_s \cdot \varphi$ as considering the conditions in the mine the relative humidity has increased values $0.8 \leq \varphi \leq 1$.

But, based on additional conditions, i.e. when the barometric pressure remains constant, (for horizontal or slightly inclined mine works) and the partial pressure of the water vapours during saturation is decreased compared to the barometric pressure, namely $p_s \ll B$, then $x_s = f(p_s)$ and therefore for a small range of temperatures the following relations may be used:

$$x_s = \bar{A} + \bar{B} t_a \quad (6)$$

$$x_s = 10^{-3} (m + n \cdot t_a + l t_a^2) \quad (7)$$

where: \bar{A} and \bar{B} respectively m , and l are coefficients the value of which depend on the temperature range chosen.

The m , n and l coefficients are determined using the equations:

$$4,419 = m + 2n + 2^2 l$$

$$9,450 = m + 13n + 13^2 l \quad (8)$$

$$20,34 = m + 25n + 25^2 l$$

where the values 4.419; 9.450; 20.34 – are the quantities of the water vapours expressed in grams within a kg of air with 100% relative humidity and the temperatures of 2, 13 and respectively 25⁰ C for a barometric pressure $B = 1$ bar.

It results therefore from equations (8) that $m = 4.013$; $n = 0.164$; $l = 0.01956$ for the temperature range 2-30⁰ C. The specific mass heat for a constant pressure is determined using the relation $c_p = (1-x)1.006 + 1.863x$.

Nevertheless, the barometric pressure given the conditions of the mine work increases in direct relation to the depth, therefore the quantity of water vapours in the air at a certain temperature in a mine shall be smaller than that corresponding to the same temperature at the surface. It is obvious that at greater mining depths ($H > 500$ m), when an exact determination is followed, the influence of the barometric pressure over the moisture content of the air is taken into consideration.

Taking into consideration relations (5), (7), (8) the before presented equation (3) becomes:

$$\frac{dx}{dy} = \frac{W}{\dot{V} \cdot \rho} + \frac{2\pi R_0 \sigma (1 - \varphi) 10^{-3}}{\dot{V} \cdot \rho} (4,013 + 0,164 t_a + 0,01956 t_a^2) \quad (9)$$

The final form of the equation being:

$$\frac{r}{c_p} \frac{dx}{dy} = \frac{rW}{\dot{m}c_p} + \frac{2\pi R_0 \sigma (1-\varphi) 10^{-3}}{\dot{m} \cdot c_p} (4,013 + 0,164 t_a + 0,01956 t_a^2) \quad (10)$$

In some vertical underground mines there are similar cases to those found in cooling towers where the contact between the ascending air and water is made in two ways:

- when water touches the air through dripping, i.e. when water droplets fall under their own weight in a natural ascending air flow or when it is sucked or discharged by a ventilator. Thus, for a certain flow of water, a contact between water and air is obtained which increases as the droplets become finer, therefore numerous;
- when water trickles along a vertical or an inclined surface through a membrane more or less thin and which may be carried out with or without water losses. Therefore, the resistance when air passes through is smaller than during air-water contact through dripping. The contact surface air-water may thus be determined easier than during the dripping contact.

The determination of the substance transfer coefficient σ is highly dependent on the precision of knowing the contact surface water-air and the characteristics of air for the anarchic variations of the weather conditions. Nevertheless, in isolation, there are mines where the affluence of humidity in a gaseous state from the massif is stopped by the support of the mine while the surface is being moistened through a membrane partially or fully, case where it may be approximated (Pasculescu et al., 2012). Therefore, the precise assessment of the influence of humidity on the temperature of air is carried out using relation (10) measuring the distance between two states, i.e. 1 and 2, and carrying out the balance of the humidity content between the considered states. In the saline the yearly temperature is constant, having a value of 16⁰C.

3. Results

The study has taken into account an underground gallery which has the hydraulic radius $R = 3\text{m}$, for which the parameters of moist air known in their initial inlet state and the final gallery state, i.e. the air density (1.2 kg/m^3); the specific mass heat for its constant pressure ($1012 \text{ J/(kg}\cdot\text{K)}$) and the latent water vaporising heat in J/K ($r = 2500 \text{ J/kg}$). Making use of relation (10) a numerical programme was developed for the determination of the variation of temperature drop per meter of underground gallery. Therefore, the coefficient for the exchange of substance was approximated $\sigma = 0.0142 \text{ kg/m}^2\cdot\text{s}$. The calculation was carried out for a 70 kg/s air mass flow and a 85% respectively 90% relative air humidity at the inlet, values which were determined through precise measurements. The obtained results as well as the temperature drop (dgr) are presented synthetically in tables 1 and 2.

Table 1. The temperature drop for a 70 kg/s air mass flow and 90% relative inlet humidity

6	20	90	$13.6 \cdot 10^{-3}$	16	$11.7 \cdot 10^{-3}$	$1.6 \cdot 10^{-3}$	0.112	$3.9622 \cdot 10^{-3}$
7	18	90	$12 \cdot 10^{-3}$	16	$11.7 \cdot 10^{-3}$	$3 \cdot 10^{-4}$	0.021	$7.5073 \cdot 10^{-4}$

Table 2. Temperature drop for a 70 kg/s air mass flow and a 85% relative inlet humidity

Inlet Temp. (°C)	Relative inlet humidity φ(%)	Humidity content at the inlet (kg _{water} /kg _{dry air})	Saline Temp. (°C)	Humidity content inside the saline (kg _{water} /kg _{dry air})	x ₁ -x ₂ (kg _{water} /kg _{dry air})	W _{water} (kg _{water} /s)	Temperature drop per meter (dgr/m)
1	30	23.4·10 ⁻³	16	11.7·10 ⁻³	0.0117	0.819	0.02892
2	28	21·10 ⁻³	16	11.7·10 ⁻³	9.3·10 ⁻³	0.651	0.023
3	26	18.6·10 ⁻³	16	11.7·10 ⁻³	6.9·10 ⁻³	0.483	0.0171
4	24	16.5·10 ⁻³	16	11.7·10 ⁻³	4.8·10 ⁻³	0.336	0.0119
5	22	14.5·10 ⁻³	16	11.7·10 ⁻³	2.8·10 ⁻³	0.196	6.9314·10 ⁻³
6	20	12.9·10 ⁻³	16	11.7·10 ⁻³	9·10 ⁻³	0.063	2.2378·10 ⁻³
7	18	11.9·10 ⁻³	16	11.7·10 ⁻³	2·10 ⁻⁴	0.014	5.0851·10 ⁻⁴

The dependencies of the temperature drop per meter of underground work were drawn in figure 1 considering the inlet temperature and the condensed water for a 90% and 85% relative humidity, knowing the values for the inlet moist air and the radius of the underground work, based on the values obtained in tables 1 and 2.

Analysing the data in figure 1 the following conclusion may be drawn: the temperature drop depending on the inlet temperature of air and the flow of water which is condensed bring forward a variation following an exponential curve presenting a slope as close to the vertical position as the relative humidity of air increases.

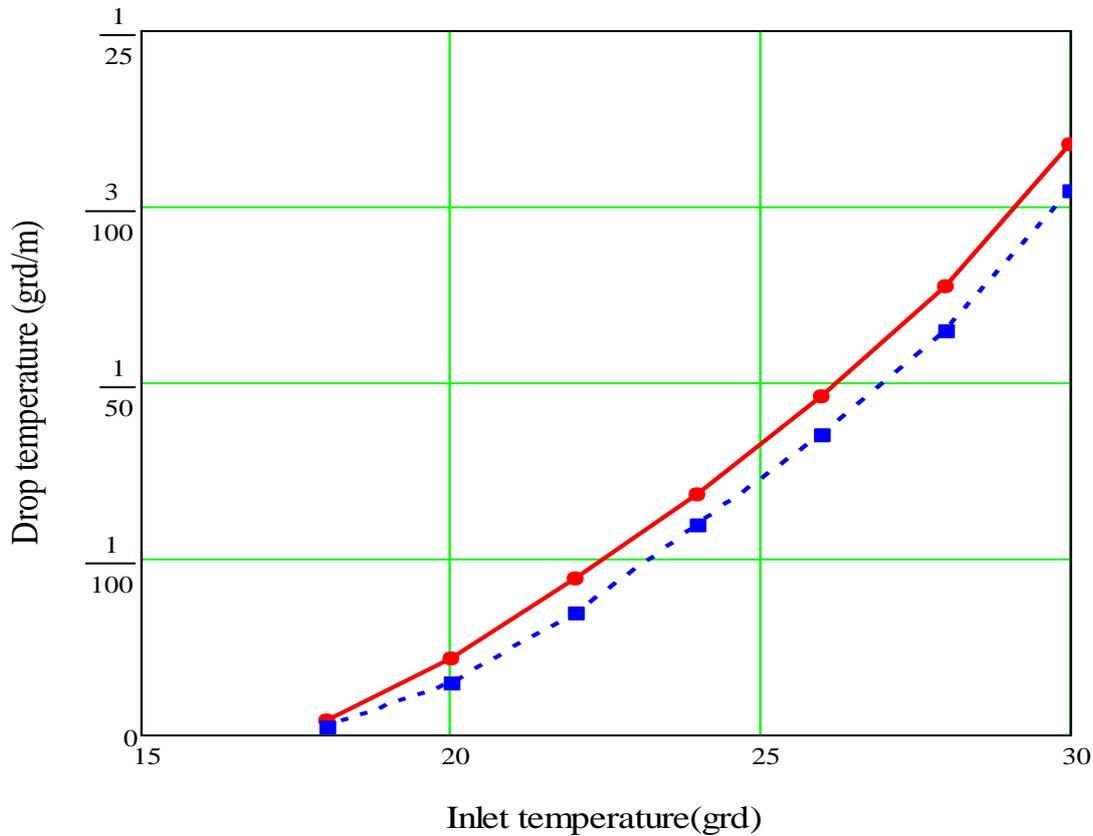

Fig. 1. The variation of temperature drop depending the inlet moist air and the condensed water flow for a 90% relative humidity (continuous line) respectively 85% (dotted line) and 70 kg/s moist air flow

4. Conclusions

Estimating the temperature drop per meter of underground work represents a very useful information when dealing with the technical documentation necessary for the works carried out to open the wet galleries in order to dimension the drying installations and / or the pumps used to remove the condensed water. Knowing the parameters of air at the gallery inlet (the temperature on the abscissa) and the mass flow of moist air on the vertical and intersecting the drawn curves the value of the temperature drop is obtained on the ordinate with a satisfying precision. (Figure 1).

The Assessment of Factors Which Influence the Energetic Efficiency of Helical Screw Compressors Found in Coal Mines

Adriana Zamora^{a*}, Sorina Stănilă,^a

^aUniversity of Petrosani, 20 University Street, 332006, Petroșani, Hunedoara County, Romania

Abstract

The use of pneumatic energy in industry and in the tertiary sector is quite frequent, the production and consumption of compressed air being carried out without any serious technical difficulties or hazards. The energetic balance of the European Union comprises the energetic consumption for the production of compressed air which is 80 ÷ 100 TWh, the pneumatic energy representing 10 ÷ 12 % of the industrial electricity consumption.

It must be therefore shown that there is a reduced energetic efficiency of pneumatic systems, the case studies highlighting the possibility to increase it as long as a series of technical solutions are implemented allowing thus energetic economies of 5 ÷ 50 %. Unfortunately, the actual community market conditions and the decision mechanisms do not allow the practical application of such an important energy saving potential.

The lifespan of compressors is relatively long, i.e. an average of 14 years for those with the power comprised between 10 and 90 kW and respectively 16 years for the compressors with the power comprised between 90 and 300 kW. The average yearly operation period of the compressors is 3500 hours/year.

The present paper highlights that the technical measures destined to increase the energetic efficiency are feasible and profitable, the first steps consisting in the implementation of a series of measures to organise and meter the consumption and to assess the cost of compressed air followed by the development of the consumption management structures and investments.

Keywords: compressed air; helical screw compressor; energetic balance.

Introduction

1. General considerations regarding the constructive characteristics of helical screw compressors

Helical screw compressors belong to the rotary screw compressors category. Eliminating the crank mechanism of the reciprocating compressor this type of machines brings forward a balanced operation having superior isothermal efficiencies and flow coefficients compared to other types of compressors. The category of helical screw compressors or expanders is well represented nowadays by a large variety of constructive and operational types leading therefore to an important increase in the number of units in the past years, representing approximately 80% of the number of sold screw compressors, 50% of them being found in operation. They operate with a wide range of liquids which may be gases, dry vapours or multiphase liquids, the change of the phases occurring inside the machine. The helical screw compressor may have a dry operation (without any oil injection), with oil injection or using other injected fluids during gas compression. In order to obtain the maximum value of the efficiency of this type of machine a special design and operation is imposed. It is therefore impossible to produce effective machineries by specifying a universal configuration of the rotor or by imposing a series of operational parameters even for a reduced class of machines.

The helical screw compressor is composed of two rotors, one being the male rotor and the other the female rotor. The rotors of the screw compressor contain a number of lobes each pair of lobes forming a helical thread. The number of lobes depends on the necessary sliding surface, being common knowledge that a lower number of lobes allow a larger sliding surface generating a pressure increase between the lobes.

The suction and discharge openings are placed in the frontal lids of the cylinder. The gas enters the helical threads which communicate in a certain succession with the suction opening. When the threads are disconnected from the

* Corresponding author: Adriana ZAMORA - Tel.: +40 724 361 686.
E-mail address: adrianazamora2001@yahoo.com

opening, gas is isolated in a chamber created by the helical threads of the rotors and the casing of the compressor. Then, within the threads of the driven rotor, the lobes of the driving rotor are inserted and thus the volume of the gas chamber decreases the gas being driven onto an axial direction and compressed in the same time until the helical threads are connected to the discharge opening found in the opposite lid of the cylinder. Rotors therefore, once they move the gas from the aspiration opening to the discharge one, they also carry out a compression of the gas depending on the variation of the volumes of the spaces inside the threads.

The suction, compression and discharge of the gas are carried out successively in each thread, formed by a pair of conjugated lobes. Therefore, the final pressure of the thread when this is connected to the discharge valve does not depend on the network counter pressure but on the geometry of the rotors and the position of the discharge opening. The helical screw compressor should be used when there is a constant pressure in the discharge pipe to the network.

3. Technical-managerial measures destined to increase the energetic efficiency of pneumatic generators used in coal mines:

- The recovery of heat exhausted while cooling down the compressed air, its thermal potential being used through an adequate recovery system in order to heat the locker room of the mine workers, to avoid the appearance of ice on the guiderail of the mining installation or to heat the water necessary for the restrooms;
- Actions to eliminate humidity from the discharged compressed air;
- Ensuring a consumption chronogram for the compressed air in order to flatten out the load curve;
- The introduction of electric control panels for the operation of compressors fitted with variable revolution motors (VSD);
- The introduction of a detailed monitoring of the consumption of compressed air.

3.1. Measures to be carried out with small investments

The reduction with 80 % of the heat losses at the compressor unit
INGERSOLL RAND type compressor

- The reduction of losses with the heat given off during compression with 11.8 kWh;
- The reduction of losses with the heat given off during discharge with 3.68 kWh;
- The reduction of losses with the heat given off during isobaric cooling with 26.76 kWh;
- The total value of the reduction of the losses shall amount to 42.25 kWh.

3.2. Measures to be carried out with large investments

INGERSOLL RAND type compressor

- Economising the energy supplied from the network $\Delta E = 43 \text{ kWh} = 154.8 \text{ MJ} = 3.7 \cdot 10^{-3} \text{ t.e.p.}$
- The value for the energetic economy $VE = (3.7 \cdot 10^{-3} \text{ t.e.p/h}) 625\text{€/tep} = 2.3 \text{ €/h}$
- The value for the investment $I = 283.46 \text{ kWh} \cdot 300 \text{ €/kWh} = 85,038 \text{ €}$
- The investment recovery period $IRP = I/VE = 85,038/2.3 = 36,973 \text{ Hours} = 1,540 \text{ Days} = 5.83 \text{ Years.}$

Conclusions

The use of pneumatic energy in industry and the tertiary sector is quite frequent, representing therefore 10% of the European industrial electricity consumption, the lifespan of compressors being relatively long, namely an average of 14 to 16 years of operation depending on their installed power.

The energetic efficiency of pneumatic systems is reduced, the studies carried out in this regard highlighting the possibilities to increase it considering the implementation of technical solutions which allow the realisation of energetic economies between 5 ÷ 50%.

Although the demand of compressed air at Lonea Coal Mine is ensured by modern efficient compressors manufactured by famous companies (i.e. ATLAS COPCO, INGERSOLL RAND), there are still countless possibilities to increase their energetic efficiency through:

- The recovery of heat given off through the cooling of compressed air;
- Actions to eliminate the humidity of discharged compressed air;
- Ensuring the creation of a compressed air consumption chronogram in order to flatten the load curve;
- The introduction of electronic control panels for the operation of compressors fitted with variable revolution motors (VSD);
- The introduction of a detailed monitoring of the consumption of compressed air;
- The parallel operation of low voltage transformers on a load curve based on minimum power losses depending on the variation of the load.

Although all the measures proposed for the improvement of energetic efficiency are feasible and cost effective, the companies are not interested in applying them due to a series of organisational deficiencies such as:

- The lack of metering devices for the consumption and respectively the cost of compressed air;
- The lack of information regarding possible economies;
- The complexity of the structures for the management of energy consumption.

Abstract

This paper presents the modeling and simulation of the sterile rocks excavation process using bucket rotor excavators. The modeling and simulation of the excavation process is carried out in Matlab-Simulink, based on an original mathematical model of the momentary capacity.

Keywords: bucket wheel excavator, induction motors; scalar control system.

1. Introduction

The excavation process of sterile rocks can be done in a cost-effective manner, both technically and energetically, only when the parameters characterizing this process, their interdependence, and the ways to improve the technical-economic indices that define the phenomenon of excavation are known.

Defining the excavation parameters, establishing them, as well as finding the relationships of interdependence, represents an important and not at all negligible problem if it is desired to know the excavation process in its depth.

Knowing these aspects does not solve the problem without performing a technological analysis of the excavation process. For this reason, this paper presents the analysis by modeling and simulation in the Matlab Simulink of the excavation process of the sterile rocks by means of bucket rotor excavators.

The analysis of the technological process of excavation is a research area dealt with over the past decade by several researchers including: Bosnjak (2006), Dandea (2013), Durst (1988), Haliti (2016), Jevtovic (2004), Ladanyi (2006), Nan (2007), Nan (2008), Pajer (1971), Petrovic (2006), Rasper (1975), Sharma (2009), Vetrov (1971).

The most important aspect of the current research, regarding the automatic driving of the bucket rotor excavators is the relatively constant maintenance with minimal variations of the material flow on the conveyor, within a swinging cycle of the excavator. Among the most recent research in this regard, we mention the following: Bosnjak (2015), Che (2014), Dandea (2013).

The main two advantages of constantly maintaining the flow of material on the conveyor belt are: reducing energy consumption and increasing the reliability of the components of the transport technology system. By constantly maintaining the flow of material on the conveyor belt, all machinery that is part of the transport technology flow can be chosen optimally so that they can be used intensively at nominal capacity.

In the simulation of the excavation process in this article, are surprised the dynamic effects introduced by the induction machines and the gearboxes acting on the port-cups wheel and the excavator's top platform. In the simulation of the port - cup wheel drive system, the gear shifter of this system is also considered.

Following the simulations are present and analyzed the variations in time of the flow coal load on the conveyor belt, variations in time of the pivoting speed and of the cutting speed over time for two distinct pivoting cycles. Simulations are customized for the EsRc 1400 rotor excavator. The results obtained from the research conducted in this article allow to highlight the possibilities of improving the cutting-loader system of the bucket rotor.

The momentary capacity of excavating of the bucket wheel excavators can be obtained with the following expression

$$Q_m(\theta) = \frac{n_c \cdot n_t}{60} \cdot \int_{\theta}^{\theta + \frac{2 \cdot \pi \cdot n_p}{n_c \cdot n_t}} A_j(\theta_m) \cdot [R_p - R + x_c^j(\theta_m)] d\theta_m \quad (1)$$

where:

- A_j is the surface of the cut in a cutting plane situated at an angle θ in relation to the main plane

$$A_j = h_j \cdot (H_1 - R) + \frac{\pi \cdot R^2}{2} - R^2 \cdot \text{asin} \left(\sqrt{1 - \frac{h_j^2}{4 \cdot R^2}} \right) + \frac{h_j}{2} \cdot R \cdot \sqrt{1 - \frac{h_j^2}{4 \cdot R^2}} \quad (2)$$

- x_c^j is the abscissa of the centroid chip in the main vertical plane

$$x_c^j = \frac{1}{A_j} \cdot \left[\frac{h_j \cdot (R - H_1) \cdot (h_j - M_a)}{2} + \frac{2 \cdot R^3}{3} - \frac{(2 \cdot R^2 + h_j^2) \cdot \sqrt{4 \cdot R^2 - h_j^2}}{6} + \frac{R^2 \cdot h_j \cdot \delta_j}{2} \right] \quad (3)$$

$$\delta_j = \text{asin} \left(\sqrt{1 - \frac{h_j^2}{4 \cdot R^2}} \right) + \text{asin} \left(\frac{H_1}{R} - 1 \right); M_a = \sqrt{2 \cdot H_1 \cdot R - H_1^2} \quad (4)$$

- h_j is the distance between M and N points

$$h_j = \left| R_p + h_0 \cdot \cos(\theta) - \sqrt{R_p^2 - h_0^2 \cdot \sin^2(\theta)} \right| \quad (5)$$

In the above relationships, or use the following notations: n_c is number of spoons, n_t is speed of the wheel with spoons, R_p represents the slewing radius, $|\cdot|$ is absolute value and n_p is slewing speed.

Under these conditions, it was kept in mind that the time of the cycle for discharging a spoon, ΔT is equal to the running time h_p of the distance between the moving adjacent spoons and pass through the main horizontal plane, the capacity of excavation for any moment in time is defined by the following:

$$Q_m(t) = \frac{n_c \cdot n_t}{60} \cdot \int_{\theta_1}^{\theta_2} A_j \left(\theta_m - \frac{\pi}{2} \right) \cdot \left[R_p - R + x_c^j \left(\theta_m - \frac{\pi}{2} \right) \right] d\theta_m \quad (6)$$

where:

$$\theta_1 = \frac{2 \cdot \pi \cdot n_p}{60} \cdot \text{floor} \left[\frac{t}{\Delta T} \right] + \theta_0 \cdot \frac{\pi}{180} \quad (7)$$

$$\theta_2 = \theta_1 + \frac{2 \cdot \pi \cdot n_p}{n_c \cdot n_t} \quad (8)$$

$$\Delta T = \frac{1}{z} = \frac{60}{n_c \cdot n_t} \quad (9)$$

In the expression (7), θ_0 represents the initial slewing angle and $\text{floor}[x]$ is the largest integer equal to or less than x .

If the final angle of slewing θ_f is known, the period for excavating a cutting on a certain slice can be calculated with the following expression:

$$t_f = \frac{10}{n_p \cdot n_c^2 \cdot n_t^2} \cdot \left[n_c \cdot n_t \cdot (\theta_f - \theta_0) - 360 \cdot n_p \right] \quad (10)$$

Additionally, using the Gaussian quadrature formula in 3 points, formula (6) becomes:

$$Q_m(t) = \frac{n_c \cdot n_t}{60} \cdot \frac{\theta_2 - \theta_1}{2} \cdot \sum_{i=0}^3 M_i \cdot f_1 \left(\frac{\theta_2 - \theta_1}{2} \cdot g_i + \frac{\theta_2 + \theta_1}{2} \right) \quad (11)$$

where:

$$f_1(x) = A_j \left(x - \frac{\pi}{2} \right) \cdot \left[R_p - R + x_c^j \left(x - \frac{\pi}{2} \right) \right] \quad (12)$$

$$M_1 = M_3 = \frac{5}{9}; M_2 = \frac{8}{9} \quad (13)$$

$$-g_1 = g_3 = \sqrt{\frac{3}{5}}; g_2 = 0 \quad (14)$$

From the expression (11) it is visible that when the speed of the bucket wheel with spoons (n_t) is kept at a constant value, then the momentary excavating capacity is directly proportional with the slewing speed (n_p).

In the simulation of the excavation process, we will consider that the flow of material loaded onto the conveyor belt from the rotor excavator component is given by the following relation:

$$Q(t) = Q_m(t) - Q_n(t) \quad (15)$$

where:

$$Q_n(t) = k_0 \cdot |\theta_1| \quad (16)$$

is the lost flow in the load process, which is directly proportional to the pivot angle θ_1 .

The factor k_0 from formula (16), is a random number from interval [0% ... 5%] · Q_m .

3. Simulation of the excavation process

The simulation of the excavation process is done in Matlab-Simulink and it is applied to excavator EsRc 1400.

The simulation program is based on a mathematical model as determined above.

In the simulation of the excavation process, the dynamic effects introduced by the induction machines that act both the port-cups wheel and the upper platform of the excavator are captured.

The bucket wheel is powered by an induction motor of 630 kW, and the upper platform of the excavator is powered by two 45 kW induction motors.

The induction motors used in the simulation are a squirrel - cage rotor.

The system which puts in motion the bucket wheel of the excavator consists of two sub-systems: the induction motor, the cone - cylinder four gear reducer and the two-speed gearbox.

The system putting in motion of the rotation mechanism of the upper platform consists of two induction motors and two cone-cylinder four gear reducers, identical, one for each motor.

The program for the simulation of the coal excavation process with the bucket wheel excavator is presented in Fig. 3.

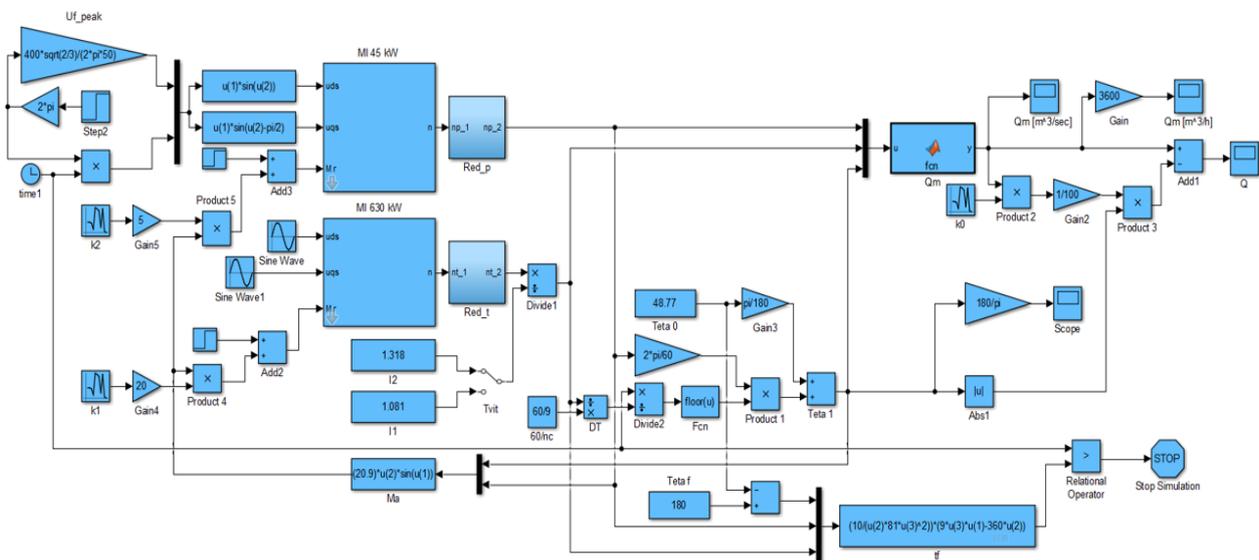

Fig. 3. The program for the simulation of excavation process

From Fig. 3, can be seen as within simulation the load torques are directly proportional to the excavation capacity.

To control the slewing speed, a scalar open-loop control system ($U/f=ct$), is used in the simulation, Stoicuta (2012), Stoicuta (2016). The simulation of the excavation process is done in the case of starting under load of the induction motors. The simulation is done using the Dormand – Prince (ode45) numerical method, imposing a relative and absolute error of $\varepsilon = 10^{-4}$. In the simulation of the scalar open-loop control system, the frequency of the supply voltages of the induction motor of 45 kW, is 25 Hz.

In the analysis of the excavation process by numerical simulation, it will be analyzed 2 pivoting cycles defined by the following initial conditions:

- case 1: $\Theta_0 = 53.09$ [degree] ; $\Theta_f = 180$ [degree] ;
- case 2: $\Theta_0 = 53.09$ [degree] ; $\Theta_f = 138.77$ [degree] ;

The results of the simulation, for cases 1 and 2, in the conditions in which the drive system of the port-cup wheel is operating in stage 1, are shown in the the following figures:

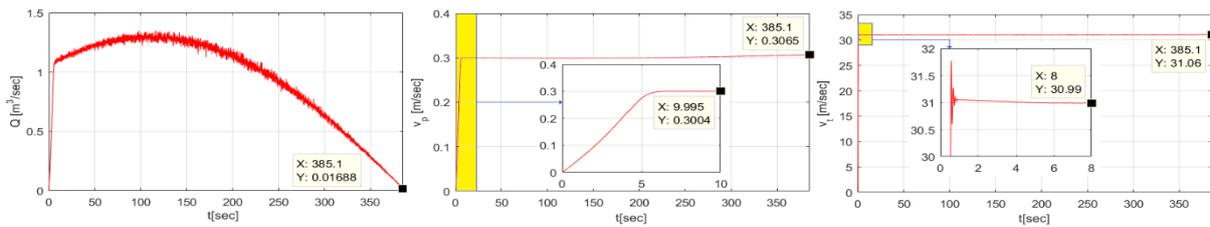

Fig. 4. Time variation of flow rate, pivoting speed and cutting speed case 1 - stage 1

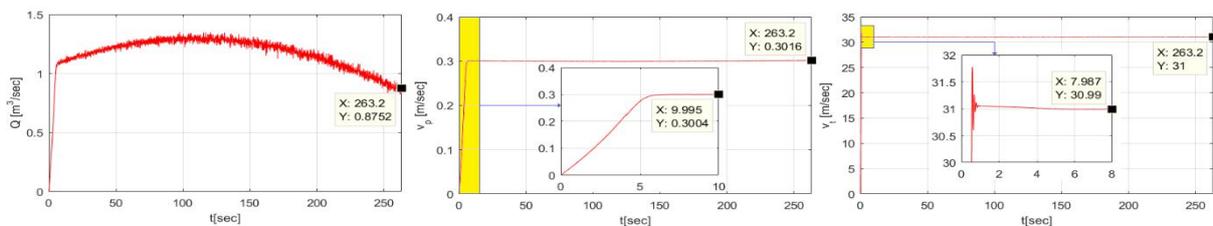

Fig. 5. Time variation of flow rate, pivoting speed and cutting speed case 2 - stage 1

From the figures presented above, it is noted that both in case 1 and 2, the pivoting and cutting speeds are maintained at a constant value throughout the pivot cycle. When the gear shifter in the port-cup wheel is operating in step 1, the steady-state cutting speed is about 31 [m/sec]. On the other hand, the stationary pivoting speeds for both analyzed cases are equal, having a value of approximately 0.3 [m/sec]. From Fig. 4 and Fig. 5, it can be seen that the duration of the pivot cycle for case 1 is approximately 385 [sec] and approximately 263 [sec] for case 2.

Regarding the flow rate of material loaded onto conveyor belt, in both cases analyzed, it is observed that it has a large variation in time, when the pivoting speed is constant.

In conclusion, the realization of relatively constant excavation flow, with as little variation possible within a pivot cycle, can be achieved by the following tandem:

- the total pivot angle is appropriately chosen (has a relatively small value);
- the required pivoting speed is calculated according to the pivot angle based on a control law, that has the role to compensate for variation in the flow time.

4. Conclusions

From the researches made in this article, an original model of the flow resulting from the excavation process was obtained.

Based on the mathematical model of the flow resulting from the excavation process, a simulation program was developed in Matlab-Simulink, with which two pivoting cycles were analyzed, highlighting the main performance of the excavation process. Simulation of the excavation process was customized on the EsRc 1400 excavator. The simulation in Matlab-Simulink analyzed the excavation process in which the pivoting speed and the cutting speed are kept constant throughout the pivot cycle.

With the simulation programs presented in the article, the optimal values of the cutting parameters can be easily extracted, which allow for a constant amount of flow of material loaded onto the conveyor to be maintained over a certain pivot cycle.

Abstract

In practice the need to know how to behavior different components of technological equipment under severe abrasive wear conditions, especially abrasive wear. Thus, various subassemblies and spare parts can be listed which through their high specific consumption, cause high production costs and lead to a low overall profitability, The paper presents the results of researches on the wear and reliability of some subassemblies and spare parts of the mining technological equipment. The research pursued the evolution of wear in time of the various subassemblies and spare parts of the mining equipment as well as determination of their reliability based on the data obtained in the production practice.

Keywords: abrasive wear, reliability, tools, teeth, technological equipment

1. INTRODUCTION

The complex friction-wear phenomenon of the technological equipment subassemblies is a research objective for determining wear capacity of other materials on them, such as the dislocated, transported or processed sterile rocks as well as determining their reliability. Mining shearers, coal screens in preparation, excavators and loaders in quarries, operate under sterile rocks, coal etc. conditions is subject to abrasive wear and change in reliability. Vibrating screens type SCC III from preparations, which take up the coal to achieve removal of material particles less than 0.8 mm, have a number of subassemblies, such as screening surfaces (fig. 1), the troughs, the loading funnel and the basic support of the screen, subjected to excessive wear.

The difference in behavior between different subassemblies of the same machine can be appreciated only after a reliability analysis, because if you take example of the screen, it found that while screening surface has a reliability of 4.8 %, after 100 hours, the trough has a reliability of 31.3 %, for the same useful life.

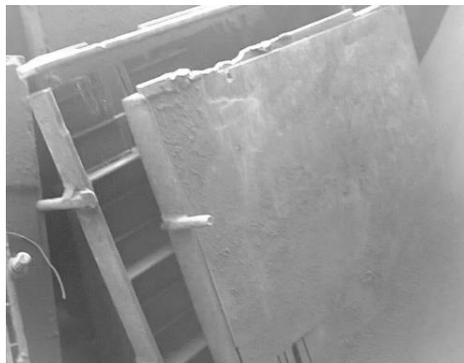

Fig.1. Worn screening surface

Rocks cutting and dislocation tools (fig. 2) are reinforced with hard alloy inserts which ensure hardness, modulus of elasticity and thermal heat transfer.

E-mail address: VladFlorea@upet.ro.

The variation of the specific wear Ψ_A of the tools, depending on rocks abrasion (fig. 3) experimentally established, can determine the degree of wear of the tools, over time, depending on this property. This is important because it has been found that the value of the tools for cutting and dislocation the rocks sometimes represents 14 % of the production costs. Alongside the shearer tools, the excavator teeth can be exemplified (fig. 4) that supporting significant wear and cause, the same measure and for the same reasons, the negative economic effects.

Fig. 2. Worn shearer tools CMR 4

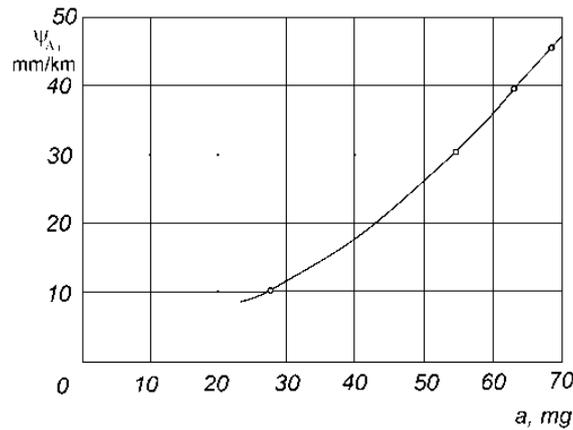

Fig. 3. Variation of the specific wear of the shearer tools depending on rocks abrasion

Fig. 4. Worn excavator teeth

Knowing reliability and practical aspects of these problems refers to the establishment of the theoretical distribution laws that can shape the mechanical phenomena of failure, including wear, and to the ways to improve the behaviour in time of different subassemblies of the technological equipment.

2. Reliability analysis of subassemblies „trough” of the screen type SCC III

Experimental data used in the analysis:

- T_f time between failures (table 1) for $n=26$ events (in increasing order);
- T_{rem} , time to repair of trough (also in increasing order).

Based on data from table 1, the mean value of operation times, calculated between failures is:

$$M[t] = \sum_{i=1}^k t_i \cdot f(t_i) = 59,53 + 49,61 + 33,06 + 36,33 = 178,53 \text{ [hours]} \tag{1}$$

And the value of mean time to repair is:

$$MTR = \frac{\sum_{i=1}^{26} T_{rem}}{n} = \frac{1730}{26} = 66,54 \text{ [min]} \tag{2}$$

Table 1 Values of time between failures and time to repair of trough

T_f	7	7	14	14	21	49	56	56	56	63
[hours]	63	70	91	112	112	133	154	154	175	203
	224	231	287	462	511	987				
T_{rem}	20	30	45	50	50	50	50	50	60	60
[minute]	70	70	70	70	70	70	70	80	80	80
	80	80	90	90	90	105				

The time interval Δt needed to determine the relative frequency $f(t_i)$ is calculated with the Sturges relationship:

$$\Delta t = \frac{t_{max} - t_{min}}{1 + 3,322 \cdot \lg n} = \frac{987 - 7}{1 + 3,322 \cdot \lg 26} = 171,9 \text{ [hours]} \tag{3}$$

where, t_{max} and t_{min} are the maximum and minimum limits of operating times and n represents the number of events

Is chosen $\Delta t = 172$ [hours], resulting $K=6$ time intervals.

For the exponential distribution law the failures rate is

$$\lambda = \frac{1}{M[t]} = \frac{1}{178,53} = 0,005601 \text{ [hours}^{-1}] \tag{4}$$

Using the obtained data, the relative frequencies $f(t_i)$, cumulative frequencies $F_c(t_i)$ and functions $F(t_i)$ can be determined (table2).

Table 2 Exponential distribution function and the distance “d” for trough

Nr. int.	Interval size Δt	Average value t_i	Number of failures n_i	Relative frequency $f(t_i)$	Cumulative frequency $F_c(t_i)$	Distribution function $F(t_i)$	d
1	0÷172	86	18	0,6923	0,6923	0,3822	0,31
2	172÷344	258	5	0,1923	0,8846	0,7643	0,12
3	344÷516	430	2	0,0769	0,9615	0,91	0,052
4	516÷688	602	-	-	0,9615	0,9657	0,004
5	688÷860	774	-	-	0,9615	0,9869	0,025
6	860÷1032	946	1	0,0384	0,9999	0,995	0,005

$n=26$

The validity of the exponential distribution law is tested:

$$F(t_i) = 1 - e^{-\lambda \cdot t_i} \tag{5}$$

The value of the distribution function obtained (table 2) allows the calculation of the distance “d” between the theoretical and experimental distribution function. It is found that this law does not validate, according to the Kolmogorov concordance test, because:

$$d_{max} = 0,31 > \frac{1,36}{\sqrt{n}} = \frac{1,36}{\sqrt{26}} = 0,2667 \tag{6}$$

It is necessary to choose another law, for example the Weibull distribution law. The values of the Weibull distribution function, presented in table 3, correspond to the parameters calculated using the relations:

$$a_1 = \frac{\sum_{i=1}^k \ln t_i \sum_{i=1}^k Y_i \ln t_i - \sum_{i=1}^k Y_i \sum_{i=1}^k \ln^2 t_i}{\sum_{i=1}^k \ln t_i - k \sum_{i=1}^k \ln^2 t_i} = \frac{35,972 \cdot 42,764 - 6,693 \cdot 219,604}{35,972^2 - 6 \cdot 219,604} = -2,8976 \tag{7}$$

where:

$$Y_i = \ln \ln \frac{1}{1 - F_c(t_i)} \tag{8}$$

Result:

$$\lambda = e^{a_1} = e^{-2,8976} = 0,05557; \tag{9}$$

$$a_2 = \frac{\sum_{i=1}^k \ln t_i \sum_{i=1}^k Y_i - k \sum_{i=1}^k Y_i \ln t_i}{\sum_{i=1}^k \ln t_i - k \sum_{i=1}^k \ln^2 t_i} = \frac{35,972 \cdot 6,693 - 6 \cdot 42,764}{35,972^2 - 6 \cdot 219,604} = 0,6694 \tag{10}$$

$$\beta = a_2 = 0,6694 \tag{11}$$

The mean time between failures (MTBF) result from the relation:

$$MTBF = \frac{\Gamma(1/\beta+1)}{\lambda^{1/\beta}} = \frac{1,344}{0,05557^{1/0,6694}} = 107,2 \text{ [ore]} \tag{12}$$

It is found that the Weibull distribution law is validated according to the Kolmogorov concordance test because:

$$d_{max} = 0,11 < \frac{1,36}{\sqrt{n}} = \frac{1,36}{\sqrt{26}} = 0,2667 \tag{13}$$

In the case of Weibull biparametric model the expression of reliability is:

$$R(t_i) = e^{-\lambda \cdot t_i^\beta} \tag{14}$$

Table 3 Values of the Weibull distribution function and the distance "d" for trough

Nr. int.	Average value t_i	Cumulative frequency $F_c(t_i)$	Y_i	$\ln t_i$	$\ln^2 t_i$	$Y_i \cdot \ln t_i$	Distribution function $F(t_i)$	d
1.	86	0,6923	0,164	4,454	19,841	0,730	0,650	0,08
2.	258	0,8846	0,769	5,552	30,835	4,269	0,885	0,11
3.	430	0,9615	1,180	6,063	36,769	7,154	0,952	0,009
4.	602	0,9615	1,180	6,400	40,963	7,552	0,977	0,016
5.	774	0,9615	1,180	6,651	44,243	7,848	0,988	0,027
6.	946	0,9999	2,220	6,852	46,953	15,211	0,994	0,059
	Σ		6,693	35,972	219,604	42,764		

The reliability values for the Weibull distribution, for different operating times, of the trough subassembly are shown in table 4 and represented in figure 5.

Table 4 Reliability variation depending on the time for trough subassembly

t [hours]	50	100	150	200	250	300	350
$R(t)$ [%]	0,479	0,313	0,219	0,159	0,119	0,090	0,070
t [hours]	400	500	600	700	800	900	1000
$R(t)$ [%]	0,055	0,034	0,022	0,015	0,010	0,007	0,004

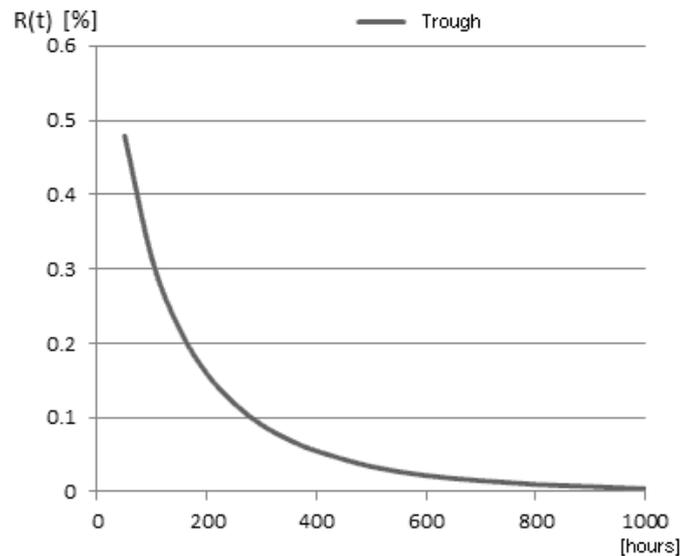

Fig. 5. Reliability variation of trough of the vibrating screens

3. Evolution wear to cup teeth of the frontal loaders and solutions to increase their lifetime

Equipping basalt quarries with dislocation and frontal loading machine on tires type Volvo L 220 E allows for the following operations

- loading crushed stone in trucks for delivery;
- transportation of crushed stone to the temporary deposit;
- feeding with broken stone of the crushing the secondary flow;
- cleaning and arranging the access ways both on the crushing platform and on the working front.

The analysis of the behaviour of subassemblies that are subject to excessive wear on Volvo L 220 E machines to point out the need for frequently replacement of some of them, especially the cup teeth (fig. 6 a). The abrasive wear of the loader teeth in the production of aggregates from basalt rocks, is mainly, determined by the dimensional changes and the weight loss at the active surfaces (fig. 6 b).

Fig. 6. Cup tooth for the Volvo equipment: a-new teeth; b-worn teeth

Determining how cup teeth wear evolve (fig. 7) have led to the necessity of finding solutions to increase their lifetime.

The methodology for improving the technical-economic characteristics of the cup teeth has as a its starting point the precise setting of their chemical composition (table 5) and hardness. The chemical composition of the cast tooth, determined experimentally, is within the mark of alloy steel G45CrNiMo4, in accordance with SR EN 1027-1.

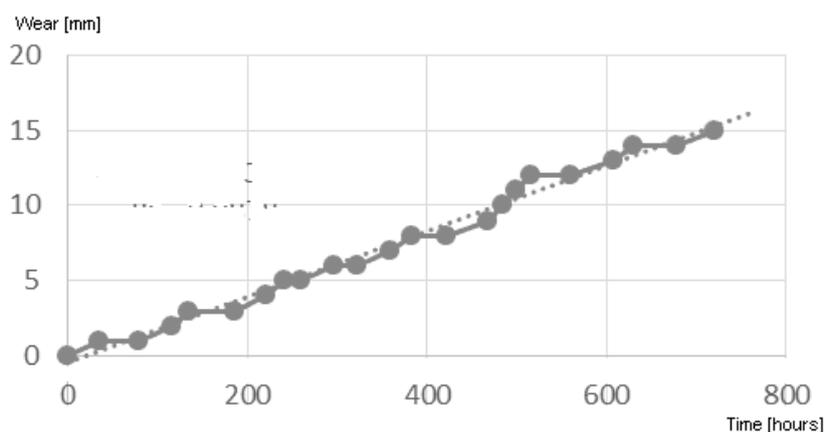

Fig. 7. Evolutions of cup teeth wear

Table 5 Chemical composition of the cup cast tooth

Cup tooth material	Chemical composition							
	[%]							
	C	Si	Mn	P	S	Cr	Ni	Mo
Alloy steel G45CrNiMo4	0,45	0,26	0,80	0,007	0,06	1,00	0,50	0,15

Sclerometric investigations to be effected on the two teeth, in transverse section in five zones randomly selected (table 6), and conversion HRC=f (HV 10) has achieved in accordance with DIN 50-150.

Table 6 Cup teeth hardness

Number of tooth	Hardness									
	HV10	HRC	HV10	HRC	HV10	HRC	HV10	HRC	HV10	HRC
1	425	43	437	44	464	46	458	46	466	47
2	421	42	442	45	473	46,5	462	47	459	46

Elaboration of self-protection system against tooth wear (fig. 8) can be done in different mode, depending on active zone position namely:

- the active tooth edge, protects with compact layer;
- the active surfaces, protects with rhomboidal systems.

Manual electrically welded load with electrodes coated containing the alloys of the type Cr25%-4%W-1%Ti-V can provide good abrasion resistance and allows reconditioning of used teeth, without demounting them from equipment, by using the existing equip in quarries.

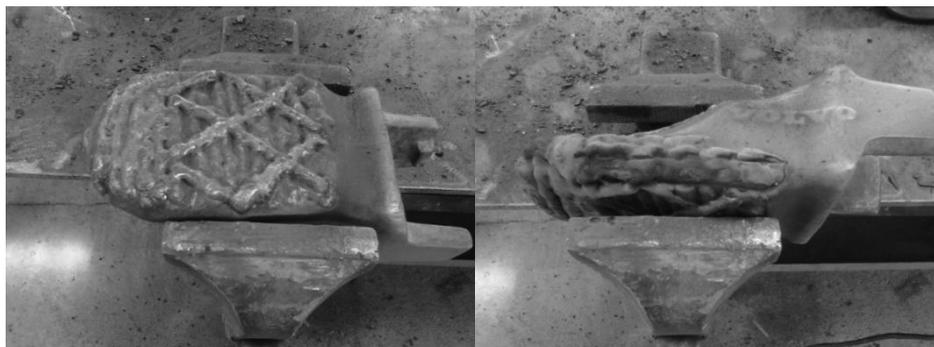

Fig. 8. Wear self-protection system

4. Conclusions

Operating conditions of the technological equipment, in general and due to mining in particular, influences their useful life especially the negative effects of abrasive wear. In this context it is necessary to create the experimental data base regarding the wear and the useful times achieved in the practice as well as the elaboration of the reliability analyses. Evaluation of reliability indicators can lead to the development of specific methodologies for rehabilitation of technological equipment which in turn can lead to savings and increased profitability in production processes.

The Use of Quality Function Deployment Method in the Transport Activity

Gabriel Praporgescu^{a*}

^aUniversity of Petroșani, University Str., 332006, Petroșani, Romania

Abstract

Quality planning represents one of the fundamental principles of quality management. Through planning, the objectives of undertaking the quality together with the human, financial and material resources necessary for obtaining them are established. The operational planning of quality relates to both external issues – customer identification and establishing their needs and internal issues – transposing the customer’s requirements into quality characteristics of the product together with developing processes that ensure the achievement of these characteristics.

Keywords: Quality, transport, quality functions

1. Introduction

The basic principles and fundamental objectives of a company, regarding quality, make up the strategic planning of quality, which comprises the following steps:

- Quality diagnosis;
- Forecast analysis;
- Establishing the fundamental objectives in quality;
- Necessary resources determination for attaining these objectives;
- Establishing the optimal actions, through the strategic plan of. (Boroiu, 2010, Boroiu, 2014, Sivasamy et al., 2015, Tsoukalidis et al., 2009)

Operational planning of quality in the transport field relates to both external issues (customer’s identification and establishing their needs) and internal issues (transposing the customer’s requirements into quality characteristics of the product together with developing processes that ensure the achievement of these characteristics).

2. Transport Company Activity

The transport services execution by DMW Logistic Company is made possible through the management and execution of the activities by qualified employees, with a large skill regarding this domain and obeying all the regulations applicable in this field of activity. The road transport services are offered to some customers from different counties of the country, but also to some external customers. The company implemented the quality management system in order to keep up with the customer’s requirements and existing regulations in this field of work. In this way, between the DMW Logistic company representatives and customers, trust, seriousness and promptitude based relationships were established.

a) Identifying the problem types

In 21.02.-16.03.2017 period, in which the activity of DMW Logistic Company was analysed, a series of causes were identified, which led to exceeding the delivery times of the finite materials to customers as well as exceeding the arrival terms of the gross material coming from the customers. At a first glance, the management reached to the conclusion that the main factor is the personnel inside the society, namely the drivers; regarding this, it was decided to make an internal audit for identifying and implementation of the measures which are needed in order to eliminate the quality deficiencies. As a result, the following conclusions were centralized (table 1).

* Corresponding author. Tel.: +0724708876.
E-mail address: gpraporgescu@gmail.com.

Table 1. Conclusions resulting from the internal audit.

Criterion	Questions
Chronicity	Usual problems: - indiscipline and carelessness of the personnel; - obsolescence of the vehicles; - improperly externalized inspections; - difficulties of orientation for the drivers regarding the foreign customers.
Importance	It is targeted the personnel problems elimination
Duration	It is proposed a 30 days
Measure of potential impact	It is desired: • keeping the old customers; • bringing new customers; • improving the satisfaction degree of the customers; • making the employees loyal.
Urgency	The results during a 3 month period are being considered
Risk	The results can be different from the desired ones
Possible resistance to change	In the first phase, only the problems which do not face resistance will be addressed
The success of the action	The most successful actions were chosen
Measurement	Consists in questionnaires sent to customers.

The major problem that was identified is: endowment with performant means of transport. The team produces the mission: In the next period of time it is desired the acquisition of performant means of transport and improving the number of customers by 5%.

b) Measurement

The measurement was made based on the feed-back received from the drivers after each route by having them completing a form with every problem they had during the transport. From these forms, the team extracted and processed the data based on which they determined the house of quality (Quality Function Deployment method – QFD).

3. Quality Function Deployment method (QFD).

3.1. General aspects. (Cristiano, et a., 2001, Ghobadian and Terry, 1995, Lockamy and Khurana, 1995, Petrescu, 2015)

The base principle of this method is the fulfilling of the requirement of customers, in every step of the provided product (service). All the activities of evolving the product are seen through the eyes of the customers, not of the producer. In this way, QFD is the methodology which allows the transformation of beneficiary's requirements in quality characteristics of the service.

QFD is a group working method, the activity being developed through brainstorming meetings together with Decision making individuals from all the departments of the company organization (marketing, production, quality etc.).

The characteristic of the method is that the fulfilling of the quality requirements is wanted in every phase of the production process. All the product evolving activities of the product are seen from the customer's perspective, not from the producer one. The start point in making new products, or the improvement of the existing ones should be the identification and evaluation of the customer's requirements. The customer's requirements are materialized in specifications which will be made accordingly for each phase of the process, ensuring the conditions for creating a satisfactory product (service) for the customer.

For applying the method, a diagram named "house of quality" is used, which is a table with two entries in which the rows are represented by the customer's requirements and the columns by the quality characteristics.

The instrument of the QFD method is a diagram called "House of Quality" respectively "La maison de la qualite" in French. The central part of the diagram has the shape of a table with two entries: on rows the requirements of the customers and the importance of them are mentioned and on columns the quality characteristics through which the requirements will be fulfilled. On top of the quality characteristics the "roof of quality house" is realized – a triangular matrix which makes the correlation diagram for the quality characteristics, which permits the identification of the opposite characteristics in order to solve the conflict situations. At the intersection of the rows with columns it is highlighted the correspondence between the customer's requirements and the quality characteristics of the product. The product between the importance of the requirement and the degree of correlation between the requirement and characteristic is computed in each cell of the matrix.

The sum of these values on column represents the absolute importance of each characteristic for fulfilling the customer's requirements. In this way, the characteristics can be ranked (the relative importance is determined), in order to establish the action priorities for ensuring the quality characteristics.

It should be mentioned that this is just the first phase from the more complex methodology QFD which comprises a continuous flow of information, starting with the customer's requirements until the operating instructions of them at the workplace (Boroiu, 2014). The whole QFD methodology comprises four phases (fig. 1):

- 1 – product planning (largely, services are considered products);
 - *inputs*: organization customer's requirements;
 - *outputs*: specifications or characteristics of the product.

- 2 – design of the components;
 - *inputs*: specifications or characteristics of the product;
 - *outputs*: specifications or characteristics of the component parts of the product.
- 3 – process planning;
 - *inputs*: specifications or characteristics of the component parts of the product;
 - *outputs*: specifications or characteristics of the technological process of production.
- 4 – production planning.
 - *inputs*: specifications or characteristics of the technological process of production;
 - *outputs*: specifications or characteristics of the production process.

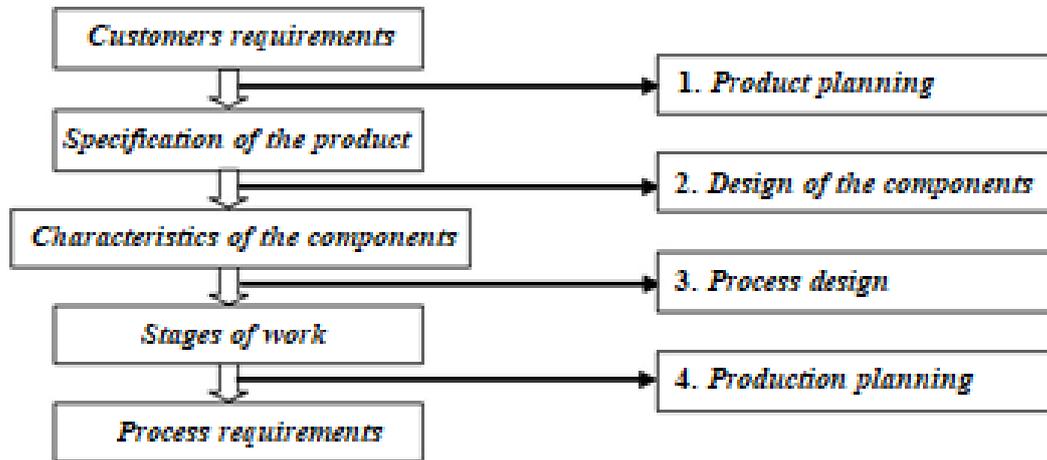

Fig. 1. QFD phases succession. (Boroiu, 2014).

For the application of the method the following steps should be performed:

- determination of the customer’s requirements and their weight function of the importance that it represents for them;
- establishing the quality characteristics; the importance of the quality characteristics is established as a total score by multiplying the importance coefficient of the customer’s requirements with the score given to these characteristics; establishing the quality characteristics value which should be obtained by assessing their degree of difficulty. At the same time, it is determined the desirable variation sense of the characteristic value: growth (↑), decrease (↓), indifferent (o);
- interaction evaluation – the correlations between the quality characteristics are studied, the results being noted in the matrix of correlations which can be found near the “roof of the quality house”. This correlation can be positive or negative, but more levels of correlation can be established: strongly positive, medium, strongly negative, or strongly positive, positive, indifferent (no correlation) negative, strongly negative;
- the comparison analysis of the planned product with the concurrence product is realized from two points of view: from the customer point of view and by comparing the technical level of the product with the concurrent product.

This methodology can be applied to the entire cycle of making a product, but it is not finished with this activity. For quality improvement, there is a continuous retaking of the methodology, this being called *the helix of never-ending improvement* through which the cycle of Deming is applied successively (*Plan-Do-Check-Act*) and QFD method.

This continuous quality improvement is known as quality helix or “Juran’s helix”, because we can find all the steps of making the product along it.

The application of QFD method imposes the crossing of an algorithm which implies the usage of the main techniques and instruments used in quality management: customer forms, benchmarking, brainstorming, weighted vote, relationships diagram, correlation diagram etc.

3.2. Using Quality Function Deployment Method

The first step is finding the customer’s desires and their importance on a scale from 1 to 5. In this aspect, each potential customer was sent a form through e-mail.

At the same time, the form was implying also the evaluation of DMW Logistic services in comparison with concurrent companies. There were received answers from approximately 45% from those asked and the team which was assigned with the solving of the quality problem that appeared made the following table (table 2).

The comparison analysis of the transport services used at DMW Logistic Company is presented in table 3. It can be seen that from the professional point of view (technical endowment and professional abilities), that the own transport company DMW Logistic is superior with respect to the concurrence. On the other hand, from the point of view of performant technical means of transport endowment and appropriate cargo packing, the company is on the same level or under other companies that offer transport services.

Table 2. Customer evaluation of the own transport company in comparison with the concurrence

Customer requirement	Requirement importance index				
	DMW Logistic	CARTRANS SA	SAFE TRANS	TRANSIBO SA	M.E.A. SRL
1. Performant transport means endowment	4	4	4	3	3
2. Respecting the taking/delivery terms	5	3	3	4	4
3. Ensuring „just in time” service	4	2	4	3	3
4. Ensuring „door to door” service	5	3	3	4	4
5. Appropriate cargo pack	3	3	5	4	2
6. Product safety	4	3	2	3	3
7. Good prices	5	2	3	4	4

The comparison analysis of the transport service made by the own company (DMW Logistic) with the concurrent transport companies is made from two points of view: from the customer point of view and by comparing their technical level with the concurrence one.

Table 3. Comparison analysis of transport services at SC ZINCHERIA SA Company.

Customer requirement	Comparison analysis									
	1. DMW Logistic	2. CARTRANS SA	3. SAFE TRANS	4. TRANSIBO SA	5. M.E.A. SRL					
						1	2	3	4	5
1. Means endowment ...	4	4	4	3	3					
2. Respecting deadlines	5	3	3	4	4					
3. „Just in time” service	4	2	4	3	3					
4. „Door to door” service	5	3	3	4	4					
5. Appropriate packing	3	3	5	4	2					
6. Product safety	4	3	2	3	3					
7. Good prices	5	2	3	4	4					
8. Seriousness and kindness	3	2	2	3	3					

Identification of the quality characteristics and their objectives. For the quality characteristics to be identified, a multidisciplinary team is put together in wich together with DMW Logistic company employees it is advised to take part also representatives of Bordignon Group. It is mentioned the preferable sense of variation of characteristic value, namely: growth (↑), decrease (↓), indifferent (o) (table 4).

Table 4. Quality characteristics and their objectives.

Quality characteristic	Objective
1. Qualified, authorized and periodically trained personnel	o
2. Technical endowment and fleet monitoring system updating	o
3. Communication training for the personnel	↑
4. Flexible work hours, adaptable to requests	↑
5. Waiting room built for customers	o
6. Partnership with packing supplying company	o
7. Housing the customer and the efficiency of communication with him	↑
8. Display of information regarding the offered services	o
9. Personnel objectiveness	o
10. Transport duration (including zinc coating services) as low as possible	↓

Putting together the correlation matrix between quality characteristics. This matrix will be the “roof of the quality house”. There are used five levels of correlation, with the following symbols:

- strongly positive (++);
- positive (+);
- no correlation (o);
- strongly negative (- -);
- negative (-)

These levels of correlation show the measure through which quality characteristics are supporting each other or are in conflict. It is determined that generally there are positive correlations or no correlations at all, and the poorly negative that exists are generated mainly by the concurrence of consuming some limited financial funds inside the same company.

Self-evaluation of the organization regarding the concurrence. The technical evaluation of the quality characteristics is made similarly with the evaluation made by customers taking into account the concurrence, only this time, the input data is not offered by customers, but by the technical leadership of the organization. The concurrence organization that obtains a superior score for one of the characteristics becomes the benchmark level for DMW Logistic company, the benchmark level becoming an quality objective for it.

Establishing the “customer requirements” – “quality characteristics” relationship matrix. This matrix (fig. 2) offers a mechanism of analysing the mode through which a quality characteristic helps fulfilling a customer requirement. A score that weights more the results can be used: 0 = no relation; 1 = poor relation; 3 = medium relation; 5 = very good relation. An index is given to each relationship and below, with bold characters it is noted the product between the importance of the requirement and the relationship index between that quality characteristic and requirement.

The absolute importance of each quality characteristic is computed by summing, on columns, the obtained products and the relative importance (priority order) of the quality characteristic is obtained by ranking from greatest to smallest they obtained values (fig. 2).

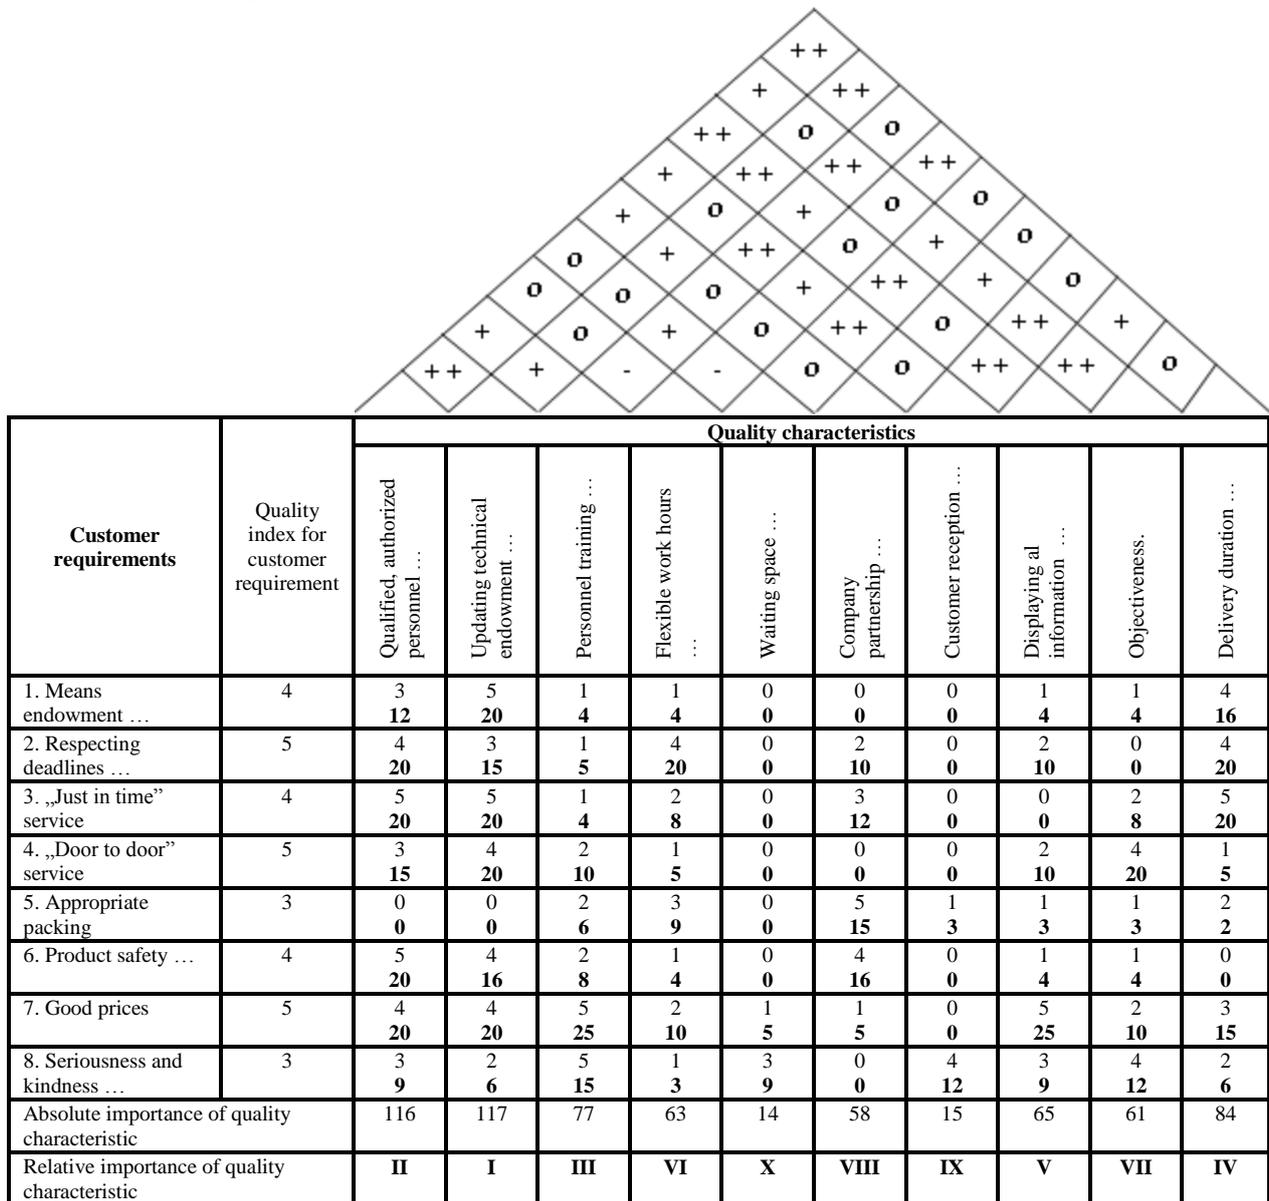

Fig. 2. Quality house.

Results interpretation. After the ranking of the quality characteristics, it can be seen that for fulfilling the customer requirements, updating the technical endowment and employee’s professionalism have priority. It can be seen that special communication abilities are necessary from the personnel point of view, which is in accordance with the position occupied by the customer in the new concept of quality management.

Also, promoting a flexible work schedule, customer reception and communication efficiency with the customer, waiting room for customers, personnel objectiveness, are quality characteristics that are important for fulfilling the requirements of the customer.

For attaining the proposed objective – to offer highly qualitative services in comparison with the concurrence – DMW Logistic company will have to act in order to obtain performances with quality characteristics determined according to the hierarchy obtained through QFD method.

For reaching these objectives, the correlations identified in the “roof of the quality house” will be taken into account, in order for the development of the quality function to ensure high competitiveness in efficiency conditions. In this way, it is usually seen that we have strongly positive and positive correlations between the quality characteristics of the transport service offered by the own company (and not by other companies) and also characteristics with no correlation and very few characteristics with negative correlation.

4. Conclusions

For attaining the quality objectives of the transport activities offered by DMW Logistic Company, there were used the QFD method (Quality Function Deployment).

The conclusion that was reached is that for the fulfilment of the quality requirements of the customers it would be necessary to take action towards endowing the auto park (endowment of the existing park with modern equipment or replacing the means that are old), but also towards the personnel which does the transport activity (incentives, taking part into specialization courses, periodic training towards customer interaction).

All these actions lead to a more efficient transport activity, on which the production rate of the DMW Logistic Company is depending. This can take place by reduced consumption for usage and maintenance of the transport means, through getting new customers, by reducing the delivery times and times for manipulating materials. In this way, the objective desired by the company can be reached, that is applying a total quality management and obtaining performance in the offered services quality field.

The man in charge with quality control ensures the logic tools used for verifying the fulfilment of the customer with respect to new market information acquiring requirements. After the data were analysed “Correction actions” or “Preventing actions” can be identified. These documents are annexed to “The Business Plan”, an important document which is emitted annually by the administration. Actually, taking into consideration the market condition and the re-evaluation of the company’s politics, the fundamental strategic objectives are identified together with the key success factors.

The final result of the analysis is indicated in the “Annual Business Plan” as a matter of improving objectives of the company. For each objective an operative planning is made for its correct management by establishing tempos, responsibilities, the intervals of checking the objective values etc.

Quality of Equipment Used in the Mining Industry

Cristian Ilioni^{a*}

^a University of Petrosani, 20 University street, 332006, Petrosani, Romania

Abstract

In the first part of the research, the five concepts used in industrial practice, quality, reliability, maintainability, maintenance and availability are defined, the definitions of which result in the structural links between them, all of which equate to the characterization of the functionality of a product.

For defining the concept of quality, it is absolutely necessary to detail the four elements that have been defined. The complexity of the concept of reliability is highlighted, which, in a complete presentation, should include technical, operational, commercial and management approaches.

The factors that contribute to defining the quality of a mining equipment or equipment are highlighted, given the particular circumstances in which they are exploited.

The cause-effect diagram, or the Ishikawa diagram, is a complex way of analyzing a product's quality.

The method is based on the detailed determination of the causes that may lead to the appearance of a defect, so that the best possible measures can be taken to remedy it or even prevent it from occurring.

Keywords: quality, reliability, maintainability;

1. Introduction

The concept of product **quality**, having a complex character, requires the consideration of a large number of concepts.

In relation to the nature and effect they have in the use process, the quality characteristics are grouped into the following typologies: technical, availability, of a general, economic social character.

The concept of **reliability** can be defined qualitatively and quantitatively.

From a qualitative point of view, reliability is the ability of a system to operate without failures within a certain amount of time under given conditions. In other words, but expressing the same essence, in qualitative terms, reliability is defined as the set of qualitative characteristics of a product (technical system), which determines its ability to perform its specific function (preservation of performance) under prescribed conditions, over a specified period of time. By its qualitative characteristics, the product is the material carrier of a service it performs. In this respect, it can be said that reliability is quality over time.

From a quantitative point of view, reliability is the characteristic of a system defined by the likelihood that it will perform its specified function within a given timeframe and under given conditions. Therefore, for quantitative expression of reliability, elements of probability theory and mathematical statistics are used, as the failure and repair mechanism is not subject to deterministic laws.

The numeric value of a reliability parameter for an item, device, product, or system is called a reliability indicator.

Maintenance is the ability of a system to operate under conditions of operation, to be maintained or restored to perform its specified function when maintenance and repairs are carried out under specified conditions with good stability. Like the notion of reliability, maintainability can be defined from two points of view: qualitative and quantitative.

* Corresponding author. Tel.: 0040764408627.

E-mail address: c_ilioni@yahoo.com

From a qualitative point of view, maintenance is the ability of the system to be supervised, maintained and repaired over a certain period of time and certain given conditions. In quantitative terms, the maintenance of a system is the probability of returning it to the operating state, within specified time limits and under given conditions, when a defect occurs.

Maintenance is the set of all associated technical and organizational actions that are performed to maintain or restore a system in the state of performing its specified functions.

Availability is the probability that a technical system will perform its specified function at a given time or within a given timeframe as a result of the combined effects of reliability, maintainability and maintenance.

Availability is the feature of systems that users perceive directly. It is the most complex and appropriate measure of the quality of the technical systems during their operation, as it is the consequence of both the probability of good functioning expressed in reliability and the probability of restoring the state of good functioning expressed in terms of maintenance.

2. The main links between reliability and maintainability

After analysing the contents of the concepts of reliability and maintainability, a series of assumptions were made that show the link between these two:

- It is noted at the outset that reliability and maintainability studies are carried out in parallel, at different stages of product promotion, namely in the development of technical documentation, execution, reception, transport, operation and renewal of the product, all of which are viewed from the point of view technical and economic view;
- Maintenance operations of whatever nature are related to the random character life of the elements, hence the reliability characteristics of the elements: the reliability function, the average running time to the first failure or between two failures, rate or instantaneous failure intensity;
- The frequency of corrective maintenance operations depends on the failure rate or severity or the risk of failure. In addition, it can be said that corrective maintenance, by reducing the failure rate, leads to improved reliability;
- Depending on the level of reliability of the equipment, it is possible to determine the number of equipment to be replaced so that a predetermined number is considered to be in operation at any given time, considered for a certain period of time $(0, t)$ taken into consideration;
- preventive maintenance operations must be carried out when the intensity or failure rate is increasing over time, the length of time for which the interventions are made is determined by the reliability characteristics of the item or product considered. When the failure intensity is constant, it is obvious that preventive renewal is not necessary.

3. Motivating the need to improve the quality of mining equipment

In the practice of exploiting useful minerals, underground and surface works, there are many reasons that recognize the need to improve the quality of mining equipment and equipment. Of these, the most important are:

- maximizing profits;
- reducing costs due to low reliability, recognizing the particular influence of real costs due to its low value;
- reducing the volume and costs of maintenance and repairs as a result of the reduced frequency of interventions and their reduced duration;
- keeping up with the changes imposed by the global competition;
- the use of higher technical achievements obtained in other areas, such as aerospace or nuclear.

Of all these factors, geological conditions have a particular influence due to their variability underground and surface, which can lead to the impossibility of carrying out the related work and to ensure the optimum conditions of operation of the machinery and equipment.

We must not underestimate the human factor that is of the greatest importance in the design of technological processes, in the production of the equipment and the equipment necessary for the production process, in testing them, in the operation of machinery and equipment, and last but not least in the management of the production activity.

4. Determining the quality of mining equipment using the Ishikawa Diagram

The Ishikawa Diagram, after the name of the Japanese teacher who first built it, is known as the cause-effect diagram. Ishikawa. It is also recognized as the fish skeleton diagram because of its skeletal-like graphic representation.

The Ishikawa diagram is a type of analysis that uses a graphical, causal and suggestive method to optimize the quality of a product, allowing efficient and cost-effective action on the process's technological parameters.

Japanese Ishikawa separates the quality characteristics of a product into real and secondary. The qualitative qualities considered real represent what the customer demands, which is mainly of interest to him and satisfies him during the use of the product. Unlike the actual qualitative characteristics, the secondary ones constitute a minimal system of factors that contribute to determining the process of achieving the main characteristic.

The diagram of the relationship between the actual qualitative characteristic and the secondary characteristics synthesizes a relation between cause and effect. That is why this type of chart is called the cause-effect diagram or the Ishikawa diagram, after the name of the designer.

The real feature becomes the effect and the secondary features are directed towards it. However, it is not about some randomly chosen characteristics, but only those whose role and value compete with the definition of the resultant, represented by the main (real) characteristic.

The cause-effect diagram is therefore a skeletal structure in which the real quality characteristic "effect" is indicated by a backbone, and the secondary characteristics (materials, methods, workers, machines, the environment - known as 5M), which are, in fact, the main causes (important factors) of the problem, are represented in the form of arrows inclined to the spine. Apart from the main factors, there are also some secondary factors, the so-called secondary causes, which are represented by other small arrows directed to the main causes.

5. Methods of drawing Ishikawa charts

In fact, building an Ishikawa diagram, or building it, is not a special issue. It can be said that the drawing of the actual chart is the last operation in a whole series of tests, checks, confrontations and re-evaluations. Once a cause and effect diagram has been drawn up for a given product, it is not the last word; it may be susceptible to improvement, at any time during the course of the product, under the umbrella of uninterrupted technical progress. There are various ways of drawing up Ishikawa diagrams. The proposed methodology for structuring diagrams on the process components involves the following steps:

1. Identify the quality feature that is intended to be improved or kept under control.
2. Write the quality attribute to the right of the format that we want to build the chart and fit into a rectangle.
3. Draw the main line (arrow) from the left to the right; the arrow can be represented by a double line.
4. The main causes (which may be "5M") that influence the quality characteristic are successively written. The main causes also fall into rectangles.

In using an Ishikawa diagram, the following points should be considered:

- Normally, an Ishikawa chart is complicated, with many ramifications. Such a chart is considered good and reflects the deep knowledge of the process;
- if, on the contrary, a diagram of this type has few ramifications, it reflects the superficial knowledge of the process, and so the diagram cannot be considered good;
- after setting a priority in solving the causes, the necessary measures must be laid down to remove these causes. It is very important to monitor the implementation of measures and to check their effectiveness.

6. The benefits of using cause-effect charts

The representation in the cause-effect diagram of all identified causes and factors and interdependence based on the analysis of the company's factors opens the way for the following activities and effects:

1. Analysis of the existing state of the technological process in the analysed sections and workshops. 2. During the creation of the cause-effect diagram, experience and new knowledge are gained by all those who work in this direction. In order to make a correct, complete diagram that clearly represents the phenomenon being researched, it is necessary to gather as many ideas from as many people as possible in the field. In this way, everyone contributes with their own experience, and in the end, by exchanging views on this occasion, new knowledge will be gained.

3. When drawing up a cause and effect diagram, where the topic of discussion is clear, useful conclusions can be drawn on how to act in the future, and many problems that have negative implications in the future are solved. At the same time, I agree with the "beating" directions to improve the business.

4. Through the persistence of permanently seeking the causes of a phenomenon, a deficiency, all the real factors behind the phenomenon are revealed.

5. Analysis of a cause-effect diagram results in the level of technological knowledge of those who make it; the more the diagram can be represented in more detail, more correctly, the conclusion is that working technology is better known in all phases.

7. Conclusions

The first part of the chapter defines the five concepts used in industrial practice, quality, reliability, maintainability, maintenance and availability, the definitions of which result in their structural bonds, all of which equate to the characterization of the functionality of a product.

For defining the concept of quality, it is absolutely necessary to detail the four elements that have been defined. The complexity of the concept of reliability is highlighted, which, in a complete presentation, should include technical, operational, commercial and management approaches.

The factors that contribute to defining the quality of a mining equipment or equipment are highlighted, given the particular circumstances in which they are exploited.

The cause-effect diagram, or the Ishikawa diagram, is a complex way of analyses a product's quality.

The method is based on the detailed determination of the causes that may lead to the appearance of a defect, so that the best possible measures can be taken to remedy it or even prevent it from occurring.

Power Demand of the TK-R 16/8 Turbocompressor Function of Inlet Conditions

Ion Dosa^{a*}, Ovidiu Bogdan Tomuș^a

^a Univeristy of Petroșani, Petroșani 332006, Romania

Abstract

There are indications in literature regarding the possibility of computing the power demand for the turbocompressor depending on variation of inlet air parameters. The formulas found can be applied only for small variations of inlet air parameters, and their precision is poor. This work presents the results obtained by considering a statistical dependency between the variation of power demand and the variation of inlet air parameters for “TK-R 16/8 Iolanda II” turbocompressor.

Keywords: inlet air parameters, power demand, tubocompressor, statistical dependency

1. Influence of environmental factors

Parameters of inlet air are function of season and the elevation against the sea level. Air temperature and pressure can be computed using equations found in literature, [Irimie et al. 1994], and they are valid for a gaseous system in equilibrium. Experimental data shows that temperature is dropping at a rate of 1 °C at every 154 m, and the value of polytropic exponent is $n=1.002$, [Irimie et al. 1994].

The power demand of the turbocompressor knowing the power demand for conditions denoted with index 1, and the power demand denoted with 2, can be computed for small variation of inlet air flow rate, using equation below, [Bacu et al. 1972, Brădeanu 1977]:

$$\frac{P_{a2}}{P_{a1}} = \frac{V_{a2}}{V_{a1}} \quad (1)$$

where P_{a1} is the power demand, W, corresponding to V_{a1} inlet air flow rate, $m^3 \cdot s^{-1}$, and P_{a2} is the power demand corresponding to V_{a2} inlet air flow rate.

Based on equation above a direct conclusion is that for different inlet conditions which influences the volumetric flow rate, the power demand of the turbocompressor will be different than the one provided by the manufacturer.

A proper assessment of power demand of the turbocompressor as function of inlet air parameters an equation must be found that has to express with good accuracy the effect of the variation of the environmental factors on the compressor power demand.

Variance of atmospheric air parameters can cause large differences in the inlet air density [Dosa 1998], so the use of the relation (1) valid for small variations of the inlet air flow rate [Brădeanu 1972] or density, can induce significant errors in the assessment of power demand.

2. Power demand of the turbocompressor

In order to express the most important factors that influence the power demand of the turbocompressor, the power demand is computed using equation below as a function of mass air flow rate at inlet m_{asp} , inlet stagnation temperature T_{asp}^* , stagnation pressure at inlet and outlet p_{asp}^* , p_{ref}^* and the polytropic exponent of compression, n [Brădeanu 1972]:

* Dosa Ion. Tel.: +40722409040
E-mail address: i_dosa@hotmail.com.

$$P_{act} = \frac{n}{n-1} \cdot \frac{R \cdot m_{asp} \cdot T_{asp}^* \cdot \left[\left(\frac{P_{ref}^*}{P_{asp}^*} \right)^{\frac{n-1}{n}} - 1 \right]}{\eta_c \cdot \eta_{tr} \cdot \eta_m \cdot 10^3} \quad [kW] \quad (2)$$

where: R - gas constant for air, $J \cdot mol^{-1} \cdot K^{-1}$, η_c - the isentropic efficiency of the turbocompressor, η_{tr} - the gear efficiency, η_m - mechanical efficiency.

Applying the above equation to a cooled multistage turbocompressor is difficult due to the fact that it is impossible to accurately measure the air parameters through its evolution at different stages of the turbocompressor.

The polytropic exponent for the single-rotor turbocompressor without cooling can be calculated using equation found in literature [Pimsner 1988], where the unknown is l_f the work of friction.

Work of friction in different components of the compressor, [Pimsner 1988], is directly proportional to an experimental coefficient and velocity.

In case of turbocompressor the compressed air is being cooled between stages and a result equation (2) cannot be applied for the multistage turbocompressor.

Achieving different degrees of cooling for the same inlet conditions results in a change of the specific volume of the compressed air that is delivered in the next stage, so even in situations where inlet conditions are the same, the power required for compressing the air has different values depending on the degree of cooling achieved in the intermediate coolers.

Computing the work of friction in various components of the turbocompressor was made in the hypothesis of the separate action [Pimsner 1988] of the different types of losses.

In the absence of data on their interaction, the assumption of a strict dependence between pressure, temperature and power values cannot be accepted.

Therefore, it is considered that the link between the analyzed parameters expressed as an equation is uncertain, the dependence of the parameters being rather a statistical dependence.

3. Statistical model

In order to elaborate the statistical model, the simplifying assumptions above regarding the hypothesis of the separate action [Pimsner 1988] of different types of losses will be considered. Equation (2) that analytically analyzes the dependence between power demand, pressure and suction temperature suggests the analysis of the separate influence of the two variables.

Since there is a relationship between the inlet pressure and temperature, the variables are not independent, as a result, in order to avoid errors due to the multicollinearity phenomenon, the two variables will be replaced by one, the density of inlet air.

An important consequence of the hypothesis regarding the value of the polytropic exponent is the number of independent variables measured and sorting of measured data.

Consequently, besides the inlet pressure and temperature, respectively the power demand, the following data will be measured: discharge pressure; inlet flow rate, which controls the friction, and consequently the value of the polytropic exponent; inlet and outlet temperature of the cooling water.

For steady water and compressed air flow rate, the difference between inlet temperature of the cooling water and the outlet temperature reflects the cooling conditions.

Equal temperature variances lead to the conclusion that there are similar cooling conditions, so it will be considered that the specific volume of air delivered in different stages remains the same.

Turbocompressor efficiency is considered constant for a given polytropic exponent, as it is the ratio between potential mechanical work and actual compression work.

Equally, drive speed, engine output, gear efficiency is also considered constant.

In conclusion, the data will be sorted according to the inlet flow rate and the increase of cooling water temperature, i.e. the difference between the water temperature at the inlet and outlet of the cooling circuit.

In the studied case, based on the results obtained with equation (1) for small variations of the flow [Brădeanu 1977], it can be stated that choosing linear correlation for the studied variables is the most appropriate.

The quantitative evaluation of the degree of correlation is made using the simple correlation coefficient [Constantinescu et al. 1980]:

$$R_{x,y} = \frac{n \cdot \sum_{i=1}^n x_i \cdot y_i - \left(\sum_{i=1}^n y_i \right) \cdot \left(\sum_{i=1}^n x_i \right)}{\sqrt{\left[n \cdot \sum_{i=1}^n x_i^2 - \left(\sum_{i=1}^n x_i \right)^2 \right] \cdot \left[n \cdot \sum_{i=1}^n y_i^2 - \left(\sum_{i=1}^n y_i \right)^2 \right]}} \quad (3)$$

where x_i , y_i are experimentally measured data sets, and n is the number of these sets.

Due to the random scattering of experimental data it is possible that the value of the simple sampling correlation coefficient is different from 0 even for two independent variables, which is why the significance of the value obtained for $R_{x,y}$ using equation [Constantinescu et al. 1980] must be verified:

$$H_{calc} = |R_{x,y}| / \sqrt{n-1} \tag{4}$$

The value obtained compares with H_α the critical value of the simple correlation coefficient.

If calculated value $H_{calc} > H_\alpha$, then with the confidence level α we can say that the variables x and y are correlated, otherwise they are independent.

Removing gross errors can be done by calculating for all n sets of values x_i, y_i the sampling dispersion s_x^2, s_y^2 and the correlation coefficient.

These values are computed for the $n-1$ sets remaining after removing the set denoted with x^*, y^* suspected to be aberrant. The resulting values are denoted by s_x^{*2}, s_y^{*2} and $R_{x,y}^*$, and the value of the equation [Constantinescu et al. 1980] is calculated:

$$R = \frac{(n-1)^2 \cdot (1 - R_{x,y}^{*2}) \cdot s_x^{*2} \cdot s_y^{*2}}{n^2 \cdot s_x^2 \cdot s_y^2 \cdot (1 - R_{x,y}^{*2})} \tag{5}$$

The computed value is compared to the critical value R_α [4] for different confidence levels α .

If $R < R_\alpha$ then the sets of values are considered to be affected by gross errors with confidence level α and eliminated.

4. Results and conclusions

In order to generate the regression equation, 124 measurements were made [Dosa 1998].

The barometric pressure B , the ambient temperature T_a , the discharge pressure of the turbocompressor p_{ref} , the drive power demand P_{act} at the motor terminals, the cooling water temperature in the cooling circuit at inlet and outlet T_{int} and T_{ies} were measured.

Resulting data were processed using a program based on the algorithm described above, aiming to eliminate the data affected by gross errors, and finding the significance of the calculated simple correlation coefficient [Constantinescu et al. 1988] [Dosa 1998].

In Fig. 1 are presented the power demand values calculated with the equation (1) (denoted by x) considering the power $P_{a1} = 1,95$ MW and the density $\rho_1 = 1.165$ $\text{kg} \cdot \text{m}^{-3}$ corresponding to the rated inlet conditions.

Large differences between the two sets of values are observed, which justifies the use of regression equations obtained on the basis of experimental data to assess the energy effects of variation of environmental factors.

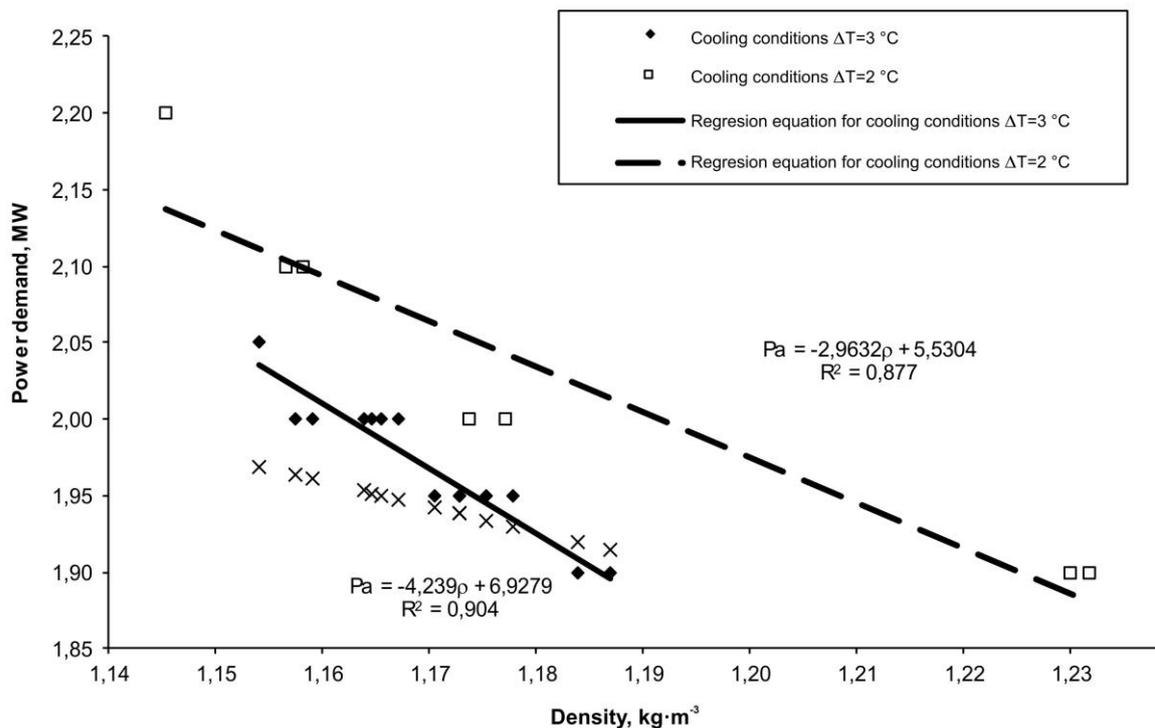

Fig. 1. Variance of power demand at a flow rate of 290.67 $\text{m}^3 \cdot \text{min}^{-1}$.

Plunger hydraulic machines. Typology, calculation principles and applications in mining

Sorin Vătavu^{a*}

^a University of Petrosani, 20 University street, 332006, Petrosani, Romania

Abstract

Hydraulic systems are either self-sustaining structures or structures incorporated into different machines, equipment or installations which have different uses, such as: the hydro-mechanical equipment of hydro-electric plants, mining machines and equipment, various machines and tools, construction machines, etc. These systems carry out the transport of the fluid, cool down equipment and, using a pressurised fluid, ensure the lubrication or the transfer of mechanical energy from one conducting element to another. The role of hydraulic energy generators, called pumps, is to supply the systems with the required flow and pressure depending on the destination. As far as the actuating / hydraulic transmission systems are concerned, the pump supplies the operation systems (hydraulic motor and operating device) with the necessary energy for the device to carry out an operation. Mining uses a large variety of operational and constructive types of pumps, piston / pistons machines being integrated in a large and diversified range, determined by the end use of the system, by the domains of the flow, pressure and the operating liquid. The paper deals with the generalities regarding constructive, operational and determination particularities of this type of hydraulic machines largely used in mining.

Keywords: Hydraulic System; Hhydraulic Machines; Reciprocating Pumps;

1. Introduction

Hydraulic systems may be used for various purposes and situations, the most important and widely met are:

- Actuation operating machineries;
- Elastic connection for the shafts;
- Lubrication;
- Fluid transportation.

The general progress reached in different fields of technics have highlighted the remarkable qualities of the hydraulic systems which may be found in wide range of applications, i.e. from agriculture and the low pressure domain to the technical domain with high pressures required to obtain artificial diamonds, over-conductive materials, respectively hydraulic jet stream cutting.

Independent on their destination, the structure of the hydraulic systems comprise sources which generate hydraulic energy, also called pumping assemblies: they are composed of pumps, motors to drive them and eventually monitoring and regulation systems for the hydraulic energy parameters, namely pressure and flow. Moreover, they comprise a hydraulic network composed of a wide range of devices (safety and regulatory elements for pressure and flow, distribution elements, etc.), pipes, tanks and conditioning elements.

Actuation systems comprise execution elements (hydraulic motors) which controllably move the working parts, while the consumers are connected at the end of the transport systems.

Figure 1 brings forward the block diagram of a fluid transport system while Figure 1,b deals with the structure of a hydraulic driving system.

* Corresponding author. Tel.: +4-072-178-3848
E-mail address: SorinVatavu@upet.ro

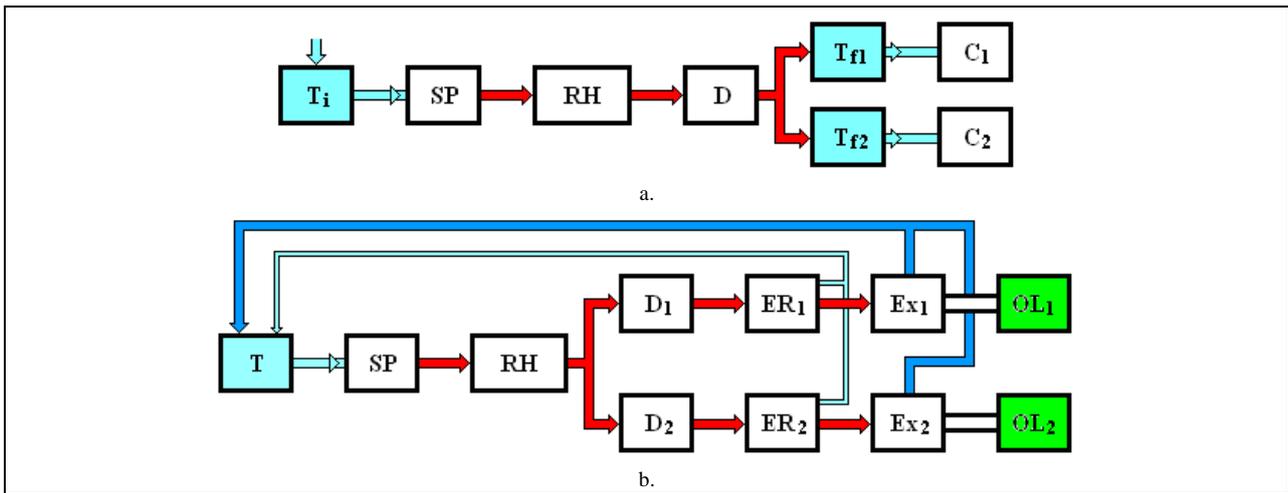

Figure 1. Block diagram: (a) hydraulic system used for transport; (b) actuating hydraulic system

2. Basic indicators for hydraulic actuation systems

The use of hydraulic actuation systems is explained by their flexibility which allows the construction of any machine or installation as well as the change and shift from a structure to another according to the changes which might appear.

The experience in the field concerning the use of hydraulic actuation systems to carry out the rotation movement in different domains, proves the necessity to continuously improve the volumetric systems in order to extend the usage range. These systems ensure the possibility to create a series of transmission reports which lead to the creation of momenta or increased speeds at the outlet shaft. In what the rotary hydraulic motors are concerned here are preferences for the ones with axial pistons (70%) and then for those with radial pistons (15%), the rest representing other types of units. The rapid extension of the servo-dynamic electro-hydraulic automatic regulation systems of the cinematic and dynamic parameters of the installations which are not fitted with a mechanic reducer must therefore be mentioned.

Taking into consideration a rectilinear movement it must be mentioned that linear hydraulic motors have been reconsidered, building therefore systems comprised by a single compact pumping assembly also called an electric-hydraulic linear amplifier. Some of the qualities of this equipment are: increased static rigidity in relation to the load, independent on the length of the track; increased response speed; superior reliability; constructive simplicity; lack of mechanic transformer; continuous speed regulation; the easy connection of the measurement and command electronic devices. The improvement of the dynamic qualities of such systems is carried out with the use of command equipment as well as through the improvement of the actuation system.

The development of the technique and the automation systems lead to the extension of the use of pressurised liquid for the operation, command and regulation of the movement of a series of mechanisms which are used for the construction of aircrafts, ships, machineries, agricultural machineries, etc.: namely from the most commonly used hydraulic crank to the huge hydraulic ship lifting installations; from the minuscule servo-valve used in spacecraft technics to the artificial intelligence robot; from the servo-commands of an automobile to those of a tip lorry or giant bucket wheel excavators; from small pressing installations to huge presses used for the synthesis of rough materials and last but not least from simple hydraulic props used to support mine works to complex installations for the actuation of modern mining machines; these are only some of the many applications offered by this large field of hydraulic automated actuations.

3. Fundamentals for piston hydraulic machines

As it has been previously mentioned, hydraulic machines are used in almost all human activity domains.

Pumps are generator type machines which turn mechanical energy into hydraulic energy, a characteristic specific to all hydraulic systems. Hydraulic motors are a characteristic component of driving hydraulic systems where they move the operating parts of the machines; the turbines of comprise by the hydro-energetic settings are also a part of this category and they drive the electricity generators.

Generally speaking, hydraulic pumps and motors may be found in categories which are established on different criteria. Any classification of hydraulic machineries being either relative or incomplete, the main classification criteria being thus the following: the operating principle, the geometry of its operating parts, its destination, the operating liquid, the actuating mechanism, the operating pressure, etc.

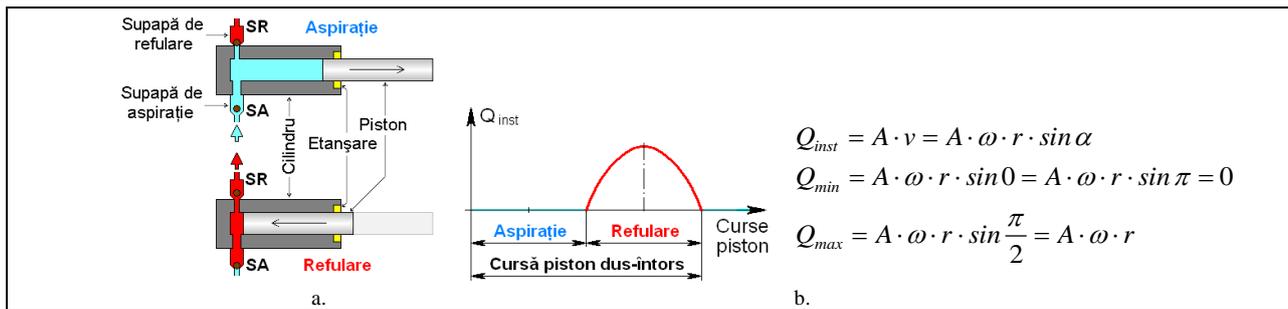

Figure 2. Simple effect piston pump (plunger): a. operating principle; b. the variation of instant flow

Taking into consideration the operating principle, the hydraulic machineries may be classified in:

- Kinetic machineries (centrifuge), also called turbo-machines which, for the conversion of mechanical and hydraulic energies, partially use the pressure energy resulted from the centrifugal forces and the kinetic energy;
- Volumetric machines, for which the energy conversion is generated by the periodic change of the liquid volume which fills in the variable space created by the moving operating parts (pistons, membranes, paddles, cogs, etc.).

The main classification criterion for volumetric machines takes into consideration the shape and the direction of movement of the machine has. According to the direction of movement determined by the closing parts, volumetric machines may be classified as follows: alternative, rotational, rotational-alternative and oscillating.

Piston hydraulic machines have a wide range of usage due to their distinct mechanical and hydraulic performances: from agricultural and building machines to mining machines and hydraulic jets, this type of machines may be encountered as pumps or motors. Nevertheless, the range of piston pumps is much more diverse and ample than the one of hydraulic motors which belong to the same family.

The liquid of the piston pump is pumped through a linear movement into the cylinder of the pump, while, successively and practically in sync, the suction and discharge valves open and close allowing therefore the access of the liquid into the immobilised cylinder of the pump respective the discharge of the liquid from the cylinder.

Piston pumps are classified according to different criteria: depending on the number of active sides of the piston (simple effect, double effect, differential); depending on the build of the piston (disk or plunger); depending on the place of the cylinder and the number of longitudinal axes (simplex, duplex, triplex, multiplex); depending on the pressure during the discharge (low, medium and respectively high pressure); depending on the actuation device (steam, internal combustion, electricity, etc.).

The pumping action of the simple effect pumps only occurs in one direction in which the piston moves (Also called a plunger), only its large surface being active as it is presented in Figure 2.a. When the plunger moves to the right the chamber of the cylinder expands creating thus in the increasing cavity a gap leading to the suction valve SV to be opened and the discharge one DV to be closed: liquid from the suction pipe will replace the free volume created by the movement of the plunger. When the plunger moves to the left it acts upon the liquid increasing its pressure and under the increased pressure the SV closes and the DV opens allowing the liquid to pass through the discharge valve respectively to the consumer. When the operation is repeated the pumping effect is thus obtained.

The pumped flow has an accentuated sinusoidal and pulsatory characteristic related to the active movement (discharge) of the piston: the shape of the instant flow characteristic depending on the movement is presented in Figure 2.b.

In line simple effect piston pumps are largely used, the triplex and pentaplex configuration being the most frequent one, i.e. pumps with 3 and respectively 5 cylinders with plungers placed in line, with lagged operation by 120° for triplex pumps and respectively 72° for five cylinder ones. This is then the result for having compacted in one casing three or five units as it is presented in figure 2, driven by a shaft which has a corresponding number of cranks.

In line plunger pumps are frequently met while operating with increased pressures but also for the hydraulic supply of actuation hydraulic systems found in coal longwall installations. There are also special constructions which contain more units with plungers driven according to a certain logic: for instance, the lubrication systems which are used for the general lubrication of the swivelling mechanisms of bucket wheel excavators.

Piston and block pumps of the swivelling cylinder represents a pumping assembly the operation of which is similar to the operation of plunger pumps. These pumps however lack the suction and discharge valves, and the closing of the operational volumes is carried out through the successive passing of the cylinders into the suction area respectively the discharge area: the pistons have therefore an alternative and rotational movement. These pumps are generally classified as follows:

- Considering the orientation of the plungers compared to the axis of the rotor they may be axial – Figures 3.a and b and radial – Figure 3.c;
- Considering the actuation organ which drives the plungers (cylinder casing – Figures 3.a and c, respectively the driving disk – Figure 3.b).

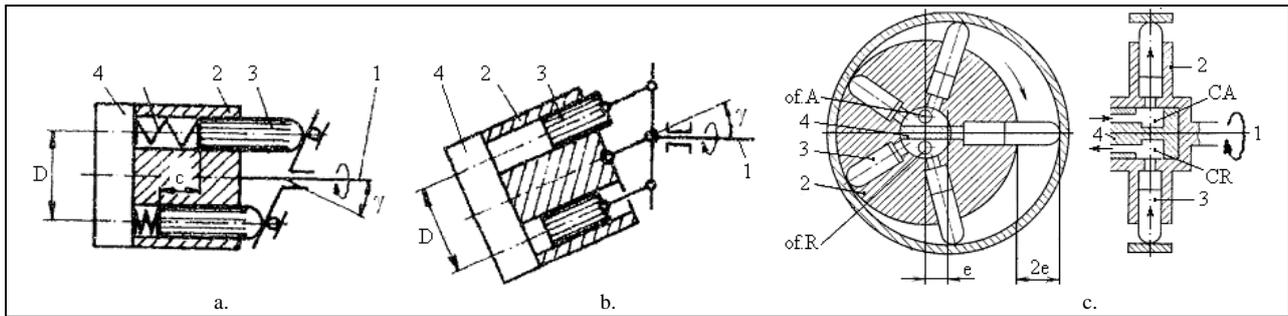

Figure 3. Plunger pumps: a, b. axial; c. radial.

The significance of the indicators presented in Figure 3 is the following: 1 –actuating shaft, 2 –cylinder block, 3 – plunger, 4 –distribution element, SI / DO - suction inlet, discharge outlet, SC / DC –suction / discharge chamber.

Axial and radial piston units are widely used in underground mining as well as surface mining as pumps and hydro-engines comprised by actuation systems for different machines and mining machineries: longwall advance feed cutter and loader units, loading machines, drills, excavators, etc. It must be also mentioned that pumps and hydro-engines are similarly built the difference being the distribution element.

4. Parameters and determination principles for simple action piston (plunger) hydraulic machines

Units having one or more plungers are volumetric machines the parameters of which have a geometric nature (geometric volume / cylinder capacity - V_g), hydraulic (effective power of the pump - P_{hp} , respectively that for driving the motor P_{hm} , with the flow parameters - Q and pressure - p) and mechanical (pump's driving power - P_{ap} , effective power of the motor P_{mm} with revolution parameters - n and torque - M).

Each movement of the plunger shall develop in the cylinder an active volume which has the following value:

$$V = A \cdot c = A \cdot 2r, \quad (1)$$

with one of the measurement units: $[cm^3/rev]$, $[dm^3/rev]$ or $[L/rev]$, respectively $[m^3/rev]$, the measurement unit being adequate to the geometric dimensions of the pump. This volume defines the geometric cylinder capacity, the main parameter of this volumetric machine being:

$$V_{gPP} = A \cdot c = \frac{\pi}{4} d^2 \cdot c \cdot z, \quad [volum/rot], \quad (2)$$

where d is the diameter; A - area, c - the sliding of the plunger and z is the number of plungers, r - the length of the crank.

The paper will next bring forward only plunger pumps which are used as components by the actuating hydraulic systems. As it has been previously mentioned, their hydraulic parameters are pressure and discharged flow.

The theoretical value of the discharged pressure p_{TP} is determined by the load S_{rezM} on the operating organ driven by the motor supplied by the geodesic height for the discharge network H_{gp-M} (the level difference between the discharge valve of the pump and the supply one of the motor) and the density of the operating liquid ρ :

$$p_{TP} = p(S_{rezM}) + \rho \cdot g \cdot H_{gp-M}, \quad (3)$$

expressed by one of the measurement units: MPa, bar or daN/cm^2 , respectively at or kgf/cm^2 .

The real value of the pressure is increased by the load losses Σh_{rP-M} on the connection network between the pump and the motor:

$$p_P = p(S_{rezM}) + \rho \cdot g (H_{gp-M} + \Sigma h_{rP-M}) = p(S_{rezM}) + \rho \cdot g \cdot H_{gp-M} + \Delta p_{P-M} = p_{TP} + \Delta p_{P-M}, \quad (4)$$

where Δp_{P-M} is the pressure loss on this route; for short or quasi-horizontal routes, $H_{gp-M} = 0$.

It is thus observed that the discharge pressure of the pump is determined by the load and the hydraulic resistance of the network.

The flow of the pump is in fact the quantity of liquid expressed in volume units or mass units in relation to time units, quantity which the pump takes over from the supply source and transports it towards the consumer. Usually, the volumetric flow is expressed in m^3/s , m^3/h or L/min .

If the reciprocating pump operates with speed n_a , then the plunger carries out n complete slides/time unit and shall discharge an average flow

$$Q_{TPP} = V_{gPP} \cdot n_a = \frac{\pi}{4} d^2 \cdot s \cdot z \cdot n_a, \quad [volume/time]; \quad (5)$$

which evidently emphasises a theoretical flow as it does not take into account the pump's losses considering the measure unit of the capacity and the revolution count, which is expressed in m^3/min or m^3/h , respectively L/min ; most often n is expressed in rev/min .

In order to have a real pumped flow then the relation takes into account the volumetric efficiency η_{vP} :

$$Q_{PP} = \eta_{vP} \cdot Q_{TPP} = Q_{TPP} - k_{vP} \cdot P_P, \tag{6}$$

where k_{vP} is the coefficient of volumetric losses at the pump; the volumetric efficiency depends on the value of the leaks interstices of the pump as well as on the nature of the transported liquid: thus, throughout the same interstice the losses are larger for liquids which have more reduced viscosities. The usual values of η_v which are taken into consideration for the determination of the real flow of a reciprocating pump are comprised between 0.8 and 0.98. the volumetric efficiency does not depend only on the losses through interstices but also on the percentage of filling the free volume generated by the piston during its suction movement: therefore, while using viscous liquid, if the speed of the pump is not correlated to the viscosity, the filling of the space is incompletely carried out with blank spaces into the mass of liquid which obviously deteriorates the volumetric efficiency of the pump.

As it has been previously mentioned (Figure 2.b) the flow of the plunger pumps has a pulsatory characteristic while the characteristic of the instant flow is sinusoidal $Q_i = f(\sin \varphi_i)$, a phenomenon which represents one of the main disadvantages of these type of pumps in comparison to the centrifugal pumps the flow of which is continuous: the coefficient of pulsation / the degree of non-uniformity of the flow of piston pumps is the parameter which characterises this pulsation and it is:

$$\delta_Q = \frac{Q_{max} - Q_{min}}{Q_{med}}, \tag{7}$$

where Q_{max} is the instant maximum flow, Q_{min} – the instant minimum flow and Q_{avg} – is the average flow of the pump which may be determined using relation (5):

$$Q_{med} = V_{gPP} \cdot n_a = A \cdot \omega \cdot r / \pi. \tag{8}$$

The pulsation coefficient of the flow depends thus on the type of reciprocating pump because even if the numerator of relation (7) would remain constant the denominator is changed through the cylinder capacity V_{gPP} .

Therefore, for the simple effect simplex pump (Figure 2.a) taking into account the diagram in Figure 2.b the following may be observed: $Q_{max} = A \cdot \omega \cdot r \cdot \sin \pi / 2 = A \cdot \omega \cdot r$, $Q_{min} = 0$, while $V_{gPP} = A \cdot c$ and it results the coefficient of pulsation $\delta_Q = \pi$. There is, though, an analogic procedure for the simple effect duplex pump, the only difference being that for such a type the flow is delivered by two plungers with a delayed operation of 180°: the flows Q_{max} and Q_{min} have the same values, but $V_{gPP} = 2A \cdot c$ resulting in the following value $\delta_Q = \pi / 2$

Considering all what has been mentioned before it results that the non-uniformity degree decreases as the number of cylinder increases: pumps with more plungers with delayed operational phases and equal angles carry out a rather good uniformity of the flow. The pulsation of the flow leads to a pulsation of pressure as well producing a phenomenon of fatigue of the pipes and the sealing elements and deteriorates the dynamic operation mode of the hydraulic motors, reducing their lifespan.

Such a pump is used to supply the hydraulic supports used in coal mines. In Jiu Valley in order to supply the open circuit individual hydraulic roof supports, the main hydraulic pumping assembly ACH 40/200 manufactured by S.C. UPSRUEEM S.A. of Petroșani is used: this have a three cylinder horizontal plunger pump which is able to produce a 40 L/min flow at a maximum pressure of 20 MPa, the pressure regulation domain being between 5 and 16 MPa.

The pumping installation is simple, being foreseen with only one safety valve SV and an accumulator A, without any possibility to regulate the flow, it is installed on the storage tank ST which contains an already prepared oil in water solution. It must be mentioned that the pneumatic-hydraulic accumulator A ensures the attenuation of the pulsations of the flow of the pump as well as the hydraulic shocks in the installation.

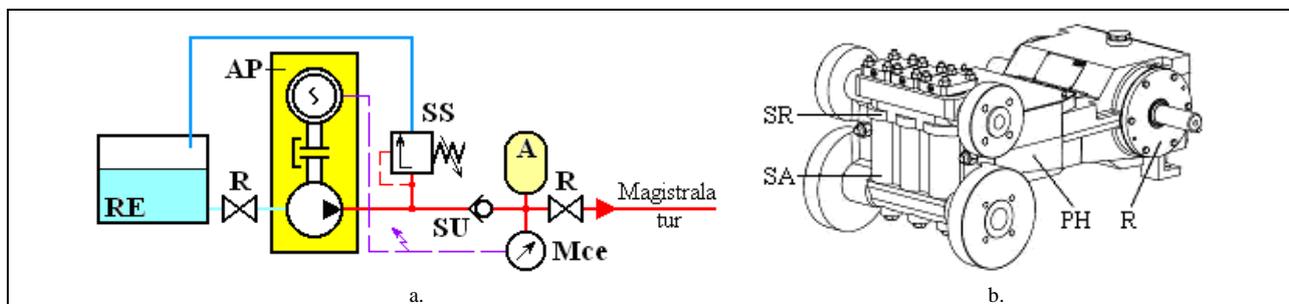

Figure 4. ACH 40/200 pumping assembly: a. hydraulic diagram; b. basic structure of the three plunger pump: PH - pump, R - reducer, SV – suction valves, DV – discharge valves.

The main technical characteristics of the simple action triplex pump are: the cylinder capacity $\approx 103 \text{ cm}^3/\text{rev}$; the diameter / the sliding of the plunger 25 mm / 70 mm; the revolution speed which drives the shaft $\approx 415 \text{ rev}/\text{min}$; the nominal power of the electric motor 30(22) kW.

Based on the calculation principles of the plunger pumps and the nominal characteristics mentioned before the geometrical cylinder capacity of the pump used by the ACH 40/200 pumping system, the theoretical discharge flow and the actuating power may be determined:

- The *cylinder capacity* is determined with the help of relation (2):

$$V_{g3P} = \frac{\pi}{4} d^2 \cdot c \cdot z \cong 2,355 d^2 \cdot c = 2,355 (2,5\text{cm})^2 (7\text{cm}) = 103,03\text{cm}^3 / \text{rot} ,$$

- The *theoretical flow* (i.e. the flow for a null load) is determined using relation (5)

$$Q_{T3P} = V_{g3P} \cdot n_a = 103,03 \frac{\text{cm}^3}{\text{rot}} 415 \frac{\text{rot}}{\text{min}} = 42757,45 \frac{\text{cm}^3}{\text{min}} \cong 42,76\text{L} / \text{min} = 0,71 \cdot 10^{-3} \text{m}^3 / \text{s} ,$$

- Usually, the flow comprised by the characteristics corresponds to the nominal pressure: it allows thus for the determination of the *coefficient of volumetric losses* using relation (6):

$$k_{vP} = \frac{Q_{T3P} - Q_{nP}}{P_{nP}} = \frac{(42,76 - 40)\text{L} / \text{min}}{200\text{bar}} = 13,8 \cdot 10^{-3} \frac{\text{L} / \text{min}}{\text{bar}} = 0,28 \cdot 10^{-11} \text{m}^3 / (\text{Pa} \cdot \text{s}) ,$$

- The *volumetric efficiency* for a nominal pressure is given by relation (6):

$$\eta_{vP} = 1 - \frac{k_{vP} \cdot P_P}{Q_{TP}} = 1 - 13,8 \cdot 10^{-3} \frac{\text{L} / \text{min}}{\text{bar}} 200\text{bar} / 42,76\text{L} / \text{min} = 0,935 ,$$

- The *power necessary to drive* the pump is determined using the following relation:

$$P_{aP} = \frac{P_{nP}}{\eta_{vP}} = \frac{P_{nP} \cdot Q_{nP}}{600 \eta_{vP}} = \frac{200\text{bar} \cdot 40\text{L} / \text{min}}{600 \cdot 0,935} = 14,26\text{kW} .$$

As it may be observed, the values determined confirm the parameters specified by the manufacturer: the power of the actuating electromotor may seem too high, but there is the need to have a backup due to the mechanical-hydraulic efficiency of the pump and the efficiency of the connecting transmission.

5. Conclusions

Hydraulic plunger machines are widely used in various fields of activity. Due to their qualities and performances they are also recommended to be used in mining both in liquid transport systems as well as in systems which actuate the operating parts of specific machines and equipment.

Investment portfolio management based on the study of the competitiveness of joint-stock companies

Abstract

Investing into stock market effectively is possible only when based on scientifically sound methods for analysing investment instruments. The purpose of this study is to develop a method for selecting financial instruments for the formation of an investment portfolio of securities. The proposed method is based on the analysis of the competitiveness of joint-stock companies by identifying the market's capacity, the share price and the company's share in of the stock market turnover. Approbation of the developed method made it possible to identify investment-attractive shares quoted on the Warsaw Stock Exchange. The proposed method has potential to become a scientific basis for effective long-term investment on the stock market.

Keywords: investment portfolio; stock market; competitiveness of joint-stock companies; research method; investment portfolio management

1. Introduction

Respective problems on the Polish market of goods and services make natural persons and legal entities seek new investment opportunities. The securities market may be an attractive place to invest temporarily available funds. The main requirement here is a balanced investment policy based on the use of scientific research methods.

According to the analysed literature, the problem of selecting financial instruments for the effective construction of the investment portfolio plays an increasingly important role in scientific circles.

Scientists, such as the following, among others, are trying to solve this problem:

– T. Węgrzyn in his article “Selection of companies for the portfolio using financial ratios and their relative growth rate – analysis in 2001–2010” [Węgrzyn, 2013]. The main advantage of the proposed method is the use of the relative growth rate; however, the number of analysed indicators, which amount to 26 in four different categories, i.e. profitability, liquidity, management efficiency and debt, makes the application of the method in practice very complicated;

– M. Tyimiński and R. Zawiślak in the article “Bi-criterial choice of financial instruments for effective construction and optimization of portfolio on the capital market” [Tyimiński and Zawiślak, 2008], which presents the concept of optimisation of the investment portfolio, but do not solve the problem of construction of such a portfolio and the method of selection of companies;

– B. Jabłoński in his article “The role of choice of groups of shares for the investment portfolio on the example of the Warsaw Stock Exchange in 1991–2009” [Jabłoński, 2010]. As the title suggests, the main subject of this study are only the so-called dividend companies. Such an approach is quite interesting, however, it does not make it possible to calculate other factors, such as price changes, market capacity and the company's market share.

It is worth noting that in the above articles, as well as in other papers, all approaches and attempts to solve the problem of selecting companies for the investment portfolio can be divided into methods based on technical analysis [Schwager, 1999; Murphy, 1999] or fundamental analysis [Bulkowski and Thomas, 2012; Ritchie, 1996; Orlova, 2014].

E-mail address: a.stopochkin@po.opole.pl.

The method proposed in the study attempts to combine these two research methods. The aim of the paper is to develop a scientific method of selecting financial instruments to build an effective portfolio of securities.

The subject of the study are shares of the companies in the banking sector listed on the Warsaw Stock Exchange. The above study is based on the analysis of statistical data from the Warsaw Stock Exchange (Retrieved from <https://www.gpw.pl>) and data available through the MT4 trading platform of the Polish Brokerage House TMS [Retrieved from <https://www.tms.pl>]. The period of the analysis is 1 January 2016–1 October 2017.

2. Method of company competitiveness assessment

The method of company competitiveness assessment proposed in this paper is based on an analysis of the attractiveness of financial investment instruments, namely shares. The proposed method is based on the analysis of the company's share in the securities market (which is both the result of the fundamental analysis – the answer to the question whether the company is a subject of interest of long-term investors – and the result of the technical analysis – since historical data on prices per share speaks of the impossibility of a transaction, which discourages traders from watching it and searching for places to buy or sell it), prices per share (technical analysis – in accordance with the main postulate of the technical analysis theory, the price of an investment instrument is the summation of all factors, including fundamental ones [Bulkowski and Thomas, 2012; Ritchie, 1996]) and market capacity (market demand). It is worth noting that the company's market share depends on the interest of investors and other capital market participants in trading the company's shares. This creates a situation of competition and rivalry in obtaining additional money for the development of the company by means of the securities market. However, this share depends not only on the activity of the company and the results of its own operations, but also on the capacity of the market itself (the amount of capital on the market, the number of large and small players and their activity in a given sector of the securities market).

The first stage (according to the proposed method) consists of finding the largest companies on the stock exchange, which have a significant market value in the sector of interest to the investor. All the data required for the analysis and establishing the investment policy in the market will be divided into basic and extended data. Basic data include: company name and its abbreviated form, date of listing on the stock exchange, number of shares issued. It is proposed to use as extended data the market and book value of the company, P/B ratio (price to book value), P/E ratio (price to earnings) and dividend rate.

According to the proposed method, the best shares for long-term investors are those of companies with a lower P/B ratio. Shares of companies with a P/B ratio below 1.5 may be useful in the investment portfolio. However, for the analysis of a given sector on the securities market, shares of companies with a higher P/B ratio may be taken into account due to their popularity among other investors.

Another indicator that should be used in the analysis of investment instruments on the securities market is the P/E ratio, showing the number of years needed until the profit generated by the company is equal to the invested capital.

Therefore, according to the presented theory, a company with a higher P/E ratio has too high expectations on the part of investors and a correspondingly higher price per share. On the other hand, shares of the company with a lower P/E ratio have more opportunities for potential price increase. The study proposes that companies with a P/E ratio above 20 should be eliminated from the investor's portfolio as such companies may have low operating income levels.

The dividend rate in this method is used as an additional indicator that may influence the investor's decision, however, it does not constitute its main factor.

The second stage of the study is to determine the point at which the market currently is: upper turning point, slowdown, recession, lower turning point, recovery, expansion. The answer to this question gives an opportunity to find the so-called big players on the market and to enter a new trend with them. Each cycle can be divided into smaller parts. Adjust your investment policy and find specific market entry points that are in line with the market trends and technical analysis principles.

Third stage of the study. The results of the third phase of the proposed research method form the basis for a final decision on the shares that are to be included in the investor's portfolio. The proposed method is based on modifications of the rules proposed by J. Bazarnik, T. Grabiński, E. Kąciak, S. Mynarski, A. Sagan on identifying the effects of price change, market capacity and the company's market share when conducting marketing research.

Therefore, the main formula to calculate the overall effect of the change in price per share, the market capacity and the market share of the company is as follows:

$$S_i = Q * U_i * P_i \quad (1)$$

where: S_i – modified total value of shares turnover selected for the analysis of the company on the stock exchange, in monetary units; Q – market capacity – modified share turnover of all companies on the stock exchange selected for the analysis, in contractual units; U_i – share of a given joint-stock company in the total turnover of companies on the stock exchange selected for the analysis, %; P_i – modified price of the company's shares for the analysed period.

Since each company has its own price and the influence of each company on overall turnover differs, an additional unit of measurement, namely the notional number of shares, is necessary when calculating the company's market share. Under such assumption, the formula for calculating the overall market capacity is as follows:

$$Q = \frac{\sum (Q_i * P_i)}{1000} \quad (2)$$

where: Q_i – turnover of the company selected for the analysis in the analysed period, number of shares.

The share of the company in the total turnover of the companies selected for the analysis is proposed to be calculated as follows:

$$U_i = \frac{Q_i * P_i}{Q} \quad (3)$$

To calculate the share price for the analysed period (P_i), the method proposes to use four prices – the opening price, the lowest price in a given period, the highest price in a given period, and the closing price. Let's assume that these prices have equal weight. Therefore:

$$P_i = \frac{1}{4} P_{otw} + \frac{1}{4} P_{nn} + \frac{1}{4} P_{nw} + \frac{1}{4} P_{zam} \quad (4)$$

where: P_{otw} – share price of the company, which is the opening price in the analysed period; P_{nn} – the lowest share price of the company in the analysed period; P_{nw} – the highest share price of the company in the analysed period; P_{zam} – share price of the company, which is the closing price in the analysed period.

In order to identify particular spheres of influence of other factors, namely changes in the market capacity, the company's share in trading on the stock exchange and changes in the share prices of individual companies, an effective chain based approach will be applied. This method is based on decomposition using an incremental form with the following formula

$$\Delta S = S_1 - S_0 = Q_i * U_i * P_i - Q_0 * U_0 * P_0. \quad (5)$$

Decomposition is carried out in a strictly defined order using substitutions:

$$\begin{aligned} \Delta S_i = & Q_i * U_i * (P_i - P_0) && \text{Effect of price change.} \\ & + \\ & Q_i * P_0 * (U_i * U_0) && \text{Effect of the change in the shareholding} \\ & + \\ & U_0 * P_0 * (Q_i - Q_0) && \text{Effect of change in demand} \end{aligned} \quad (6)$$

Companies with the highest positive meanings of ΔS_i (sum of effect of a given company in the analysed period) may be added to the investor's portfolio. The end result is necessary because the increase of one effect may happen at the expense of the decrease of the other and vice versa.

3. Method of company competitiveness assessment

First stage of the study. Assuming that the investor considers investing in shares of companies listed on the Warsaw Stock Exchange, and is interested in the banking sector for the transaction, the main companies in such a case would be those listed in Table 1. The companies in Table 1 are presented according to their market value. The most expensive company is PKOBP; its market value is over PLN 45.625 million, and it has been listed since 2004. The oldest companies selected for the analysis are MBANK and MILLENNIUM (listed since 1992). Their market value is PLN 18,621.18 million and PLN 9,037.72 million, while the P/B ratio is 1.36 and 1.23, respectively.

The youngest companies are ALIOR and GETINNOBLE (listed since the end of 2012). Their market value is PLN 9,113.09 million and PLN 1,343.53 million, while their P/B ratio is 1.43 and 0.27, respectively. In accordance with the proposed theory, there is a strong undervaluation of GETINNOBLE's shares on the market. This suggests the investment attractiveness of such shares. BGZBNPP has to be removed from the investment portfolio because of the P/E ratio, which is higher than standard value (20) and amounts to 40.40.

Second stage of the study. In accordance with the results of the calculations presented in Figure 1, the market was at its lowest turning point at the end of 2016.

The total turnover of the companies on the stock exchange selected for the analysis amounted to PLN 36.75 million and 192.46 thousand shares, with the nearest upper turning point showing the turnover of about PLN 66.13 million and 341.24 thousand shares. The difference between the discussed lower and upper points on the market is PLN 44.87 million (or 49%) and 148.78 thousand shares (or 56%). The analysis shows that the last analysed period (1 October 2017) is also attractive in terms of investment activity oriented towards a longer perspective.

Table 1. Basic and extended data on operations of companies selected for the analysis*

#	Basic data				Extended data					
	Name	Abbreviation	Listed since	Number of issued shares	Market value, PLN million	Book value, PLN million	P/B ratio	P/E ratio	Dividend rate, %	
1	2	3	4	5	6	7	8	9	10	
1	PKOBP	PKO	Oct. 2004	1,250,000,000	45,625.00	34,352.00	1.33	16.60	0.00

Fig. 1. Turnover of shares of companies on the Warsaw Stock Exchange selected for the analysis

At this stage of the analysis, the study periods were established, namely: T0 – starting point (1 January 2016); T1 – first study period (1 January – 1 December 2016); T2 – second study period (1 January 2016 – 1 October 2017).

Third stage of the study. The calculations of market shares of respective companies selected for the analysis are presented in Table 2.

Table 2. The share of companies in the turnover on the stock exchange in accordance with the proposed method of company competitiveness assessment*

Index	Name of the bank	Study period			Accrual (Δ)	
		T0	T1	T2	T1 - T0	T2 - T0
Share (U_i), %	PKOBP	2.34	1.80	2.26	-0.54	-0.09
	BZWBK	33.50	38.07	28.08	4.57	-5.42
	PEKAO	15.98	9.37	4.73	-6.61	-11.25
	INGBSK	3.48	2.77	7.17	-0.72	3.69
	MBANK	36.19	41.76	48.49	5.57	12.30
	ALIOR	4.25	2.96	7.20	-1.29	2.95
	HANDLOWY	4.17	2.77	1.96	-1.40	-2.21
	MILLENNIUM	0.09	0.04	0.11	-0.05	0.02
	GETINNOBLE	0.0008	0.0019	0.0063	0.00	0.01

Source: own study based on official data of the Warsaw Stock Exchange [Retrieved from <https://www.gpw.pl>] and data available through the MT4 trading platform of the Polish Brokerage House TMS [Retrieved from <https://www.tms.pl>]

According to the results, the largest market share is held by MBANK – 48.49% of transactions in the T2 period, which at 12.30 p.p. is more than at the starting point. PEKAO (share decreased by 11.25 p.p.) and BZWBK (share decreased by 5.42 p.p.) lost the most shares in the analysed period. INGBSK and ALIOR gained increasing investor confidence. HANDLOWY occupies the third place, which corresponds to the change of market share by 2.21 p.p. Therefore, from the point of view of a potential investor in the T1 period, it is worth noting MBANK and BZWBK companies. Investing in PEKAO would suggest significant losses.

The company with the highest price per share, according to calculations, is MBANK with price per one share of PLN 437.13 (Tables 2 and 3). For the analysed period T2 (1 January 2016–1 October 2017), the share price of this company increased by PLN 137.69. At this stage of the analysis, the increase of $\Delta(T1-T0)$ should be noted. From the investor's point of view, the following companies are worth noting: BZWBK, INGBSK and MBANK.

Table 4 presents the results of calculation of the turnover of companies on the stock exchange in accordance with the proposed method of company competitiveness assessment. According to the data, in the T1 period in relation to the starting point T0 the highest turnover was lost by PEKAO (78.18% of turnover). The turnover of HANDLOWY and BZWBK decreased by 63.95% and 10.24%, respectively.

The analysis of turnover of the companies selected for the analysis confirms the results of the previous stages and indicates the advisability of investing capital in the shares of BZWBK and MBANK in the period T1. However, the final decision regarding the investment portfolio can be made after the calculation of individual effects of changes in demand, prices per share and market shares of the company for companies. The results of these calculations are presented in Table 5.

Table 5. Respective effects of changes in competitiveness of companies on the market

Name of the bank	Demand effect		Share effect		Price effect	
	T1	T2	T1	T2	T1	T2

GETINNOBLE	-0.001	-0.033	0.21	84.46	0.49	174.57

Source: own study based on official data of the Warsaw Stock Exchange [Retrieved from <https://www.gpw.pl>] and data available through the MT4 trading platform of the Polish Brokerage House TMS [Retrieved from <https://www.tms.pl>]

According to the results of the study, almost all companies lost from the change in market capacity in the analysed periods T1 and T2. This indicates a decrease in the number of investors and capital on the Polish securities market in the banking sector.

Almost all companies incurred losses on the share effect in the specified T1 study period. Only MBANK, BZWBK and GETINNOBLE were able to achieve a positive value of the share effect in the T1 period. According to calculations, the negative price effect in the T1 period can be observed in the case of two companies – PEKAO and ALIOR. It shows that, assuming that market shares can be maintained and that market capacity remains unchanged, these companies would lose the confidence of investors in any case and there is currently insufficient interest in them.

Let's try to determine the total competitiveness effect of companies on the market. Calculations show that only four companies in the T1 period can be satisfied, namely MBANK, BZWBK, INGBSK and GETINNOBLE. Despite the fact that the overall turnover on the stock exchange decreased, they managed to achieve a positive total effect of the change in turnover, thanks to maintaining the interest of investors in the operations of companies and increasing their shares, which resulted in an increase in the prices of their shares.

If the conducted study on historical data of changes of share price of companies selected for investment in the T1 period indicates that the effectiveness of the investment portfolio meets the investor's requirements, then in the period T2 companies MBANK, BZWBK, INGBSK, ALIOR, PKOBP, MILLENIUM, GETINNOBLE will be worthy of interest in terms of investment.

Due to the P/B ratio, adding BZWBK (1.74) and INGBSK (2.23) to the portfolio of shares may increase the risk for the investor, but it may also increase the profitability of the portfolio (the price may continue to rise as the profitability of operating activities of these companies increases). The companies with the highest risk in the T2 period, according to the results of the analysis, are HANDLOWY and PEKAO (in the T2 period, the negative meaning of the total effect is greater than in the T1 period).

4. Summary

Based on the obtained research results, as of 1 October 2017, the shares of such companies as the following have been attractive for purchase in order to invest on the stock exchange: MBANK, BZWBK, INGBSK, ALIOR, PKOBP, MILLENIUM, GETINNOBLE.

The method of analysis of companies competitiveness presented in the study may become an effective tool for long-term investment on the securities market. This method is based on three basic indicators: total turnover on the stock exchange of selected companies, the company's market share and the price per share. Practical application of the described method may increase the attractiveness of investing in securities markets.

Abstract

This research aims to test the loyalty of tourists who visit tourism village as one of the community based tourism. The loyalty model that is proposed explores the relationship between attractiveness, trust, service quality, positive attitude, intention to visit, and intention to recommend. This research uses the respondent survey of domestic and foreign tourists who visit community based tourism tourist village in the Province of Daerah Istimewa Yogyakarta (DIY), Indonesia. The sampling technique is using purposive sampling with the respondent criteria of tourists who are motivated to visit because of special intention. The number of respondent is 400 people. The data analysis technique is using Structural Equation Modeling (SEM). This research result explains that the research model is accepted, this means that there is a relationship between attractiveness, trust, service quality, positive attitude, intention to visit and intention to recommend. This research result gives a direction for the manager of tourism village about the increased tourist loyalty through infrastructure improvement either in tourism location or home stay provided by the community, ease of access, security, hospitality, and professional tour guide. This research has originality such as the setting of tourism village based community and analyze tourists loyalty with the antecedent of trust and attractiveness which mediated by service quality and positive attitude that is different with tourist loyalty model that have been researched before.

Keywords: *trust; attractiveness; quality; attitude; loyalty.*

1. Introduction

Community based tourism (CBT) in the context of sustainability tourism development has a very important role. CBT can empower the community through a sustainable tourism management and give priority to the community as central position in the management of tourism are. CBT is the management of community-based tourism that provide many opportunities to the empowerment of local community, especially in developing country (Sugandini et al., 2017b; Diharto et al., 2018; Wróblewski, et al., 2017, Kurowska-Pysz, 2015). The community involvement in the management of these tourism areas will also give an important role for the community in maintaining and developing tourism village to be sustainable and building a strong regional economic activity for the sustainability of household economy and the welfare of the community itself (Feriyanto, 2016a; Feriyanto, 2016b).

The research about CBT is important to be done because: (1) the measurement of CBT impact is still difficult to observe, because it is indirect and intangible. The economic impacts are easier to be analyzed, but the social and environmental impacts are very difficult to be measured; (2) local issues has a direct impact on tourism experience, a bad experience with local community can bring a hostility toward tourists, so understand the positive attitude of tourists toward a CBT can show an alignment that occurs between local community and social climate which will have an impact on tourism benefits and there will be no victim of the existence of CBT (Wahab and Pigram, 1997); (3) trust is usually studied only for electronic-tourism context (Nguyen et al., 2011), e-loyalty, online tourism and information technology related to tourism (Diharto, et al., 2018). This research studies about trust in relation to trust toward

* Corresponding author.

E-mail address: sebacat@zim.pcz.czest.pl

community-based tourism destination sites. Trust toward local community, natural environment, infrastructure, facilities, and special events or festival become an important factor to be considered in this research.

This research tests the impact of CBT from the success of CBT. The success of CBT can be seen from the increasing loyalty of tourists towards community-based tourism destination. The loyalty of this research is seen from the intention to visit community-based tourism and intention to recommend the tourism to other potential tourists/travelers. Loyalty becomes important to be analyzed because if the loyalty program is managed properly, it is very possible to manage and control the buying behavior of the tourists (Sugandini et al, 2018d; Štefko, et al., 2017). Loyalty also become an important contributor in gaining profitability (Darnell and Johnson, 2001; Hsu et al., 2008, Simarmata, et al., 2017).

This research was conducted to test the model of tourist loyalty in CBT in the Province of DIY. CBT that is analyzed is a special interest type of tourism, such as home stay, nature tourism, and live in tourism village. Some tourism village in DIY offer educational, cultural, and natural tourism for their visitor. These tourism villages also offer traditional game facilities such as *enggrang*, *engklek*, *dakon*, *gobaksodor*, and others, which can be played in that location. Tourism village in DIY also has a very beautiful scenery, fresh air, and a clear and well-maintained river. There are also home stay as a place to stay for the tourists that equipped with a restaurant provided by the community. Tourism villages in DIY are fully managed by the community, empowered by the community, and it is include in community-based tourism (CBT). This research is conducted based on the approach of social exchange theory, because in CBT there is a high involvement between community and tourists, so the high involvement will create social exchange between the two. Social exchange theory can show a framework of reference where the theories are built based on several assumption about human and relationship nature. This theory can be used to explain the use relationship between community and tourists in community-based tourism destination, because there is a very strong interaction between tourists, manager, and community (Sugandini et al., 2018c; Diharto, et al., 2018).

2. Literature review

2.1. Social Exchange Theory

Social exchange theory is a general sociological theory (Ward and Berno, 2011), which can be applied on the exchange of tourism resource, travel experience, and social interaction between tourism stakeholders. This theory sees interpersonal relations as a commercial transaction. Social exchange theory is rooted in economic theory, social psychology, and sociology. Social exchange theory is that every individual are voluntarily enters and stays in social relationship as long as the relationship is satisfying, in terms of rewards and costs.

2.2. Attractiveness, service quality and positive attitude

Ajzen (1991) defined attitude toward behavior as “how far a person has a favorable or unfavorable situation of a product and service”. Several factors affect tourists’ attitude toward tourism destination can be classified into two major determinants. According to Middleton and Fyall (2009), several factors that affect tourists’ attitude is the attraction of tourism destination such as nature condition, culture or entertainment events, the availability of major and supporting facilities in the tourism destination, accessibility, image, price level, and the quality of destination and promotion from tourism organization to introduce a tourism destination (Sugandini et al, 2018a; Muafi, 2017; Roostika and Muafi, 2014).

Besides affecting attitudes, attractiveness also has a positive influence toward destination quality (Al-Ababneh, 2013; Roostika and Muafi, 2014). Perceived service quality of a destination includes a good souvenir, a restaurant, and a comfortable lodging. A person who perceived attractiveness of a good tourism destination will affect the perceived service quality of a destination, and it will subsequently affect the positive attitude (Sugandini and Djawoto, 2018).

H1: Attractiveness has a significant positive impact towards perceived service quality

H2: Attractiveness has a significant positive impact toward positive attitude

H3: Perceived Service quality has a significant positive impact toward positive attitude

2.3. Trust, service quality, and positive attitude

Singh and Sirdeshmuskh (2000; Garbarino and Johnson, 1999), stated that if the customer does not trust the company, the customer will not place his first purchase. Trust is an important determinant factor of attitude formation and loyalty (Chinomona, 2016). According to the commitment-trust theory (Morgan and Hunt, 1994), trust is the main variable in the development of a lasting desire to maintain a long-term relationship with brand (Nguyen et al., 2011). When consumers have a level of trust, they will be more likely to have a positive attitude with the service (Kim, et. al., 2008; Muafi, 2017). Hsiao, et al. (2010) shows that trust is positively affect attitude and subsequently, intention to purchase.

H4: Trust has a significant positive impact toward perceived service quality

2.4. Positive attitude and loyalty

The loyalty toward service provider is considered a major consequences from positive attitude (Susilowati and Sugandini, 2018; Yu and Dean, 2001). Tourists' loyalty to a destination is showed by their intentions to revisit the destination and their willingness to recommend it (Oppermann, 2000). Recommendations by previous visits can be used as a credible source of information for potential tourists. Recommendation to others through word-of-mouth is a type of information that is needed by people who will visit a destination. The proposed hypothesis is as follows:

H5: Positive attitude has a significant positive impact toward intention to visit

H6: Positive attitude has a significant positive impact toward intention to recommend.

3. Research method

This research is a survey research. Respondents that is used in this research is tourists who is motivate to visit natural tourism and special interest destination (tourism village and live in it). These respondents are considered the most appropriate respondents in predicting tourist loyalty of CBT. The population of this research is tourists who visit community-based tourism destination in the Province of DIY, such as tourism village of Kembangarum, Kasongan, Bleberan, Kampong cyber, and Nglingo. The number of respondents are 500 people. The response rate is about 80%, so there is 400 people. The data analysis technique is using Structural Equation Modeling. The direct influence is observed from standardized regression weights with comparable significance test of CR (Critical Ratio) value that equals to t test values (Sugandini et al, 2018a; Muafi, 2017). The significance assessment is based on the probability (p) value and the limit of significance that is used is the p value $\leq 0,05$. The test toward the model is developed with various criteria of Goodness of Fit, such as Chi-square, probability, RMSEA, GFI, and TLI (Hair et al., 1998). This research is using the data collected from 400 CBT tourists in DIY. The result of confirmatory factor analysis explained that the six construct which is: attractiveness, trust, service quality, positive attitude, intention to visit, and intention to recommend are consist of 22 question items which are stated to have a good validity because they have standardized factor loadings ≥ 0.3 and reliable, which shows from the value of *construct reliability* over 0,7 and the recommended *variance extracted* is $\geq 0,50$ (Hair et al., 1998).

4. Research result

The majority of respondents are man, which is about 65%. Special interest tourism are more favored by men because there are tracking facilities and others that are also very popular, such as river, waterfalls, and mountain climbing. The age of the respondents are mostly ≤ 20 years old, which is about 51%, tourists with educational background of junior high school and senior high school is about 56%, tourists with the background job of student and college student is about (43%), because the destination in this tourism village are mostly visited by student and college student as the place to live in and outbound. The CBT is special interest, which is tourism village and live in (stays in the village). The test result of consumer loyalty SEM model using AMOS can be seen on Figure 1. The result of model evaluation explain that the criteria of goodness of Fit which is; cmin/DF, probability, RMSEA, GFI, TLI and CFI are fulfilled. It can be explained that the model can be accepted. In order to test the causal relationship between attractiveness, trust, service quality, positive attitude, intention to visit, and intention to recommend, it is presented a path coefficient that shows the causal relationship between those variables. The hypothesis test is conducted by comparing the probability (p) value. It is consider significant if the p value is ≤ 0.05 . By using the criteria, it can be seen that all paths are significant, so all hypothesis are accepted.

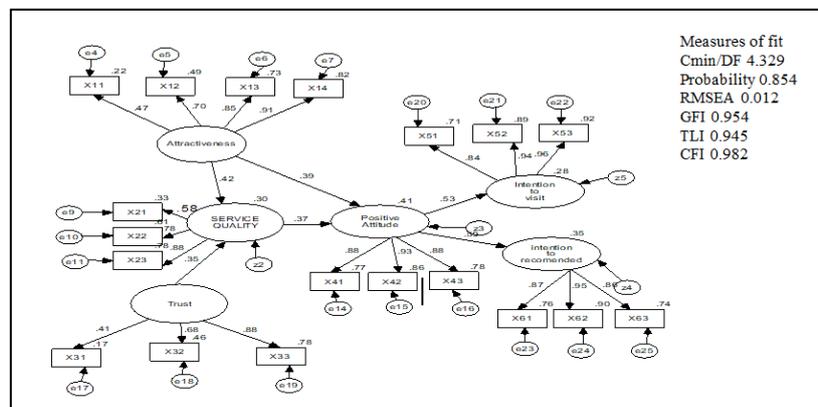

Fig 1: The Test Result of Model

5. Discussion

This research result explained that the structural loyalty model in the CBT is fit, which means that the loyalty model can be explained by attractiveness, trust, service quality, positive attitude, intention to visit, and intention to recommend. The influence of attractiveness toward loyalty (intention to visit and intention to recommend) in this research supported the research findings from Middleton and Fyall (2009); Horner and Swarbrooke (2007). Tourists who perceive that the tourism village has a high attractiveness will affect perceived service quality, positive attitude, and loyalty (Sugandini, 2003; Roostika and Muafi, 2014). Tourists who visit the tourism village will feel that the natural scenery in the tourism village in DIY is very beautiful, fresh, and natural. This tourism village also has easy access and there is a homestay as a place for the tourists to stay. This tourism village has a professional tour guide who can speak foreign language quite well. The influence of trust toward perceived service quality is also supported, which means that tourists who visit tourism village in DIY can feel confident with the honesty of community in the tourism village and believe that others will not utilize their presence in the tourism village. The tourists also feel that the infrastructure in the tourism village has a good quality, the village is also safe, they received a quite clear information, and the tourism village has a friendly and on-time service. This research result is also supports the research findings by Singh and Sirdeshmuskh (2000); Garbarino and Johnson (1999); Nguyen et al., (2011); Chinomona (2016); Slusarczyk et al., (2016).

The influence of positive attitude toward loyalty is also supported. This means that the tourists have positive attitude toward the tourism village in DIY, which is showed by the tourists' pleasure of their visit, their happiness to interact with a different life style, and the existence of a sense of togetherness. This positive attitude is also able to increase the loyalty of tourists, which is showed by their desire to visit this tourism village in the future, making this tourism village as the main tourism destination, and their desire to recommend this tourism village to others. The result of this study supports the research result from Oliver (1981, 1997); Susilowati and Sugandini (2018). Their findings stated that positive attitude has a positive contribution toward destination loyalty, which is showed by their intention to revisit the destination and their willingness to recommend.

This research contributes in addressing three gaps in the previous tourism literature by exploring the influence of trust, attractiveness, perceived service quality, and positive attitude in the destination loyalty with CBT setting. *First*, this research analyzes the loyalty of the tourists using attractiveness and trust as the antecedent in the community-based tourism that is different with other types of tourism. During this time, trust variables are mostly used in the setting of e-tourism (Koufaris and Hampton-Sosa, 2004; Salo and Karjaluoto, 2007; Yung Yeh and Li, 2009), trust is also rarely used in CBT settings (Sugandini et al., 2018b). This research contributes in the influence of trust toward tourists' loyalty that mediated by service quality and positive attitude on the CBT setting, so that it can strengthen the previous literature about the influence of trust. *Second*, this research also analyzes the influence of attractiveness toward loyalty by mediating perceived service quality and the positive attitude of the tourists. Previous studies have shown that attractiveness can directly affect loyalty (Wu et al., 2015; Wu, 2016). This research succeed in showing that attractiveness can affect loyalty through the mediation of service quality and positive attitude. Attractiveness can also affect the positive attitude of the tourists, either through mediation or through direct variables. This research also shows the direct influence of positive attitude toward loyalty.

Third, this research extends loyalty model by analyzing the variable of attractiveness, trust, service quality, and positive attitude. This research does not use satisfaction to predict loyalty as it has been widely used by previous researchers (Sugandini et al, 2017a, Sugandini et al., 2018b; Jianqiong et al., 2018). This research uses positive attitude to predict loyalty. The research settings are on the type of special interest tourism, such as home stay and live in that exist in DIY, Indonesia. This research result can increase external validity of the findings of the previous research about tourists' loyalty that have existed before.

The result of this research is also can show that tourists' loyalty can be increased through the improvements in infrastructure both in the tourism attractions and on home stay provided by the community. Ease of access, security, hospitality, and professional tour guide are also able to grow a positive attitude of tourists in the tourism village. Thus, in the end this positive attitude will affect tourists' loyalty. The development of tourism objects and attraction will be able to bring more tourists from time to time to provide a great economic contribution for the region from taxes and levies that are needed as a source of funds for regional expenditures for economic development of district/city in DIY (Feriyanto, 2016a; Feriyanto, 2016b; Haryono et al., 2017).

6. Limitation and Future Research Directions

This research only explores the success model of CBT from the side of the consumers, which is measured by tourists' loyalty who visit the tourism village. The measurement of CBT impact should also explore the impact of CBT for the community. For future research, researcher should do research by taking the dyad setting, which combines the perception between tourists and CBT managers. This can be done using the research method of multi trait multi method. In this way, researchers will get a clear picture about the success of CBT from all aspects.

Abstract

The development of digital creative industry in Yogyakarta Special Province (DIY), Indonesia is growing rapidly. This condition is supported by the emergence of other businesses such as hotels, culinary, fashion, furniture and other creative industries. Beside that DIY known as education city. The purpose of study is examine and analyze the level of business strategy alignment which implemented by digital creative companies in DIY and associated with organizational structure and work processes. Population in this study is leader/manager of digital creative industry company in DIY with sample size target is 200 respondent. After conduct an identification, the respondents who answered the questionnaire completely are 172 respondents. Statistical technique uses *euclidean distance (ED) regression*. The result concludes that there is an alignment between; (1) business strategy (prospector-defender) with organizational structure (organic-mechanic) and work processes (non routine-routine) both in contingency and configuration, (2) prospector strategy with organic structure and non routine work processes both in contingency and configuration, and (3) defender strategy with mechanic structure and routine work processes both in contingency and configuration.

Keywords: *business strategy; organizational structure; work processes; alignment.*

1. Introduction

Nowadays, the globalization era makes company must be able to take the challenges and capture the opportunities. The world seems limitless and the science and technology development are unstoppable. There are many ways taken by the company to become a successful company. The automation process, education and training, quality improvement of management, and redesign the organizational structure within the company are the various ways that company can use to save from failure. However, these methods require high costs and sometimes in efficient (April et al., 2006; Kandemir, 2006). The company must be careful in designing and finding business models which implement the appropriate business strategy and should be in accordance with internal and external organization's conditions so the company does not fail. The organization of fit theory states that organizational strategy must be compatible with other factors in order to achieve improved business performance (Galbraith and Nathanson, 1978; Homburg et al., 1999). Therefore, to make an organization has an increasing performance continuously, it is necessary to have an organizational structure and work processes align with the business strategy which implemented by the company.

This study is focused on the digital creative industry which currently grows rapidly in Yogyakarta Special Region (DIY), Indonesia. The digital creative industry is a group of companies that always being dynamic and follow very high and volatile market's demand changes. Digital business in DIY is dominated by software house (21.05%), followed by commerce players (11%), fintech (10%), and digital agency (8%). However, other categories such as travel, education, game house and IoT still can be found. The startup size is majority driven by 2-5 people (36.84%) while the others are single player (14.04%) (<https://dailysocial.id/post/temuan-menarik-tentang-startup-di-yogyakarta-tahun-2017>, accessed

on May 10, 2018). IT companies are competing each other. Every year, new IT companies appear inside and outside DIY and even from abroad. This competition should be considered as a good opportunity so that each company will be motivated to have superior performance compared to its competitors. The purpose of this study is to test and analyze the alignment between business strategy, organizational structure, and work processes of digital companies in DIY. The alignment concept uses the ideal relationship of typology that has extreme continuum differences and being analyzed from the aspect namely: business strategy (prospector Vs defender), organizational structure (organic Vs mechanic) and work processes (non routine Vs routine). The impact is if there is an alignment business strategy with contingency variables such as organizational structure and work processes, it will be able to improve business performance increasingly.

2. Literature review and hypotheses. Business strategy, organizational structure and work processes

Organizational strategy typology that used in this study refers to competitive strategy proposed by Miles et al. (1978) namely; prospector and defender. The prospector strategy has characteristics; always wanted to be a pioneer in the creation of new products/services, emphasize innovation and creativity, doesn't care with the efficiency, find and earn external resources expansively, and environmental uncertainty are very high. While the defender strategy has characteristics; concern with efficiency, maintain and protect market share from new competitors, require formalities and centralization, rarely to innovate and environmental uncertainty easy to predict (Muafi, 2009a). Kumar, et al. (1997) says that Miles and Snow's strategy is similar to Porter's generic strategy (differentiation and cost leadership). Prospector (Miles and Snow) is similar to Differentiation (Porter). Defender (Miles and Snow) is similar to cost leadership (Porter). Cost Leadership and Differentiation are mutually exclusive. If both are combined, there will be stuck in the middle because they are contradictory but if each strategy is combined with a focused strategy then Hybrid will occur. It does not mean that stuck in the middle conditions cannot happen. Hlavacka, et al. (2001) adds that 'Porter's generic strategies are not mutually exclusive and each strategy can be linked to other various strategies' (Muafi, 2009a, Muafi, 2009b). This study uses two typologies of organizational strategy prospector and defender because these two types of strategies have firm characteristics so they can be used to deal with the demands of external environment (Doty et al., 1993; Muafi, 2009a). The two of internal organizational variables that should have align with organizational strategy is the organizational structure and work processes within the organization.

The changing business environment requires organization must be able to design their organizational structures efficiently and effectively. This is important because it involves individuals and groups behavior within the organization. Robbins (1990) and others authors (Steers, 1977, Muafi, 2009a, Szczepańska-Woszczyna, 2014, Pacana and Ulewicz, 2017) recommend when managers design an organizational structure, there are several points to consider, including; job specialization, departmentalization, chain of command, span of control, centralization, and formalization. The change of business strategy in the company requires company to make adjustment with organizational structure and other contingency variables that affect the achievement of business performance (Muafi, 2009a, 2009b, Kovács, 2017, Shpak, et al., 2017). The previous studies have concluded that companies that have organic structure will be alignment with the prospector strategy, and companies with mechanical structure will be alignment with the defender strategy, which will enhance the company's performance (Muafi, 2009a, Robertson and Chetty, 2000). The mechanical structure emphasizes the importance of achieving high-level production and efficiency, formality, the low specialization of the labor force, and the presence of centralization. While the organic structure emphasizes the importance of achieving adaptation, flexibility, specialization of labor amount and high-level centralization. This organization's design less rely on existing rules and procedures (Robbins, 1990; Robertson and Chetty, 2000; Muafi, 2009a). Chandler (1962; Kavele, 2012) says that the organizational structure should follow the organization's strategy because the organization's strategy is the direction to achieve the goal and must be supported by the organizational structure. The organizational structure must be integrated with the company's strategy to achieve the organization's vision, mission, and goals.

Related with work processes, Garcia (2014) simply defines a "process is a series of actions or activities that combine to achieve an end or outcome". Work processes is very important process in the process of creating the internal value of a product/service which offered by the company. The working process include product design and delivery, customer support, supply chain management, business, and support from multiple processes. This condition requires core competencies of the organization in order to have a relative success compared to competitors who are all oriented to customers, stakeholders and stockholder value (http://www.baldrige21.com/BALDRIGE_GLOSSARY/BN/Work_Processes.html, accessed on May 10, 2018). According to Ringrose (2018, in <https://www.promapp.com/resources/10-best-management-practices-for-work-processes/> accessed on May 10, 2018), there are some management practices that can conduct to improve the work processes, such as; (1) design and document core processes, (2) monitor and control the control process to ensure service standards to be consistent; (3) monitor and control the control process to ensure the service standard system to be consistent (eg quality, work environment, health & safety; (4) anticipate or adapt to changes, (5) take corrective action when problems occur; (6) prevent recurrence of problems when there are process changes; (7) analyze the process regularly and make changes which aimed at continuous improvement; (8) communicate the process changes to all employees who involved in the process; (9) involve the customers, suppliers, and/or partners in designing and analyzing processes; and (10) use the external data to compare performance with other organizations.

Garcia (2014) adds that when the work processes is consistent or systematic, the characteristics of the result will be more predictable and controlled. If this condition occurs, the work processes performance quality will be easily guaranteed, so it will be able to improve the growth and sustainability of the company's business. Working process requires different tasks and expertise/skills. Garcia (2014) suggests that work processes in business should be mapped. It is important because it will be useful for; (1) understand the entire flow process, if no one has a complete view, (2) facilitate new employees, (3) identify improvement in response to external or environmental threats, (4) identify improvement of project targets which need to be improved, (5) understand the stakeholders, market share, or supply chain impacts in strategic planning, (6) provide insight into new functions about how work is conducted, (7) identify quality control issue to understand better and improve the process, and (8) require mapping process from organizational functions and processes on merger and acquisition activities.

Kandemir (2016) concludes that the outcome of the work processes relies heavily on the tasks assigned to the employees. Managers must select employee's competency to fit their workload to minimize the average duration of a work process while keeping employees below the workload threshold to prevent errors caused by overloading. This is important for organizations to improve performance, manage excessive workloads, and produce a satisfactory environment for employees, without modifying the structure of a work processes itself (Kandemir, 2006; Kamrani et al., 2012, Smolağ, et al., 2015, Ďuríková and Seková, 2016). Valle et al. (2000) divides the work processes with two extreme approaches namely routine and non-routine work processes. Routine work processes is characterized; repetitive and predictable, cooperation and interdependency, demand quality standard, require to take decisions involving risk, application of little expertise and skill. While non-routine work processes is characterized; creative and innovator, long term results, autonomy, undemanding, no risk, considerable expertise and skill needed. Valle et al. (2000) conclude that routine work processes tend to adopt mechanical training models that use defenders strategies, whereas non-routine work processes tend to adopt organic training models that employ prospectors strategies.

H1. By contingency, the higher the level of business strategy alignment (prospector-defender) and organizational structure (organic-mechanic), the higher the business performance, vice versa (bivariate fit).

H2. By contingency, the higher the level of business strategy alignment (prospector-defender) and work processes (non routine routine), the higher the business performance, vice versa (bivariate fit).

H3. By configuration, the higher the level of business strategy alignment (prospector-defender) with organizational structure (organic-mechanic) and work processes (non-routine), the higher the business performance, vice versa (multivariate fit).

H4. By contingency, the higher the alignment level of the prospector strategy and the organic structure, the higher the business performance, vice versa (bivariate fit).

H5. By contingency, the higher the level of alignment of the prospector strategy and non routine work processes, the higher the business performance, vice versa (bivariate fit).

H6. By configuration, the higher level of alignment of prospector strategy with organic structure and non routine work processes, the higher the business performance, vice versa (multivariate fit).

H7. By contingency, the higher the level of alignment of the defender strategy and the mechanical structure, the higher the business performance, vice versa (bivariate fit).

H8. By contingency, the higher the level of alignment of the defender strategy and the routine work processes, the higher the business performance, vice versa (bivariate fit).

H9. By configuration, the higher the level of alignment of the defender strategy with the mechanic structure and the routine work processes, the higher the business performance, vice versa (multivariate fit).

3. Research methods

This study was conducted on digital creative industry in DIY Province, Indonesia. The number of digital creative companies in the DIY region is huge and always growing. The population in this study is the overall leader/manager of digital creative company in DIY. The sample size is targeted to 200 leaders/managers and chosen purposively. After the identification, the total of respondents who answer the questionnaire completely is 172 leaders/managers. This study uses a system approach by analyzing the effect of ideal type alignment of business strategy variables (BS) (prospector Vs defender), organizational structure (OS) (organic Vs mechanic) and work processes (WP) (non-routine Vs routine) related with business performance (BP) (Van de Ven and Drajin, 1985; Muafi, 2009a; Muafi, 2009b; Selto and Renner, 1995). The business performance in this study is based on the perception of the leaders/managers on the company's performance which they lead compared to the average industry of similar companies with indicators; ability to gain profit in the long term, sales growth, job satisfaction, organizational capability, work adaptation and service quality. Statistical technique using euclidean distance (ED) regression and one way Anova with SPSS software. The uniqueness of the ED regression is the greater the ED score means the alignment between the variable is smaller (the distance between the variables is closer) so that it will negatively affect the performance, and vice versa. In this case, the number of regression coefficients sought is negative and significant. While, one-way Anova is used to analyze the differences of business strategy group between prospector and defender. The scale of measurement of organizational structure variable and work processes is using semantic scale with score 1-7. This scale is recommended for two different typologies (Cooper and Schindler, 1997, Muafi, 2009a, Muafi, 2009b). For business performance, researchers are using Likert

scale with score 1 (very low) to 7 (very high). The result of the whole respondents is organisations that used the prospector strategy (code 1) was 111 companies (mean score ≥ 3.5), while the rest (average score < 3.5) of 61 organisations using defender strategy (code 2). The result of calculation with one way Anova is significant F value (sign = 0.000), it means there is significant difference between group of prospector strategy and defender. The results of validity and reliability test item questionnaire of all variables are valid and reliable.

4. Research results

Majority the leaders/managers have Bachelor degree (52%), the business form is CV (53%), have 5-10 employees (61%), and using their own funds for establishment and management (56%).

Regression Analysis for Overall Strategy (Prospector and Defender)

The result of t test in Table 1 turns out to conclude that the significance < 0.01 so that hypothesis to 1 till 3 is accepted.

Table 1. Overall strategy test results (Prospector and Defender n = 172)

Regression Equation Model	Coefficients (B)	Std Error	t	Sign	Decision
Y = a + b dist (OS.BS)+e	-.591	.069	-8.57	0.001	H1 accepted
Y = a + b dist (WP.BS)+e	-.367	.051	-7.19	0.000	H2 accepted
Y = a + b dist (OS.WP.BS)+e	-.441	.038	-11.60	0.002	H3 accepted

Similarly, the t test results in Tables 2 and 3 yield the same conclusion that the significance < 0.01 so that the hypothesis to 4 to 9 is accepted.

Table 2. Prospector strategy test results n = 111

Regression Equation Model	Coefficients (B)	Std Error	t	Sign	Decision
Y = a + b dist (OS.BS)+e	-.411	.081	-5.07	0.003	H4 accepted
Y = a + b dist (WP.BS)+e	-.225	.023	-10.22	0.000	H5 accepted
Y = a + b dist (OS.WP.BS)+e	-.247	.041	-6.02	0.000	H6 accepted

Table 3. Defender strategy test results n = 61

Regression Equation Model	Coefficients (B)	Std Error	t	Sign	Decision
Y = a + b dist (OS.BS)+e	-.122	.052	-2.35	0.005	H7 accepted
Y = a + b dist (WP.BS)+e	-.247	.033	-7.48	0.000	H8 accepted

5. Discussion

It is known that the whole hypotheses is accepted. The findings proved that there is alignment between business strategy both prospector and defender with organizational structure and work process. It is indicate generally that these findings support the contingency and configuration approach. This result also supports the research and opinion of Delaney and Husehild (1996; Richardson and Thompson, 1999; Priyono, 2004) that is 'a successful strategy relies on external or vertical and internal/horizontal compliance' which must complement and encourage each other. In the implementation of business strategy (prospector and defender) it turns out the company has been consistent in designing the organizational structure and work processes that exist. Business performance will increase when organizational structure both organic and mechanic in accordance with selected business strategy. It is also applies to non-routine and routine work processes. It is proven that the growth of digital industry in DIY is increasing from year to year, there are even foreign companies that compete in the industry. This indicates that its market share is still wide open for both new players (start up) and old players.

Further, both the prospector and defender strategy respectively, it was found that there is a match between the prospector strategy with organic structure and non routine work processes, vice versa. This result supports Robertson and Chetty's finding (2000, Muafi, 2009a; Valle, et al., 2000). It should be remembered that the configuration model in organizational fit theory says that "if there is a corresponding relationship between organizational strategy, organizational structure, system and organizational culture, it will be able to reduce internal barriers for the organization to have superior performance" (Galbraith and Nathanson, 1978; Priyono, 2004). Similarly, it was found that contingency with the choice of organic structure and non routine work processes has been in accordance with the prospector strategy that has been implemented by the company. It is reasonable given the level of intense competition makes them have to act quickly and aggressively without considering the formalization, rules, procedures that exist, and the centralization of authority. However in a different perspective, it was found from the interview's results with some of the leaders of the company that the tightness of the existing level of competition makes them need to be careful in making decisions related to business run. They remain guided by high-level production and efficiency, formality, rules and centralization because they generally fund their own business (self-funded = 56%), business stages are still in the level of product development (51%) rather than market development, and have not been dare to follow the trend

because they still have business as usual principle (52%). These results reinforce study findings from Jogja start.up (<https://dailysocial.id/post/temuan-menarik-tentang-startup-di-yogyakarta-tahun-2017>, accessed on May 10, 2018). The results also reinforce the study findings of Valle et al. (2000) that routine mechanical structures and work processes are more subject to them because they are in line with the defender business strategy which implemented. They are more concentrate on systematic and routine work processes as well as patterned and align with the employee skills. All are oriented for long-term profit improvement, sales growth, job satisfaction, organizational capability, work adaptation, and service quality.

6. Theory and managerial contributions

This study has contribution to theory namely; (a) the organization needs to approach the ideal type of configuration and contingency between the business strategy-the contingency variable (organizational structure-work processes) so that further can improve the overall business performance, (b) the organization needs to be consistent in implementing the strategy by considering other factors in internal management organization to achieve more business performance and (c) difference strategy election will influence difference perception of company leaders to contingency variable which influenced it. While this study gives managerial contribution, such as; (a) management should pay attention to strategic issues affecting the company's business strategy to boost its performance. The strategic issues must be identified and analyzed then adapt with their business strategy, so as it can improve their business performance, and (b) need to design the right organizational structure and work processes so that the company can be more effective and efficient in operating and oriented to the achievement of its business performance.

7. Limitations and future research

This study does not distinguish the form of business entity so that sometimes the perception of respondents to the variable still requires detailed explanation and intensive mentoring because the level of leaders/managers education diverse so it can confusing in perceiving the submitted questionnaire. Besides that, this study uses static approach because it does not examine the strategy change from time to time, so it is necessary to consider the dynamic approach using longitudinal study although it requires high cost and long time (Priyono, 2004). In the framework of organization fit theory, there are many other variables that can be considered in models such as environmental uncertainty, HR practices, organizational culture, role behaviors, and other contingency variables.

Some considerations on management internal control of stocks in the field of construction societies

Răvaş Bogdan*

University of Petrosani, University Str, no. 20, Petrosani, Romania

Abstract

Lately, dependence has become a reality between the need for information, the existence of a system that ensures their delivery and the development of society in general.

The system that can provide the required information is the information system, for which the technique and differentiated means are used depending on the type of system to be built, the level of development of the company from the economic and informational point of view.

The development of computerized electronic systems has made it possible to replace traditional primary documents with technical information carriers that fulfill both the role of primary documents and those of technical data support necessary for their further processing.

Improving inventory evidence leads to increased productivity growth, and the improvement of the information system is in fact the essential element for the transition to a new quality throughout the economic activity.

Keywords: control, management, stocks, accounting, information, decision

1. Literature review

In order to complete this paper I have used also internal and external literature sources composed by books, papers, articles written by some more or less known authors in the field. I have taken and developed some of their ideas in order to reach the purpose of this study, meaning to underline the importance of the internal audit also in the field of construction companies.

2. Research methodology

The qualitative research methodology was utilized in this study. The study started with a thorough analysis of the current internal audit methodology and practice. Next, best practices on the areas of problem were gathered and analyzed based on a literature review and on the author's previous papers concerning similar problems. Based on the results of the best practices review and considering also the objectives of the internal audit function, solutions to the problem were constructed.

3. The base of the research

A significant feature of inventories is that they go through a continuous cycle of acquisition, use in production and sales. In both cases, the producer and trader, the inventories and the cost of sales are significant both for the financial statements of synthesis and for the appreciation of the achieved performances.

There are many risk factors that can affect stocks, including:

* Corresponding author. Tel.: 0040721521866;.
E-mail address: ravasbogdan@yahoo.com.

- the volume of procurement, production and sales transactions is generally high, thus increasing the risk of errors in accounts;
- there are always non-violet points with regard to inventory valuation, such as identification, sizing and allocation of indirect costs, accounting for residual products, estimation of deviations from standard costs, correct allocation of costs for the manufacture of complementary products, etc.
- special procedures are sometimes required to determine the quantity or value of inventories, such as the valuation of inventories by other experts;
- stocks are often stored in different places, creating difficulties both in controlling them to prevent theft or physical degradation and in accounting for stocks in transit;
- stocks are vulnerable to changes of the economic circumstances that may lead to a reduction in demand, sales and, therefore, the application of different treatments in such cases for their assessment;
- stocks may be subject to return contracts (for example, packaging).

4. The need for management internal control of stocks in the field of construction companies

In planning of the inventory management process, we need to be aware of the high risk of management's claims regarding the existence and stock valuation. As regarding the assets, the company management is motivated to overestimate inventories rather than underestimate them. Due to the non-existence of third parties in the case of production stocks, as is the case with construction companies, it is much easier to overestimate the value of stocks than in the case of other assets such as receivables, treasury, etc.

Preventive measures to mitigate the impact of risks on stock records at the disposal of the manager of the economic entity

In the case of a satisfactory managerial control system in operation, the following activities must be controlled:

- stock purchases;
- storage of stocks;
- exit from inventory management;
- determining the existence, physical integrity and rights of the stocks;
- inventory valuation.

Determining the moment when the transfer of rights to inventory from supplier to client is taking place is very important. There are situations in which stocks are transferred with or without property rights over them. From this point of view, we must appreciate the existence of effective controls on this type of transaction.

Depending on the nature of the stocks held in construction societies, the storage conditions, as well as the security conditions must be checked. The type of stock control storage as well as the security conditions will be different for company profile stocks.

In addition to direct control, in such cases, it is expected that restrictions on the exit of the respective assets will be in force - leaving the management on the basis of duly authorized documents. In addition, stockpiling should be done under appropriate conditions to prevent damage, destruction, and facilitate access and stock identification.

Control of exit from inventory management is often demonstrated by strict procedures (documentation) (which must be duly authorized) and assessment (in the case of the disposal of stocks that are difficult to sell for waste products, etc.).

Controlling the existence, physical integrity and rights of inventories requires the application of adequate physical inventory inspection procedures and conciliation of inventory results with accounting records followed by the investigation of inventory differences.

The existence of inventory differences (inventory pluses / minus) indicates a high risk. In addition to inventory availability, the inventory allows to determine the physical integrity of inventories and helps to identify exploitation rights on inventories.

Obtaining evidence of stock rights is more difficult, which leads to the need to apply additional control procedures. The basic principle retained for the valuation of inventories in the synthetic financial statements is to select the minimum cost between the cost and the net realizable value. Thus, all the controls exercised in this sphere of activity must ensure compliance with this principle. Particular attention should be paid to controlling deviations from the standard costs and the measures adopted to that end. Significant unplanned deviations may indicate a high control risk.

In order to verify management's statements in the financial statements about the existence and completeness of stock information, we must be able to choose a control strategy based on the company policy adopted to determine the amount of inventory held. The control strategies identified as possible in construction companies are the following:

- when inventories are accounted for by the permanent inventory method and the inventory is made close to the balance sheet date, the control strategy permits the control risk associated with inventory records to be relatively high;
- if inventories are determined quantitatively by inventory at the balance sheet date, the control strategy requires a predominant approach based on substantive procedures that does not test the control system applied to inventory accounting because it may be completely absent.

5. The determined internal control targets and risks in this area of activity

A major focus is on verifying the existence and evaluation of stocks, given the inherent risk associated with these two allegations. In general, the risk of not being detected is assessed at a low level for the existence and valuation of inventories, while for the rest of the allegations of inventories, the risk of not being detected may be at higher levels to averages.

In order to verify the initial balances, we must ensure that all adjustments agreed in the previous year on the occasion of the control have been recorded. Moreover, especially in situations where inventories are accounted for by the intermittent inventory method, we need to verify that all inventory records are kept up to date and kept up to date.

The analytical procedures applicable to stocks are very varied. An analysis of trends at branch or sector level may be essential for the development of the program of analytical procedures that will be applied to assess the analytical information of the company.

Verification of records in stock accounts is based on supporting documents. Where, at the balance sheet date, inventories are determined solely on the basis of the intermittent inventory, the appropriate detail tests shall consist of:

- verification of the physical existence of the stocks through inspection;
- investigating significant differences between physical inventory results and stock records.

If the quantity of stocks is determined by counting (weighing, etc.) at a date other than the end of the financial year, adjusted by reference to the accounting records for the period up to the quantitative verification, the detailed tests may be applied only to the remainder of the financial year between the time of the quantitative verification and the closure of the exercise.

Testing for compliance with the independence of procurement and sales exercises is important for identifying transactions that have taken place near the end of the financial year and for checking how they have been attributed to the year to which they relate.

When inventories are of significant importance in the context of the company's financial statements and stock inventory is not impossible, inventory observation is one of the major management responsibilities.

Where there is insufficient evidence of the existence of the initial balances or when the physical inventory at the end of the financial year can not be found and when it can not obtain sufficient and appropriate evidence by applying alternative control procedures, we have to abstain from issuing a decisive opinion that we should pass into the control report.

Applying this procedure allows us to provide evidence of management's assertions in the financial statements about the existence, completeness, valuation and rights, respectively obligations on stocks.

After inventory, the company uses inventory lists to compile the inventory report. All items after being counted, weighed, etc. are then evaluated, and the results are the basis for the bookkeeping corrections. Due to the importance of inventory lists together with the inventory register, we must ensure that the inventory lists faithfully the outcome of physical inspection, both in quantitative and in terms of value.

To determine if inventory lists faithfully present inventory results, you must:

- compare our own test results with those included in the inventory lists;
- to identify the lists drawn up when the inventory was assisted and to check their compliance with the inventory register;
- compare the results of the inventory with the accounting records, identify and ask for explanations regarding the differences noted;
- check the calculations for determining the value of inventory items.

Verifying inventory valuation involves determining the cost of inventories and their net realizable value, as well as comparing the two values to keep the minimum in the synthetic financial statements.

In the case of stocks of finished products, finished products and semi-finished products, the cost has to be checked in the light of cost accounting. The calculation system used by the entity is assessed in principle during the interim control when applying tests on costing methods of production. If inventories in production are valued at standard cost, the variations recorded against it should be analyzed.

International Accounting Standards (in this case IAS 2) require that inventories be reflected in the balance sheet at net realizable value if it is lower than cost. The estimation of the net realizable value implies the use of accounting estimates, which means that we have to take into consideration the provisions of the accounting estimates that imply:

- analyzing and checking the estimation methods applied by management;
- the use of independent estimates;
- continuous analysis and review of further developments.

In the case of inventories valued at net realizable value, the method of calculation and net realization should be checked. In some situations, the starting point is the current value or the contract sale price, corrected for the sales / realization costs involved. In other situations, calculation formulas that take into account age, previous changes, and expected future changes to those stocks may be used. We need to examine the data and assumptions underlying the formulation of the estimates, verify the calculations, analyze the previous evolution of the stock, and verify that the estimates are properly approved by the management.

Regarding the inherent risk assessment through the under-valuation of inventory book value adjustments, we must apply the substantive procedures that allow us to identify the needs for further adjusting the inventory book value. IAS 2 retains the following situations in which the adjustment of inventories may be required: lowering the sales price; physical damage; perimeters; the decision to sell at a loss; purchase or production errors.

The specific procedures normally applied consist of:

- analysis of sales made after the balance sheet date;
- finding obsolete stocks during assisted inventory
- analysis of stocks held in relation to the scheduled turnover to determine the excess stocks;
- discussions with the company's management, sales and production staff;
- analysis of the minutes drawn up during the meetings of the Executive Board, etc.

If the assertions made in the financial statements about the value of inventories are related to complicated technical issues, the assistance of technical experts in the field may be required.

When stocks are deposited with third parties, we must obtain evidence of stock availability through direct communication with custodians. The application of this procedure may provide sufficient evidence, unless the amounts involved are not material in relation to the total assets or current assets. In such circumstances, we have to decide on the following procedures:

- assessing the integrity and independence of the custodian;
- assisting with the inventory of stocks in custody;
- obtaining and analyzing the report of a specialized person, if the latter has carried out the physical inspection of the stocks under custody;
- creditors' confirmation of warranties lodged as collateral for contracted loans.

The application of this procedure provides evidence of the assertions contained in the financial statements regarding the rights and obligations on the stocks. Similarly, the procedure may allow evidence to be provided of the completeness of inventory records if custodians confirm a quantity of stocks greater than that identified in the company's accounts.

Confirmation of stocks by the custodian does not provide any evidence of the value of the stored stocks, as the custodian does not have legal competence in this area.

There are situations in which companies can hold stocks that belong to their customers at their request, after the sale has taken place. Another possible situation is the purchase of stocks with either a return or a payment obligation if there is a subsequent sale. In this way, management will be required to separate the inventories of commodity stocks during inventory. In addition, a written confirmation of stock ownership is usually required.

In the reverse situation, management is asked to confirm the inventory of the company, but it is "recorded" to customers. For such cases, we need to look at the contracts we have agreed with third parties and ask them to confirm the quantity of "recorded" stocks.

In another possible scenario, stocks can be used as collateral for contracting credits. In this regard, we need to obtain information / explanations from the management on the existence of such credit agreements and verify the publication of additional relevant information in the notes to the financial statements.

Also, we must not ignore the creative accounting techniques applied at the stock level. Thus, recording a significant sales volume close to the end of the financial year to a customer who appears not to require the immediate delivery of the goods may hide an attempt to lower inventories and increase liquidity, leading to an erroneous picture of the calculated economic indicators based on this accounting information. Often, such techniques are followed by the acquisitions in the period immediately following the end of the financial year. Such transactions must be accounted for according to their economic substance: secured stock loans.

Through this procedure, we have the ability to provide proof of management's assertions in the financial statements about the rights and obligations on stocks, as well as the presentation of stock information in the annual accounts.

We also need to ensure that the main stock categories have been identified and grouped correctly in the financial statements. In addition, the notes to the balance sheet must provide additional information on: the methods used to determine the costs; stocks used as collateral; the existence of major procurement commitments.

Talks with the company's management are a commonly used procedure for determining whether there are constraints on future stock purchases based on third-party conventions. In the event that there are such restrictions, we must examine the contracts concluded and evaluate the honesty of the accounting and reports prepared by the company to the extent that significant losses are recorded in the acquisition contracts, they should be recognized in the financial statements together with the disclosure in the notes additional information on the circumstances that led to such an evolution.

The evidence regarding the disclosure of information in the financial statements is obtained through the substantive procedures described above. Further evidence can be obtained, as necessary, by consulting and reviewing the minutes of the board meetings and discussions with the company's management. On the basis of the evidence obtained and the comparison of the financial statements prepared with the requirements of the relevant presentation and publication standards, we have the possibility to determine the honesty of the presentation of the stocks in the financial statements.

6. Some suggested solutions

Lately, the dependence between the need for information, the existence of a system to ensure their delivery and the development of society in general has become a reality.

The system that can provide the required information is the information system, for which the technique and differentiated means are used depending on the type of system to be built, the level of development of the company from the economic and informational point of view.

The development of computerized electronic systems has made it possible to replace traditional primary documents with technical information carriers that fulfill both the role of primary documents and those of technical data support necessary for their further processing.

Construction company's management should aim at implementing modern and up-to-date computer systems, namely choosing a multiuser database management system, meaning multiple users use the same remote database at the same time, resulting in a good use of resources server and memory savings, thanks to the unique database memory.

The facilities provided by the distributed databases provide the design of computer systems characterized by:

- the existence of a distributed database ensures the homogeneous grouping of all system data projected for shared use by all the functional compartments of the unit;
- ensuring an interaction between the creation and exploitation processes of the distributed database, allowing dynamic collaboration between its own applications and the link with other external systems;
- the availability of data in the current form required by the functional compartments and their operational transmission for the constitution of information support in decision-making.

7. Conclusion

Improving inventory evidence leads to increased productivity growth, and the improvement of the information system is in fact the essential element for the transition to a new quality throughout the economic activity.

As a result of the study I consider that the main functions and characteristics that a manager has to follow for correct inventory evidence in a construction company are:

- inventory tracking at multiple levels: at unit / subunit level with own balance; at the management level, with the possibility of defining multi-level management hierarchies; in some cases management may choose to track physical location;
- transparent tracking of multiple inventory criteria: Different article codes need not be defined to track the same article entered into stock with different prices, the system solving transparently the management for each price; it is possible to track inventory with lots with distinct evidence on each, it is possible to track a serial number of stocks
- automatic cost calculation at management outputs: calculation method is selectable at management level (FIFO, LIFO, CMP set price with update after each move);
- real-time information and reports: stock lists at different levels, inventory balance, stock records;
- transfers between management, inventories and stock adjustments: transfers between administrations with automatic generation of appropriate operations according to predefined rules; in the transfer between administrations in two subunits, each with its own balance, the accounting records required in the records of each sub-unit are transparently generated; the system has inventory capabilities including sample inventory by the ABC method; pluses and gaps are controlled by documents, with the specification of the causes.

Following the study, I found that the inventory management system of construction companies should allow accurate inventory records by performing the following functions:

- the existence of a unitary inventory of stock items;
- access by authorized persons to all necessary information. For example, the ability to set in real time the stock for an item in all the company's warehouses (headquarters, bases, units);
- all internal transfers are authorized only if they are in the budget. It is recommended that the degree of freedom from the budget should be at the recommendation / warning level and not at indicative / imperative level. Thus, if it does not fit into the budget, the system will allow for the transaction but will warn about overcoming budgetary provisions;
- the same initiation, approval and execution procedure for all sub-units on the same level;
- unitary, scientific, annual need determination;
- unitary, scientific, operative stock insurance procedure;
- unitary, scientific, periodical inventory management;
- the possibility of keeping records up to the storage position within the management;
- the possibility of requiring certain articles to be stored only in certain administrations or locations;
- the ability to restrict access to transactions only to authorized persons, by group of articles, for query / modification as appropriate;
- keep track of the history of the changes made to the inventory database, as well as of the persons who performed them;

- drafting stock value reports, by stock structures;
- the evolution of the stock structure over time based on framework contracts and the unit deliveries over the past 3-5 years;

Regarding the main objectives of stock management control at construction companies I believe that it should concern the following aspects:

- stocks are in good condition and are owned by the company;
- the costs of bringing inventories to the current condition and location were determined correctly;
- stocks were valued at the lower of cost and net realizable value, and adjustments were made to reflect the current state of inventories;
- all stocks are accounted for in the accounts;
- inventory valuation policies are adequately disclosed in the financial statements;
- the principle of independent exercises is respected;
- expenditures registered (materials, raw materials, labor, indirect costs etc.) are included in the production cost;
- the cost of production (materials, raw materials, labor, indirect costs, etc.) was correctly calculated;
- production costs were appropriately allocated,
- all the costs involved in production have been properly identified and recorded in the accounts;
- the cost of production affects the corresponding financial year.

The Gender Gap in the Labour Market

Dorina Niță*

University of Petroșani, University street no. 20, Petroșani, 332006, România

Abstract

Nowadays we can speak about an intensification of concerns at national, European and global level relating to the presence of the female population in the labour market even though geographical, historical, economic and cultural contexts differ from one region to another, from one country to another.

The gender gap favours men, if we consider the rate of participation in the labour market, wage discrepancies or self-employment, or on the contrary, it is in the favour of women when we speak about atypical forms of employment (part-time work, or fixed-term contracts), precarious jobs, etc.; the gender gap is currently the subject of numerous studies and research that have the purpose of finding solutions for an efficient management of this phenomenon from the perspective of maximizing the benefits arising from the presence of women in the labour market.

Keywords: labour market, gender gap, wage, employment, precarious jobs

1. Peculiarities of female population in relation to the labour market

Discrimination against the female population, to varying degrees, is a real phenomenon that cannot be challenged, nor ignored, even though most Europeans consider that gender discrimination is no longer a problem nowadays, it was more predominant in “our parents or grandparents’ time”, than and anyway not as persistent as in the case of developing countries or Arab countries.

The reasons that lie behind such realities can be found in the patriarchal structure of societies, within the culture specific to various ethnic groups or peoples. With regard to participation in the labour market, the research report *The gender employment gap: Challenges and solutions* (2016), published by Eurofound identified, *in order to explain the persistent gender differences on the European labour markets*, the following determinant factors: individual characteristics (e.g. age, education, nationality and work experience), family and household circumstances (e.g. the presence of children and older relatives, civil status and unemployed partners), policy regimes and institutions (regarding the regulations on labour protection, tax and unemployment systems and or social policies relating to statutory maternity leave and child raising benefits), cultural attitudes and gender stereotypes (customs and stereotypes most often lead to segregation on the labour market meaning that men and women prevail in various fields of activity. Women can often be found working in health and social welfare, education, commerce as sales assistants or qualified and unqualified workers; these positions represent almost half of the female work force, with fewer representatives in administration and management). Moreover, it is considered that many of these factors overlap and are dependent on each other, which complicates the identification of key factors. The assimilation of modernity in different rhythms and ways for men and women, with its implications of expanding urbanization, the continuance of schooling or amplification of the participation of women in the labour market, has changed the mentalities and lifestyles among the female population. While men are reluctant to give up their dominant role, women much more easily let go of the humble and submissive attitude. At the same time, women have gradually exceeded their private space (which belonged to them exclusively and it still belongs to them to a large extent) getting into the public space (even though it is still dominated by men); this new situation has made women's lives more complex and even more difficult for this reason, raising a number of challenges relating to the reconciliation of family life with professional life.

Currently, at the level of European Union countries, the legislative framework includes rules that relating to the prevention and punishment of discrimination, alongside with ensuring equal opportunities for men and women in the context of making the issues of equal opportunities the main part of the European Strategy for Employment. At international level, in most democratic countries, a number of conventions, declarations or treaties talk about gender equality in all areas of economic and social life. Any citizen living in a democratic country should have guaranteed fundamental rights, including gender equality, alongside the right to freedom of speech and opinion, the right to work and education.

2. Current situation of women's participation in the labour market

At present, the European Union labour market is facing a series of challenges and in order to deal with them it has to find realistic and effective solutions. Along with the aging workforce, discrimination and wage differentiation, predominant atypical forms of employment (part-time work, temporary work through an agency, etc.), the precariousness of jobs, chronic unemployment among young people, emigration, etc., one of the problems is the existence of a gender gap considered important between the participation of women and men in the labour market.

While the Lisbon Strategy established a target of 60% for women's employment rate in the EU which had to be reached until 2010, alongside the target of total employment rate of 70%, the Europe Strategy 2020 Growth Strategy for employment and smart, sustainable and inclusive growth, establishes the objective of achieving an employment rate of 75% for the population aged 20-64 years, without any set goal on gender equality.

Statistical data published by Eurostat shows that in almost all countries of the European Union the rates of participation of women in the labour market have registered an increase over the past decades, however their values continuing to be lower than those of men. At the same time, women's inactivity rates are much higher than those of men, mainly due to the inability of women to work because of their responsibilities towards the family.

In order to reveal the gender gaps between men and women in the labour market, a series of indicators can be taken into consideration:

- gender employment gap;
- unemployment rate, by sex;
- forms of employment;
- gender pay gap.

Gender employment gap is defined as the difference between the employment rates of men and women aged 20-64. The employment rate is calculated by dividing the number of persons aged 20 to 64 in employment by the total population of the same age group.

Women's employment rate shows the percentage of women out of the total of employees (men and women) aged between 20 and 64 years of age.

Data provided by Eurostat reveal an increase in the employment rates among women over the last few decades, however such an increase is due not only to the increase in the number of women employed, but also to the decline in the number of men employed. The employment rate among men registered groan increase between 2005-2008 at EU-28 level, losing 3.5% during the period between 2009 and 2013, however in the interval 2014-2017 slight trend towards recovery was recorded; the value reached in 2017 (78%) was slightly higher than the one recorded in 2008 (77.9%). The countries with the greatest drops in employment rates among men were Cyprus and Greece (more than 10%), followed by Spain (9.1%). During the same time period, the countries with the highest employment rates among women were Sweden, Germany, Lithuania, Estonia and Denmark, all with rates over 75%, while the EU rate was 66.5%. Greece recorded the lowest rate of employment among women of 48% at the level of the year 2017, followed by Italy (52.5%) [<http://ec.europa.eu>].

Table 1. Gender employment gap (%)

Country	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
UE-28	15,6	15,1	13,4	13,0	12,8	12,2	11,7	11,5	11,6	11,6	11,5
Malta	41,3	39,1	37,5	36,6	35,2	32,6	29,6	28,4	27,8	27,7	25,0
Italy	25,8	24,7	24,0	23,2	22,6	21,0	19,8	19,4	20,0	20,1	19,8
Greece	28,4	27,5	25,6	24,2	22,1	19,8	19,4	18,3	18,0	19,0	19,7
...											
Romania	13,1	14,3	14,4	16,6	15,3	16,1	16,3	16,7	17,5	17,6	17,1
...											
Latvia	10,2	7,4	0,3	-0,5	2,2	3,6	4,2	4,6	4,1	2,9	4,3
Finland	4,7	5,3	2,3	3,0	3,7	3,0	2,8	1,9	2,1	3,3	3,5
Lithuania	7,5	6,9	-0,4	-1,5	0,6	1,2	2,6	2,5	2,4	1,9	1,0

Source : EUROSTAT

The biggest differences between the values of the employment rates for men in relation to those of women, have been registered in Malta, Italy and Greece, between 19.7% and 25%, while in countries such as Latvia, Finland and Lithuania, the differences are less than 5%.

Unemployment by sex. If one analyses employment and the gender gap in employment, in parallel with the evolution of unemployment regarding both sexes, it can be observed that, with the exception of the years 2009 and 2010, when unemployment rates among men exceeded those of women, throughout the time interval 2008-2017 unemployment among women is higher than among men.

Table 2. Unemployment rate, by sex, in UE-28 (%)

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Males	6,6	6,6	9,0	9,7	9,6	10,4	10,8	10,1	9,3	8,4	7,4
Females	7,9	7,5	8,9	9,6	9,8	10,6	10,9	10,3	9,5	8,8	7,9
Gender gap	1,3	0,9	-0,1	-0,1	0,2	0,2	0,1	0,2	0,2	0,4	0,5

Source : EUROSTAT

As far as long-term unemployment rate by sex is concerned, it has reached almost similar values throughout the past years, being equal 4 years in a row between 2012 and 2015, whereas in the following years the values were higher in the case of women.

Table 3. Long-term unemployment rate, by sex, in UE-28 (%)

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Males	2,8	2,4	2,8	3,9	4,1	4,6	5,1	5,0	4,5	3,9	3,3
Females	3,3	2,7	3,0	3,7	4,0	4,6	5,1	5,0	4,5	4,0	3,5

Source : EUROSTAT

If one takes into consideration age when monitoring the evolution of the unemployment rate between men and women, data will show that the unemployment rate among young men (aged 15 to 24) is higher than the unemployment rate among young women.

Table 4. Youth unemployment rate, by sex, in UE-28 (%)

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Males	15,6	16,0	21,4	22,2	22,4	24,0	24,4	22,8	21,1	19,4	17,4
Females	16,2	15,9	20,3	21,4	21,8	23,3	23,8	22,2	20,3	18,7	16,8

Source : EUROSTAT

Forms of employment. When analysing the participation of women in the labour market it is not enough to consider just the quantity (the number of women employed, the number of unemployed women, respectively), but also the quality of their employment (by analysing the prevailing forms of employment). From this point of view, the participation of women when it comes to part-time jobs or temporary jobs is relatively high, and also when considering the sectors of economic activity with low pay rates, compared to men, a fact that significantly reduces their financial independence.

At the same time, women stand less chances of becoming entrepreneurs and better chances of becoming employees, as specialists explained due to the difficulties face by women in obtaining financing to start up or develop a business, to benefit from training or the need to reconcile professional life with family life.

Nowadays, another concern of specialists is related to atypical forms of employment, which have undergone significant development in the past few years (favoured by the outbreak of the global crisis); they are often associated with the so-called *precarious jobs*. As an alternative to standard employment contracts (for an indefinite period and full-time), fixed-term employment, part-time work, temporary work through an agent, sub-contracting, are forms of employment with a high risk of precariousness (due to job insecurity among the elderly, less protection of the employee in terms of social protection and pensions, etc.).

During the period 2008-2017, the employment rate of the population working part-time increased in all European Union countries, with significantly higher percentages among women. At the level of the year 2017, women who worked part time represented 31.7% compared to 8.8% in the case of men.

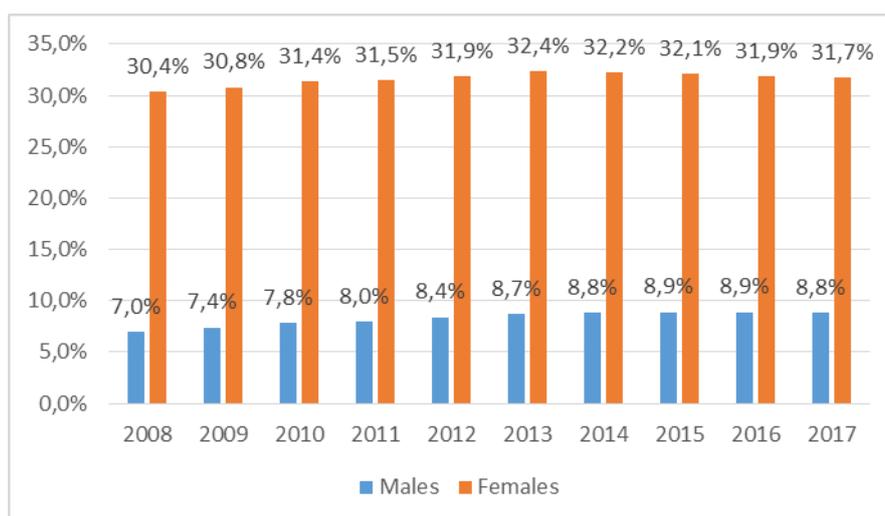

Chart 1. Part-time employment as percentage of the total employment, by sex

Source: <http://appsso.eurostat.ec.europa.eu/nui/submitViewTableAction.do>

As shown in the previous chart, the rate of part-time labour performed by women is about 30% for the analysed period, as it was the result of extremely different values recorded at the level of EU member countries. Thus, the Netherlands, which has the highest rate of participation of women in the labour market, also has the highest rate of part-time working women reaching almost 75.8% in 2017; followed by Austria, Belgium, Germany and the United Kingdom with rates ranging between 40% and 50%; at the same time, the proportion of women who work part-time was below 9% in Bulgaria, Croatia, Hungary, Romania and Slovakia. In comparison, men have recorded much lower rates to those women at the level of the same countries (in the Netherlands the percentage of men who worked part time was 26%, whereas in the vast majority of other countries, the rates ranged between 2% and 10%). The gender gap was negative in all countries during the period 2008-2017, the differences being higher in countries such as the Netherlands (where it reached 51.5%), Germany, Austria and Belgium [data provided by Eurostat].

It is considered that temporary agency work (fixed-term) was the first way of managing problems in the labour market as a result of the global crisis. Thus, the restriction of the number of jobs in response to decreasing sales volumes and demand had been implemented by many companies, large and small, by not renewing the contracts of employment concluded for an indefinite period of time. If one analyses the evolution of the same indicator taking into account the share of women and men who provide services for a fixed period of time, then the data show higher rates for women in relation to men.

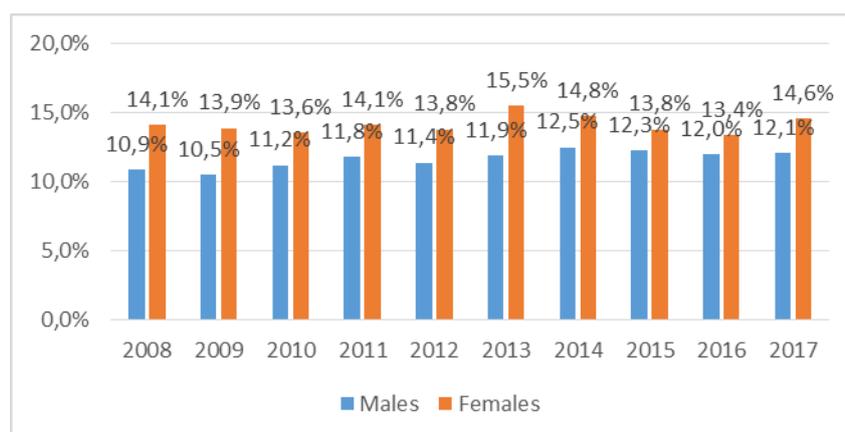

Fig. 2. Temporary employees as percentage of the total number of employees, by sex

After studying the development of fixed-term work at the level of the EU member countries, one can pick up on significant differences between their values. Thus, while the European average (EU-28) was approximately 13.3% in 2017, countries like Latvia, Lithuania and Romania registered much lower values (under 3%). At the same time, countries such as Cyprus, the Netherlands, Poland and Spain had the highest values related to temporary work among women (with values of over 20%) [data provided by Eurostat].

Gender pay gap. Despite the legislation aimed at fighting off wage discrepancies between men and women, there are still wage inequalities in all member countries of the European Union. The difference in remuneration between men and women represents the average difference between the pay rate of men and of women per economy as a whole. In Europe, women earn on average about 16% less than men and in some countries, the difference in remuneration between men and women is exacerbating.

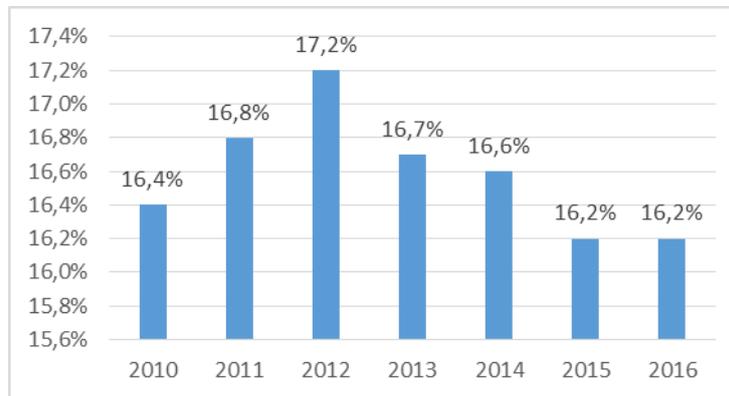

Fig. 3. Gender pay gap

Wage differences under 8% are registered in countries such as Belgium, Croatia, Italy, Luxembourg, Poland, Romania and Slovenia) while in the other five countries they exceed 20% (Austria, Estonia, Czech Republic, Germany and the United Kingdom).

The difference in remuneration between men and women has a significant impact on women's earnings throughout their life, as well as on their pensions. Lower pay rate means smaller pension and represents a higher risk of poverty for older women. The difference in pay between women and men is the consequence of continuous discrimination and inequalities on the labour market which, in practice, affect women in particular. This difference is relating to a number of elements both legal and of social or economic nature, which go far beyond the single issue of equal pay for the same work.

3. Economic costs of gender gap in the labour market

Of the disadvantages associated with the existence and maintenance of an important gender gap on the labour market we have listed the following:

- as women register lower levels of participation in the labour market this makes the national economy to be prejudiced by the additional income and a potential production;
- the lack of a job deprives women of welfare, thus the material security of the family can be affected if the husband does not bring in enough income;
- additional expenses incurred by the State with the assistance of this segment of the population (individual transfers of welfare and social benefits)
- the persistence of wage discrepancies between men and women for the same services provided makes women bear the consequences when they retire as pensions will be lower;

4. Conclusions

The purpose of this analysis is to highlight the importance of women in employment and to develop a perspective on how things could be different in the event that their participation would be higher; it is well known that reducing the gender gap in employment does not only lead to substantial monetary gains but also to social benefits (it is considered that the participation of women in the labour market improves the perception of the person in question on the quality of life in general and enhances the quality of the company. Women who work will assess life more positively than those outside the labour market. They enjoy a higher level of economic security, social inclusion and emancipation).

In all the countries of the European Union, there are gender inequalities even though with significant differences mainly on the labour market, where the employment rate of women is lower in comparison with that of men; women are to be found in larger numbers in lower paid sectors and they rarely in decision-making positions; the chances of becoming entrepreneurs are more reduced and the rate of pay differs too although they work the same jobs.

Despite the efforts of the institutions of the European Union and national legislation on the prevention and punishment of discrimination of women in the labour market and providing equal opportunities for women and men, progress is considered to be slow.

Economic Value Added Relevance for Stakeholders Regarding the Quality of Performance Analysis of Romanian Metallurgical Companies

Elena Iuliana Ion^a, Mariana Man^{b*}

^aCraiova University, Faculty of Economics and Business Administration, Craiova, Romania, ion_elena_iuliana@yahoo.com

^bPetroșani University, Faculty of Sciences, Petroșani, Romania, man_mariana2006@yahoo.com”

Abstract

The effects of the economic crisis have had negative consequences on the economic sector that undergoes a vast process of improvement and continuous adaptation to the market requirements. In this context, companies are in a constant competition, looking for new levers to attract their customers and, implicitly, to increase their performance. Based on these considerations, this paper analyses the *Economic Value Added (EVA)* relevance for stakeholders measuring the performance of companies in the Romanian metallurgical sector, whose shares are listed on the Bucharest Stock Exchange (BSE). The theoretical and practical aspects presented regarding the EVA are points of support for achieving the objectives of the study and testing the two research assumptions: EVA determined depending on the global result provides a full picture on the global performance of the company; the company's level of performance is assessed similarly depending on EVA determined based on the global result, the total net profit and net profit in operation. The result of the research have been obtained through a careful study of the literature, as well as based on the quantitative analysis carried out in the case of a Romanian company in the sector of metallurgical industry. At the level of the company that was subject of the case study, EVA was determined and analysed depending on the global result, net profit from operation and the total net profit. It may be observed that EVA determined depending on the global result presents the company's global performance most accurately, which translates by creating value and achievement of profit.

"Keywords: Economic Value Added, performance, result."

1. Introduction

The sector of metallurgical industry is an indicator with a significant impact on the evolution of real economy in Romania. Taking into account that in the metallurgical sector, public investments are almost equal to zero and the foreign ones are decreasing from one year to another, we can affirm that metallurgical industry is going through a long period of crisis.

Under the conditions of economic growth registered in recent years, the Romanian metallurgical sector does not provide added value, being affected by the increase of the volume of imports. According to the statistics, in 2016, the turnover in the metallurgical industry has registered the lowest level in the last 4 years. Also, lowering the export demand, rising the prices of raw materials, as well as significantly lowering the public infrastructure projects are just a few of the reasons that have led to entry of many companies in this sector into insolvency.

The Romanian metallurgical industry is 100% privatised, being an extremely important branch for the national economy. This is why knowing the profitability rates expressed in relative size is even more important for stakeholders and, particularly for shareholders. They will want to know at any time the actual level of the company's performance, so that it can make long-term forecasts and prevent any financial imbalances. In this context, it is essential to know the factors that influence the performance of companies in the metallurgical sector, given that the Romanian industry faces a new challenging trend.

The analysis aimed at highlighting the EVA relevance in assessing the performance of national companies in the metallurgical industry, whose shares are traded on the Bucharest Stock Exchange. Based on the data taken from the

* Corresponding author. Tel.: +40 764 34 94 33

ALRO S.A. annual financial statements related to the 2012-2016 period, we conducted an empirical study on the analysis, based on the EVA indicator. ALRO S.A. is a joint stock trading company, with a fully private capital operating in the field of metallurgical industry. The shares of the company are traded on the Bucharest Stock Exchange under the "ALR" symbol. (www.alro.ro)

2. Reviewed Literature

In the current economic context, taking into account the negative consequences of the economic crisis, globalisation is the main concern of business specialists and not only. We witness a process of adaptation and continuous improvement of information provided by the content of the annual financial statements under the conditions of increasingly more sophisticated needs of the accounting financial information users.

The company's profit obtained at the end of the financial year does not provide information on the created value to the holders of interests, but only shows the correlation between the company's incomes and expenses. Therefore, in order to know the shareholders' equity, specific tools to measure the managerial performances are required. Since maximising the value created by shareholders is the goal of any company, it is required to correlate the results obtained by the company at the end of the financial year with the shareholders' interests. The company's performance and culture indicators should aim at maximising the value created for the shareholders along with improving the company's financial statement. (Arnold, 2003)

Unlike the profitability rates reflecting the results generated by the activation at their historical value, EVA places a great deal of emphasis on maximising the value and on restating the components of the profit and loss account. EVA reflects the degree of a company's enrichment, after the company's investors' have been remunerated, or the profit acquired after deducting the cost of the invested capital. (Sichigea and Drăcea, 2006).

EVA is a modern indicator to measure the companies' performance, promoted by the Stern Steward consultancy office, which provides a higher level of company's profitability analysis compared to ROE (Return on Equity). (Sulger, 2008). This profitability indicator is of great interest especially for stakeholders, because it allows the assessment in absolute value of the equity in a company, respectively of the profit remained after decreasing the invested capital.

The main disadvantage of the EVA indicator is given by the influence the external factors have on its calculation, which shows a high degree of subjectivity in assessing this indicator. Given the current economic environment, characterised by a strong decline of predictability, the calculation of the EVA indicator is quite difficult to achieve because the method to calculate the cost of the capital invested has a significant influence on this indicator.

EVA tends to become a performance indicator of the company's management. According to EVA, the value can be created only if the investment brings to stakeholders a result better than their expectations. Therefore, a company can get profit when the value obtained is related to a profit better than the one it should get. EVA can be considered an indicator for measuring the internal performance of a company, calculated on the basis of the data observed. (Man and Vasile, 2009).

Because managers are responsible for the economic process performance and for the results of the main activities in operation, EVA should serve as evaluation and decision-making factor in the investment process. EVA reflects the company's performance in terms of the value created and not the profit. In order to create the economic value added, the profit earned after deducting the tax, it needs to be higher than the invested capital multiplied by the capital costs generated by the interests paid to the investors and incomes demanded by the shareholders. (Knapová, 2011)

At the level of companies and industries, EVA can be considered an ideal tool to compare the value created. A high value of the EVA indicator does not necessarily mean an increase in cash availability. Therefore, EVA cannot be considered an indicator for measuring the financial liquidity, as this refers only to the value created and not to the requirements regarding the company's liquidity. (Bharata and Alok, 2016)

According to Suwinto Johan (2018), at the level of the groups of companies, there is a connection between EVA and the return on equity (ROE) and the weighted average cost of capital (WACC) of the parent company. At the same time, this claims that a negative value of the Market Value Added (MVA) will generate an EVA negative value and, implicitly, a negative value of the difference between ROE and WACC.

3. Research Methodology

In terms of the research methodology, the first step to carry out this study is to select the company that meets certain preset criteria. Among the criteria taken into account in selecting the company on which we have carried out a practical analysis, we list: the company has been active in the sector of metallurgical industry in Romania for at least 10 years, has shared traded on the BSE on 31.12.2016, drafts annual financial statements in compliance with the International Financial Reporting Standards, has an attractive and generous history for investors and, last but not least, it requires the easy access to financial and accounting information on the activity carried out. Thus, our case study will be conducted on the financial-accounting data reported by the ALRO S.A. company for the period of 2012-2016. The data required to carry out the study was collected by consulting official documents published by the company. The main objective of the research is to study the relevance of the result/profit when determining the EVA for the stakeholders who analyse the performance of companies in metallurgical industry.

This research has certain limitations, as it is specific to any scientific research. Thus, the main limitation of the research is the singular case of the company selected in the sample, as well as the limited time range subject to the research. Also, the lack of information regarding the managerial accounting and the substantiation of managerial decisions determine an incomplete formulation of future research directions.

The assumptions of the research carried out based on the analysis of the economic value added we want to test are:

H1. EVA determined depending on the global result provides a full image on the global performance of the company.

H2. The company's level of performance is assessed broadly depending on the EVA determined based on the global result, total net profit and net operating profit.

4. Results and Discussions

The Economic Value Added (EVA) can be seen as expression of the profitability of the capital invested by the shareholders, following to determine that the difference between the net operating profit and the cost of the invested capital (invested capital * weighted average cost of capital), according to the calculation equation (Jacque, 1997). Also, as can be seen in the Tabel no. 1, EVA can be determined as difference between total net profit/total result and cost of the invested capital.

Determining *the weighted average cost of capital (WACC)* assumes establishing the cost of the invested capital. (Venazi, 2012). This indicator reflects the level of profitability of the invested capital and is calculated based on the calculation formula presented in the Table no. 1.

The cost of the invested capital is determined by summing up the distributed dividends and the interest expenses. Thus, the relative level of the costs with the dividends and with the interest used in the financial resources of the company is determined by relating to the total value of the capital. The invested capital is that part of the total assets financed based on equities and long-term debts. *The invested capital (IC)* consists of the equity and the interest bearing debts. This indicator is determined according to the formula presented in the Table no. 1. (Peterspen and Plenborg, 2012)

Table no.1. EVA – calculation formulas

No.	Indicator	Calculation formula	Observations
1	Economic Value Added (EVA)	NPO $EVA = NPO - IC * WACC$	NPO - Net profit from operation
		TP $EVA = TP - IC * WACC$	TP - Total net profit
		GR $EVA = RG - IC * WACC$	GR - Global result
2	Invested capital (IC)	$IC = Eq + Ltd$	IC - Invested capital
			WACC – Weighted Average Cost of Capital
3	Weighted Average Cost of Capital (WACC)	$WACC = \frac{Cic}{IC}$	Eq – Eguity
			Ltd – Long-term debts
4	Net profit from operation (NPO)	$NPO = Si - Cgs - Gamc + Ooi - Ooe$	Cic – The cost of the invested capital
			Si – Sales income
5	Total net profit (TP)	$TP = Or - Ei +/- G/Lfin +/- OG/L +/- Nfed - Tp$	Cgs – The cost of the goods sale
			Gamc – General, administrativ and marketing costs
6	Global result (RG)	$RG = Rp + OENR$	Ooi – Other operating income
			Ooe – Other operating expenses
			Or – Operating result
			Ei – Expenses with the interests
			G/Lfin – Gains/losses from financial derivatives incorporated instruments
			OG/L – Other net gains/losses
			Nfed – Net foreign exchange differences
			Tp – Tax on profit
			Rp – The result of the period
			OENR – Other elements of the net result, net of tax

Source: Processing based on the specialty literature

The literature emphasises the importance of a company's performance analysis based on the EVA indicator as the variation of the prices of company's shares is correlated with the evolution of the EVA indicator. (Bogeanu, 2013)

Even if using the EVA as indicator of analysis implies a high dose of subjectivity, we consider that the informational power of this indicator is quite high. In order to issue a personal opinion on the companies' performance analysis based on EVA, an empirical study was conducted in ALRO S.A., by using the financial data from 2012 to 2016. We chose to conduct the study in this company as this is representative in the sector of metallurgical sector, having the largest share of this market. In our analysis, EVA was determined as difference between the net profit from operation and the cost of the invested capital. EVA was also determined in the case of substituting the net profit from operation with the total net profit and the global result. Carrying out a comparative analysis of the results obtained resulted in issuing a personal opinion on the use of EVA as analysis indicator.

In Table no. 2, the EVA values are calculated for the period 2012-2016, in the ALRO S.A. company. EVA is determined depending on the net profit from operation, the total net profit and the global result. The values shown in Table no. 2 are expressed in thousands of Euros, at the exchange rate of the National Bank of Romania on 31.12.2017 (1 EURO = 4.6597 LEI).

The values recorded by EVA in the analysis time interval emphasise an ascending trend of the indicator, with the specification that only in 2016, EVA determined depending on the three factors registers positive values.

Table no. 2. Calculation of EVA for S.C. ALRO S.A.

No.	Indicator	2012	2013	2014	2015	2016
1	Net profit from operation (thousands of Euros)	-46,247	-45,210	6,826	33,764	36,399
2	Total net profit (thousands of Euros)	-19,745	-25,877	-23,321	-5,158	14,426
3	Global result (thousands of Euros)	-40,141	-26,620	-23,908	-4,015	14,337

Source: Processing based on the annual financial statements drafted by S.C. ALRO S.A., <http://www.alro.ro/ri/rapoarte-alro>

From the EVA calculations shown in Table no. 2, it may be observed that S.C. ALRO S.A. creates value for the shareholders only in 2016. The company has not created value for the shareholders in the time interval 2012-2015, EVA recording negative values.

One of the causes of registering some negative EVA values, between 2012 and 2015, would be the weighted cost of the capital that is too high for the company's shareholders. In order to increase the EVA, the company should pay particular attention to the evolution of the interests related to the borrowed loans as well as to the fluctuation of the course of the shares.

Following the calculations made and presented above at the level of ALRO S.A., **we emphasise the importance of EVA (calculated depending on the global result), on the assessment of the company's global performance expressed by the profit value during a financial year, as well as the by the value created for the shareholders.**

Using the EVA as tool for measuring the company's global performance brings benefits to the managers who will carry out the assessment of the efficiency of using the invested capital based on the profitability-risk relation. The main advantage of the EVA calculation depending on the global result is that company's managers will be oriented towards creating value and not towards getting profit. Thus, the interests of managers converge with those of shareholders, due to developing the levers that generate revenues higher than the cost of the invested capital, the ultimate goal of the managerial decisions being that of achieving economic value added, respectively profit.

Thus, by analysing the information shown in Table no. 2, it results that the **research hypothesis no. 1 is validated**, according to which *EVA determined depending on the global result provides a full image of the company's global performance.*

In terms of the EVA calculation depending on the net profit from operation, the total net profit and the global result between 2012 and 2016, it may be observed from Table no. 2 that these indicators register different values. In 2015, the assessment of EVA depending on the net profit from operation is a positive one as opposed to the assessment of EVA depending on the total net profit and the global result. Thus, in 2015, the company creates for shareholders an economic value added equal to 11,177 thousands of Euros taking into account the net profit of operation. If we relate to the net total profit or to the global result, in 2015, EVA will be equal to -27,746 thousands Euros, respectively -26,602 thousands of Euros.

In Table no. 2, one may observe the ascending evolution of the EVA indicator calculated depending on the net profit from operation, the total net profit, respectively depending on the global result, in the interval of 2012-2016. Although the evolution of the three indicators is approximately the same, the major difference is the significance of these indicators. In 2016, the EVA indicator registers positive values in the case of the three methods of calculation. These positive values of EVA show that the shareholders create value over the last year analysed. The reason would be a decrease of the weighted average cost of the capital, which determines an increase of the profitability of the invested capital.

It can also be observed that the negative values of EVA in the interval of 2012 – 2015 show the company's depreciation and destruction of the shareholders' value. In 2016, the company registers profit, after four years of consecutive losses. EVA obtained depending on the global result in the interval 2013 – 2016 registers approximately the same values as EVA calculated depending on the total net profit. The data in Table no. 2 are graphically transposed in Figure no. 1.

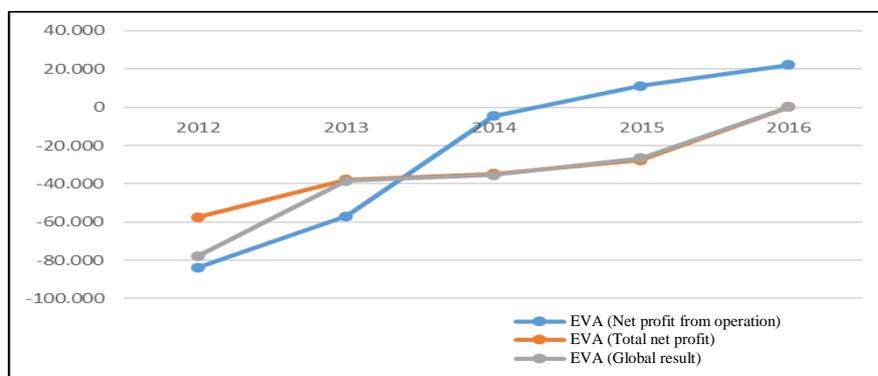

Figure no. 1. The EVA evolution calculated based on the net profit from operation, of total net profit and global result, for ALRO S.A.

Source: Processing based on the annual financial statements drafted by S.C. ALRO S.A., <http://www.alro.ro/ri/rapoarte-alro>

Figure no. 1 shows the ascending evolution of the three indicators and the value differences recorded by them. In the period of 2013-2016, EVA calculated based on the total net profit and based on the global result registers approximately equal values, with the specification that the global result provides information on the global value created for shareholders. Summarising, we may observe that the evolution of EVA determined depending on the global result is approximately similar to the evolution of EVA determined depending on the total net profit. Thus, the two indicators based on which EVA has been calculated provide comprehensive and appropriate information on the company's financial position. Also, from Figure no. 1, one may observe that EVA determined depending on the net profit from operation registers an ascending evolution in the analysed period, with the specification that the values of this indicator are higher between 2014 and 2016 and smaller in the interval between 2012 - 2013 compared to the values related to the EVA indicator determined depending on the total net profit and depending on the global result.

Based on the information shown in Figure no. 1, the **research hypothesis no. 2 is invalidated**, according to which *the level of company's performance is assessed similarly depending on the EVA determined based on the global result, total net profit and net profit from operation.*

5. Conclusions

Following the research carried out in the SC ALRO SA company, the influence of the EVA determined based on the net profit from operation, the net total profit and global result, over the level of assessment and company's performance. The results obtained following the processing of financial data reported by the company between 2012-2016 represented a real informational support on testing the research hypotheses formulated.

Thus, *the research hypothesis no. 1 has been validated* according to the results obtained. In this regard, we can state that EVA determined depending on the global result provides a full image on the global performance of the company. The interests of shareholders and of all users of financial-accounting information must be oriented towards a single purpose, respectively to create value and implicitly the acquirement of profit.

According to the information of the study conducted, *the research hypothesis no. 2 is invalidated*. Therefore, the level of company's performance is evaluated differently depending on the EVA determined based on the global result, total net profit and net profit from operation. EVA determined based on the global result provides information on the global value created for shareholders, while EVA determined based on the total net profit is the profit obtained by the company as a result of the economic activity carried out and EVA calculated based on the net profit from operation provides information on the company's profit from the operating activity.

In our opinion, a complex analysis of the indicators for assessing the company's performance should take into account a number of internal and external factors, as well as the increasingly more demanding of information users. We consider that EVA is a profitability indicator primarily oriented towards the value demand by the company as well as towards getting profit. Therefore, we appreciate that EVA provides a global image of the company's performance and brings more information to interested users. Taking into account the way to calculate the global result, **we consider that determining the EVA indicator based on the global result provides complex and realistic information on the value created to shareholders.** Thus, for a most faithful appreciation of the company's performance, we recommend the use of the EVA indicator calculated depending on the global result as it provides information on the **value of the profit obtained during a financial year, as well as the value created for shareholders.**

The main limit of the research is the limited sector for analysing the importance of EVA on assessing the company's performance. Therefore, future results shall take into account the expansion of the EVA analysis determined depending on the global result, total net profit and net profit from operation, at the level of several sectors of activity both nationally and internationally.

Bitcoin - the economic unit of humanity?

Cosmin Rus^{a*}, Ileana - Sorina Rakos^a

^aUniversity of Petroșani, Street Universității, no.20, Petroșani, România

Abstract

This paper highlights aspects of the Bitcoin digital paradigm that use decentralized technology for secure payments and the storage of money that does not require banks or names of people and which occurred in the context of the economic and financial crisis of 2008. The main objective of the chapter is the understanding of the dilemma synthesized in the question: Is the bitcoin a currency of the future, of technological innovations?

From the user's point of view, Bitcoin is a mobile application, a computer program that provides a Bitcoin personal wallet that allows the user to send and receive bitcoin messages representing the purchase or sale of goods and services. The massive public register called the "blockchain" used by the Bitcoin network is comparable to what was twenty years ago for the public finance world. The Internet for the Information World: a technology that allows fast, secure and decentralized transactions. This leads us to believe that over the next 50 years, more and more people will enter this network using electronic money as a means of payment. The fact that today renowned companies use this exchange rate also causes us to believe in its power and ultimately its acceptance as a means of payment. What is interesting about this digital coin is that much of Bitcoin's trust comes from the fact that it does not require any confidence. Bitcoin is fully open and decentralized. This means that anyone can access the entire source code at any time. Any developer in the world can accurately check the way Bitcoin works. All transactions and bit marks issued in existence can be viewed in a transparent, real-time manner by anyone. All payments can be made without relying on a third party, and the entire system is protected by peer-review cryptographic algorithms, such as those used for on-line banking. No organization or person can control Bitcoin, and the network remains secure even though not all users can be trusted. The issue here is whether it will replace today's physical money and whether it will have a central regulator over the course of time, as Bitcoin has become a very popular currency in recent years, being the most widely used global ban . What seems impossible now can be widely used in the future. The issues presented by the authors are based on the literature that has existed so far in the world. Through the authors' contribution, the conceptual framework of the emergence and use of this exchange coin is disseminated, leaving time to say its word on all aspects of creating and using it.

Keywords: bitcoin; stock market; financial market; payments; currency; risk

1. Introduction

With the progress of mankind, the need to move goods acquired through specific activities began to increase. In the prehistoric age, when people were carrying a nomadic way of life, hunting and collecting supplies to support their tribes, there was no need for exchange, because once the supplies were completed on a certain territory, the group moved to other unused territories. But with the transition to the sedentary way of life, the Natural Economy emerged, given that in the newly formed localities the social-economic network was not so well developed, so people produced by the processing of the earth, hunted and picked, the whole spectrum of goods needed for survival, basically not demanding exchange (the exchange was rare and in the form of a barter). Over time, due to social development, this type of economy has become ineffective because households have failed to self-supply because of the increase in population, economic specializations such as metal processing (especially in cities) have emerged, so the need for a standard to serve as an intermediary, the ban being virtually eliminated, that is, an economic standard, with which the value of a good can be measured, and, if that standard is in possession, the purchase. So the concept of money appeared.

At first, a lot of materials circulated in the form of money: from pearls and spices in Oceania and India to animals and fur in Euro-Asiatic areas. Over time, the role of money has begun to fulfil its metallic materials, thanks to the appreciation of skilled metalworkers. For this reason, the role of money was at the top of arrows, targets, nails, etc. Due to the efficiency (for that era) of this mode of payment, the metal was used in its entirety: copper, bronze, iron, silver. The more rare the metal, the higher its price, the gold is the most valuable. In some states, such as Assyria and Egypt,

*Prof. assist.drd. Rus Cosmin, University of Petroșani, e-mail: CosminRus@upet.ro

gold was used as gold, even 2000 years before our era. But the metal circulation in the economy brought inconveniences, since there were no coins, the metal was transported in large pieces. For any exchange activity, the metal had to be weighed and checked its purity (sample). To avoid scams, the metals began to be marked with public seals, so coins and coins appeared.

During the use of the coins, there was a tendency to wear out and the inconvenience of keeping it, because the metal was difficult to transport and vulnerable to theft. So money retention organizations appeared: The First Banks. They were working on the following principle: a person puts his money in storage, the bank offers him a certificate confirming that his fortune is at the banker, and once the person presents that certificate (receipt) to the bank, he can withdraw the amount of money deposited. Thus, to pay a bulk purchase, people could only offer the certificate instead of a large amount of coins. Over time, these certificates began to have the same economic power as real money. Thus, the first form of paper money came from: the practice of using bank certificates for buying a good. The very term banknote originates from the English bank note meaning "bank certificate". The bank's economic goal is the bank's commitment to freeing real money. Today, however, this concept is out of date, with the banknotes already fulfilling the real money function.

2. Bitcoin, between scam and revolution

In 2009, due to the increasing popularity of electronic payment systems, a person or a group of unknown people, under the pseudonym Satoshi Nakamoto, created Bitcoin. It can be defined as a decentralized electronic payment system, but also a digital coin. The purpose of this coin is to ensure security and transaction anonymity, free business finance, and investment protection without resorting to public or private financial institutions, thus excluding dependence on a certain financial structure. As we know, the world currencies have a special issuer: The dollar is issued by the US Federal Reserve System, the Euro is issued by the Central Bank of Europe, etc. Unlike these coins, Bitcoin does not use a central issuer, being totally decentralized. Economically speaking, Bitcoin has no value, and is used as a measure of the value of traded items, basically fulfilling the original money function. Bitcoin's value is based on the confidence of all participants in this coin's trading network.

Next we will address the technical aspect of this coin, because without it, we cannot understand its principle of operation. It's a bit heavy, but we'll try to make it as suggestive as possible. Due to its construction, the Bitcoin can be anonymously transmitted, and saved on the user's computer as a portfile. In order to make a transaction, users need two "keys", a public one, which is used to encrypt the transaction code and BitTorrent, and a private one, with which the code is decoded, and finalizing the transaction, offering anonymity and security.

Another feature of bitcoin is transparency: any Bitcoin user can see all transactions made by all network users in real time. Anonymity in this context is that we only see transactions between wallets, not who owns those wallets, we basically see just how money is handled. This is possible thanks to Blockchain, which is nothing more than the register where all transactions are entered, and which helps to achieve the transparency mentioned above.

The end point of transactions is public keys or addresses. Any user can generate an unlimited number of addresses, which increases security and anonymity. Transactions on Bitcoin are based on the following principle: When a user transfers an amount to user B, A drops the property on the BitTorrents sent by adding the user's public key B and signing it with their own private key. It spreads these bitcoins with an appropriate message, the transaction, into the bitcoin network. The rest of the network nodes validate the cryptographic signatures and transaction amounts before accepting it.

In our opinion, the concept of crypto-labelled is perspective, but Bitcoin does not have a high practical capacity, because of how paradoxically it would be, its main plus: decentralization. Because of this facility, this currency cannot be controlled by the state, it does not depend on any bank, it cannot suffer inflation (the number of bitches being controlled), what is the problem then? The problem is the financial value of a Bitcoin coin. The course of this cryptovate is very unstable, sensitive to crises in economic life and investor actions. Let's do a little analysis: In the year of its creation: 2009, a Bitcoin could be bought with \$ 0.30, but by 2012, over three years, its value has risen to \$ 14. So, if I was investing a small amount of money in Bitcoin, over three years I would have done 46 times more. This increased the number of miners hoping for a slight gain. If this course change looks strange, the next one seems fantastic: in 2013, a Bitcoin's price explodes from \$ 14 to \$ 1,000, that is, it's 71 times higher. This was due to the economic crisis in Cirrus, which led to the blocking of depositors' accounts in several banks, and investment in infrastructure for Wall Street investors. These events have influenced entire companies to go through a professional mining process, buying a lot of computers for this purpose, and more and more people have started investing in this currency with the hope of further growth.

But in many countries Bitcoin was banned, China being the most representative. For this reason Bitcoin's price has fallen from \$ 1000 to \$ 400. Following the multitude of fluctuations, ups and downs, Bitcoin reaches its historic record in 2017: \$ 16,500 could be bought with only one Bitcoin coin. It should be noted that, like the physical currency value distribution (one dollar is equal to one hundred cents), the Bitcoin has its subdivisions, so analogically to Bithoin in the Bitcoin system is Bitcent, which uses 0.01 bitcoins. The smallest subdivision is considered Satoshi worth 0.000000001 bitcoins. At the time of drafting this work, the bitcoin rate was \$ 7300 per unit. We have avoided the expression "at the

moment" because of the instability of this cryptoplane, because the price of this coin cannot be said with certainty at the moment of rereading the work.

For this reason, we consider Bitcoin as an ordinary user of economic facilities not to give me great advantages because, suppose: in a supermarket we paid a sum of 100 ron in Bitcoin. In a while, if Bitcoin drops, I'll make a profit because I've lost a bit of Bitcoin that has now devalued more, but if the Bitcoin course grows, it turns out we lost much more than if I paid in ron. It follows that no matter how innovative and perspective the Bitcoin idea would show, the fact that they cannot apply it in practice stops me from everyday use of this coin. In addition, there are arguments that claim that Bitcoin is just an experiment, or a Pyramidal Game designed to enrich those who speculate the market behavior of this coin. The biggest scandal in the history of this coin was the theft of 120,000 bitcoins, which destroyed the myth of the safety of this cryptobucket.

3. Blockchain and cryptocurrency

We have to understand that creating cryptolatte is not the only single use of Blockchain. In 2015, the Ethereum network was launched that generated far more modern technologies than Blockchain and other concepts such as smart-contracts. Ethereum was a Blockchain, but more technically advanced not only to perform currency transactions but also to initiate and process smart-contracts, create its own Token devices (identifies you as a user and authorizes your transactions) for use in any other (third) projects.

Smart-Contracts is a new direction, which became known with the development of the Blockchain. Imagine a smart electronic contract that records all business conditions and cannot be changed by anyone. This technology will generate the complete disappearance of scams and lies, both from simple people and from the state. For example, you have created a smart contract for the sale of a good (your own house), you have scheduled the necessary conditions after which the smart-contract will create the necessary events (in our case the sale of the house (sale of the private-real estate)). Therefore, the buyer transfers the necessary amount of money to the smart-contract to the corresponding smart-contract, after which the smart-contract verifies daily the update in the State Property Register. As soon as the property registration letter is displayed after the new owner, the smart-contract will transfer to your account the amount equal to the price. If within one month this inscript will not be displayed, the smart-contract will return the buyer's crypt. This is one of the simplest examples that make it clear that in front of Blockchain technology there is a big future. Blockchain and cryptocurrency are now like the Internet in 1993, everything that's more interesting is going to happen. And it is very important that we all understand this new direction, and if we have the opportunity, let us even take part in it.

The analysis of the theories that refer to the two largest and most crippled in terms of capitalization shows us the following: Bitcoin - \$ 290 billion and RIPPLE - \$ 120 billion, data recorded on January 6, 2018. The total capitalization of all crypto- today is about \$ 800 billion, just one month ago, rising to \$ 450 billion. And these are small drops in the sea, because, according to analysts, by 2022 the total capitalization will grow to 20-30 trillion dollars, an enormous market and an ultrafast growth.

Blockchain is a total decentralization, no intruder has access and the ability to introduce changes in information and transactions. Decentralization is accomplished by distributing servers that store and process information. The more servers are left each other and the less the server owners are linked to each other, the deeper the decentralization system is.

4. The hazards associated with bitcoin

Until now, we only talked about how positive and efficient the cryptocurrency and the Blockchain technology system is. But you probably wonder why the paper is called "Bitcoin - the Economic Assassin of Humankind." What we have exhibited so far provides us with a basis for understanding the second part of the paper, which actually makes reference to its title. Next we will address the danger and risks associated with Bitcoin and RIPPLE.

Not in vain we have called the work, the bitcoin is wonderful, the technology through which it is created is even more beautiful, and what is happening now is totally the merit of the bitcoin, but we must understand that bitcoin is not just a simple technology, it accumulates enormous amounts of money, it has practically become digital gold, as many people call it. Before people bought gold, and gold itself served to beat certain coins of different states, but that is already history. For a long time, no country has guaranteed its national currency by covering its gold reserves. This phenomenon has transformed the issue of the world's most important currency, the dollar, into an endless process. US Federal Reserve Printing Machines are printing dollar-type banknotes infinitely and unrestrictedly in order to have enough American food supply. Thus, new figures will appear in the accounts of banks, which will later turn into credits for companies and simple people. This phased process then causes inflation. You will never be able to raise enough dollars because they devalue over time. You'll just have to get credits when you want to buy something, because the "entire" amount you need will never be enough. This is how the world monetary system works. This problem has begun to battle the bitcoin and other cryptoplane. If the total bitcoin capitalization is currently \$ 290 billion, digital extraction can be obtained or extracted around 16-17 million dollars coins-bitcoin, and in 2140, for example, it will be possible to extract 21 million coins.

If Bitcoin now costs \$ 17,000, it does not mean you can buy Bitcoin from at least one currency. This moment was thought from the start. Thus, a bitcoin is divided into several parts, called "Satoshi". The minimum bithole is equal to one millionth Satoshi, assuming it would cost \$ 100 (suppose, because the cost will change permanently, because the currency is constantly rising). That is, any of us can buy a part of a Bitcoin coin if it has the equivalent of the cost of that million Bitcoin. Finally, we have a currency that is not controlled by anyone and whose cost increases. On January 6, 2018, a coin worth \$ 17,000, and according to analyst data, in 2022 a Bitcoin's price will reach \$ 100-200,000, when everything started when Bitcoin was worth less than 1 cent. As soon as Bitcoin moves to a certain psychological threshold, his price worsens to a new rise, as it has come to worth a thousand dollars, ten thousand, and so on. No one can stop transactions in the Bitcoin network and other encrypted ones, no one has access to data on your accounts, block them, or do anything else. This particularity of Bitcoin we consider, as is normal, welcome and positive.

As we know, the creator of Bitcoin is a person, or a group of people, known under the pseudonym Satoshi Nakamoto, who first launched the Bitcoin network. For testing and verification, around 7% of all Bitcoin coins were extracted, and today, in a few years, those 7% represent colossal amounts, approximately \$ 20 billion, and after forecasts only 7% will almost equal \$ 200 billion, and by 2050, these percentages will turn to \$ 5-10 trillion. And it is very possible that at that moment to be the opposite of the present, ie the value of the dollar to be calculated in bitcoins, even if that sounds funny, this is likely to happen. So funny sounded for that boy who bought a 10,000 Bitcoin pizza in 2010, hearing that in 2018 the equivalent of that price would be \$ 150 million. Ask a financial analyst or economist who you know about the danger of this phenomenon. What will happen if 7% of all Bitcoins are extracted in a single day at cryptocurrency exchanges?

We will see how soon Bitcoin, but also the other cryptocurrency, will be destroyed. Their value will decrease hundreds of times, creating such a catastrophe in the world that most financial organizations, traders and others will have to stop trading and sales. In fact, the entire world economy will stop in just two or three days. Stores, pharmacies, no trader will be able to accept payments, because everyone, a day ago, bought goods at a price hundreds of times higher. Everyone will wait for clarifications, which they will not receive. There will be such a crisis and waves of robberies as they have never met. People will have nothing to do but get the necessary burglary. This situation will use the poor class of society, and under the tide of robberies will hit not only the shops and pharmacies but everything that will appear in their path. It is possible that the states of siege and everything we have seen in the films about the future will happen. And the probability of this situation is very high.

Imagine that in your house there is a room that is full up to the bridge with \$ 100 banknotes, so if you want to open the door, you will be covered with waves of money. And you have been living in that 9-year-old house, and in all these 9 years you've passed that room without taking even \$ 1. Tell me, would a simple man be capable of this? I do not think anyone would have this strength.

That would be the main feature of Satoshi Nakamoto, if it were one man. But we understand that this is not possible. Whoever would have used this enormous fortune. But since 2009 no transaction has been made from Satoshi's accounts, no Bitcoin has been spent, except for a small portion that was spent on testing at the beginning. This initiator, either a person or a group of people, unites them with an extraordinary purpose for which they are ready to reject billions of dollars and wait even more than 10 years. It all resembles a Hollywoodian movie where a team of programmers creates a new digital or virtual financial network, waiting for a moment to squander the entire economic system, generating waves of looting and chaos in which the world will shake and it will transform into something, something unimaginable. But the goals of this anonymous group are of serious concern, and we must understand this and strive to prevent this variant of the future. How do we do that? Everything is simple.

We must not allow a sudden rise in the cost of the Bitcoin, and its capitalization, until it is understood who Satoshi Nakamoto is. If he is an ordinary man, then he will have to transfer an overwhelming part of his Bitcoins to an account (his own account, in which to secure some of his wealth) from which it will not be possible to carry out the transactions future. Simply put, he has to destroy some of Bitcoin's sum of his. In this case, it will eliminate the danger of such events that we have previously talked about. But it is unlikely that Satoshi Nakamoto will appear, and he will not do that, since he waited nine years without touching his or their wealth. Each of us tends to hope that Bitcoin will destroy the current financial system in which 50% of all the riches of the world are concentrated in the hands of a small percentage of the population, but we now see that 40% of all Bitcoins have only a few thousands of people. Then what is the difference between digital gold and the current financial system? It's nothing. This is also an unfair distribution, even more unfair than the present one. Bitcoin Blockchain, however, has an algorithm that allows you to introduce changes in transactions, changing transaction history, account balances, and other actions by someone else outside of you. How is that possible? Simple, if someone controls 51% of the Bitcoin network servers. You will say that it is not possible, because earlier we said that these are the advantages of Bitcoin and Blockchain. But everything is different. When Bitcoin was born, its existence and maintenance needed to create a network of volunteer servers that had to be rewarded for using their computers. That's how the mining appeared. The mining was first introduced into the Bitcoin algorithm and thought out in detail until the year 2140, where with some passages of time, mining becomes more and more difficult. From the very beginning, the Bitcoin network was composed of enthusiasts who offered their computers virtually free of charge, when Bitcoin was worth less than a cent. But then, with Bitcoin's price rise, professional miners began to appear, after which mining pools appeared, where powerful miners joined, mining equipment manufacturers emerged and created a capable system to resolve Bitcoin's requirements much faster than any other regular computer,

how powerful it was. Bitcoin attempts on ordinary computers have completely disappeared. Mining is a very wasteful electricity process, for the location of large mining devices, very cheap electricity access is needed, as is a favorable climate area. Mining equipment produces a large amount of heat that needs to be absorbed. After these clues, in your opinion, in which country are the capabilities and basic tools that Bitcoin is shuffling for? This is China. In the percentage ratio, it looks like this: China 81%; Japonia5%; Czech Republic 2%; Georgia1% etc. If most of Bitcoin's power is in a single country, it allows for a simpler connection between mining equipment owners, which causes danger. It is enough that these owners, uniting themselves, form 51% of the administrative equipment to make changes to the Bitcoin network. Mining pools already have their own brands and names, they have long known each other, and possibly keep in touch with each other.

When the Bitcoin network was designed, it probably did not think of such an unfolding of events. According to the initial ideas, the Bitcoin network was to be distributed all over the world between the small, separate and independent miners, but everything went different. Mining is an enormous process that has long gone beyond millions of dollars. Today's modern cryptodoletes are no longer in need of mining. More secure and cheaper Blockchain projects have been designed and are already in place, where the role of mining is diminished, not much electricity is needed (Bitcoin currently consumes energy as a city with a population of 1 million people). Here too we can add accelerated demodulation of mining equipment, it will be an endless race. The equipment purchased yesterday, tomorrow, may be old and out of date with the release of new ones.

I reviewed and analyzed the most important hazards that Bitcoin might pose. But what to do to avoid all this? Everything is simple and complicated at the same time. Cryptocurrency's company must not change Bitcoin's price higher than it has at present. Most believe that \$ 50-60 thousand is a reasonable limit for the Bitcoin value and safe for the cryptocurrency market, because if someone tries to destroy Bitcoin, the rest of the cryptocurrency will fall. We need to assess the situation correctly and not lift the Bitcoin up to those heights that may prove dangerous. We, society, can create a more positive future in this respect, which we will continue to talk about.

5. RIPPLE and ICO

We can think that only Bitcoin can create danger, but it is not. There is also the Altcoin, which, like Bitcoin, does not have to get big bucks in its capitalization. RIPPLE is also a digital coin and a company that connects global banks and cross-border payment processors. But what's wrong with this cryptocurrency?

RIPPLE is created by bankers for bankers, and most importantly, it is not even Blockchain, but a centralized network. This is the most interesting case. How could such a project get into the cryptocurrency society ... So if the network is not decentralized then all the management tools, all the assets and functions belong entirely to the owners and founders. An even more scary factor is that of all the monetary units issued, only 40% is available for transactions on Crypto-markets (online currency exchange service). Thus, it is noticed that the largest quantity - 60% stands, or is owned by the project owners. We can attribute this to the term cryptomonetic balloon. The second frightening factor is the newcomers to the crypto-loop society, who do not yet know how to distinguish the true crypt-dubbed projects like RIPPLE. Because of this, it responds with enthusiasm to any outburst of information that raises the RIPPLE capitalization to the sky. Right now RIPPLE takes second place after capitalization, yielding only to Bitcoin. 120 billion versus \$ 290 billion, is a very alarming trend, with great chances that RIPPLE will soon become a leader. But let's hope that common sense will triumph, and these projects will not rise up as this "cryptomonetic balloon" can be created specifically so that when the banks will need to ruin the world of cryptocurrency.

We have all heard of big gains by investing in cryptocurrency, but beginners notice that investments in top-rated cryptocurrency that reach peak heights do not yet bring as high profits as they would have desired. Blockchain technology needs development. There are many projects that work to develop Blockchain technology to implement it in real life. The cryptocurrency world is looking forward to the moment when Blockchain will start to be used in daily society and this trend is facilitated by ICO (Initial coin offering). This is a new concept that has recently appeared. One of the largest ISO has become Ethereum, which we talked about earlier. The team and founding organization needs financial resources to create and implement ideas within the realm, mainly related to the Blockchain and cryptocurrency network. ICO is the first stage when the currencies of a new forward-looking project can be bought at their minimum value, after which the project collects a sum determined from individual sponsors and investment funds, then project processing and ICO coins start appearing on cryptographic markets. Subsequently, depending on the project, the cost of the coins increases. The most striking growth after the ICO was the Stratis coins, which grew by 151,000 per year only in one year. That is, if you had invested \$ 1,000 in the Stratis coins when you were in the ICO, then in just one year your investment would have brought you \$ 1.5 million. But there are risks too, because these stunning successes are used by the scammers, initiating impossible projects, only to cause damage to society. So, think well what you decided to invest in.

Since this year, more and more projects are being called for to unite real life with Blockchain technology. For example, the ICMP ARMPACK project to be launched this year. ARMPACK aims to escape the world of speculation and fake goods through Blockchain and provide a useful mobile application for anyone to pay for the purchase of cryptoduites, keep different cryptovates, check the originality, the origin of the product, the manufacturer's contact details, get discounts, participate in different actions, and the manufacturer pay you with Bitcoin for shopping.

ARMPACK manufactures logistic servers in Blockchain which represent more advanced marketing opportunities for customer communication. The use of the ARMPACK network by any company will allow the technology to penetrate into all Business processes. All processes are united and interdependent in a single Blockchain ecosystem, taking place in smart-contracts that offer 100% security against fraud. Unfortunately, such projects appear rather rare, but we notice that the market is being corrected over time and there is a great future ahead of Blockchain technology. No cryptopod must have a huge domination. The list of 150 cryptovalents must be constantly capitalized. There must be no encryption of 10 to 20 or 30 percent of the total capitalization of all cryptovalents. But if this happens, the same dollar will be earned, and again, an inequality between people if there is something unique in the world. There must be no such thing. All members of the crypto-loop society must understand that the market will be safer and steadily growing when there is not a strong dominant danger.

6. Conclusions

We have approached Bitcoin from the multitude of cryptovudes on the market because of its popularity, being the most used electronic money. From the ideas outlined above we can deduce that Bitcoin has no practical value, but it is not. Even if bitcoin use is somewhat more difficult because of its volatile course, the popularization of this coin has led to the development of cryptoplane itself, which is economically important. More stable and more practical cryptoscopes appear: Ethereum, Litecoin, Yota, which, over time, may replace the concept of paper money, and move to electronic money. Technologies are growing at an accelerated rate, and financial security is getting bigger every day, so implementation of cryptobodies might be an action that would provide economic prosperity in the future, yet they eventually meet the concept of money base: measuring the value of a product, and facilitating the exchange, that is money is a tool with which the exchange becomes effective. Money presents our economic capacity, and cryptovalata is a concept that attempts to implement this money feature in reality. As mentioned earlier, once and spices were considered "gold", which means that the nature of money is flexible, and what seems impossible now can be widely used in the future.

Management of succession in family businesses

Claudia Isac*

University of Petrosani, 20 Universitatii str., Petrosani 332006, Hunedoara County

Abstract

In the introduction of this paper, we have revealed a few issues relating to the development of family businesses in Romania and the necessity of implementing a management of succession in businesses set up after 1990. Thus, using statistical methods we have highlighted their evolution based on several criteria and by comparing them with EU and US models I have created a profile of their successor. Considering that the majority of businesses in Romania are at a stage of being handed over to next generations, we have managed to bring out the defining elements of implementing an efficient management of succession/generations with direct implications on the continuation of the company's activities, the types of succession processes and management principles applied within Romanian companies. At the end of the paper we have compared the successor's profile from the Romanian business environment with the U.S. successor's profile using data gathered from Forbes charts.

Keywords: family businesses; management of succession; entrepreneurship.

Introduction

Most of the existing businesses in the current business environment can be treated as a family business, from small companies and medium-sized enterprises to multinationals with a turnover of million euros.

In the academic literature in Romania, the term 'family business' is not very common, on the one hand due to the fact that after 1990 people had a wrong attitude towards businesses, as there was the tendencies to believe that it was a fraudulent way to make a fortune and on the other hand, specialists were more interested in analysing other economic concepts which were more obvious. "Family Business" is a term that has become very common in the current language, but very little analysed and studied in Romania and, generally, *the family business* is a form of economic organization, consisting of an individual entrepreneur and his family, therefore in order for a business to be a family one, it must have three coordinates such as the family, shareholding and the business. A completely different situation can be found worldwide where there are multiple approaches regarding this concept, culminating with magazines and associations that have multiple and intense interests in this respect. It is generally accepted that the family's involvement in the business makes the family business unique; but the literature continues to have difficulty defining the family business.

Traditionally, the family business can be understood as a combination of terms - family and business. There are differences between theoretical and operational definitions (Chua et al., 1999). If we are looking for a theoretical definition, one can put it as the intention of the family to be in control, or maybe as one with the unique, inseparable, synergetic resources and capabilities arising from family involvement and interactions (Habberson et al., 2003)

An operational definition has focused on a combination of the four components involved in the family's involvement in the business, namely ownership, governance, management and trans-generation succession (Machado & Melo, 2014).

It is worth mentioning the definition of the concept given by Professor Jean Davis who stated that the family enterprise is the collection of a family's economic interests and meaningful activities that help to identify, support and unite the family.

In conclusion, the definition of the concept and the characteristics of the family business are influenced directly by the family involvement in ownership and management which makes the family business to differ from other types of business.

Comparative analysis of theories about family businesses

Family Business Network Romania Association shows that a family must meet several criteria: at least one member of the family is involved in the management of the company; companies should be listed on the stock exchange; the person who founded or acquired company or his family must own at least 25% of the decision-making rights to which they are entitled to through the holding of equity; the majority of the decision rights belong, directly or indirectly, to the founder or to the spouse, parents, children or direct heirs.

After several studies, it has been established that family businesses are superior to non-family businesses in terms of profits, productivity and other indicators of profitability. When the business is a family business and it is owned entirely by the members of one family, they have common goals and together they invest time and effort into their entrepreneurial development. As a result, high performance is a strong point that family businesses have.

As in any type of business there are disadvantages which may be related to management efficiency, the relations with relatives but also to how financial resources are shared between family members because sometimes their unbalanced contributions may lead to conflicts that affect both the business and family life. Management and family business challenges have resulted in the emergence of two theories on the family business, they either focus on the family, or on the business (Văduva et al., 2011).

Over-focusing the attention on the business results in the deterioration of the relationship with the family; its affects communication and feelings within the family, the emotions of the family and it reduces family time especially when only one part of the family is involved in the management of the business.

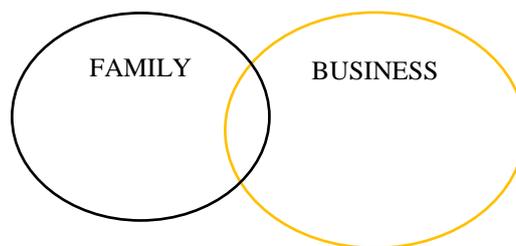

Chart 1

Over-focusing the attention on the business

It is obvious that this theory has a counterpart due to over-focusing one's attention on the family which causes communication disruptions within the business, it influences negatively the decision making process and can lead, in the end, to spoiling business relations.

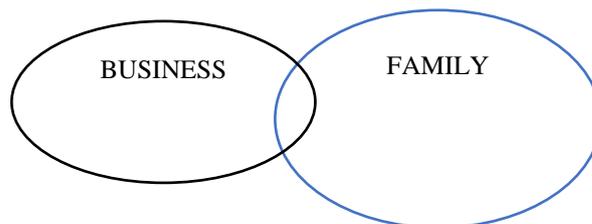

Chart 2

Over-focusing the attention on the family

Family businesses ensure the needs and well-being of the family and, in general, their management focuses on resistance more than performance and they stock up on surpluses available during periods of prosperity in order to increase their chances of survival during periods of recession. In this context, the strategic management implemented has certain characteristics. For example, even though the Chief Executive of a family-run company may have financial incentives similar to those of the Executive Directors of non-family businesses, their strategic decisions are influenced by the obligation to the family that will lead to very different strategic options. Thus, the period of time needed for the implementation of strategies varies between 10 or 20 years, while the objectives are focused on what one can build now so that future generations will take advantage of (Kachaner et al., 2012).

In essence, one can point out several differences in the strategic management of family and non-family businesses. The specific elements that influence the strategy in a family business are (Kachaner et al., 2012):

1. Systemic components. The family business is a complex system consisting of three subsystems: the family, the shares and the business. Thus, strategic risk arises primarily due to blockages that may appear on the part of the "family" subsystem which in the case of non-family companies is inexistent and the two subsystems balance each other out;

2. The value of debts. In modern corporate finance, a considerable value of debt is considered a good thing, because the financial lever maximises the newly created value. In family businesses the notion of debt is associated with the concepts of risk and fragility, and the debt is deemed to be an obstacle which provides a "restricted operating space". Obviously, debts are not totally excluded; it is just that the optimal value of the debt is linked to the attitude towards investment risk and with a short term of repayment. The maximum amount of debt in the case of family-run businesses is 37% of the equity, while non-family firms often reach the threshold of 47% of their capital.

3. Expansion policy

In general, in family businesses, the expansion policy involves purchases of smaller value and/or size in areas relating to existing activities or transactions with a simple geographical expansion that generates organic growth. Most small and medium-sized family businesses avoid high risk transactions based on "radiant" acquisitions. There are, however, exceptions to this rule — when the family is convinced that the traditional sector is faced with structural changes or when it is considered that the business does not take part in the consolidation of the industry and might endanger the long-term survival of the company. On average, it was found that the average value of acquisitions is worth only 2% of the turnover, compared with non-familiar businesses that made purchases of 3.7%, which is almost twice as much.

4: Capital expenditures

Family-run businesses are particularly judicious when it comes to capital expenditures, also called CapEx which represents money invested by a company in the acquisition, maintenance or improvement of fixed assets, such as be property, buildings, factories, equipment and technology. Often, in the context of family businesses one must make sure that these costs are balanced in relation to the cash flow in order to create a surplus for times of recession.

5. Personnel policy

If one analyses the financial indicators in the last economic cycle, i.e. in a crisis, it is observed that family businesses have entered the recession with minimum cost structures and thus the likelihood of implementing restructuring policies and laying off staff is low. Passing on family values has a direct effect on personnel policy and it is mainly focused on complying with principles of ethics and social responsibility, employees are not just names on the payroll or a bar code on an access card.

6. Strategic planning. In family businesses strategic planning can be done over a period of 20 years so that an effective strategic planning will have beneficial effects on the following generations (Kachaner et al., 2012).

In conclusion, a family firm is a firm dominantly controlled by a family with the vision to potentially sustain family control across generations (Zellweger, 2017).

Management of succession

One of the most important factors in the continuity of a family business is the implementation of succession management for the transfer of property between generations. The academic literature has examined characteristics of successors and founders, succession processes, and the influence of other family members on succession (Blumentritt et al., 2012).

Succession planning is beneficial to the business, and from this perspective, specialists appreciate that the most important challenge for this type of business is the test of time. A study by John Ward in 1987 concluded that, statistically, only 30% of family businesses are taken over by the second generation, 13% are passing on to the third generation and only 3% survive to be taken over by the fourth generation.

The topic of business continuity is therefore of paramount importance, which any family business leader has to consider. Early preparation of the successor / successors and the definition of a medium to long-term action plan, with or without the help of a specialist, should be a priority.

The succession in family businesses is a process that takes place over a long period of time. Le Breton-Miller et al. (2004) regarded succession management as a complex process with four main stages: establishing basic rules, cultivating and training the group of potential successors, selecting successors and establishing the final successor. Most research on the succession family businesses focuses on the second stage regarding the cultivation and training of the group of potential successors, while the other focuses on the final step following the selection (Mazzola et al., 2008; Mitchell et al., 2009). In most studies, the succession is a risk period of survival for a family (Royer et al., 2008 Shepherd & Zacharakis, 2000) and one of the main reasons for the high rate of failure among family businesses first and second generation is the inability to manage the emotional aspects of the succession process (Blumentritt et al., 2012). They have made an inventory of many studies conducted by various researchers in family businesses domain and have shown that they have not found any study exploring specific decision-making procedures for succession management and which could include decisions on the choice of successor.

The fundamental challenge of any family business is, on the one hand, the tension between business needs for growth and development and, on the other hand, the family's interests for continuity, succession and preservation of its vitality. Succession management is influenced by elements specific to family governance. In most cases, the family needs resources to support itself, while the business needs funds for investment and expansion, and the adoption of a form of governance allows the adoption of clear procedures that apply when conflicts and misunderstandings arise between family and business.

In terms of succession management, two governance models considered to be most effective are generalized:

1) Establishment of an Administrative Board made up of independent members, with no business or family interests, but with a large business experience and who may make the founder and / or successor be more accountable. Practice has shown that family businesses with the Board of Directors are growing faster, are more active on international markets, and the probability of following a succession plan is greater;

2) Creating a family governance structure before moving to the second generation and avoiding subjective choices in judging hiring other family members or choosing the successor. For example, in the Raventos family, who runs the Condorniu Group of Wine Producers in Spain, family members have known since childhood conditions for becoming employees: English knowledge, university degree and experience of at least five years in a another company.

Succession management studies

Concerning the results of studies comparing sustainability reporting practices between family firms and non-family firms, two orientations are observed: the undifferentiated orientation of the results on the sustainability of family and non-family businesses and differentiated orientation through which the studies suggests that there are more differences in the sustainability of family and non-family businesses.

This topic was also addressed in the 2015 and 2017 Romanian Family Barometer, edited by EY Romania. The 2017 study was applied to 247 businessmen involved in family businesses who responded from the 27 online questionnaire questions from February 8 to March 5, 2017. Of these, 80 are family-run businesses with a turnover exceeding EUR 1 million.

From the perspective of those questioned, the business succession planning is done taking into account the following elements: 100% of Romanian entrepreneurs with family businesses with incomes of over 1 million euro have identified successors, compared with only 87% globally; on a global level, the Board of Directors is most often responsible for the succession (44%), followed by owners and CEOs, unlike Romania where the owners are responsible in 78% of succession management, followed by the CEO (15%) and Board of Directors (5%).

The answers in the case of identification of the person responsible for planning the succession remain similar to those in previous editions of the survey. In conclusion, more than 3/4 of respondents believe that the owners are the ones planning succession, followed by General Director and the Board of Directors.

The economic importance of family businesses

In Europe, the over 14 mil family businesses that turn out around 50% of the GDP have generated over 60 million jobs, approximately 40%-50% of the total employment figure. Comparisons between different countries show different shares of family businesses in the total of companies, ranging between 38-90%. Research demonstrates that, in Denmark, all family businesses are SMEs, and nearly 80% of them have less than 25 employees. A similar situation can also be found in Finland, and Ireland, where 98% of the family businesses employ less than 50 workers. In Lithuania, more than 90% of family businesses take on up to 9 persons, and the rest, about 10% are small businesses with less than 50 employees. In terms of turnover, it is noted that the share of family businesses with an annual turnover of over EURO 2 million in the total of companies is different in Europe, ranging from significant percentages, such as 18% in Italy and 16% in the United Kingdom while lower percentages have been recorded in Spain 7% or Sweden 4%.

Statistical data collected by the European Family Businesses show the impact of the activities of the family businesses on local economies, national economies, international relations and even on the process of globalization. In detail, the most important key figures regarding the share of family businesses in the total of the European companies are summed up in the following chart. Countries like Estonia and Slovakia have taken the lead with 90%, the Czech Republic with 87%, or Spain with 85% while other countries which have registered smaller percentages, such as Lithuania 38%, Latvia 58% or Romania 65% prove to have a deficient entrepreneurial education system due to communism that ruled out the notion of private property in favour of equal incomes among citizens. Even though over 96% of all family businesses are SMEs, including family farms, the difference is made by great family-run businesses by being in the top European and international companies.

Statistical reports on *The Statistics Portal* show that the most important family businesses in Europe with an impressive market value which allows them to maintain their top position as the biggest businesses for many decades are reputable businesses with a major influence on the world's economy, such as Roche from the Netherlands, BMW and Volkswagen from Germany or Anheuser-Busch InBev from Belgium.

A suggestive picture relating to family businesses can be formed on the basis of the research *undertaken for the drafting* of Top Forbes 100 for the year 2018, and it reveals that there are three European family businesses run by women: the French Françoise Bettencourt Meyers (L'Oréal, ranked 18th), the German woman Susanne Klatten (BMW, 32nd place) and the Dutch Charlene de Carvalho-Heineken (Heineken, ranked 86th) and the youngest billionaire in the world is also a woman, the Norwegian Abbas Abid, aged 21 years, with a wealth of \$1.4 billion ranked 11th in Norway.

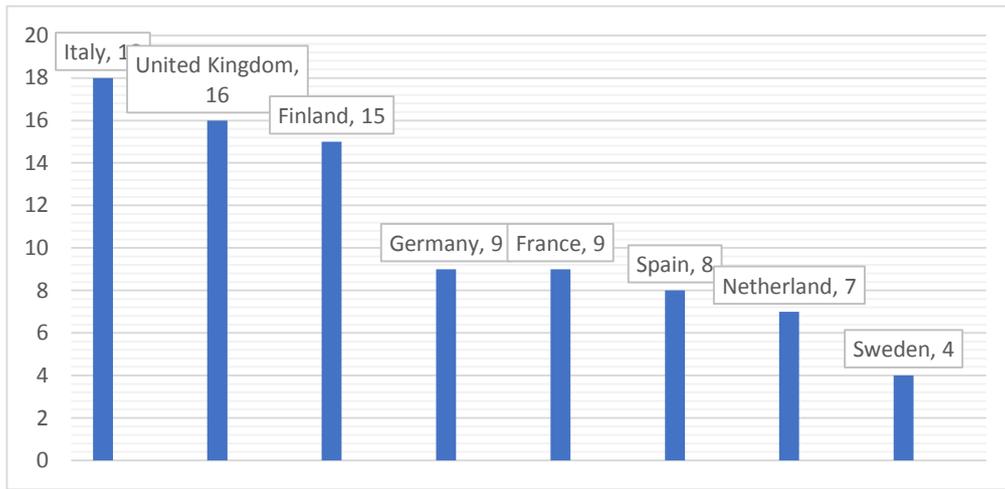

Fig. 1. Annual turnover of over EURO 2 million in the total of companies

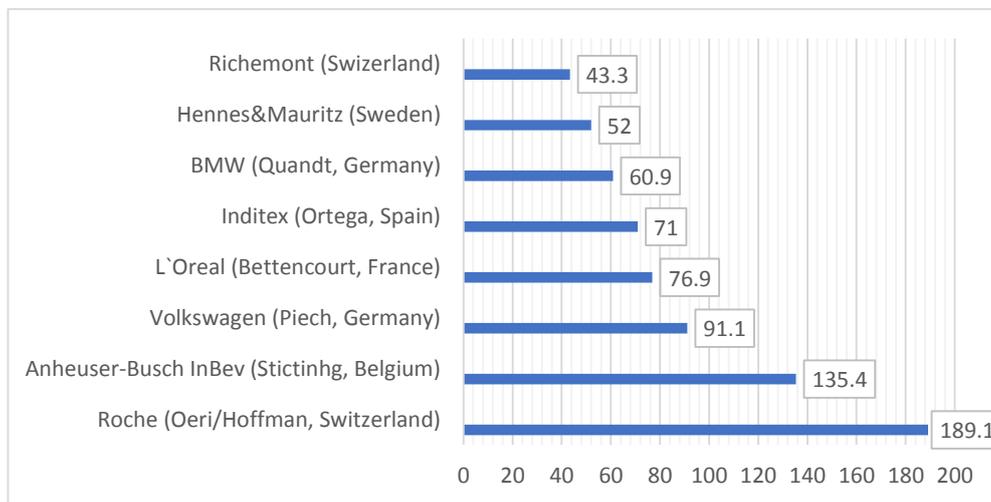

Fig 2. Largest family businesses ranked by market capitalization in Europe (billion euros)

Some of the world's largest family-run businesses are Wall Mart (United States), Volkswagen (Germany), Samsung Group (Korea) and Tata Group (India). According to the study carried out by Sarah Anderson and John Cavanagh within the *Top 200* researches: *Explosion of Global Corporate Power* Wall Mart is the biggest family business, and the added value of this company exceeded the gross domestic product of some national economies such as Poland or Greece (Anderson & Cavanagh).

Conclusions

In conclusion, family businesses are among the biggest and most sustainable businesses in the global economy, managing to remain innovative, flexible, focused on what they're doing and on growth for decades, if not centuries. The story of each successful family business starts with someone who had the passion, courage and confidence to invest in their own ideas. Entrepreneurs are creative and willing to reach their goals, they have the ability to see business opportunities where others cannot.

Family businesses are the most popular and they play an important role in many countries and are also the foundation of the world's economic development through the creation of numerous jobs which results in a stable and prosperous social life. Most family businesses have grown and have become stronger after they have overcome many obstacles and have undergone several stages of development from simple SMEs e.g. ASUS, ACER, or GIANT and long-term strategies have enabled a consistent development. From entrepreneurial point of view, family business turned out to be incubators for entrepreneurs, developing the entrepreneurial culture from one generation to the next. *In conclusion, one can say that family businesses existed, are and will be present as long as mankind will continue to exist and will be the 'glue' that holds to the world's economy together.*

Some Practical Tools to Mitigate Occupational Safety and Health Risks within the Industrial Environment

Ana Petrina Păun^{a*}, Mirela Monea^a, Codruța Dura^a

^aUniversity of Petroșani, University Street No. 20, 332006, Romania

Abstract

The paper reviews the methodological framework for assessing occupational risks and employs the analytical approach in order to estimate workplace accidents and health risks. Occupational risks are determined in a classic manner through taking into account the probability of occurrence of an unwanted event in the industrial environment, multiplied by the maximum predictable consequence of the event. The method applied within our case study aims at quantifying workplace risks within a Romanian company specialized in producing paints, varnishes, removers and accessories, at identifying the risk factors affecting the production system and at computing the actual level of risks on the basis of the severity and frequency of maximum expected loss. The results of the determinations make possible the drawing out of a mix of preventive organizational measures in order to mitigate the accident risks or to narrow down work circumstances that are likely to generate casualties and/or work-related diseases.

Keywords: occupational safety and health; risk management; risk assessment matrix; risk analysis and mitigation

1. Methodological Framework for the Assessment of Occupational Safety and Health Risks

Regardless of their field of activity and their size, corporations are nowadays confronted with various categories of risks, which can seriously impact both the achievement of their operational objectives – activities, processes, technological flows – and the financial outcomes, market performances or reputation. This is why risk management represents a relatively new concept, which was coined in literature due to the prerequisites that condition companies' efficient operations under the circumstances of minimizing the impact of uncertain events on objectives' achievement process and of drawing up possible measures programs for the recovering of sensible areas of activities.

Therefore, under the Occupational Health and Safety procedures, risk management designates a logical, step-by-step process of identifying, assessing and eliminating/ restraining hazards upon the organization's operations, assets and outcomes, followed by monitoring and controlling uncertainties associated with any type of risks. Given the direct link between Occupational Health and Safety Management issues and real life problems that emerged from practical challenges within the industrial environment, expertise in OHS has developed in recent years under the strong influence of academics and practitioners of OHS who sought pragmatic solutions for many particular cases. As a consequence of this trend, the prescriptive literature now overshadows the theoretical debates, aiming at setting up tools, methods and practices rather than substantiating definitions, theoretical models or concepts.

Our paper joins the aforementioned trend, by putting forward a quantitative approach which can be used in order to quantify the level of workplace risks within a Romanian company specialized in producing paints, varnishes, removers and accessories. The essence of the method lies in the identification of risks factors that affect the analyzed system, followed by the assessment of risk magnitude, which represents the product of the degree of gravity and the frequency of maximum expected loss. The output of the evaluation enables managers to conceive, based on previous estimations, a set of preventive technical and organizational measures aimed at reducing those risks of injuries and/or professional health issues which were classified as extremely high and, therefore, unacceptable.

* Corresponding author. Tel.: 0040722363536.

E-mail address: codrutadura@upet.ro.

The activity assessing professional risks is part of the present legislation regarding labor security and health, namely of *Law no. 319/2006 of Labor Security and Health*, with subsequent changes and completions and of *Romanian harmonized standards EN 12100 and SR EN 1050*, which stipulate the obligation and principles of the risk evaluation of workplaces. Consequently, the two measurable parameters that define risk, in accordance with standard EN 12100:2003, are the following ones:

- *Probability* that may determine an unwanted event (labor accidents or professional illnesses);
- *Severity* of the consequences of the unwanted event, namely the maximum predictable and probable seriousness.

With a view to quantifying these parameters within the context of the analytical methodology for the evaluation of the professional risks which we are going to apply in the case of the company our case study focuses upon, a series of practical work instruments are going to be employed, which will be briefly described below. The first one, **the grid of the parameters evaluating consequences**, classifies these effects in five distinct classes of severity while taking into account the probable effects of possible professional accidents upon the labor capacity of the human resources involved (Table 1).

Table 1. Grid of the parameters evaluating consequences

Severity classes	Consequences	Severity of consequences
1	Insignificant	Minor, reversible consequences with predictable labor incapacity for up to 3 calendar days (recovery without treatment)
2	Minor	Reversible consequences with a predictable labor incapacity ranging between 3 and 45 days, which require medical treatment
3	Medium	Reversible consequences with predictable labor incapacity ranging between 45 and 180 days, which require medical treatment and hospitalization
4	High	Irreversible consequences with diminution of labor capacity of 50 % at least, the individual being able to carry out a professional activity (3rd degree invalidity)
5	Serious	Irreversible consequences with 100 % loss of labor capacity, yet with possibility of self - serving, of self - management and space orientation (2 nd degree invalidity)
6	Very serious	Irreversible consequences with total loss of labor capacity, of self - serving, of self - management or space orientation (1 st degree invalidity)
7	Maximum	Death

The **probability of unwanted events occurrence** is, at its turn, measured through six categories of distinct events that can be associated to each class of probability: from extremely rare events with a very small occurrence probability (estimated at over 10 years) to events that might occur with a very high occurrence frequency (occurrence probability is considered, in such cases, to be less than 1 month) – Table 2.

Table 2. Grid of the parameters unwanted events occurrence probability

Probability ranks	Event	Probability of consequences - P
1	Extremely rare	(extremely small), $P > 10$ years
2	Improbable	(very small), $5 \text{ years} < P < 10 \text{ years}$
3	Remote	(small), $2 \text{ years} < P < 5 \text{ years}$
4	Occasional	(medium), $1 \text{ year} < P < 2 \text{ years}$
5	Probable	(high), $1 \text{ month} < P < 1 \text{ year}$
6	Frequent	(quite high), $P < 1 \text{ month}$

The **level of professional risk** associated to each event and, implicitly, the **extent to which the objectives of occupational security are or are not met** is measured owing to the grid quantifying the level of risk, displayed by Table 3, which observes the estimated values afferent to risk R, with a variation range between 1÷42. Meanwhile, the colors and fields shown by Table 3 allow the identification of acceptable risks and their separation from the values of unacceptable risks.

In accordance with the identified and classified levels of risks displayed in Table 3, a series of alternatives have been elaborated, which regard the **attitude of decisional factors when facing risk** and the categories of measures that should be adopted in the case of each particular situation – Table 3.

Figure 1 displays the matrix of risk analyzer resulting from the combination of the seven classes of consequences severity appreciated together with the occurrence probabilities associated with each of them. The content of the matrix shows various levels of risk R, in relation with which the evaluation of professional risk is displayed both as a value

dysfunctions that might be determined by that factor; *technical and organizational measures* that should be taken with a view to decreasing/ eliminating the risk; *legal references and documents* owing to which these measures are grounded; *the concrete manner of implementing the proposed technical and organizational measures*, namely: *estimating the probable residual risks* that may occur within the industrial context in view. In order that the risk evaluator might forge a global image of all the categories of partial risks that were shown by the analysis at different work places and jobs within a company, an *Index of the forms for the analysis and diminution of risks* may be conceived; the index will draw out an inventory of all the risk factors classified as unacceptable from the point of view of their magnitude; in accordance, it is possible to elaborate a coherent and unitary *plan of technical and organizational measures* that makes possible the implementation of an efficient risk management with immediate results in the area of increasing the level of health and security of the employees.

2. Case Study: The Use of Risk Assessment Matrix within an Industrial Company

We have chosen as an example capable of showing the manner of implementing the instruments of analysis of the risks described by the previous paragraph, a Romanian company which operates in the domain of the technology of paints and varnishes and detains the position of regional leader in this field in the area of South - Eastern Europe. Emerged from the fusion between a local company and a company having a similar object of activity, which used to operate in Bulgaria, Policolor – Orgachim Company conceives and provides full solutions for the consumers on the market of goods, for industrial consumers, and for clients in auto vehicles industry.

The evaluation of the risks at work places and jobs within the company was made for all organizational sub-divisions, irrespective of their having an operational or functional role within formal organization. The level of risk was estimated through the two parameters described by the previous section, namely the *probability of the occurrence of the danger generating the risk* and the *maximum predictable consequences for human organisms*, in accordance with the scale of ranging the level of risk/ security, shown by Table 4:

Levels of risk/ security	Values of risk R estimation	Evaluation of the level of professional risk	Evaluation of the level of occupational security
1 / 7	(1,1) (1,2) (1,3) (1,4) (1,5) (1,6) (2,1)	Minimal risk	Maximal security
2 / 6	(2,2) (2,3) (2,4) (3,1) (3,2) (4,1)	Very low risk	Very high security
3 / 5	(2,5) (2,6) (3,3) (3,4) (4,2) (5,1) (6,1) (7,1)	Low risk	High security
4 / 4	(3,5) (3,6) (4,3) (4,4) (5,2) (5,3) (6,2) (7,2)	Medium risk	Medium security
5 / 3	(4,5) (4,6) (5,4) (5,5) (6,3) (7,3)	High risk	Low security
6 / 2	(5,6) (6,4) (6,5) (7,4)	Very high risk	Very low security
7 / 1	(6,6) (7,5) (7,6)	Maximal risk	Minimal security

The level of global risk (N_r) afferent to the work place is calculated as a weighted average of the levels of risk settled for the risk factors identified as active in the case of that work place. In order that the result obtained mostly comes near to reality, a weighted average element is employed, that is the rank of risk factor.

$$N_r = \frac{\sum_{i=1}^n r_i R_i}{\sum_{i=1}^n r_i} \tag{1}$$

where: N_r= the level of global risk per work place; r_i = the rank of risk factor „i”; R_i= the level of risk afferent to the risk factor „i”; n = the number of risk factors identified at the work place.

In the case of the work places and jobs within the company for which we have elaborated this case study, a series of organizational sub-divisions have been identified; after the evaluation of risks, these sub-divisions appeared to range within the area of unacceptable risks. The instrument owing to which the “sensitive points” in view have been identified was the risk analyzer whose matrix was displayed by Figure 1. After having taken into account these aspects, we went further to implementing the procedure of analysis and decrease of these risks through conceiving a coherent program of technical and organizational measures with a view to preventing and fighting the causes that determined the undesired events (labor accidents and professional illnesses). As an example, we are going to display below the form for the analysis and decrease of unacceptable risks determined for the Environment Department.

Focusing upon the technical and organizational measures systematized by their analysis form, a consecutive decrease of the level of professional risk initially quantified at 24 (which matches a degree of risk appreciated as *medium*) towards level 18 is estimated (which matches a *low* degree of risk), so that, at the end of the implementation period, a value equal to 13 could be reached, implying that the activities carried out at the level of this Department will move towards the *area displaying a very low risk*, while the level of security and health of the employees will increase in accordance.

3. Conclusions

The literature provides practical guidance for managers in order to initiate and make improvements in the process of industrial risks assessment. A mix of variables, risk factors, triggers and combinations must be taken into account in the process of constructing the most adequate tool that covers the peculiarities of the industrial environment to be applied. No matter if qualitative, semi-quantitative or quantitative, we believe that risk ranking systems will continue to expand and to grow in efficiency, keeping up with managers' necessities related to the process of conceiving an implementing pragmatic and innovative solutions to increase the level of security for their workplaces.

OHS Disclosure in Romania in the Framework of CSR Reporting

Codruța Dura^{a*}, Imola Drigă^a, Ana Petrina Păun^a

^aUniversity of Petroșani, University Street No. 20, 332006, Romania

Abstract

The paper aims to assess the magnitude of OHS disclosure phenomenon in Romania, in the context of CSR and sustainability reporting. In order to achieve our research objective, we have performed a qualitative study, based on the content analysis method. Thus, we have focused on identifying a few cardinal aspects that are able to facilitate a general insight on the issue of OHS disclosure: the novelty of the reporting routine; the core OHS themes presented in the sustainability/CSR reports; the compliance of reports with the international standards, the number of pages dedicated to OHS issues etc. Our outcomes substantiated the idea that the occupational safety and occupational health issues are highly important for managers who activate in the industrial sector and acknowledge the risk of physical hazards occurrence. Moreover, subsidiaries of multinationals operating in Romania, benefit from the experience gained by their parent companies in terms of OHS reporting, but they still have to do a lot of improvements in their practices, in order to comply with the international reporting standards.

Keywords: OHS disclosure, CSR reporting, sustainability reports, non-financial reporting, multinational companies

1. CSR Development and Reporting in Romania – facts and figures

CSR received a great deal of attention in the literature, during the last two decades, being accounted between the most argued topic of the global economy. The significance of the CSR concept and the related practices developed under the pressure of stakeholders towards increasing of transparency and adoption of ethical behavior in business. The main stimulus that set off the occurrence and the proliferation of CS reporting, seem to lose itself among the mechanisms that drove the very development of the international economy (Lungu et al, 2016). The prerequisite of integrating social aspects of business with the financial information occurred in 1970s, when the first non-mandatory reports were issued. In the 1980s the environmental issues became prevalent, due to the high level of risks associated with the impact of economic activities on nature's degradation. Environmental-related risks proved themselves to be capable of even threatening the market survival for numerous of the Globe's largest corporations. Sustainability reporting has spread in the 1990s, when the holistic approach emerged and the *triple-bottom-line* reporting acknowledged the interplay between economic, social and environmental facets of business (Dura et al., 2017).

In Romania, the culture of sustainability reporting is still in the making, under the positive impact of large multinationals that have assumed the role of disseminating managerial practices proved to be efficient in their countries of origin (Grabara et al., 2016). Until the issuance of Order No. 1938/2016 by the Romanian Ministry of Public Finances, both CSR programs and reporting practices were initiated and unfolded rather as discretionary and non-mandatory activities; after the 1st of January 2017 when the aforementioned legal act came into force, the majority of the Romanian companies begin to comprehend the topic, while seeking the proper solution to adapt.

In order to have an insight of the status of CSR development in Romania, we are going to use statistical data provided by some representative surveys conducted at the national level by renowned consultancy firms: CSRMedia & Valoria, Ernst&Young, The Azores. Thus, according to the research *Dynamics and Perspectives of CSR Domain in Romania*, conducted in 2018 on a sample of 107 enterprises from 16 industries, the main reason that drives a company's involvement in CSR programmes are represented in figure 1. Unfortunately, CSR is still viewed, by an important share of the analyzed companies, as a component of PR strategy, aimed at disclosing solely favorable appearances. Thus, the same survey reveals that the budget line for CSR is drawn up, for 63% of the companies included in the sample, within the PR&Marketing Department (Figure 2).

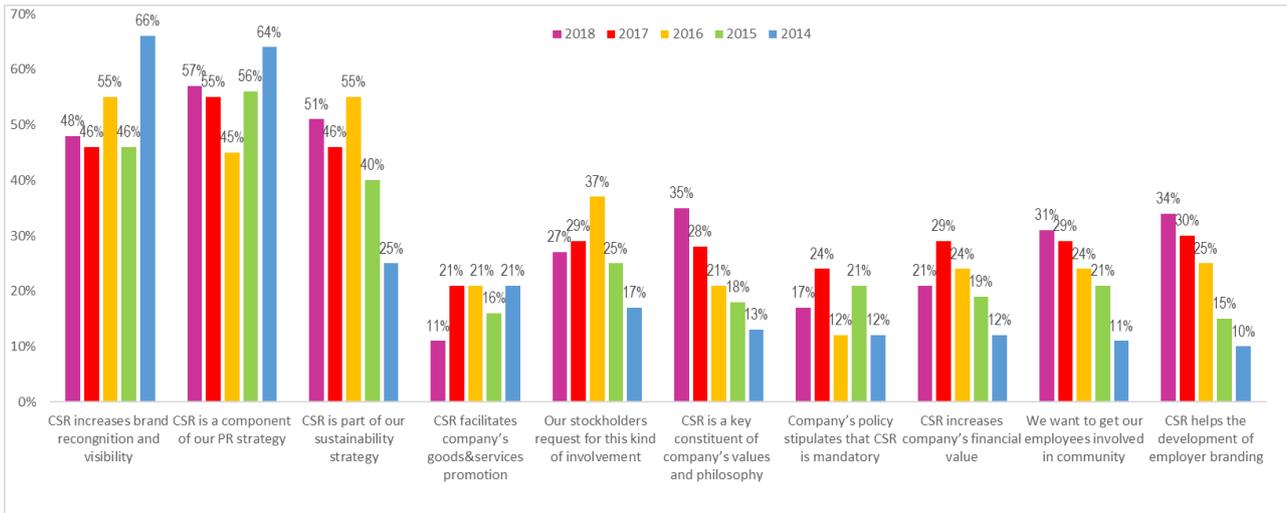

Fig. 1. Main reasons that drive Romanian companies' involvement in CSR (Source: *The Dynamics and Trends of CSR Domain in Romania*, CSR Media & Valoria, 2017)

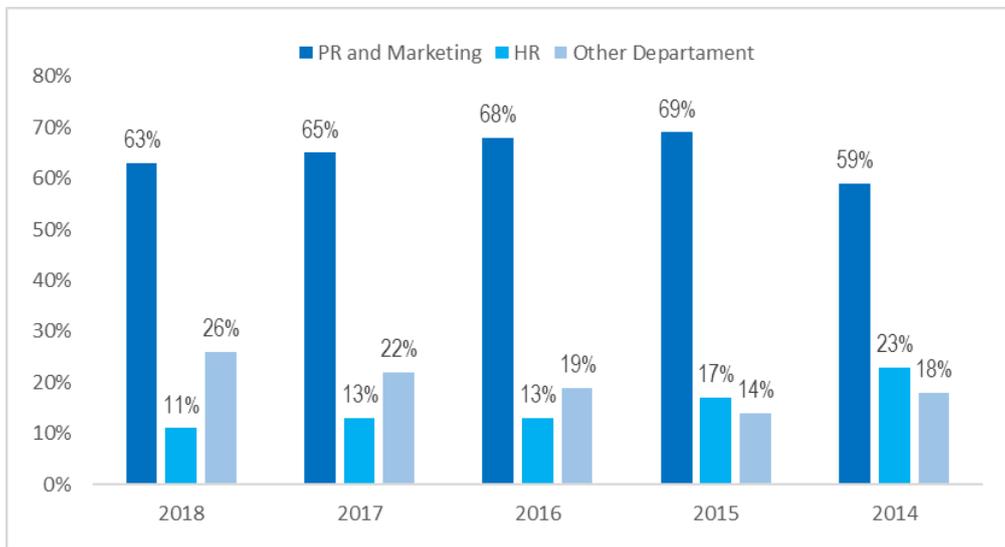

Fig. 2. Departments that draw up the main budget line for CSR (Source: *The Dynamics and Trends of CSR Domain in Romania*, CSR Media & Valoria, 2017)

However, it is worth-mentioning that the majority of companies (51%) are beginning to be aware that CSR represents a key component of the sustainability strategy. When it comes to revealing the instruments employed for the public disclosure of CSR activity, we have noticed that annual reports hardly rank the fifth position (34%), after social media (84%), press releases (81%), websites (78%) and CSR dedicated platforms (59%) – figure 3.

Little data is available from empirical studies undertaken in Romania with the focus of CSR communication. But the few proofs we discovered tend to advocate our belief regarding the absence of a strategic approach in CSR communication by the Romanian companies. In fact, except for subsidiaries of multinational corporations, an insufficient number of small and medium enterprises originating from our country have already settled a constant CSR/sustainability reporting practice (Gliogor-Cimpoieru&Munteanu, 2014).

2. OHS disclosure in CSR/Sustainability Reports

Promoting transparency and increasing the extent of non-financial business information disclosure constitute vital issues placed on EU's agenda. It has been shown that the Western part of the European continent represents the most committed area when it comes to measuring the magnitude of CSR reporting (Montero et al., 2009). According to *The KPMG Survey of Corporate Responsibility Reporting 2017*, "reporting integration is the new normal and non-financial is the new financial".

In other words, if CSR data was regarded in the past as strictly "non-financial" and not enough pertinent to be inserted in the content of annual financial reports, more than three quarters of the world's 250 largest companies incorporate now at least a few non-financial facts and figures in their financial statements.

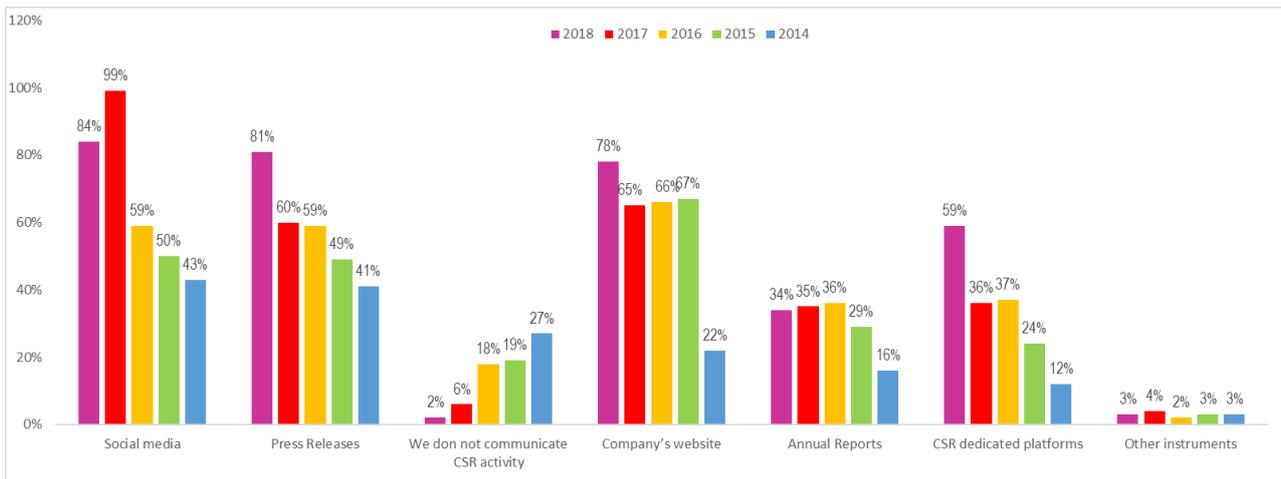

Fig. 3. Instruments employed by the Romanian companies for the public disclosure of CSR activities (Source: *The Dynamics and Trends of CSR Domain in Romania*, CSR Media & Valoria, 2017)

Figure 4 shows CSR reporting rates in Western Europe, Eastern Europe and Romania, between 2015 and 2017. Under the pressure of regulation changes and investors' constraints, Romania is included among the group of countries with CSR reporting rates higher than the global average. Thus, it is estimated that more than 700 Romanian companies will have to satisfy requirements stipulated by The Directive 2014/95/EU on Non-Financial reporting, but the estimated synergistic effect for other companies that do not fall under the incidence of this law is expected to be outstanding, due to the benchmarking phenomenon (Ogrea, 2017).

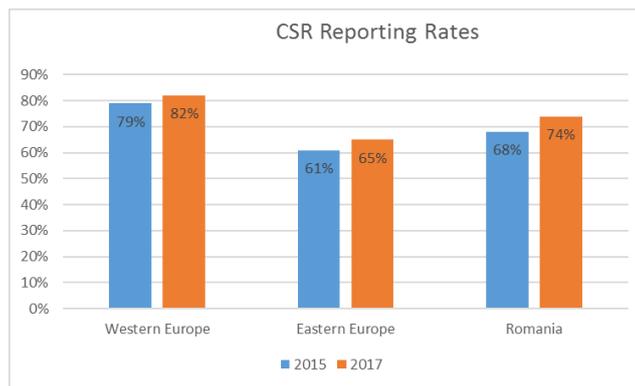

Figure 4: CSR reporting rates between 2015 and 2017 (Source: *Survey of Corporate Responsibility Reporting*, KPMG, 2017)

In the framework of CSR, employee-related issues received a great deal of attention over the past two decades. Yet, early empirical studies, with very few exceptions, brought little insights when it comes to OHS disclosure topic. The main emphasis of these studies was limited to highlighting the peculiarities related to quantity, quality and communication modes employed for miscellaneous CSR issues (Habek et al., 2016). The common denominator of these researches has resulted in demonstrating high levels of reporting on OHS within the content of annual reports, CSR reports, sustainability reports and websites (the overall frequency was estimated to range between 70% and 95%). (O'Neill, 2010). As the OHS domain flourished, many scholars addressed issues of content and quality in reporting, driven in a certain degree, by the appearance of GRI 403, a customized sub-set of GRI Standards designated to the harmonization of reporting practices in the area. The GRI framework directs both the process a drawing up the sustainability report and, more specifically, the content of the report which is split off in two parts: management approach and topic-specific disclosures. The management approach covers the following issues: *OHS management system; hazard identification, risk assessment and incident investigation; occupational health services; worker participation, consultation and communication on OHS; worker training on OHS; promotion of worker health; prevention and mitigation of OHS impacts directly linked by business relationships*. Topic-specific disclosures refer to the following aspects and key-performance indicators (KPI): *workers covered by an OHS management system; work-related injuries and work related ill health* (GRI 403, 2018).

In order to provide a wide picture of OHS reporting by the industrial Romanian companies, we have chosen *the content analysis method*. Content analysis concerns the procedure of drawing replicable and valid conclusions from the analysis of a given text (Krippendorff, 2004). Several content analyses of corporate reports were performed in the literature and they have used different units of analysis, such as word count, sentence count, page count or word-level coding with the help of a modern software (Koskela, 2014). Our analysis relies on statistic data collected for a sample

of large industrial corporations that operate in Romania as local companies or as subsidiaries of renowned multinationals (see Appendix A). In the process of sample selection, we have taken into account the research findings of *Romania CSR Index 2018*, a study undertaken at the national level by *The Azores* consultancy agency. The main objectives of the survey were as follows: to bring to the fore the Romanian leading and trendsetter companies in the field of CSR; to strengthen responsible business practices in the context of the IT&C development and the requirements towards competitiveness increasing; to enhance the exchange of good practices between corporations both at the national and international level; to raise the CSR awareness among the business men and policy makers; to build a strong CSR/sustainability professionals network focused on responsible business practices dissemination (The Azores, 2018). The methodology employed by *Romania CSR Index 2018* was aimed at computing the CSR composite Index for each of the 696 companies included in the survey, namely the entire population of companies with more than 500 employees operating in our country. The assessment of CSR Index was based on 49 indicators divided into 9 categories: corporate governance; diversity; company's economic impact; environment; human rights and anti-corruption policies; employees; marketing and creating awareness; community investments and supply chain management. The study has yielded the top 3 CSR players classified by industry: automobiles; banks; beverages; chemicals; computers retail; construction; construction materials; electrical equipment; environmental and facilities services; food products; food retail; gas utilities; hotel restaurant; insurance; machinery; metals/mining; oil&gas; pharmaceuticals and so on.

Keeping the main focus of calling attention on the most responsible companies in Romania and having in mind at the same time the importance conferred to OHS management systems in the industrial field, we performed our content analysis by choosing 10 different companies mentioned in the *Romania CSR Index 2018* from the following industrial sectors: oil&gas; metals and mining; construction and engineering; machinery; chemicals; construction materials; automotive. In order to substantiate our findings, we made use of the following sources of information: CSR and financial reports issued by companies, academic articles and research papers approaching CSR development in Romania, company's websites, on line platforms for CSR programs and other media communications.

Given the national context and the incipient phase of OHS disclosure development, Appendix A was tailored in order to highlight the following aspects: the level of producing the sustainability/CSR report (the company level was colored in green while the group level was pointed out in yellow); year of issuing the first report (in order to see the novelty of the reporting routine); core themes approached from the OHS domain; the compliance of reports with international standards; the number of pages addressing OHS issues and the total number of pages of the report. While going through the process of gathering information and filling in the table 1 from the Appendix A, we were able to have a clear picture regarding the genuine stage of OHS disclosure in Romania. The main findings are summarized below:

✓ Subsidiaries of multinationals benefit from the experience gained by their parent companies in terms of CSR and OHS reporting, in the developed markets. For instance, in the oil&gas industry, OMV Petrom and Rompetrol (a member of Kaz Munay Group) are the only examples of companies which were able to provide sustainability reports in compliance with GRI standards. Thus, according to Database Global Reporting, there were only 5 companies from Romania that issued a non-financial GRI report in 2017, as compared to 98 GRI reporting companies from Italy and 151 GRI reporting corporations from France. Other empirical studies showed that the oil&gas sector ranks in the first place among the most dynamic fields embracing reporting standards, due to the international scope of their business (Filip et al., 2012). Moreover, OMV Petrom's first sustainability report date back to 2011, but the company had already gained in-depth knowledge in reporting, due to its previous CSR communications;

✓ The fact that the majority of the selected companies published their first sustainability reports in 2016 or even in 2017 (Romgaz and Vimetco Alro Group are two of the most relevant examples) demonstrates that the Romanian companies still linger in the incipient phase of reporting. Although Romania lags behind Western countries with respect to sustainability awareness, the widespread adoption of international standards represents an opportunity that could allow our country to align itself to the global routine while skipping some time-consuming learning cycles (Păun&Isac, 2016);

✓ Regarding the themes tackled by OHS dedicated sections of sustainability reports, one can observe that they are generally consonant with the international practices and with the content of GRI 403 Standard for Occupational Health and Safety. Thus, the values of key performance indicators, the description of the work environment, training and education programs, occupational safety initiatives or the diversity and non-discrimination issues are among the most frequently encountered subjects;

✓ The length of sections dedicated to OHS issues shows that, in average, approximately 9-12% of the information provided in sustainability reports addresses the aforementioned field. It is a relatively high proportion that give evidence of the growing interest regarding OHS metrics and policies in our country.

3. Conclusions and limitations of the research

Despite the need for further research in the area, a few OHS reporting trends became visible from our analysis. First, the importance of occupational safety and occupational health issues is evident for the industrial companies in the sample, because managers running business in these fields are aware, to a great extent, that their company is undoubtedly exposed to a higher probability of physical hazards occurrence than in other areas. Another factor that fueled this evolution consisted in the process of OHS legislation's improvement, which continuously accompanied

efforts made by corporations in order to comply with reporting requirements. Moreover, the complementary role of occupational health and occupational safety seems to be properly recognized in most of the companies from our sample. On the other hand, the reading of sustainability reports enabled us to see that the companies reported both the outcomes (Key Performance Indicators) and the operations “behind the scene”. In other words, beside the effective management of OHS activities in the workplace, there were developed many internal programs, addressed to employees, that targeted shaping and consolidation of the safety culture.

Authors are also aware that the present paper is subject to some limitations. First of all, using the qualitative content analysis method, inevitably implies to some extent, that the subjectivity of the researchers affects the outcomes. Secondly, it is pointed out in the literature that the process of counting the number of pages assigned to a specific topic within a report addressed to the general public can be unrealistic sometimes, because such reports variably include unnecessary photos that are not always related to OHS issues. However, given the fact that all the companies in our sample have used, averagely, comparable illustrations in their disclosures and the reports’ formatting were very much alike, we concluded that taking into account the amount of pages in order to approximate the level of OHS reporting was sufficiently reliable. Thirdly, another limitation of our research is represented by the fact that our sample cannot be considered representative enough to reflect the overall status of OHS reporting at the national level. We can rather state that our study can be seen as a starting point for an empirical study on the subject, that will involve a larger sample of sustainable-oriented businesses from Romania.

Abstract

As a result of digitalisation and technological development, the nature of markets is changing, and companies are using every innovative activity and operation to maintain their positions. Some companies channel their profits back to research and development. Others appreciate the potential of acquisition activities. They invest in them as they realise the potential of the immediate positive synergy effects of these activities. This article examines the complex acquisition process from the buyer's point of view. The authors focused on the due diligence process and the necessity of performing an HR audit as part of the acquisition activities. The HR audit is regarded as the key process in acquisition mainly in the case of SMEs. The authors used a specific horizontal acquisition process to describe corporate cultures and harmonisation processes in an international environment. Cultural integration is usually one of the main reasons for failure of the acquisition process. All the steps described are critical to the successful operation of a newly emerging organisation.

Keywords: Acquisition; corporate culture; Due Diligence; HR audit; potential; processes;

1. Introduction

In the last few years, there has been a great deal of discussion about the fourth industrial revolution, which will have as part of its scope an impact both on industry and the economy, while also causing social changes. The objective of each company is long-term growth and the growth of its value, a significant position on the market and a powerful brand. However, as technologies develop and digitalisation and globalisation consolidate their place in business, the nature of markets alters. All these changes epitomise the phenomenon of Industry 4.0. Companies are using all the innovative tools available for their sales and marketing activities and set their operations while considering both geographic and product growth. Global companies are currently operating on almost all markets worldwide and are competing with other global players as well as with smaller local regional companies or start-ups.

An impact of globalisation and technological developments is an intensification of the competitive environment. Furthermore, this intensification complicates any adequate response to it. The frequency of the emergence of new companies, or rather new competitors on the market and of new products and technologies, has an exponential tendency, thus exerting significant pressure on large companies at any scale – local, regional or global. They in turn try to keep or reinforce their positions by creating their unique solutions, so they channel a high portion of profits back to internal research and development. The effects of these efforts have been very limited in the last decade as development and research initiated in reaction to the market events has enormous time limitations. That is why leaders in their segments, who dictate technological progress, mainly support their own development and research to a significant extent, and all other companies direct their other resources to acquisition activities, rather than to the costly development of new products.

Companies realise that investments in acquisition activities may have an immediate effect, and the companies may advance technologically, or even advance to other segments, thus diversifying their products or scope of operations, while also eliminating threats, such as during financial crises. Another advantage of acquisition activities is the mitigation of competition and the obtainment of competitive advantages in relation to other market players. In terms of acquisition, the current situation is characterised by two basic strategic cases – buying companies for the purpose of increasing market share or buying up small start-ups with exceptional ideas, technologies or solutions with enormous

potential. In such a case, big players are willing to buy such start-ups even if there is a high level of insecurity about whether the solution under development may be ultimately capitalised on the market, or not. The reason is the high level of competition, resulting in fear that the start-up might be bought by a competitor, and also a desire to grow at a low investment cost, compared to the company turnover. A current example may be the pharma segment, with quite a limited number of large players and a lot of small start-ups which are often formed with the aim of being sold.

Acquisition as such can be described as a process of one company acquiring or the buying another. The whole process, including the pre-acquisition stage, is very sensitive. In most cases, negotiations are held behind closed door and any leaks of information can make employees and business partners feel insecure. If the companies' shares are traded on financial markets, the value of shares would change significantly. In some cases, the offer for sale is public and often demonstrative, just to cause the said effects.

As the acquisition process period is quite short, it has its clearly set and defined steps to eliminate risks on both sides. In large-scale transactions, the process is managed by external companies who set the recommended price, level of risks and other important information for both buyers and sellers. The aim of the article is to describe this complex process from the buyer's perspective and to emphasise the importance of the process and of performing all of its stages. One part of the acquisition process is only rarely used and described– the HR audit. In this respect, we would like to point out in this article the importance of including this part into the standard due diligence process as a key factor of successful acquisition.

2. Acquisition process

The whole acquisition process will be described from the buyer's perspective. The reason for this is to highlight the strategic management of a company which has the objective of implementing its visions and objectives through acquisition activities.

The acquisition process is clearly defined and may be divided into three essential stages by Sherman, 2010, and Gaughan, 2017:

1. Strategic analysis and finding an acquisition target
2. The negotiation and due diligence process
3. Integration of a company followed by an audit

The first stage is mostly performed internally in the company. Finding the right acquisition should be in line with the company's long-term vision and objectives, so the top management of a company is mainly involved in this stage, e.g. Soltes et al., 2015. Whatever the object might be, e.g. the consolidation of market positions, portfolio diversification, elimination of the competitors etc., the decision is made based on management consensus and appointment of an executive acquisition team, with all required competencies and responsibilities.

Other parties then become involved in the negotiation process with the purchased company. Here, the authors will focus mainly on global companies or large-scale acquisitions as they make up most of the acquisitions in terms of investments and their process is unified. Besides the company's executive team, advisors and the external company who manage the due diligence process also come into play, see Dvoracek et al., 2014. The extent of due diligence is optional. It is possible to either check only the basic areas of interest to the buyer or to make an extensive in-depth check. It depends on the buyer's particular requirements and the size of the sold/purchased company. These requirements are usually set in the beginning; however, they may change in the process depending on the findings made.

In this respect, due diligence can be described as a series of steps characterising the purchased company in three main areas – financial, legal and operational. Although the due diligence process is divided into three main areas, remember that it is a complex process providing the buyer with a complex characterisation of the purchased company. Following the due diligence process, either the price is verified, or a new price is set. It is also the basis for the subsequent integration and other steps. Before the process, a non-disclosure agreement is signed, and the terms of cooperation are set. The result of this process is a report available to the buyer and, in some cases, to the seller as well, e.g. Ernst and Young, 1994, and Dvoracek et al., 2014.

Financial due diligence is agreed between the buyer and the seller in advance, and it is focused on the accounting and economic aspects of the company that the investor is considering buying. It does not concern only the buyer, and the seller should not approach it lightly. Experience shows that it may confirm the asking price as realistic to both parties or indicate another real price and all potential risks in the process of sale preparations. The most significant threats are according to Dvoracek et al., 2014:

- No records of (potential) payables (such as from a court dispute)
- Non-rotation stock
- Tax optimisation
- Non-compliance with legal obligations
- Dependence of the target company on one (or only a few) customer(s)
- Bad debts of high value etc.

In the case of smaller companies, data concerning the companies' real operations must be considered. As part of tax optimisation, accounting operations are performed to reduce the company's real profits, thus reducing tax payments. In most cases, such operations are one-off expenses and should be excluded from the calculations of profit/loss. Then, it is possible to determine the real value of the company. This part of due diligence uncovering the real profit/loss is absolutely essential for both parties, more in Gleich et al., 2012, and Howson, 2012. The buyer has a real idea of the purchased company and may then plan the integration and progress of the whole company. The seller, on the other hand, has the value of the company raised by increasing the economic parameters including EBITDA.

In terms of a financial audit, the assessment of working capital is an indispensable part of due diligence. The appreciation of the working capital is different than in the operational part. The efforts here are to quantify it as part of the purchase price. Working capital means the difference between operating current assets and operating short-term liabilities. But this is just the theory. In practice, opinions on which item should be included in and excluded from the calculation differ widely. (In most cases, account details must be considered.) It should be the main subject of agreement between the buyer and the seller. The acquisition price is often agreed on a cash-free, debt-free basis. In such case, all financial funds and credit lines are excluded from the working capital, e.g. Gleich et al., 2012, and Howson, 2012, and Dvoracek et al, 2014.

It is worth noting that the efficiency of working capital management can draw the line between a successful company and a dying business.

Legal due diligence must always be performed from the lawyer's perspective. A lawyer should especially review all agreements the company entered into and check whether they are correct and of significance to the prepared acquisition. In addition, all available registers or shareholder links and participations in subsidiaries are checked. In this case, too, it is important to note relevant issues where the lawyer may have a different opinion than management. The lawyer's task is to point out these issues. The final decision, however, is management's responsibility.

During the operational part of due diligence, the company's operational data are collected, including, but not limited to, the list of suppliers, customers, production parameters, HR operations, etc. These data and evaluations are quite accurate and easy to characterise, except for the HR audit. In a large number of acquisitions, it is not performed at all. The significance of its absence is diminished with the size of the purchased company; however, it is absolutely fundamental for smaller acquisitions. In family-type companies or companies with a lower number of employees, dependency on individuals and individual teams is above all high. An HR audit may reveal the level of dependency and potential risks from losing such employees after acquisition. This information is so fundamental that in some cases, acquisition is subject to various competitiveness clauses, the prohibition on the executive team leaving the company, etc. The level of dependency and potential threats also changes the price of the company. When acquiring large or global companies, the HR audit loses significance as these companies are process-managed and the influence of individuals on the operation of the whole company is eliminated, more in Rao, 2014, and Nelson, 2015.

All the areas described above must be regarded as part of a complex. In other words, one threat (a shortcoming) may and does have an impact on other areas. For example, long-term overdue payables have a negative impact on cash flow. In terms of taxes, the company may become obliged to tax the payables in arrears. That is why in financial audits, cooperation with experts and advisors from other areas, e.g. taxation, law etc. working on the particulars of due diligence is frequent. Only in that case, will the buyer get complete information required for correct decision-making in negotiations.

If we take a closer look at the HR audit, each purchasing company tries to understand and describe each aspect of human resources of the purchased company. It includes a description of the following company parameters – organisational structure, competencies in individual positions, decision-making matrix, substitutability and dependency on individuals. An integral part is the identification of key employees and key positions and, last but not least, characteristics of its corporate culture. It is based on the above-described parameters and also defined by the management style and the style of communication regarding requirements and expectations. We can say that the corporate culture is unique in each company. Any change happens over a long period of time and with difficulty; it depends on the company management and its vision.

In the company integration process, the harmonisation of corporate cultures and processes and the centralisation of individual company sections are fundamental for the successful formation of a new merger, see Litavcova et al., 2017, and Hurta et al., 2017. Process unification depends on the centralisation of individual components, meaning most of all on human resources. As the whole integration process is managed in the change management system, the harmonisation of corporate cultures, branches and the selection of the right people is the initial element of success. And this important element will be described on a real example of acquisition harmonisation.

3. Corporate culture formation process as a part of acquisition

The horizontal acquisition process is explained by an example of a company operating in group C, the processing industry, group 11 production of beverages, based on the CZ-NACE classification of economic activities. Based on the decision of the company management and strategic analysis, a foreign holding (purchased company) was selected and an initial agreement on the merger of the companies was entered into with that holding. The strategic objective was to use significant cost and income synergies which will be attained by the companies' merger, thus intensively developing trademarks in a global scope.

An analysis of objectives, visions and individual elements indicated that the corporate cultures in the companies in question were very different. Visions and objectives were identical; however, the communication among managers of individual companies seemed problematic, complicating the acquisition process. Therefore, one of the partial objectives was to harmonise corporate cultures, implementing corporate culture into the daughter company.

Based on the findings of the horizontal acquisition of its foreign businesses, Figure 1 illustrates the specific procedure of formation of a new corporate culture.

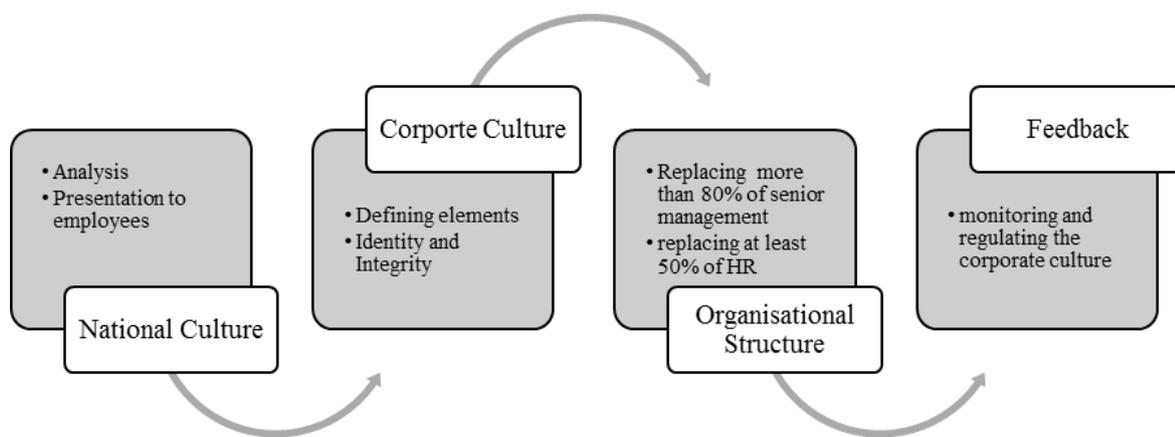

Fig. 1. Corporate culture formation process

The basic step for corporate culture formation was the analysis and comparison of national cultures. The results were then presented to employees, including the planned changes. Corporate culture was determined by defining the pivotal elements which will lead to the harmonisation of employees with the vision, objectives and strategy of the organisation and to integrity.

Another step, which proved to be the most time-demanding, was the formation of a new organisational structure. First, it was necessary to purchase all shares of managers in the company and then, it was possible to make extensive personal changes in senior management. By replacing more than 80% of senior management in the purchased company, it was possible to harmonise corporate cultures and begin the change process in the operation area, too. As senior management replacement was only the first stage of personal changes, in the second stage, 50% of human resources at lower positions were replaced as well. The reason was the employees' unwillingness to accept changes and the new corporate culture, including the new company management.

After introducing all the personal and process changes, the company takeover reached the final stage – monitoring and continuous supervision over introduced changes, with the efforts to improve them and react to the situations at hand immediately.

In the case outlined above, the whole process took 17 months. Frequent and transparent communication with employees and the identification of problematic individuals in the purchased company proved important for the whole process. Their attitude had a negative impact on individuals who were willing to believe in the new corporate culture and who were proactively assisting the management with its introduction. These negative and problematic individuals were replaced, and this step ultimately proved essential for speeding up the companies' integration, not only for the harmonisation of corporate cultures.

4. Conclusion

We can say that acquisition activities are changing the situation on the market. To illustrate, based on Mergermarket, 2017, the global value of the mergers and acquisitions market is estimated at USD 3.15 trillion, with 18,433 transactions implemented in 2017. Compared to 2016, there was a slight drop, from USD 3.26 trillion. 2017 was the fourth year in a row where the value of transactions exceeded USD 3 trillion. The largest transaction was Disney's acquisition of Fox at USD 68.4 billion.

The whole acquisition process has a similar character across segments and individual differences may be seen in each part of the process. The most distinct and specific part is the above-discussed HR audit as part of due diligence and the HR area as part of companies' integration.

The complexity of acquisitions dictates the necessity of using external companies which have experience and a range of experts in various fields available. Only a limited number of these companies exist, and they are mainly global businesses. This allows for the sharing of information, experience, processes and experts across countries and continents, thus setting global standards in almost every country. From this perspective, the countries of Central and Eastern Europe are attractive for investors. They see huge potential in the companies operating in this region. Also, thanks to the global standard of the acquisition process managed by an external multinational company, they perceive such investment as safe. If we look at acquisitions in the Czech Republic, there were 246 transactions at almost USD 12 billion, which means 16% growth in transactions value compared to 2016. In this respect, it is important to note that the Czech Republic has been one of the leading countries of Central and South-East Europe in the number of transactions for several years now, more in Ernst and Young, 2017.

The contrast between the stagnating acquisition development on the global market and two-digit growth of acquisitions in the Czech Republic is proof of the appeal of Central and Eastern Europe. A similar trend is expected to continue. The above-mentioned example of an acquisition mainly emphasises the HR and financial area of the due diligence process and the companies' integration. They are fundamental to a successful acquisition.

As HR operations are a huge risk for the whole process and, sometimes, an unknown intangible quality, they should be one of the relevant areas. But in reality, they are not. It is one of the main reasons for the failure of a large percentage of acquisitions whose outcomes lag far behind the expectations.

Eighty-seven per cent of organisations report that the harmony of corporate cultures was important or absolutely necessary for a successful acquisition. The broad conception of corporate culture including the corporate strategy, decision-making processes and corporate management, top management's expectations and organisation values and standards are all important aspects in acquisitions. Nevertheless, 58% companies report that they were not specifically concerned about the issue of culture. Moreover, none of the surveyed companies reported that the cultural process in their organisation had been effective. According to Elizabeth Fealy responsible for Merger and Acquisition Solutions in Aon Hewitt, 2018 in the U.S., "This is very telling. The bottom-line is that, while organisations understand cultural integration is critical to deal success, they continue to struggle to implement processes that drive cultural integration forward."

What element has the largest share in the success of corporate culture and thus in the success of the acquisition process? Based on content and secondary analysis, the authors ranked these elements in the following order: Values, Attitudes, Standards of Behaviour, Fundamental Beliefs, Corporate Architecture, Habits, Rituals and Ceremonies, Organisational Language.

The Quality of Lending the Economy

Gabriela Corina Slusariuc *

University of Petrosani, 20 Universitatii str, Petrosani 332006, Hunedoara County

Abstract

Credit has a very important role in the economy, and the evolution of national economies has become largely dependent on the private banking system. Credit policy has become one of the main means of action on the economic conjuncture, being called upon to prevent the uncorrelations and potential imbalances that may arise. Poor credit risk management can cause the banking system to collapse, with unimaginable economic, social and political consequences.

Keywords : quality; loans; economy; credit; banks; companies; development

1. Economic growth is the goal of any state or company

Specialist papers (Lombardi et al., 2017) point out that economic growth is strongly influenced by debt levels. So the evolution of indebtedness generates a series of nonlinear effects. Measures to stimulate short-term lending have positive effects on the economic sector, but in the long run, the growth of private sector indebtedness leads to negative economic externalities.

Some authors (Schularick and Taylor, 2012, Jordà et al., 2013, 2015 and 2016) have pointed out that increased levels of private sector indebtedness are good predictors of financial crises and determinants of the intensity of implicit recessions. Other studies (Mian et al., 2015) mention that in times of contraction, households with high levels of indebtedness are most affected by the occurrence of adverse shocks.

His approaches (Cecchetti and Kharroubi, 2015 or Borio et al., 2016) based on the effects of debt on the supply sector demonstrate that excessive credit growth periods have long-term adverse effects on productivity through inefficient allocation of funds.

The EU financial system is very dependent on the banking system, with a significant impact on economic growth. The EU banking system has reached a level of magnitude that will have a negative impact on economic growth, leading to additional risks at both bank and sector level as a whole. Since the 1990s, banking intermediation has accelerated its pace of growth, with the share of credit in GDP in Europe increasing significantly compared with other regions of the world (US).

The size of the European banking sector is considered to be oversized in relation to GDP, as compared to the income and wealth of the population, as well as to other sources of intermediation. Large-scale universal banks have a higher systemic risk than smaller specialized activity banks, and they have a major share of total banks in recent years at EU level.

The main challenges facing the European banking sector are:

- increasing concentration within it,
- increasing the size within it,
- higher degree of indebtedness of European banks.

The ESR Advisory Scientific Committee (ASC) report shows that in countries with a financial system dominated by banks, there are lower increases in the long run, even after being controlled for other specific factors. The bank lending offer is more volatile than other sources of funding such as the capital market, amplifying financial and economic instability.

An economy that is mostly funded through the banking sector has contingent liabilities larger than an economy that is mostly funded through the stock market.

Thus, in bankruptcy of banks, the state is always the ultimate lender to cover possible system losses, even though this risk has diminished with the emergence of the bail procedure and the bank resolution framework. By contrast, a stock crash does not present contingent liabilities for the state, in which case the risk is entirely assumed and borne by the investors on the stock exchange.

In this context, the main policy measures that have been proposed to be adopted at European level are:

- 1) the elimination of preferential tax treatment of debts;
- 2) adopting more aggressive competition policies to diminish the importance of large banks;
- 3) increase in minimum capital requirements (either by setting a minimum leverage ratio or by setting up a capital buffer for systemic risk) in order to increase the resilience of banks and protect taxpayers from the potential risks generated by an over-sized banking system;
- 4) policies that encourage access to non-bank credit sources;
- 5) the formulation of requirements for the separation of certain non-banking activities from the core business of banks
- 6) increasing the risk weights associated with the existent intra-financial exposures, in order to reduce the excessive activities within this sector (as stipulated in CRD).

Romania, in the first years of the post-communist period, has witnessed a strong financial disintermediation process, the share of credit to the private sector in GDP falling from 79.7% in 1990 (a characteristic of the planned centralized economy) to only 19.1% one hundred in 1994.

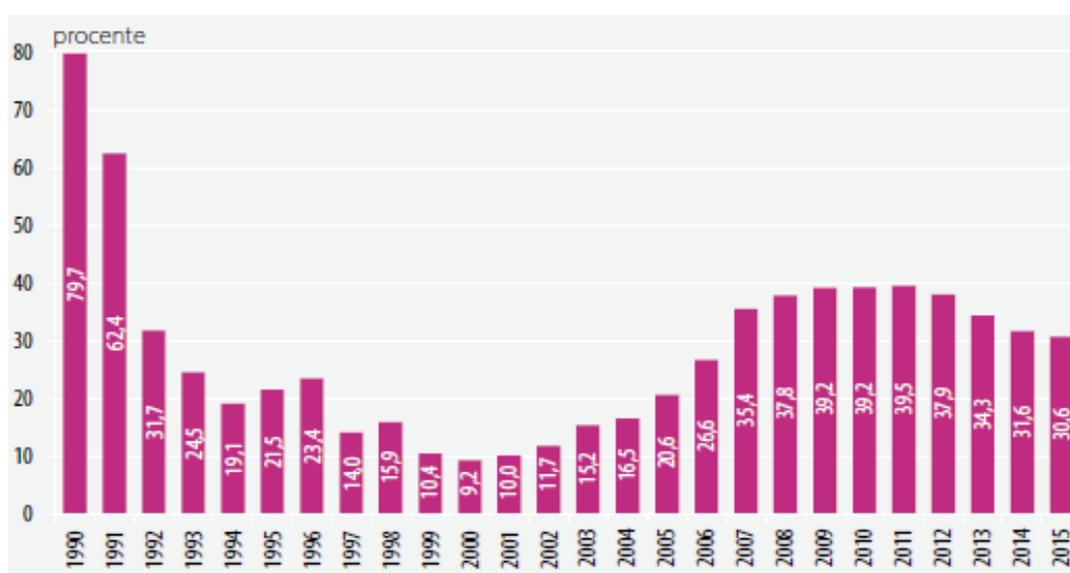

Fig. 1. Credit to the private sector / GDP in Romania. Source: EBA, NBR

High inflation recorded since 1990 has led to the limitation of credit. The very high inflation rates (in 1992 and 1993 close to hyperinflation) and their high volatility drastically limited the possibility of financing medium- and long-term projects (Isărescu, 2007). Also, the negative interest rates led to the rapid erosion of the population's economies and banks' reluctance to lend to the population.

Banks have faced the problem of not having a profitable client for lending because there was no portfolio of creditworthy firms, state-owned companies were in cumbersome privatization processes, and private ones were poorly developed.

Against the backdrop of financial indiscipline, they replaced bank credit with arrears - which reached about 85% of GDP in 1991.

The location of financial intermediation on a low level after 1990 was also determined by the very modest level of credit for the population, its share in credit to the private sector being up to 6 percent, almost exclusively focusing on companies.

The period 1995-1996 was characterized by an increase in targeted credit, but with negative effects in the economy.

Thus, the banking system soon faced a very high level of bad loans, but also a severe deterioration in corporate governance, and rescue from bank failures had a budget cost between 4.6% and 6.6%. After 2000, private sector lending was on an upward trend, supported by economic growth, inflation and interest rate cuts, as well as the presence of foreign banks in the domestic banking system, which strengthened.

The real annual growth rate of credit to the private sector recorded negative values in the period 2012-2014, returning positively from 2015. This year, the RON component became dominant in the credit structure after a period of 8 years in which the foreign currency credit held the majority position.

The credit for the population became a more dynamic component in 2016, being predominant in the structure of the loan stock. Sustainable lending to non-financial corporations is a priority of the Romanian banking system, as many SMEs are not eligible for credit, and many corporations resort to intragroup loans.

2. Credit to companies and the population

Sustainable growth of financial intermediation, particularly by widening the lending sphere to the corporate sector, remains a desideratum for the banking sector.

Between September 2016 and September 2017, the volume of new loans granted by credit institutions amounted to about 42 billion lei, representing a credit growth rate of 18.5 percent. The new flows of loans to non-financial corporations recorded a more rapid dynamics than those of the population (8% increase in the first case, compared to 6% in the second, in nominal terms), while in the case of loans granted to the sector of the population, an important part (about 31 percent) was achieved through the "First House" program.

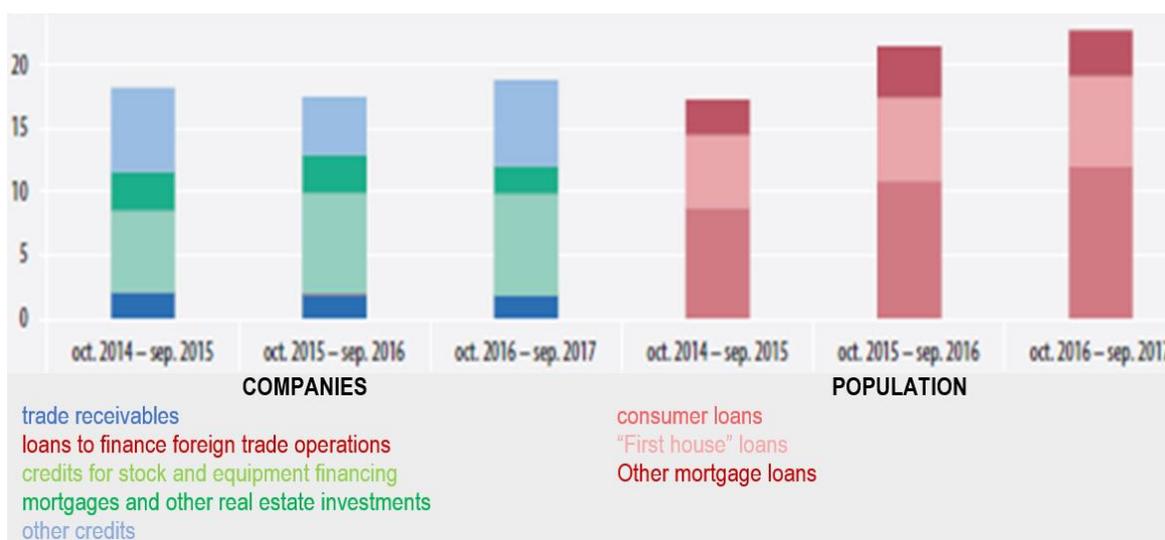

Fig. 2 Structure of the new loan granted. Source: EBA, NBR

Individual borrowers who accessed loans in the years 2015 and 2016 have a moderate but pro-risky risk profile. The indebtedness of borrowers who have accessed new loans has been in recent years on an upward trend beginning in 2013-2014, as revenue has seen a positive trend in recent years.

Thus, debtors who currently have bad debts have a very high degree of indebtedness (47 percent, compared with 33% for people with high-performing exposures) and a significant share of them is remunerated with a salary below the average at national level (about 80% of them).

Maintaining an adequate degree of prudence, even if it can reduce the access to credit for low-income and very low-income people (below the minimum wage), provides additional protection to eligible borrowers in the event of shocks, especially for those who will contract mortgages, which are particularly vulnerable to interest rate shocks. Slight developments in bank financing are due to structural features such as demand and supply. The main elements limiting the solvable credit claim are represented by:

- the high degree of indebtedness of certain categories of companies, especially micro-enterprises;
- the high number of companies with negative or non-performing equity;
- deficiencies in the insolvency framework of legal persons.

The credit offer raises issues related to the training of bank staff, the provision of financing products that do not address the specific problems of non-financial companies and the preponderance of real estate collateral.

The demand for bank lending by the non-financial corporations sector is low, with other sources of financing being used, such as commercial credit, loans from shareholders or affiliated entities, respectively from non-resident financial institutions. In the period 2004-2017 no more than 15% of the economically active companies have used such loans.

3. Bad credit against banking institutions

The quality of the portfolio of loans to non-financial corporations continued to grow, dynamics being mainly influenced by the aggregate improvement of the financial situation of firms. However, the constraints generated by the existence of structural vulnerabilities, such as the undercapitalization of a significant number of companies, the high degree of indebtedness in certain sectors, the reduced capacity to recover commercial claims, especially at micro-

enterprises, combined with the large number of firms of the portfolio of credit institutions that have not gone through a complete business cycle are risk factors for the banking sector.

The rate of non-performing loans decreased by 4 percentage points between September 2016 and September 2017, reaching a value of 15.8 percent. The annual change in the rate of non-performing contributed both to the decrease in the volume of loans with a higher payment delay 90 days (by 0.7 percentage points), as well as the reduction of loans in the implausibility of payment (by 2.3 percentage points).

The average default rate for Romanian companies fell to 3.1 in September 2017, from the 3.9% recorded in September 2016, as the number of companies that entered the default for the first in the last 12 months continued to remain on a declining trend.

Fig. 3. Rate of non-performing loans according to the size of the companies. Source: NBR, MFP

An important role in determining the evolution of the non-performance of the portfolio of loans granted to companies by banks is provided by firms with a capitalization below the regulated threshold. They accumulate late payment loans for more than 90 days, of about ROL 5.6 billion in September 2017, accounting for 55% of total exposures of this type.

If are taken into account the credits that are unlikely to payment, the loans classified as non-performing by the undercapitalised firms amount to lei 7.7 billion, or 46% of the total non-performing loans generated by the companies sector in banks' balances.

Given the relatively high exposure of banks to companies with capital values below the regulated limit but not yet in default (about 13% in September 2017), the fragile financial situation of this category of companies may put pressure on the balance sheets of credit institutions over the next period. Another important factor that may lead to an increase in the default rate on loans is the high proportion of newly-granted variable-rate loans under the resumption of the cycle of interest rate hike due to rising inflation. Most companies would quickly feel a potential shock on the interest rate.

New loans are granted mainly with variable interest rate, 88% of the new loans granted in MDL, respectively 85% of those granted in euro have the variable interest rate.

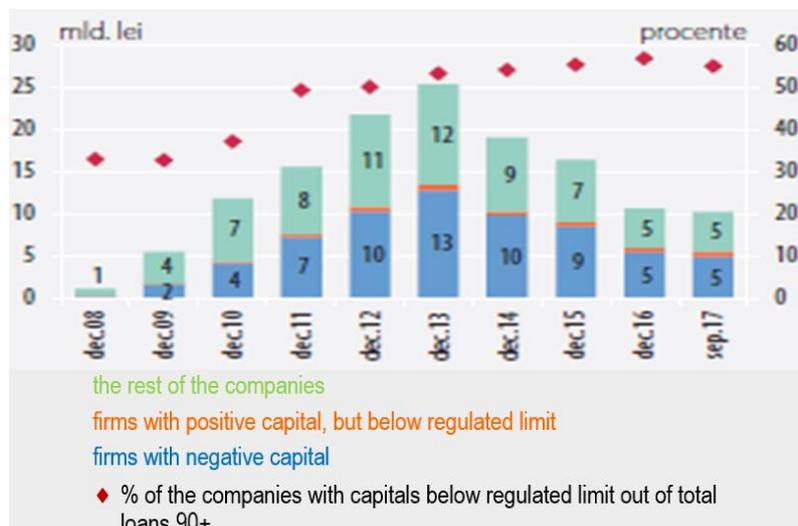

Fig. 4. Loans with overdue payments of more than 90 days, according to the capitalization of companies. Source: EBA, NBR

Companies with the highest risk profile are micro-enterprises, with a non-performing loan rate of 28.8% in September 2017. However, both small and medium enterprises and corporations recorded credit risk mitigation between September 2016 and September 2017. In the case of SMEs, the rate of non-performing loans fell from 23.4% to 18.7 percent, while for corporations it was 9.2% in September 2017, from 11.5% in 2016.

The rate of non-performing loans still places the Romanian banking sector, together with many other EU countries, in the red signal band of the Risk Chart developed by the European Banking Authority, but, as a counterweight, the coverage ratio with non-performing loans is at an adequate level and growing.

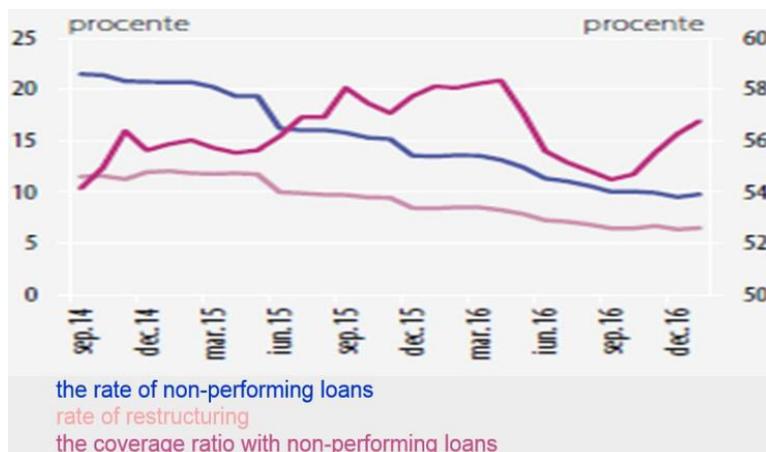

Fig. 5. Evolution of asset quality indicators in Romania (EBA definition). Source: NBR

4. Reducing bad loans is a priority both in Romania and at European level

Romania has witnessed a significant increase in the non-performing loans rate since the financial crisis of 2008. The main result of the NBR's supervisory and regulatory measures as well as banks' balance-of-payments efforts was to reduce the non-performing loans ratio to a level 9.8% in January 2017 (in September 2014, the rate of non-performance was 21.5 percent, as defined by EBA). At the same time, these measures proved their effectiveness and generated one of the fastest reductions in the rate of non-performing loans among EU countries.

According to the EBA, a level of non-performing loans of over 8% of total credits (the case of Romania) is in the red band; a level of non-performing loans of 3-8% falls into the yellow band; a level of underperforming loans of less than 3% of total credits falls into the green band.

The Central and Eastern European countries, which are under the low red-tape credit rating, have a negative growth rate of credit (Croatia, Russia), or a weak pace similar to that of Romania and Bulgaria.

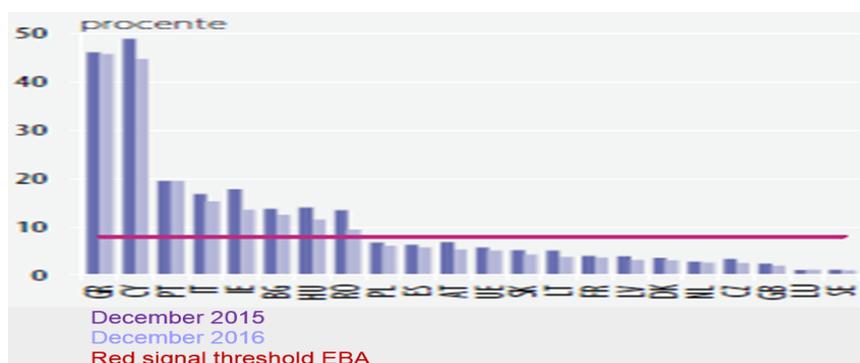

Fig. 6. The rate of non-performing loans in EU countries. Source: EBA, NBR

Conclusions

The rate of non-performing loans continues to remain high, despite the banks' efforts to reduce them, especially in certain business segments, which advocates continuing the process of solving exposures in state of non-reimbursement by credit institutions.

Macro-prudential regulations target the segment of lending to the population (especially foreign currency lending), but also the non-financial sector. The measures consist in establishing limits on the degree of indebtedness in relation to the amount of disposable income and the value of the collateral.

Thus, the role of credit needs to be repositioned, the new economic conjuncture requires changing the engine of economic growth with a more autonomous one, based more on productivity and domestic saving and less on capital influxes and indebtedness.

Digital Public Sector Auditing: a look into the future

Tatiana Antipova*

ICS Rusia, Rusia

Abstract

This paper considers future features for public sector auditing. Digital Public Sector auditing provides a window to view trends, issues, and relationships across a wider expanse of data, and provide more meaningful and insightful observations to Public Sector leaders and stakeholders for improving Public Sector performance. Auditor highlighted the top transformative changes of Public Sector Auditing and based on this changes builds a logical scheme of digitalization with look in the future. The use of digital technologies in Public Sector auditing will help to analyze the result of budgetary funds using of audittee, find ways to solve the problem of rational use of budget resources and optimize fiscal relations in each Public Sector unit. In author's opinion digitalization's framework consists of three blocks: Standardization, HR Management, Data Management. During future auditing procedures public sector auditors must use modern digital technologies; strengthen investigative powers; encourage more professional designation; support the international transparency. In addition, using day-to-day digital technologies is a perfect way to prevent any kind of fraud with budget money.

Keywords: Public Sector auditing system; Supreme audit institutions; control procedure; digitalization; digital technologies; digital auditing.

1. Introduction

Nowadays, with globalization of the economy, good governance of public finance is of fundamental importance for all countries to ensure the sustainability of the national budget and financial systems, as well as mutual financial security and sustainable economic growth. The public sector of many economies has been subject to dramatic change and auditing is a major mechanism by which many of these changes have been enacted. Effective budget implementation is an important factor in influencing the volume and quality of public services. Furthermore, it is important to bear in mind that leakage of resources through poor accounting directly threatens fiscal stability since it requires more resources than should be necessary to achieve any given result. Public Sector auditing provides independent assessments of that information for the benefit of those charged with oversight and for the public. When public are confident that the information they receive is relevant, reliable, understandable, consistent and comparable, it creates trust. Transparency and public accountability further engender trust in a representative democracy. Working together, these factors lead to greater citizen satisfaction and better access to capital at a lower cost. As long as budget resources come from the public in the form of taxes, every citizen demands greater understanding of where their tax money goes and how it is spent and control (Antipova, 2016). To understand this control mechanism it is necessary to know the structure of the Public Sector. The most common public sector comprises General Government and Public Corporations. Government-owned enterprises, such as the central bank, post office, or railroad are often referred to Public Corporations. General Government usually consists of three levels: Central Government, State or Regional Government, and Local Government. Public Corporations are divided on Nonfinancial (e.g. post office) and Financial (e.g. Central Bank).

Public Sector auditing focuses attention on how budget resources are spent. Assessment procedures of Public Sector auditing serve to avoid misrepresentation and fraud in public sector financial statements. Since the public sector financial statements are placed on the Internet, any citizen can get acquainted with this reporting. And citizens can trust the information set in these financial statements if auditors verify it properly. Public Sector Auditors should assess fair presentation of public sector financial statements. When financial statements “furnished by a state agency are in fact

* Corresponding author. Tel.: +7-912-982-4618.
E-mail address: antipovatianav@gmail.com.

reliable, citizens' trust should be increased by auditors. When, on the other hand the information is significantly unreliable, auditors should reveal that and consequently decrease citizens' trust" (Budding & Grossi, 2014).

Improving access to public sector information provides numerous benefits, particularly as increased transparency and efficiency within Public Sector (both state and local) can be quite advantageous. During audits, Supreme Audit Institutions (SAI)s often accumulate and process potentially useful information for various stakeholders, but this information is not readily accessible. To enhance information accessibility, these initial information files could be made public if they do not contain classified or personal information. Auditing every auditee would be daunting and resource intensive. However, it is important to spread audit findings and best possible. While press conferences, seminars and webinars present traditional channels for disseminating information, it is also possible to actively engage local Public Sectors in assessing their own situation (Antipova, 2017). We are in a "wired world" with information of all shapes and sizes available 24/7. All levels of Public Sector have substantially invested in modernizing information technology (IT) systems and service delivery models to take advantage of dramatic IT advances (Lewis et al., 2014) but the basic methodology for auditing hasn't changed significantly in decades (McCollum, 2017).

2. Public Sector Auditing digitalisation

As point A. Lewis (Lewis et al, 2014), the benefits to modernizing the Public Sector audit approach for both the auditors and auditee are: enhanced effectiveness, additional business insights, greater efficiency, better detection of fraud, waste, and abuse. Public Sector Auditing digitalization advanced continuous monitoring and continuous auditing programs, expanded forensic and recovery auditing capabilities, and sophisticated data analytics and business intelligence efforts. A natural first step in implementing data-driven digital techniques is to determine to appropriate transactions in the context of an auditee's day-to-day life. Because these guidelines vary by agency and program, it is important for agency administrators and subject-matter experts to collectively brainstorm the common-sense ways that online operation may be used, as well as the ways they should not be used (Antipova, 2017).

To manage Public Sector auditing results we need to use of modern digital technologies but digital Public Sector auditing is not just a technology-based effort. It involves changing the expectations of what is included within an audit, and adjusting auditors' knowledge, skills and abilities (Lewis et al., 2014). This is especially true in terms of implementation of results-based budgeting, as well as openness and transparency in the sphere of Public Sector auditing (state financial control) (Antipova, 2016). The formation of an information portal in the field of Public Sector auditing will allow for the recording, monitoring and analysis of inefficiencies and take measures to optimize budget expenditures. The Internet portal will provide the opportunity to hold videoconferences, implement electronic document management, work with documents, create and use an electronic library, conduct training, store information of the Supreme Audit Institutions and other control and accounting agencies and implement other services. It would be great if the results of Public Sector auditing were taken into account when budgeting for the next period. In the future, it is possible to link the definition of the size of the budget subsidy to the results of the Public Sector auditing while ensuring the transparency of the results of control through digital information technologies and the standardization of Public Sector auditing. The use of digital technologies in Public Sector auditing will help to analyze the result of budgetary funds using of auditee, find ways to solve the problem of rational use of budget resources and optimize fiscal relations in Public Sector unit, see Fig 1.

As wrote Farr L. (Farr L., 2017), auditor highlighted the top five transformative changes that are driven by modern information technology (IT): 1. Governance complexities; 2. Cyber everything; 3. Full transparency; 4. Reporting on steroids; 5. Skill set shortages.

1. Governance complexities. In many organizations, cybersecurity is "owned" by the IT function, which is tasked to implement, supervise, and maintain new systems and applications. Today, cybersecurity must be owned by the entity itself, because the location, accuracy, and security of a company's data, and the resiliency of its network to withstand cyberattacks, represent a business and compliance issue of importance to senior executives and board members. Cybersecurity involves more than just technology networks and systems, given the people and processes that may inadvertently make an organization susceptible to a cyber-attack. Cross-collaboration across the enterprise is essential.

2. Cyber everything. Technology is embedded deeply across every company today, producing a fast-changing array of cybersecurity risks. "Cyber is in everything," Katcher said. "Although technology itself is becoming more secure, the weakest link remains people, followed by inferior processes for attack detection, system recovery, and crisis management." Here, there, and everywhere data. Every company has what IT professionals call its "crown jewels"—highly sensitive customer data such as credit card numbers or proprietary business information. Unfortunately, many businesses have not identified their crown jewels, much less who is allowed to access these data and on which types of devices. "If you don't know where the critical information is, how can you secure it?" Katcher said.

According to B. Bebre (Bebre, 2018) there are three way to cibersecure: (a) data protection; (b) cybersecurity considerations; (c) staff training.

(a) designe to protect data. Examples of this work include reports on the National Cyber Security Program and Protecting Information Across Public Sector. Both reports document the difficulties involved in protecting information while redesigning public services and introducing necessary technology to support them.

(b) cybersecurity considerations are increasingly featured in a wide range of projects and initiatives, from digital transport schemes to smart energy meters and secure online financial transactions. The NAO noted in its report on Online Fraud that the internet is changing the nature of crime, and law enforcement responses are struggling to keep up. As more and more public services are delivered online and internet connectivity is steadily becoming a feature of everything—from military equipment to medical technology—considering cyber elements is likely to become a bigger part of audit work.

(c) training staff to help auditors think about cyber issues they may face. Cybersecurity is a fast-paced area, and Supreme Audit Institutions should continue to learn about technical and policy developments. Spreading good practice and awareness can help auditors adapt. For example, during the annual training and development week, Public Sector and industry representatives, addressed Supreme Audit Institutions staff and provided them with the latest developments.

3. Full transparency. The transparency of cybersecurity risk management is important for the good governance of all business entities. Corporate leadership seeks transparency into business and market data to increase the speed of operational decision-making. And boards of directors expect accurate reporting on the security of the organizations they serve.

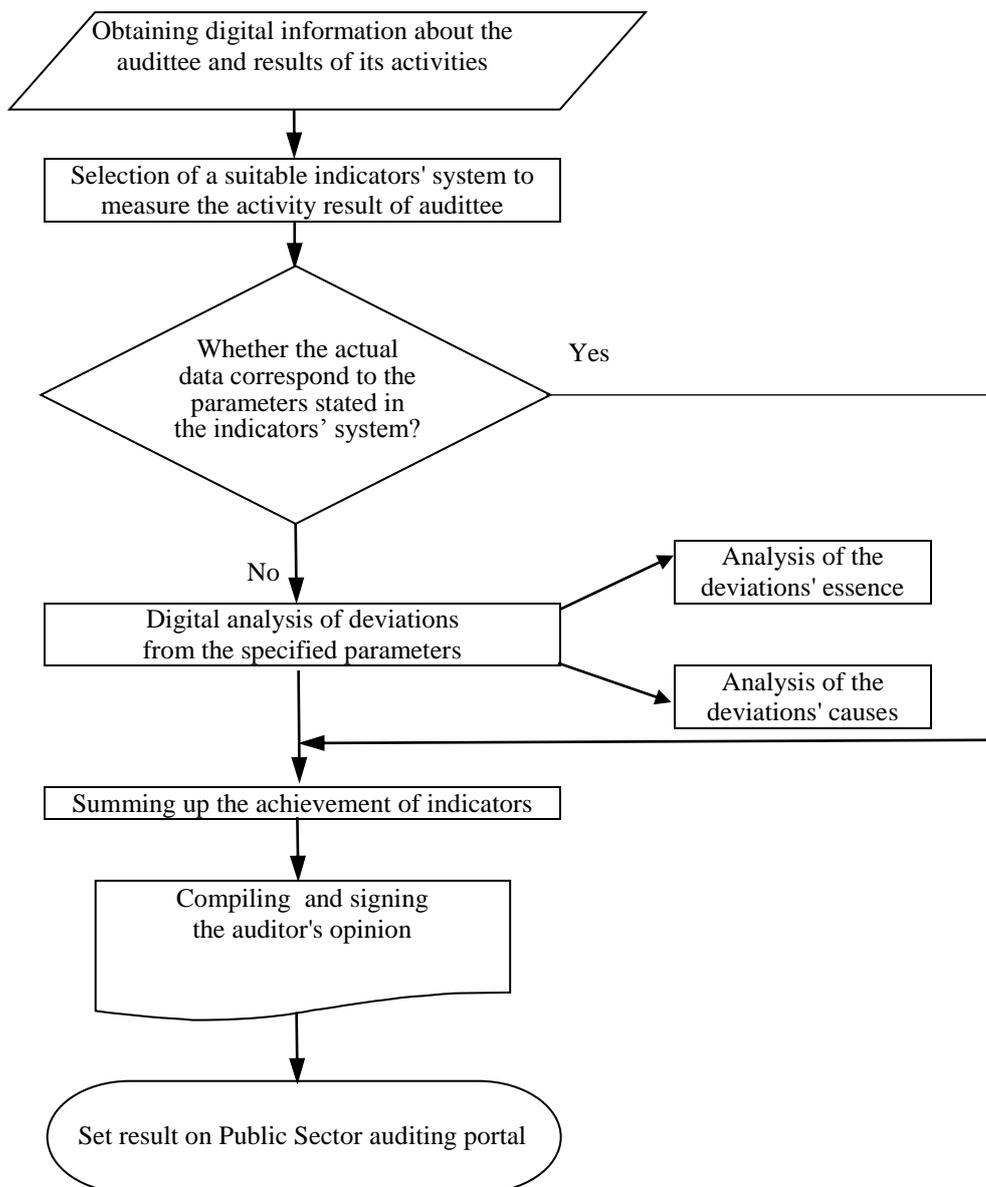

Fig. 1. Block-scheme for using digital technology in Public Sector auditing (author's elaboration).

4. Reporting on steroids. Reporting used to entail an analysis of the financials and the application of judgment. Today, accurate reporting depends upon how the data are input, processed, and stored, and the security risks presented in each scenario. "Simply stating information and reporting that the data is accurate no longer is enough," Katcher said. "CPA firms must provide evidence demonstrating that a client's data is complete, accurate, valid, and secure."

5. Skill set shortages. With technology increasingly driving how business is conducted, the tasks traditionally performed in the work environment are rapidly changing. Augmented intelligence, machine learning, robotics, and other transformative technologies are combining in unique ways to replace some jobs, augment others, and demand the development of new skills. The challenge for many organizations is the dearth of talent to fill these roles.

These transformative changes cause to Public Sector audit digitalization. And digitalization's framework consists of three blocks:

- A. *Standardization*
- B. *HR Management*
- C. *Data Management*

A. Standardizations

To unify verification procedure Blockchain Data must be standardized. Standardization can help to maximize compatibility, interoperability, safety, repeatability, or quality. It can also facilitate commoditization of formerly custom processes. The idea of standardization is close to the solution for a coordination problem, a situation in which all parties can realize mutual gains, but only by making mutually consistent decisions. In the context of supply chain management and materials management, standardization covers the process of specification and use of any item the company must buy in or make, allowable substitutions, and build or buy decisions.

B. HR Management

It is well known that "cadres decide everything." In the face of global competition can not continue to base education on the use of cheap labor. Principles of formation and staffing of personnel policy are determined by the new requirements of the Public Sector auditing body in terms of improving the quality of the training process and scientific research, its results and the reflection in Public Sector auditing. To achieve quality auditing, it is necessary to develop and effectively implement operations throughout the value chain organization, and this will require the development of knowledge, skills and abilities of auditors. It is advisable to develop a scheme for premium pay for auditing services, depending on their quality, meeting deadlines. There is no need for initiatives to award or the number of procedures performed. There should be rewarded for results. There is another issue in designing the reward - is the choice of the number of criteria. Indicators formulated in accordance with auditing strategy should be consistent with two or three strategic areas (such as more efficient use of assets).

In auditing, the priority is given to auditors, who can draw a general picture of the cause-and-effect relationships that unite the various factors to achieve results. Activated involvement in auditing activities related to the priority areas, increasing the number of scientists and adviser is changing the structure of the load in the direction of its greater focus on research.

The effectiveness of human resource management can also help and a clear allocation of responsibilities and accountability. In addition, the leadership of the Public Sector auditing body needs to keep track of the passage of the regular training of the teaching staff. It is also very important to include measures to reduce the potential for conflict of interest in the audittee environment. This is important for the creation of a positive atmosphere in the team with the approved policies and procedures. In addition, with a more educated and specialist workforce, Public Sector audit bodies are now taking on managerial and policy roles that previously may have been the domain of generalist civil servants. In turn, this gives Public Sector auditing work greater credibility and a more informed approach.

C. Data Management

Data Management means the need to implement it on all the major management activities: counting and regulating the number, registration, identification of management unit opportunities, planning, evaluation, promotion of affairs unit, etc. Managing of the connection base and works, is a traditional works management process, and should be carried out by the executors of these works.

3. Future of Public Sector auditing

Over the past six years, the author has led the Public Sector auditing for more than 60 of Federal agencies/entities and private firms. Analyzing as a scientist the results of numerous audits' results, the author singled out the main directions on which it is desirable to develop Public Sector auditing.

Existing manuals/instructions of Public Sector auditing aimed at identifying violations after the fact, studying financial statements, when nothing can be corrected. Comply with current guidelines, Public Sector auditors/inspectors can only led follow-up control. Future technologies should be aimed at preventing the misuse/violation of budget spending, when it is possible to stop the suspicious transactions, using information obtained from scanning banking operations of the observed audittee.

Analising past practical experience, author reached to conclusion that trends in Public Sector auditing in the future may include four main blocks that have shown on Fig.2.

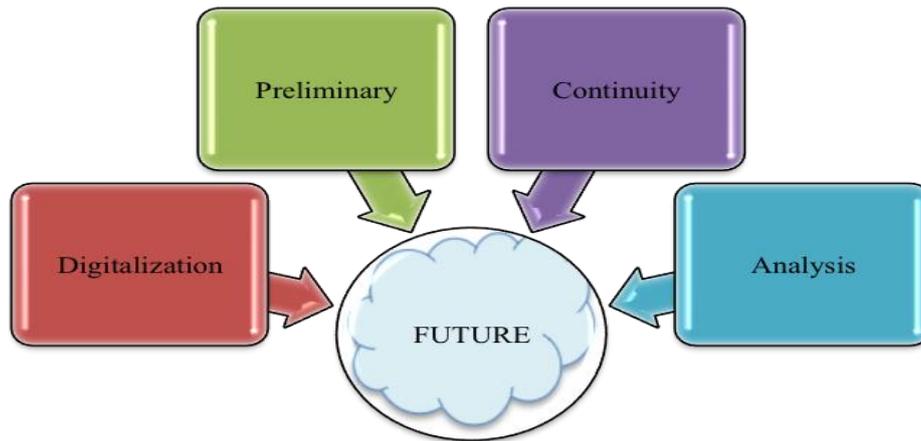

Fig. 2. Look in the future of Public Sector auditing (author’s elaboration).

Fig.2 shows four main component of the future trend of Public Sector auditing: Digitalization; Preliminary; Continuity; Analysis.

Digitalization. Computerization has covered all aspects of our life and, naturally, this has not bypassed the scope of Public Sector auditing. Nowadays it is unthinkable to led auditing without using of modern digital technologies. For example, audits are more effective when auditors have online access to the movement of the funds of the inspected object on bank accounts opened with the Treasury bodies. Agencies looking for more out-of-the-box solutions might find audit-specific tools, referred to as computer-aided audit technology, more effective. The key for the future is learning to communicate and work virtually with auditee. Being familiar with this technology positions auditors/inspectors for the audit of the future. A digital audit turns the practice on its head: The work that's usually done in the field is done virtually in the office, and the wrapup phase, which is normally done in the office, is done in the field. Rather than traveling to auditee offices, the auditors perform the routine work of examining the client's documents in the auditors' office using information uploaded to a secure portal. Once the routine tasks are completed, engagement leaders visit the client for the wrapup phase. In the audit of the future, with artificial intelligence and analytics, many of these bindings will be executed virtually. For more details, see the previous section.

Preliminary. Public Sector auditors must ensure reasonable confidence in preventing or detecting suspicious acquisitions in a timely manner at the expense of budgetary funds. To enable predictive modeling, data sets must comprise transactions considered suspicious and the outcomes of investigations. Combining observations and their outcomes allows supervisors to begin to build the link needed to predict future occurrences of purchase misuse. While rule violations are not always indicative of misuse, they are an effective and simple way to alert program administrators to aberrant behavior. Whether a public sector transaction supervision system is automated or manual, supervisors should explore ways to integrate business rules and rule violations into the Public Sector audit process. Wherein an effective notification system operates over the Treasury central server, delivers event messaging to predefined employees in "real time," as the event occurs, and is sent directly to the employees and their smart devices. This level of event notification ensures that the people who need to know about an incident are made aware in a timely manner and fosters immediate and unified response as required (Antipova, 2017).

Continuity. Continuous auditing involves frequent monitoring throughout the year to ensure that transactions are captured properly and are flowing correctly to the income statement. During Digital Budgetary Transactions Surfing flows of transactions are continuously monitored, identifying transactions that match certain pre-determined integrity constraints and, in the event of a constrain violation, alert the Public Sector auditor and copy the transaction data to a file. A natural first step in implementing data-driven techniques is to determine to appropriate transactions in the context of an agency’s day-to-day life. Digital audit techniques can be combined with this.

Analysis. Data analytics will be the foundation of Public Sector auditing in the future. Exploratory analysis and trending allow program administrators to identify patterns and detect anomalous behavior. Basic statistics like mean, standard deviation and skew, along with commonly accepted “tests,” help identify transactions that are unusual. Such outliers and anomalies should raise red flags with supervisors and indicate the need for further investigation. Using existing technology, auditors examine a auditee transactions to spot trends. For example, a customer whose previous ontime payment suddenly slows to 10 days late may signal a risk of default.

If machine learning algorithms become too smart, can they be controlled? Domingos says there are ways to control machine learning algorithms, most notably by raising or lowering their ability to fit the data such as through limiting the amount of computation, using statistical significance tests, and penalizing the complexity of the model.

He says one big misconception about AI is that algorithms are smarter than they actually are. “Machine learning systems are not very smart when they are making important decisions,” he says. Because they lack common sense, they can make mistakes that people can’t make. And it’s difficult to know from looking at the model where the potential for

error is. His solution is making algorithms more transparent and making them smarter. “The risk is not from malevolence. It’s from incompetence,” he says. “To reduce the risk from AI, what we need to do is make the computer smarter. The big risk is dumb computers doing dumb things.” (McCollum, 2017)

4. Conclusions

Introducing new approaches and techniques in Public Sector auditing has been a challenging yet immensely rewarding process. By improving the impact of audits, Public Sector audit Institutions’ can steadily move closer to better public governance. Embracing digital Public Sector auditing is a necessary investment to move auditors to new and evolving techniques that modernize Public Sector auditing by making full use of current and emerging technologies. We are in an information age and the exponential growth of data brings both challenges and opportunities to overhaul traditional sampling-based auditing approaches and fully leverage technology (Lewis et al, 2014). Digital Public Sector auditing provides a window to view trends, issues, and relationships across a wider expanse of data, and provide more meaningful and insightful observations to Public Sector leaders and stakeholders for improving Public Sector performance. During future auditing procedures public sector auditors must use modern digital technologies; strengthen investigative powers; encourage more professional designation; support the international transparency. In addition, using day-to-day digital technologies is a perfect way to prevent any kind of fraud with budget money.

In Public Sector auditing digitalization we will enable Public Sector auditors’ professionalism to move into the future and add even greater value to managing the cost of Public Sector and providing the highest levels of accountability and transparency to the civil public.

Is outsourcing the best solution in increasing organisational performance?

Olga Bucovetchi^{a*}, Radu D. Stanciu^a, Dorel Badea^b

Abstract

In the last decades, a broad range of activities has been grouped under the logistics term. For a long time, it has only been limited to external flows, i.e. transport and distribution. Nowadays, the high complexity of the logistics function leads to a situation where industrial and trade enterprises outsource more and more their logistics activities. As a consequence of the outsourcing phenomena, the logistics sector has grown, becoming a sector of self-employment. It became a new economic area, which besides transportation includes storage, handling, IT, consultancy services, etc. Logistics activity has met important developments that have made it develop from the support function within the enterprise to a cross-business function between businesses. The purpose of the present research is to analyze which of the two options - internal logistics department or outsourcing of logistics services - is the best when managers aim business performance. There were defined several KPIs (key performance indicators) that were assessed as the authors addressed to performance management as a multi-criteria decision analysis.

Keywords: business; logistics; outsourcing; performance

1. Introduction

Logistics has evolved over the last few years in an accelerated way by transforming it from an internal support activity into a new link between companies. The logistics function has increased in complexity, therefore both industrial and commercial organizations have had to reshape to the outsourcing of their logistics sectors, thus allowing for the emergence of a logistics market. The logistics market is evolving constantly and rapidly, being marked by many large and structural directions

Logistics activity is traditionally divided into two essential forms. (Cohen, L. and Young, A., 2006). One improves the continuous flow of raw materials, products and materials through a transport network and storage centers, making so-called global logistics. The second part directs a part of the enterprise's resources to carry out a specific activity: the logistics of certain activities in the enterprise (transport logistics, storage logistics, and logistics of supply).

In 2004, Corbett defines outsourcing as a management tool to drive an enterprise from its traditional, vertically integrated structure, an organizational structure that no longer meets the demands of an increasingly competitive economic environment, increasingly oriented towards performance.

Outsourcing helps the enterprise to change its business structure into a structure capable of making specific investments in areas closer to the unique advantage it has. In logistics, outsourcing is a phenomenon that is experiencing massive growth. Companies that are active in this area have grown more and more and competition has become more and more fierce.

Given these, the purpose of the present research is to analyze which of the two options - internal logistics department or outsourcing of logistics services - is the best when managers aim business performance.

E-mail address: olga.bucovetchi@upb.ro.

2. Methodology

The method used during the primary research is the survey and the tool – questionnaire. Furthermore, after a significant literature review, there were defined several key performance indicators (KPIs) that were assess in order to see the impact of each KPI in choose in favor or not to outsourcing. (Jennings, D., 1997, Dolgui, A and Proth, JM, 2010, Lin, N. et al, 2016)

The questionnaire was applied to 30 small and large companies, both local and multinational, with Romanian and foreign capital. The 9 questions in the questionnaire wanted to encapsulate the most important information about the chosen topic, focusing on the key performance indicators that influence the decision in choosing or not outsourcing.

In the case of this research, the purpose is to clarify which of the two options is best suited for the companies for which this department is needed - own logistics or outsourcing of logistics services. Confirmation or invalidation of the hypotheses of this research was achieved by analyzing the answers obtained within the questionnaire. There were made the following assumptions:

- Most customers are more than 500 kilometers away from picking points.
- Most of the goods transported are light and compact, which makes logistics processes more efficient.
- The main trend among large companies is to outsource logistics services to third parties.
- Most companies see logistics as a department of tactical importance.
- Most companies outsourcing logistics activities are satisfied with the services they receive.

3. Research results

The first question of the questionnaire concerned the size of the company. When analyzing the responses, one can see that the majority of respondents, namely 40%, indicate medium enterprises with staff members between 50 and 249 employees in Romania; second place is occupied by large enterprises (more than 250 employees) in proportion 27% (see fig. 1).

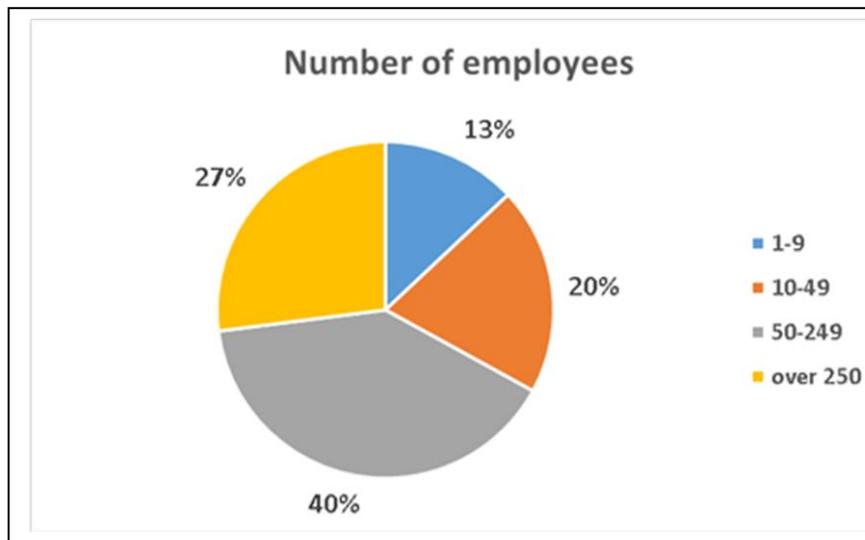

Fig.1 Categories of organizations

As far as "the distance to which most of the customers are," is concerned, the answers are as follows: 30 percent of the respondents said that most of their clients are at distances between 150 and 499 km, respondents whose customers are between 75 and 149 km are the second place with 27%. The customers with distance over 500 km away from picking point are, in the proportion of 13%. Thus, the "Most customers are over 500 km away" hypothesis is not confirmed.

Furthermore, the respondents were asked to join the four freight types with their frequency to verify the hypothesis that most of the goods produced and / or marketed are light and compact and thus all logistics processes are more efficiently achieved. The result are emphasized in fig. 2; one may easily conclude that the second hypothesis was confirmed.

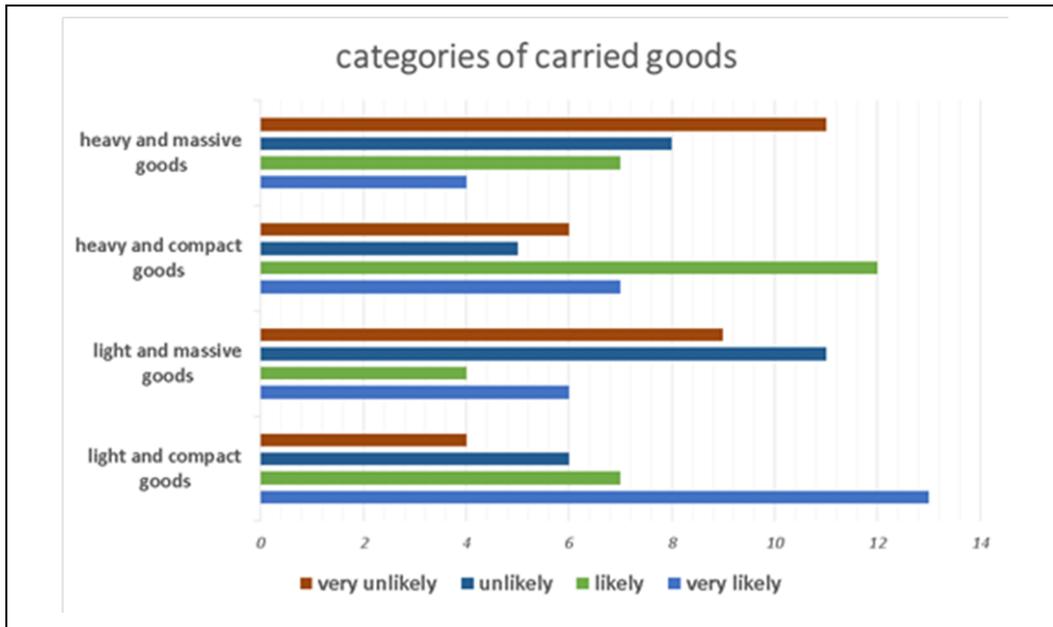

Fig. 2. Categories of carried goods

Being asked "In what type of warehouses do you keep the goods?" most respondents chose "rented warehouses" - 43%. On the second place are the companies that use both leased warehouses and their own warehouses, namely 37%. 13% are those companies that use exclusively their own deposits. Only 6 percent of respondents said that deposits are unnecessary, with a perfect balance between the goods produced or purchased and the merchandise sold. Analyzing the results of the research, one can confirm the hypothesis that "the main trend among big companies is to outsource logistic services to third parties", at least as regards the storage of products. (see Fig. 3).

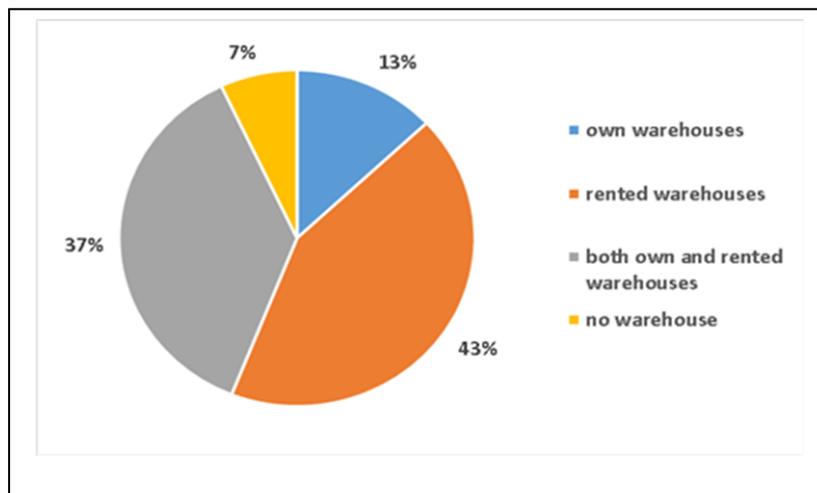

Fig. 3. Types of warehouses to keep goods

Question 6, "Does your organization have a logistics department," was designed to make the research as relevant as possible; companies that do not need dedicated logistics staff were not part of the target group of this research. Only two of the interviewed companies said they did not need dedicated staff and did not respond to the rest of the questionnaire questions, with the remaining 93% of respondents. Most of the logistics departments of the respondents have more than 10 employees (48%), 41% have between 5 and 9 employees and 15% no more than 4 employees.

There were defined six elements that weight in decision making process of outsourcing or not the transport of products. Those elements were evaluated in terms of satisfaction or dissatisfaction. Once an organization is satisfied with the results of externalizing an activity (they give 5 points for that indicator) it's more likely to continue to decide to make outsourcing permanent.

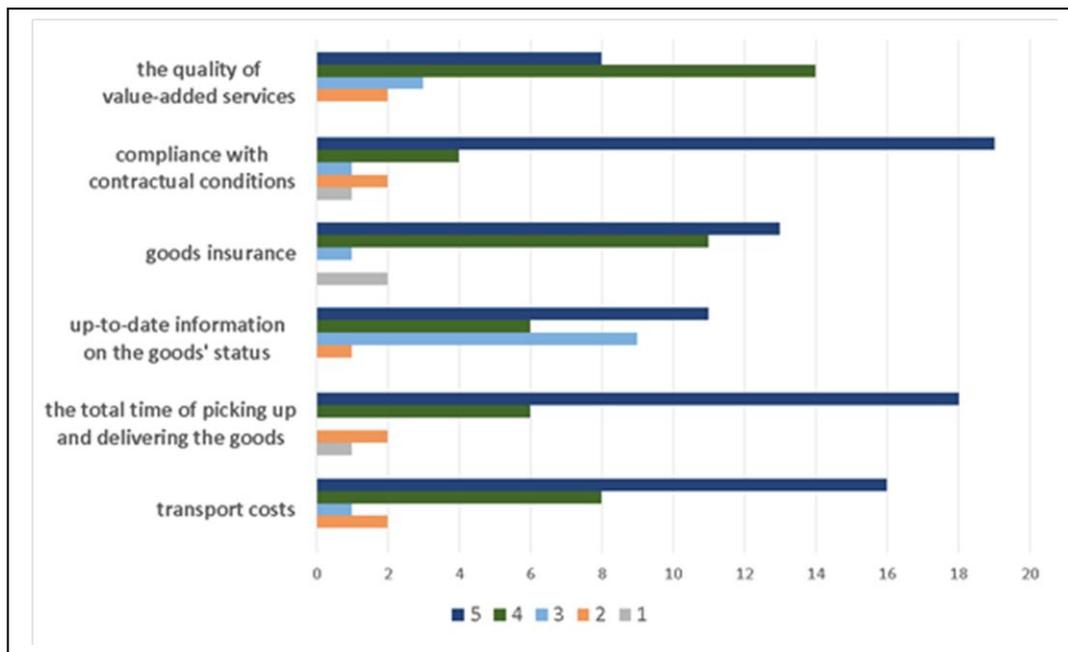

Fig. 4. Key elements in decision making process

The most important thing a company's logistics manager can do is to evaluate both the company's activity (internal logistics) and the offers found on the market (the companies offering the services that want to be outsourced) according to the same key performance indicators.

These indicators must be objective and significant to organizational. Moreover, the above-mentioned analysis needs to be restored whenever one or more factors of the company's external or internal environment change. Also, the market trends are particularly important for an enterprise that wants to compete

4. Conclusions

“One of the various conditions of successful business is to be able, in the long term, to focus the effort and the resources on the core company activities” (Milecova, M. et al, 2010). Organizations often benefit from focusing on basic operations and outsourcing outreach activities to specialists. These peripheral activities could be anything from cleaning and catering to accounting, legal services and information processing. Logistics is a very popular feature for outsourcing, with specialist service providers taking over part or all of the materials for movement and storage. This use of 3rd party logistics (3PL) has the usual benefits of low fixed costs, service experts, economies of scale, flexible capacity, lower risk exposure, increased geographic coverage and guaranteed service levels.

Sometimes managing multiple 3PL contracts becomes so complicated that another company is used to manage it - creating the fourth logistics part (4PL).

Trade Marketing – An Innovative Concept in Logistic Cooperation between Manufacturers and Traders

Oana Dobre-Baron^{a*}, Alina Nițescu^a

^aUniversity of Petroșani, Str. Universității nr. 20, 332006, Petroșani, Romania

Abstract

Interdependence between producers and traders has not always been a collaborative relationship, but rather a conflicting one in which both parties pursue their own interests. The expansion of mass production, the emergence of large commercial areas and the globalization process have led to a reconsideration of the role of traders in their relations with producers, becoming strategic partners and at the same time a target of manufacturers marketing policies. Thus, three innovative concepts emerge and develop over the years: Trade Marketing, Category Management and Efficient Consumer Response. One of the longest-living and most successful American companies, Procter & Gamble, is the one that has innovated the concept of Trade Marketing as a convergence between the marketing of the trading company and the marketing of the manufacturer. This paper aims to analyze this concept and emphasize the role that P & G has had in reconsidering the position of the manufacturer in the logistic cooperation between him and the trader.

Keywords: trade marketing; supply chain partnership; logistic cooperation; manufacturer; retailer; consumer; customer

1. Trade Marketing – general considerations

During the 1990s, the dynamic in relations between manufactures and distributors changed. The concept of Trade Marketing had appeared as an attempt of a form of partnership between manufactures and distributors, which has put a significant mark on relations between commerce and industry. Trade Marketing marks the moment in which, for the producer, no longer does the final consumer represent the only source of creating the fiscal and profit values, but also the distributor, which surpasses the passive role it has fulfilled up to that point, becoming a principal facilitator in the success of sales. (Vasiliu et al., 2010)

1.1. The evolution of relations between manufactures and traders

Commerce is an activity sector engaged in continuous evolution, being influenced by a variety of factors, among which the following should be mentioned: production, consumption, transport conditions, technology, facilitating services (banking sector, logistical services, marketing firms which conduct a variety of studies, consulting societies etc.).

Production has influenced the evolution of commerce through the increasingly abundant and diversified offer, which translates into the expansion of markets and the necessity of exposing a growing number of products.

Consumption has evolved under the action of certain demographic (size and evolution of the population. average lifespan, household size etc.), economic (buying power, income size etc.) and sociological (through the vehiculation of topics related to environmental and health concerns, for physical aspect, for safety etc.) factors.

Transport has benefited over time from the appearance and spreading of long-distance means of travel (aerial, railway and naval), which brings together places of production and of consumption. Furthermore, over the last few decades, the car has represented a factor which has encouraged population migration towards the periphery of urban

* Oana Dobre-Baron. Tel.: +400722553771;
E-mail address: oanabaron2014@gmail.com.

areas, determining the emergence of commerce situated on the edge of major urban agglomerations, which has led to changes in consumption habits and lifestyles.

Technological progress manifests itself in the domain of commerce through the use of software development, of the scanner and of the means of telecommunication. They have led to changes in managerial practices, modes of managing products and stocks, relations between business partners, to the appearance of new apps in various connected fields – logistics, marketing, training and recruitment of personnel etc.

Facilitating services are in full evolution as well. The nature of relations between commerce and financial institutions, in general and banks in particular – sales in installments, cashing using credit cards, diverse credits etc. is changing. Transport and logistics companies are closely following the evolution of commerce, being closely tied to it. Marketing and consulting firms, too, are developing instruments applicable to commerce and proposing solutions adapted for this sector.

As a result of the action of these factors, commerce is becoming a sector which a large capacity of innovation regarding utilized concepts, ways of commercial management, offers directed towards clients, selling techniques, types of enterprises etc.

In this context, relations between producers and traders can be better understood, their evolution over the past few decades being able to be structured in four stages, as follows (Vasiliu et al., 2010):

- The first stage, begins in the 1950s, years marked by powerful economic growth and the beginning of mass production. During this time, there appeared the first superstores. Distribution in this period of time still remains only lightly concentrated, manufactures wielding the largest negotiating power, resulted from the larger force and, as such, are the ones which impose conditions in the largest capacity. Marketing specific to this period is oriented towards a production optic. Producers are preoccupied with placing products on market segments utilizing mass marketing. Distributors are regarded as passive entities, fulfilling the middle role of circulating products from the producers to the consumers. What follows is a period of progressive rebalancing in the relations between producers and distributors in which the latter privileges the strategies of small prices. Producers adopt a marketing in which the main focus becomes selling.
- The second stage begins with the 1970s financial crisis, when economic growth slows and the negotiating power of large trading enterprises becomes stronger due to the increased power of distribution firms. During this period a boom in large selling surfaces occurred, as well as the tendency of focusing of important firms. As such, buying conditions change, the role of purchasing centres strongly rising in importance. Consumption-centred marketing begins to be accompanied by trader-centered marketing. Department management and management of selling space are expanded, words like merchandising, key accounts, assortment management etc. becoming popular.
- The third stage begins in the 1990s when the concept of trade marketing appeared, as the common will of producers and distributors of transitioning from previous conflicting relationships to those of cooperation. The interdependence between the two forces them to realize that both of them require the other part as well, being unable to ignore the existence and interests of the other component. Manufactures become conscious of the role of traders and, as such, the latter become a target of the marketing policies of the former. Manufactures begin to consider the retailers as strategic partners with which relationships much be tightened and maintained. Producers extend individual promotion campaigns, realize plans for clients, attempting the development of an intense cooperation with distributors. The end results of this phase are not spectacular because producers often only refer to reductions for pushing their products on the retailers' shelves. Cooperation between the two partners effectively manifests only in the domain of promotion campaigns.
- The fourth stage is known as "partnership". Partnership is an umbrella concept which includes the circulation of information and integral management of the logistics chain, paving the way for a vast domain of cooperation. Partnership is no longer a unilateral option, as it is initiated jointly by producers and distributors. It is the moment when two other concepts also appear, namely Category Management and Efficient Consumer Response (ECR).

1.2. Trade Marketing – conceptual boundaries

Despite being a new concept which has appeared only recently, Trade Marketing has enjoyed, in its defining, different approaches. Today, authors of prestige as well as those interested and involved in the field have given the same content of the definition's concept.

As such, Philip Kotler and his collaborators have emphasized: "Trade marketing represents the business to business concept of marketing, which treats the distributor as a client. Its objective consists of identifying the individual expectations of every distributor in order to develop long-term personalized relationships. Trade marketing is involved in assortments, product policies, merchandising, logistics and promotion."

Regardless of whether they are more succinct or whether they detail the essence of the concept, other definitions relay the same definition as well: "Trade marketing, to put it simply, is a B2B marketing strategy aimed at getting a product onto store shelves. This is done by making other businesses recognize the value of your product, and convincing them that helping you sell your product will ultimately help them make money too. The purpose of trade marketing differs from that of traditional marketing, as it is not focused on the final sale. Instead, trade marketing focuses on the means by which that final sale is made. You need to get your products in front of consumers before they

can make the decision to purchase them.” (Sonntag, 2017); “Trade marketing is a form of B2B marketing. It’s the art of marketing products specifically to businesses... Normally, the objective of a trade marketing campaign is to sell products to companies who can then go on to sell those items to their customers.” (Press, 2018).

We have previously established that today, between producers and traders there exist relations of partnership. The number and type of partners differ on a case by case basis, depending on the distribution channels used by the producers. They are actually those which utilize trade marketing.

The aim of trade marketing for a manufacturer is to increase demand for their product with supply chain partners. A sales chain partner is a person or business that’s involved in the movement of products in commerce (and, as such, is the collective term for distributors, wholesalers and retailers). The process is simple: For a product to be sold in a shop, the retailer first needs to purchase the item from somewhere. Retailers will buy products either directly from a manufacturer, or via a wholesaler or distributor. The retailer will then sell those products to the public.

Manufacturers need trade marketing methods to try and create demand for a product with retailers, wholesalers and distributors and the aim is always the same: to sell a product that can then be resold. In another train of thoughts, manufacturers must market a product before it reaches the consumer because regardless of whether a retailer is buying a product from a wholesaler, a distributor or directly from a manufacturer, the retailer obviously still gets to choose which items they want to sell. The retailer is in the position of power. As such, there’s an ongoing battle to get products in front of retailers and into their stores so that it can be sold. Trade marketing is the difference between a retailer choosing one product to sell over another. And whether a product gets pushed or not affects everyone in the supply chain (but mostly the manufacturer of the product). (Press, 2018).

Today there are lots of different trade marketing methods that a manufacturer can use. The most widely used strategies are: trade shows; trade promotions; trade magazines and websites; branding; relationships; ongoing market research; digital marketing.

For these strategies, producers need adequate tools. These are differentiated as such:

As far as digital trade marketing is concerned, they are: an efficient website; various social media platforms; email marketing software; landing pages for lead generation; branded content.

For physical trade marketing the tools are: posters, display boards, kiosks, banners, stalls, brochures, flyers and business cards.

2. The Procter & Gamble Company – general overview

Procter & Gamble (P & G) is one of the largest producers of non-alimentary consumer goods worldwide with annual sales of over \$65 billion and total actives of over \$130 billion.

Founded in 1837 by William Procter and James Gamble, the Procter & Gamble Company started as a small family business which produced candles and later soap, in Cincinnati, Ohio state, USA. The company triggered its first “revolution” in industry in the 1940s with the launch of detergent brand Tide. Beginning with the 1970s, the company has known a significant development through the launch of several new products, including: dish soap (1972), the first Duracell battery (1974), Always absorbents (1983), Head & Shoulders shampoo (1986). One of the most important events in the company’s life happened in 2005 when Procter & Gamble bought the rival company Gillette for the sum of \$57 billion.

Presently, Procter & Gamble is a multinational company operating in 70 different countries which has over 95.000 employers. P & G products are commercialized in over 180 countries all around the world and are consumed by over 5 million people globally.

Procter & Gamble has in its portfolio 23 product brands which generate annual sales between \$1 and \$10 billion, and 14 brands generate sales between \$0.5 and \$1 billion, continuing to have a huge potential for growth. Procter & Gamble contains in its portfolio two out of the first 100 most valuable brands globally, as shown by the ranking done by Forbes Magazine for the year 2016. This way, the Gillette brand occupies the 26th place, being evaluated at \$20.4 billion while the Pampers brand occupies the 49th place, being evaluated at \$11.1 billion. (https://www.brkfinancialgroup.ro/fileadmin/user_upload/Brosuri/Analiza_prezentare_P_G.pdf)

The operational results of Procter & Gamble are presented on 5 business segments: Beauty (18% of sales made in 2017, 19% of profit achieved in 2017); Grooming (10%, respectively 16%); Health Care (12%, respectively 13%); Fabric and Home Care (32%, respectively 27%) and Baby, Feminine and Family Care (28%, respectively 25%). (<http://www.pginvestor.com/PG-at-a-Glance/Index?KeyGenPage=1073748355>)

The business segment with the largest share, 32% from all net sales is represented by „Fabric and Home Care”. On the opposite side of the spectrum, with a percentage of only 10%, there is the „Grooming” segment. In the case of the net profit generated by each business segment, „Fabric and Home Care” is still at the top, with 27%, closely followed by baby, feminine and family care products, on last place being, with 13% from the total, health care products.

Over the course of the year 2017, the company has finished its previously announced plan of making the product portfolio significantly more efficient through yielding, giving up or consolidating approximately 100 non-strategic brands. The resulting portfolio, of approximately 65 key brands, is contained in 10 product categories, those being business segments where P & G has the position of market leader, strong brands and production technologies relevant to consumers. (P & G, *Annual Report, 2017*)

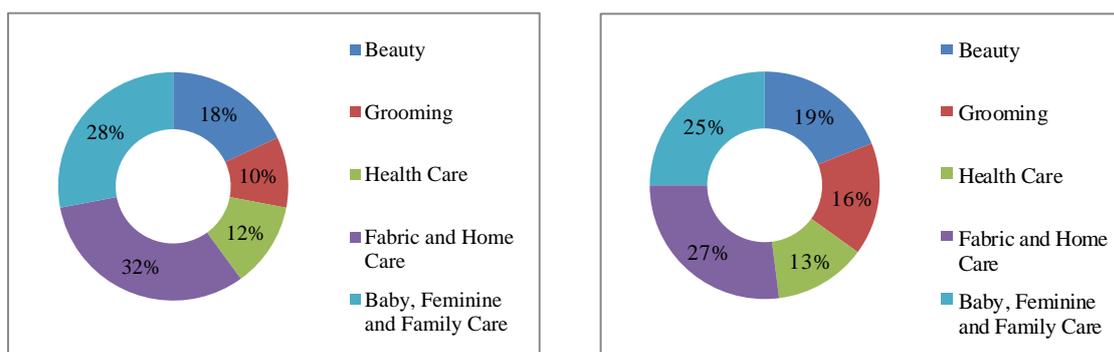

Fig. 1. (a) Net sales by business segment (2017); (b) Net profit by business segment (2017)

At a global level, the main competitors of Procter & Gamble are: Unilever NV, L'Oreal SA, Colgate Palmolive Co and Kimberly-Clark Corp. It can be observed from the data contained in Table 1 the fact that in matters regarding sales, as well as net profit obtained in 2015, P & G is in first place. (https://www.brkfinancialgroup.ro/fileadmin/user_upload/Brosuri/Analiza_prezentare_P_G.pdf) The main competitor of the company is Unilever NV which, despite being in second place, has had less sales than P & G by \$24.4 billion. With regard to net profit, it has nearly been twice as small.

Table 1. Main competitors on the consumer goods market

Company	Net sales (\$ bill)	Net profit (\$ bill)
Procter & Gamble	83	11,5
Unilever NV	58,6	6,3
L'Oreal SA	27,3	5,9
Colgate Palmolive Co	17,3	2,3
Kimberly-Clark Corp	19,7	1,4

The company's business model is based on continual economic growth and on the success of brands and existing products, as well as creating new products. The markets and industry segments in which these products are offered are extremely competitive. P & G products are sold in more than 180 countries and territories primarily through mass merchandisers, e-commerce, grocery stores, membership club stores, drug stores, department stores, distributors, wholesalers, baby stores, specialty beauty stores, high-frequency stores and pharmacies.

Net sales registered in the USA arrive at 42% of total net sales. No other individual country surpasses 10% of total net sales. Operations outside the USA are generally characterized by the same conditions outlined in the description of the business at a global level above and can be affected by additional factors, such as changes in exchange rates, different rates of inflation, economic growth, but also doubts and political and economic turmoil. Company sales on geographical regions are presented in Table 2. (P & G, *10-K Report, 2017*)

Of course, the largest percentage of total sales is of North American sales, registering a 3% increase in 2017 from 2015. The largest and most important client of P & G is the American company Wal-Mart, which is currently the largest retailer in the world.

Sales towards Wal-Mart Stores, Inc. and its affiliates represent approximately 16% of total company sales in 2017 and 15% in 2016 and 2015. No other client represents more than 10% of total sales. The first ten clients have represented approximately 35% of total sales in 2017, 2016 and 2015.

Table 2. Structure of P & G' sales per geographical regions

Region	2015	2016	2017
North America (USA., Canada and Puerto Rico)	41 %	44 %	45 %
Europe	24 %	23 %	23 %
Asia and the Pacific	8 %	9 %	9 %
China	9 %	8 %	8 %
Latin America	10 %	8 %	8 %
IMEA (India, Middle East and Africa)	8 %	8 %	7 %

The company's management considers that it should continue offering new, innovative brand name products to consumers in order to develop its business. Consequently, its marketing and research activities – development of products, conceived to allow permanent, sustained, organic growth, have continued and will continue to have a high priority every year. (P & G, 10-K Report, 2017)

3. The Procter & Gamble Company – an innovator in Trade Marketing

Markets in which P & G products are sold are extremely competitive. Its products compete with similar products of many big and small companies, among which there are known global competitors. The company's products are supported by publicity, promotions and other marketing channels with the aim of informing the consumer about its existence and the necessity to buy them, together with an extensive selling force. Company management considers that this combination offers the most efficient marketing method for these types of products. Product quality, performance, value and packaging are also important differentiating factors. (P & G, Annual Report, 2017)

But things haven't always been like this. Under the old management system P&G had 12 national sales forces, each hawking a product line such as detergents or foods. Retailers were faced with numerous P&G salesmen pushing 12 different product lines with all sorts of different promotions. At that moment producers dominated the market and imposed their products. Then the balance of power shifted from big manufacturers like P&G to the retailers. What tipped the scales was consolidation among supermarket and drugstore chains and the widespread use of scanners at the checkout counter. Electronic bar coding helped retailers gather their own sales data. Analysts have considered that from that moment P&G could no longer bully its way into the stores, waving figures a retailer couldn't dispute. Slowly P&G realized that it would have to start fussing over these power-punching retailers and switch from a product to a customer approach. This way in the summer of 1987, the company began organizing its 4,000-strong sales force to do something pretty obvious: focus more on the customer, in this case, supermarkets and department stores. (Dumaine, Kuhn, 1989) One of the most important clients of P & G was Wal-Mart. At that time, the relationship between P & G and Wal-Mart was characterized as anything but collaborative. As a matter of fact, their relationship was adversarial, obsessed by day-to-day transactions. Wal-Mart did not like doing business with P & G because P & G organizations were too complicated and inflexible. P & G were obsessed by day by day selling. Efforts were made to push for sales irrespective of what the customer needed, or was rewarded for. There were no testing or long term planning. Relationship and activities were managed by the buying and selling function only. The selling function within P & G was responsible for all customer activity. They were responsible for selling at the customer. The role that information systems played in the relationship was non-existent. (Grean, Shaw) It was obvious that things would not continue in this manner for long.

In 1988, after a discussion between the top managers of the two companies, both unhappy with the way its business partner was only acting in self-interest, but especially the lack of information from both ways, P & G formed a team of analysts which, in the course of a few months, would work at the headquarters of Wal-Mart. They understood, with astonishment, that the fragmented system of division based selling of company products heavily encumbered the work of the trader, meaning lost time and money. Furthermore, the information which the manufacturer had regarding sold products did not coincide with those of the trader. Walmart had loads of data that came from scanners in all of their stores. P & G had data that it used to develop products. By putting the information together they could answer questions like "what products do customers buy and why?". By analyzing Walmart's in-store data, the companies, working together, were able to eliminate losing products from store shelves and replace them with winners, thus increasing sales. (Gray, Vander Wal, 2014)

Thus it isn't surprising that the two companies have decided to take their collaboration to the next level and to create values for both through the channel partnership. To emphasize the strong commitment to develop this mutually beneficial partnership, the P & G and Wal-Mart team developed a mission statement, which reads: "*The mission of the Wal-Mart/P & G business team is to achieve the long-term business objectives of both companies by building a total system partnership that leads our respective companies and industries to better serve our mutual customer - the consumer.*" (Grean, Shaw)

The partnership started with the simple desire to improve business relationships, and was gradually enhanced by sharing information and knowledge about their respective markets. The process has been possible because of technology, which has played a key role in logistical cooperation between the two companies and has relied on using the following instruments: joint scorecards and measurements; driving out costs through automation; sharing data to better understand the consumer and drive sales. This sharing in turn enabled more effective execution of such concepts as category management, continuous replenishment, and process coordination, which collectively helped make the supply chain more efficient.

We know today that an important strategy for managing integrated supply chains is to share information among supply-chain partners. One of the main benefits of sharing information is the reduced need for inventory. As a result, the supply chain achieves better performance in terms of financial returns, service level, and turn-around times. P & G and Wal-Mart have been the first to understand the importance of collaborating in the supply chain. With information shared among the manufacturer and the retailer, the manufacturer can use the information about the inventory level of the retailer to manage the frequency, quantity, and timing of the shipments-- instead of waiting for the retailer to place

orders. This practice, referred to as continuous replenishment process (CRP), enables the manufacturer to reduce the inventory necessary and to plan the shipments more efficiently, as has been implemented by P & G and Wal-Mart.

Moreover, P & G and Wal-Mart have improved the profitability of both companies by using multifunctional resources to drive out costs and improve sales. The two organizations use joint scorecards to review the joint business and make annual plans to drive category growth for both companies. Together they use technology as a method to drive out costs, and openly share data to better understand their joint customer - the consumers. (Grean, Shaw)

4. Conclusions

The P & G Company, as a producer, has been the first to understand that, despite its products being marketed towards final consumers, its client is the trader, which has the same point of interest. With the aid of one of its most important clients, retail company Wal-Mart, P & G has become aware of the strategic benefit of partnership based on innovation inside the supply chain. This has led to the adoption of business to business, which, in essence, relies on the fact that the producer must help the trader which, further on, will sell its products towards the final consumer. And this is, in fact, the essence of Trade Marketing.

Analysis of the Romanian Agricultural Sector in European Context

Alina Nițescu ^{a*}, Oana Dobre-Baron^a

^a University of Petrosani, University Street, N^o. 20, Petrosani, 332006, Hunedoara County, Romania

Abstract

In recent years, the Romanian economy is part of the economies in Europe with notable economic growth. It is the economy where the industry plays a major role but also has great potential in the agricultural sector due to favorable natural conditions. Agriculture plays an important role in Romania, relative to the size of the rural population and to the primary natural resources they own. However, there are major differences between rural and urban areas, the former being marked by a significantly higher level of poverty and a correspondingly lower living standard. The development of agriculture and the provision of public goods in rural areas is therefore essential for Romania's economy and for achieving the objectives of social cohesion. Compared to other EU countries, the Romanian agricultural sector has a relatively high share in gross added value but has lagged behind in terms of labor productivity.

Keywords: primary sector, agriculture, agricultural policy

1. Introduction

The role of the primary and general sector and of agriculture in particular is an indisputable one. The agricultural sector is in close connection with other sectors of the economy, especially with the industrial sector and contributes to economic development.

Over time, the agricultural sector has evolved and can be characterized by three stages: the first stage addresses the preconditions for agricultural development - which relate to the improvement of the land structure, access to the consumer goods market, information on available techniques; the second step is to increase the efficiency of agricultural production processes by spreading innovation "labor intensive" and "saving capital"; the third and final phase of the evolution of agriculture is characterized by "intensive capital" and "labor saving" technology. This phase is that of the industrialization of agriculture.

A process of structural transformation is taking place globally as a result of the emergence of new global challenges with a long-term effect, which require a strategic vision in the field and concrete actions by the competent authorities. The growing global population, increased pressure on natural resources and global warming are creating a new framework at national and international level. In Europe, the aging process is also an additional challenge. All these aspects will have profound implications for agriculture and rural areas.

World food demand is on the rise, increased urbanization, rising input prices, pressure on water resources and growing crop and animal vulnerability to climate change will limit food production.

It is forecast that global demand for food will increase by 70% by 2050 as a result of the growing population and increased revenue. Developing countries will contribute most to this trend, with their demand for food to double in the coming years.

For the agri-food sector, these issues are both an opportunity and a challenge. Growth prospects for the agri-food market constitute a significant advantage for farmers around the world. However, imperfect market infrastructures and socio-economic vulnerabilities in the most densely populated areas of the world are expected to increase food insecurity. In addition, world agricultural systems will increasingly face the negative effects of climate change (changing rainfall

* Corresponding author. Tel.: +40722503696.
E-mail address: al.niturescu@gmail.com.

patterns, extreme weather phenomena, water shortages) as well as price volatility. On the other hand, increasing agricultural productivity can be achieved through investment, research and innovation, good agricultural practices and adequate public policies.

Although agriculture has always focused on food security and has been a positive engine for economic growth, the growing concern of the environmental society in recent decades has affected global agricultural policies. Consumers have become more and more concerned with the environmental sustainability of agriculture. The desire to know where the food comes from, how it was produced, and whether farming practices respect the environment are just some of the demands of today's consumers.

2. Characteristics of the Romanian agricultural sector in the European context

Agriculture was the main component of the primary sector in all Member States. According to the national accounts around 10 million people worked in agriculture in the EU-28 in 2015 and accounted for 4.4 % of total employment. Almost three quarters (72.8 %) of the agricultural workforce in the EU-28 was concentrated in seven countries: Romania, Poland, Italy, France, Spain, Bulgaria and Germany. (https://ec.europa.eu/eurostat/statistics-explained/index.php/Farmers_in_the_EU_-_statistics)

Agriculture plays an important role in Romania, relative to the size of the rural population and to the level of employment. About 45.7% of the Romanian population lives in rural areas, compared to about 23.6% in the EU member states. About 30% of the population is engaged in agriculture, compared to about 2% in the old Member States (EU-15) and 3-14% in the new Member States (EU-8). But at our country there are major differences between rural and urban areas, the former being marked by a significantly higher poverty level and a correspondingly lower living standard.

Romania ranks 6th in terms of the agricultural area used in the EU countries, with about 13.9 million hectares in 2013, after France, Spain, Great Britain, Germany and Poland – Fig. no.1

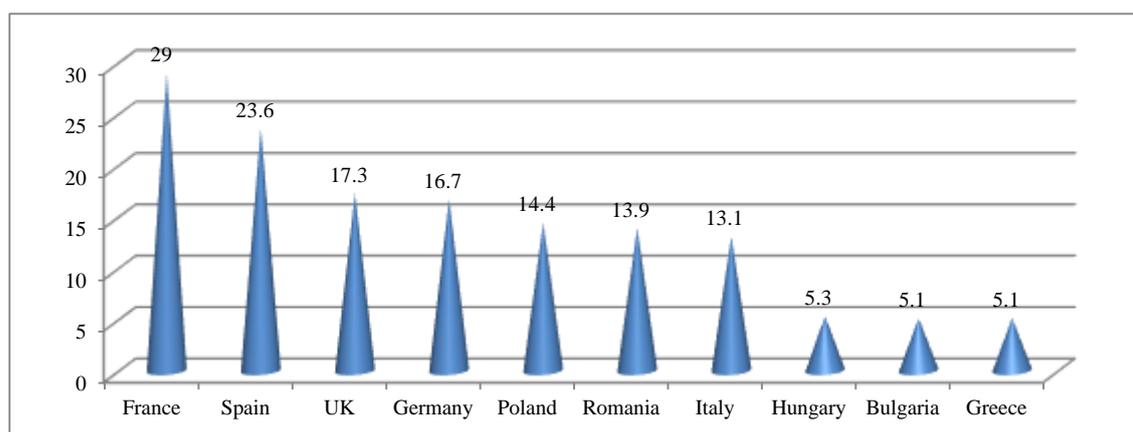

Fig. no.1. Top ten EU countries by agricultural area used (million hectares, 2013)

Source: Eurostat

Of the total agricultural land used, more than half represents cultivated arable land, with an important share of cereal crops. Other uses of the agricultural area used include livestock, pasture, hay, etc.

At EU level, the Common Agricultural Policy (CAP) favors mass production and industrial agriculture, a model to which agricultural systems in Eastern Europe should also rally. There are three versions of modern agriculture in the EU:

- German model, with large farms;
- The model centered on support for small producers;
- A model aimed at coexistence of intensive industrial production in regions that allow this and which can add value to products on world markets, alongside small farms operating in more difficult conditions, but can provide high-quality goods in local markets.

The image of contemporary Romanian agriculture does not fully correspond to any of the above models, being structurally different from the rest of Europe. In fact, Bulgaria and Romania are characterized by a "historic" absence of medium-sized family farms due to the communist tradition and legacy.

Romania suffers from one of the most pronounced structural divisions of agricultural land between all EU Member States and, in particular, from the new Member States. Of the new Member States, Slovenia has the largest percentage of its arable land cultivated by many small farms. Romania, Croatia, Poland, Latvia and Lithuania have relatively evenly distributed land between different categories of farms, but Romania stands out due to the lack of a middle class. Hungary, Estonia, Bulgaria and to a certain extent Slovakia have more than half of their agricultural area cultivated by farms over 100 ha, but all hold a relatively large number of small farms. Instead, the Czech Republic is characterized by the most productive agricultural production oriented to large scale farms.- Fig.no. 2

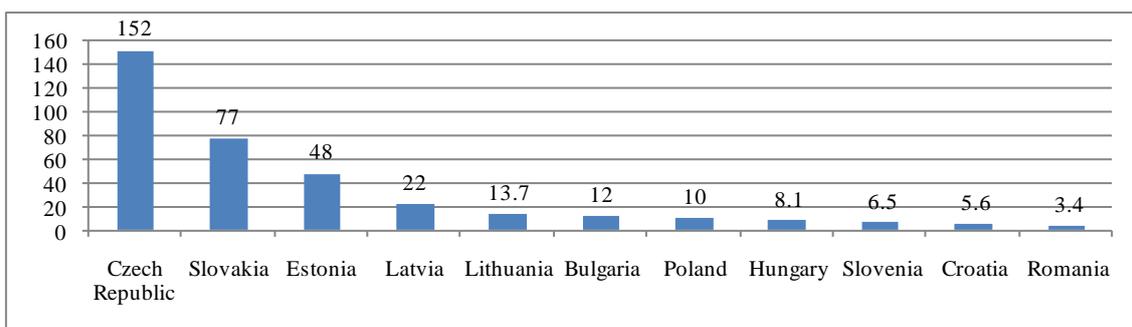

Fig. no.2. Agricultural holdings according to the average size of the farm (hectares)
Source: Eurostat

Romania has certain structural characteristics similar to those of the agricultural sectors of the other EU Member States, but it is unique in terms of the size of the gap between the category of farms and small farms and the prevalence of subsistence / semi-subsistence farming.

As far as the share of the employed population in agriculture is at the level of the European Union, it is around the average of 4.4%, with higher percentages in the countries of Central and Eastern Europe, while in the Western European countries the share of the population in agriculture is below the European average.

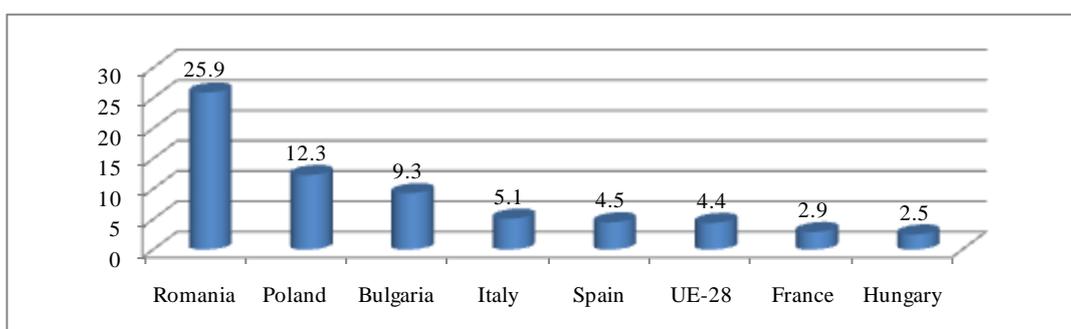

Fig. no.3. Share of the employed population in agriculture (% of the total employed population)
Source: Eurostat

The countries with the largest number of employees in agriculture are the ones with the highest gross added value generated at the worker level. In Romania, however, the vast majority of agricultural workers fall into the category of non-salaried staff (patrons, self-employed workers, unpaid family workers and members of co-operative associations).

All this leads to the fundamental problem facing the Romanian agriculture, namely the low productivity of labor and implicitly the relatively low yield of agricultural production.

In the aftermath of the fall of the communist regime, Romanian agriculture has undergone several changes that can be highlighted by the analysis of the gross added value (VAB) share of the agricultural sector in gross domestic product (GDP).

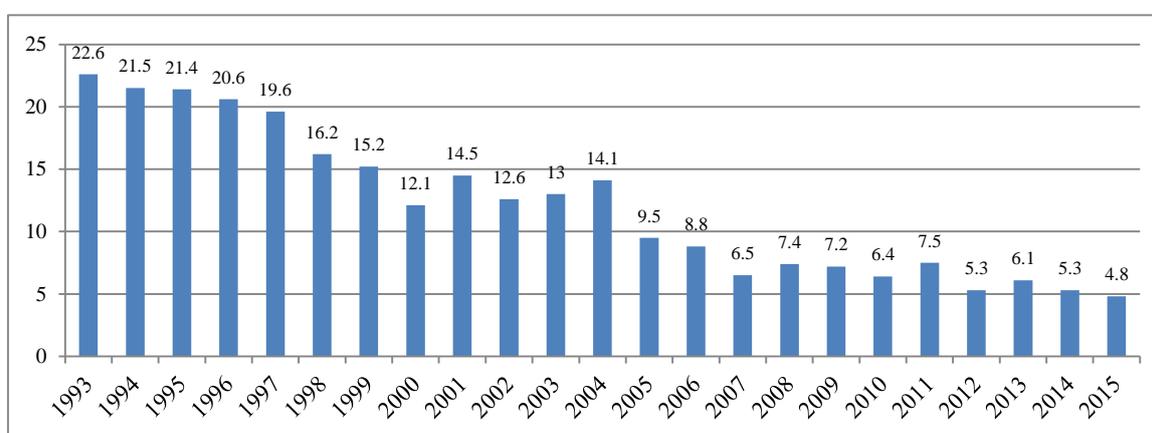

Fig. no. 4. Evolution of VAB share of agriculture in GDP (%)
Source: National Institute of Statistic

Despite the natural agricultural potential of our country, as can be seen from the above figure, the share of the agricultural sector in GDP has suffered considerable reductions over the last two decades. In 1993, the VAB share of the agricultural sector was 22.6% of GDP, and at the end of the analysis period it fell to 4.8%. This development is largely explicable by increasing the importance of industry and the service sector in the national economy as a whole, as well as poor technologies and low labor productivity in the agricultural sector.

Even under current productivity conditions, Romania is one of the main exporters of corn and wheat worldwide, due to the size of the available agricultural area. Thus, our country ranks thirteenth in the top of the world's largest maize producers, finding a net grain exporter. Romania holds the second most favorable position among the world's largest maize producers among EU economies, France being traditionally the largest corn producer in the EU. Romania is at the same time the third player on the Black Sea corn market after Russia and Ukraine.

3. Limits and perspectives of the Romanian agricultural sector

Considering the generous agricultural area available to our country, the high land use rate but a reduced share of VAB in GDP, we can deduce that there are a number of limiting factors.

First of all, we can consider the fragmentation of agricultural holdings - Romania suffers from the most serious fragmentation problem in agriculture among all countries of the European Union and has an average holding size similar to Malta or Cyprus, two countries with a very small overall size. Almost 75% of the farms in Romania are under 2 hectares and farms with a size of more than 100 hectares represent only 0.5% of the total, but they exploit 49% of the agricultural area. Here we can take as an example countries with high yields on agricultural production that have concentrated their agricultural potential on farms over 50 hectares - which offers them advantages such as economies of scale, the ability to attract trained farmers, easy access to finance and, implicitly, fast.

Secondly, we must take into account the age and level of training of farmers. The labor force in the Romanian agricultural sector is of an advanced age and an inadequate level of training compared to that of other European countries. This may result in a reluctance to change, to the adoption of new technologies, to innovation. According to the European Commission data, an overwhelming majority of 96.4% of Romanian farmers said they learned their agricultural skills strictly on the basis of practical experience. Another problem characteristic of the Romanian agricultural sector in terms of human resources is the fact that there is no clearly defined professional status of the farmer. This has strong implications for tax and social security and health care.

Another weak point of the Romanian agricultural sector is the low level of capitalization. This modest capitalization can be attributed to a low degree of technology of agricultural holdings in Romania. Less than 2% of holdings in Romania have a tractor - one of the basic technological facilities in the agricultural field, as opposed to 84% of the holdings in the Czech Republic. At the same time, many agricultural holdings are working with already depreciated or bought second-hand machines. The lack of a modern machinery and equipment park is a major obstacle and will not be able to achieve the European average yield without massive investment in state-of-the-art agricultural technology. There is no need to neglect the storage of agricultural products, which in many cases are inappropriate for efficient use.

Another problem facing the Romanian agriculture is tax evasion. The field of agriculture in which this type of tax evasion manifests most strongly is the sale of primary agricultural products, especially cereals and fruit-vegetables, as the producer sells production directly from the field and it reaches the final consumers through intermediaries to a several times higher, and the amounts are not declared.

Agriculture is also strongly affected by the phenomenon of non-legal work, but this is harder to quantify, as subsistence agriculture and unpaid family labor are widely practiced. Many agricultural activities are occasional and they can not be hired by workers with an individual contract of permanent work. These activities need unskilled labor only occasionally at different times of the year and should be done by employing day-laborers. Day workers who work in agriculture are part of the most vulnerable social category and are at the same time beneficiaries of social benefits paid by the state. In many cases, although hiring daytime workers is legally regulated, they refuse to work day by day because they lose the social benefits they receive from the state, so they work without legal forms.

Transforming agriculture and rural areas in a way that makes effective use of available resources requires public action and involvement, along with strategic coordination.

Among the measures to improve the efficiency of the agricultural sector, we mention:

- ✓ *Encourage land merging and stimulate farmers' association.* Although consolidation of farms is a slow process, the integration of small and medium-sized farms into agricultural producer / cooperative groups or organizations may be the safest way to allow access to markets and at the same time to obtain credits for production or investment in facilities common. The difficulty of small farmers, either to reach the market or to obtain market confidence to maximize their income, can be overcome if they understand the benefits and agree to get associative. Consideration should also be given to optimizing the way grants are awarded to small farms;
- ✓ *Decrease of the average age of the population in the agricultural sector and increase of the professional training of farmers,* because a still high agricultural area is used by older farmers (over 65 years old) without professional training. This phenomenon, coupled with a low level of education and training, had a negative impact on the performance of the sector. In the future, it is important to continue encouraging the transfer of agricultural assets between generations through incentives for young farmers together with efforts to increase

knowledge, skills, skills and skill levels. In this case, an important role is played by the education system, which should place greater emphasis on modernizing and diversifying agricultural specializations and harmonizing them with the realities of the agricultural sector in a European context. Young people are more receptive to the association, application of new technologies and environmental issues;

- ✓ *Developing entrepreneurship in rural areas* with the aim of decoupling the activity of these regions from subsistence agriculture. Entrepreneurship is a major factor for economic growth, innovation, competitiveness, employment and social integration. In rural areas there are opportunities for economic diversification through non-agricultural activities, such as rural tourism, which have gained ground in recent years in Romania. The entrepreneurial initiative can support rural actors in identifying and promoting viable strategies and actions that respond to the important economic changes in rural areas as well as to the social needs in rural areas;
- ✓ *Sustainable rural development through the adoption of good practices in EU countries and the formation of rural clusters* that would promote innovation through collaboration between universities, public and private entities. Rural cluster formation can increase the yield of the agricultural sector in the area, but it is mainly a measure of the local economy - because these clusters will not only contain agricultural activities. Promoting modern farm management models would add value to agriculture through rotational or diversification methods, but also through IT or robotics. In fact, the European Commission encourages cluster formation. Thus, in 2016 it developed a typology based on statistical and cluster analysis, according to which Member States are grouped into five categories (clusters), the interpretation of which depends on the importance given to the objectives of the CAP: the sustainability of food production, the sustainable management of natural resources and balanced territorial development. Romania is part of the first group of countries, alongside Austria, Germany, Latvia, Malta and Poland, characterized by internal convergence, flexible implementation of green payments, support for small farmers and sustainable development of rural areas;
- ✓ *Use of environment-friendly agricultural practices and the development of organic farming*. Organic products have a spectacular year-on-year increase across Europe and the world, despite the fact that at this time there is no dominance in the food market. This type of farming could be a niche market for some farmers. In the European Union, countries like Germany, France, Great Britain and Italy represent the most important organic-consuming countries. This phenomenon has expanded also in Romania, which manages to attract more consumers from year to year;
- ✓ *Facilitating access to European and national funds* would contribute to the import of know-how, the renewal of the farm machinery and agricultural machinery, and the modernization of agri-food processing units. These are imperative requirements because the increase in agricultural productivity depends to a large extent on the mechanization of the sector;
- ✓ *Encouraging the cultivation of technical plants* (in, hemp). At present there is an increase in demand for fiber, which can provide an income for growers in areas that are suitable for such crops, but can also represent an alternative to crop rotation and the recovery of the processing sector;
- ✓ *Increase of greenhouse and solarium surfaces*. In this way, the necessary extra-season vegetables can be provided and vegetables can be protected from climate change as a result of global warming;
- ✓ *More efficient promotion of domestic agro-food products on foreign markets*.

By applying the above measures, it is intended to increase the yield in agriculture and increase the volume of exports, which will have a significant impact on GDP and the state budget.

At the same time, we must consider that in order to achieve food security, the European Union claims for implementing food safety management systems, systems that on the one hand help manufactures achieve safe products, and on the other hand, give traders and consumers the confidence that the products they buy do not endanger their health. (Criveanu, 2012)

That is why, in the future, I believe that every effort must be made to cope with competition on European and agri-food markets, especially through the development of agriculture at European standards.

4. Conclusions

In spite of the considerable agricultural potential of our country, the yields in Romanian agriculture are modest, indicating a utilization of the factors of production far below the optimal values. Properly exploited, the existing potential allows for extra value and employment in a more productive way, thus contributing to real progress towards reducing rural poverty and eliminating income gaps in urban areas.

Romania has to make the most of the favorable global and European trends and its own competitive advantages in the agricultural sector. Romania also needs to maximize the opportunities and benefits it can achieve through the implementation of the CAP and through its participation in the EU and third countries market. At the same time, Romania must manage the main internal constraints and identify the best ways to address some factors such as climate change.

Agriculture and rural development in Romania in the 2030 horizon aims at achieving a level of coherence between agriculture, environment and rural development through the smart and sustainable valorisation of agricultural land, labor and capital.

The Romanian farmer in the 21st century must be competitive, connected to current information, open to innovation and new technologies, reaching the same level of well-being and similar living conditions as the inhabitants of urban areas. In this way, Romania will ensure its food security and become an important player in European and international agri-food trade. At the same time, the competitiveness of agrifood products must be related to the sustainability (sustainability) of their production.

The Public-Private Partnership in Romania -Theoretical Approaches

Maria Ciurea^{a*}

^aUniversity of Petrosani, University Street, No. 20, Petrosani, 332006, Romania

Abstract

Along with the new challenges in the process of adapting to the market economy, targeting the demand and supply law, the competition law and the process of Romania's integration into the European Union, the rehabilitation of transport infrastructure, water supply, waste recycling, environmental protection, monitoring state aids, ensuring a loyal and predictable business environment, are the main reasons for using public-private partnership as a way of working together between the public sector, the initiator of public utility projects and the private sector, the fund holder and the executive management. Increasing the availability of the private sector to take on a range of responsibilities and risks as well as the public sector to privatize public utility services has resulted in the multiplication of efforts to introduce the concept of public-private partnership to achieve economic and social objectives and projects from Romania.

Over time, the concept of public-private partnership has been the subject of legislative regulations both in the Member States of the European Union and in Romania, which recently adopted a new normative act on this type of partnership and which constitutes a objective of the Governance Program over the period 2018-2020 on the objectives of economic growth and strengthening fiscal-budgetary sustainability by significantly increasing the budget-financed investments or by accelerating the absorption of the European funds and by stimulating private investment. In view of the above-mentioned aspects, we propose that through this paper we address the theoretical issues of the public-private partnership and from the investigations carried out to highlight the advantages and the limits of a partnership of this kind, but also the main categories of institutions that are most effective in realizing of such partnerships with major benefits for the entire national economy.

Keywords: Public - Private Partnerships, Private Sector, Public Sector, Legislation, Policy Management, Benefits and Limits .

1. Introduction

The Public-Private Partnerships (PPP) is the way in which stakeholders have a common goal of attracting private investment to increase efficiency and deliver high performance public services, based on clearly defined and coordinated rules to achieve the expected results. A public-private partnership is a form of cooperation between the public and the private sector, based on certain regulations on the basis of which such partnerships may arise and which may take the form of: works or service contracts, concession contracts, joint venture contracts, which will bring important benefits to both partners, and the risks and costs are distributed proportionally between them. Although the interests of the partners are different, the private entity is profit-oriented and the public one is aimed at respecting the principles of economy, efficiency and effectiveness in the use of public funds, ultimately the same is the goal of financing, building, renovating, managing or maintaining goods through which they want high quality public services. In doing so, each partner contributes to planning and mobilizing the resources needed to achieve a common goal, each based on a voluntary decision and contributing with its own, material, financial or other resources (Man and Măcriș, 2014).

A public-private partnership is made on the basis of a long-term contract concluded between partners for the purpose of carrying out activities of public interest, based on the capacity of each partner to equitably allocate resources, risks and benefits, being the main opportunity to introduce private management in public services.

The sectors of the economy that are suitable for public-private partnership projects are very diverse, including water, electricity, gas, sewerage, waste treatment, telecommunications, collective restoration, research and development, education, health, tourism, maritime and air transport, justice, defense and others.

* Corresponding author. Tel.: +0-000-000-0000 ; fax: +0-000-000-0000 .
E-mail address: author@institute.xxx .

Although in Romania there have been and there are various forms of collaboration between public and private entities in various fields, the legal mechanisms of such a partnership have so far not been used with maximum efficiency to achieve the expected results in these sectors, although they would could have been a viable option for financing public or infrastructure services.

2. Research methodology

The need for knowledge in this field has led to the investigation of the topic addressed. In order to accomplish this approach, certain principles and rules specific to the research methodology were observed, among which mention: review of the specialized literature, use of other sources of information: respectively: various analyzes and studies elaborated on this topic and the specific legislation in the field. The basis of this paper was the theoretical research on the methodological aspects used in the case of the public private partnership in the context of the new regulations imposed at the level of Romania or at European level, quantitative method, observation, analysis and synthesis. In the context of the new approaches, based on the ideas found in the literature and in the normative framework, a synthesis of the various aspects of the public-private partnership resulted in various opinions with consequences in the evolution and development of the economy.

3. Theoretical and legislative approaches to public-private partnership

As a result of the various forms of collaboration between public and private entities, it is rather difficult to formulate a template definition of public-private partnership. Different perception of this type of partnership is due to the existence of various systems of administrative organization and public services encountered in different communities and political cultures. Currently, public-private partnership (PPP) is a notion often present in political speeches and in economic, financial and legal publications, in the economic press, or in international institutions. The notion of public-private partnership is any form of collaboration between the public and the private sector that is legally different from the point of view of the way in which partnerships are expressed and is different from one legal system to another.

In Romania, the emergence of the first public-private partnership structures has been formed at national level since 1990 as a result of developing sectoral, national strategies and institutionalized structures that have been generated by the new challenges emerging in the development and consolidation of the economy the privatization of public utility services, the development of the business environment, which led to an increase in the private sector's willingness to take on a range of responsibilities and risks, the urgent need for local government to find new financing solutions for activities, as well as the process of integration into the European Union (Dima and Man, 2013; Grabara et. al, 2013).

Legislative approaches since the onset of these partnerships to date did not lead to the achievement of outstanding results related to the development of major public-private partnership projects that will contribute substantially to economic development, especially local communities, but also the economy in its whole. For these reasons, but also due to the fact that the concession legislation was incomplete and unclear at that time, it was the main obstacle for the optimum development of PPP projects, and it is necessary to adopt new legal regulations that have succeeded over time.

In this respect, in 2010, through the Public-Private Partnership Law No.178, it was attempted to regulate the way of realizing a PPP project that had as main objective the design, financing, construction, rehabilitation, modernization, operation, maintenance, development and the transfer of a public good or service. Surprisingly, this law did not bring the desired results, as no public-private partnership project was concluded during the period in which it was in force. This law could not be put into practice for *several reasons*, namely:

- ✓ *its unclear formulation;*
- ✓ *the establishment of a legislative parallelism, i.e. its implementation realises when the concessions and public procurement legislation is not applied;*
- ✓ *the rigidity of the regulations in this normative act;*
- ✓ *the lack of an interface in the Electronic Public Procurement System (SEAP) useful in publishing selection ads.*

These issues did not allow the development of PPP projects and the attraction of private funding, as expected with the entry into force. The SEAP functionality became operational only in early 2013 when it was possible to publish selection and PPP contracts.

As our country as a member of the European Union through the commitments assumed had the obligation to ensure the harmonization of the legislative and institutional framework for the development of investment projects under public-private partnership regime, it established by a Government Decision under the subordination of the Ministry of Public Finance, The Central Unit for the Co-ordination of Public-Private Partnership (UCCPPP), having the role of a central institution in the field of public-private partnership projects with tasks of guidance and monitoring of the public partners and of the private investors interested in organizing and carrying out activities a public-private partnership project.

In 2012 at the level of the central public administration a series of reorganizations took place which led to the passing of UCCPPP under the subordination of the Department for Foreign Investments and Public-Private Partnership (DISPPP), a specialized body with legal personality from the Government working apparatus, which functioned until the end of 2016 when it was totally divided by a new legislative act and its activities were taken over by the Ministry of

Public Finance. Although the law has been altered by the European Commission's observations on non-compliance with principles governing public contracts, it has proved to be a regulation that can not be adapted to the economic and legal realities of the moment.

Regarding the fact that the law adopted in 2010 proved to be inoperable, in May 2018, the Government adopted the Government Emergency Ordinance No. 39 on public-private partnership, which is one of the objectives of the Governance Program for the period 2018-2020, with on the objectives of economic growth and strengthening fiscal-budgetary sustainability by significantly increasing the investments financed from the budget or by accelerating the absorption of European funds, as well as by stimulating private investments. Thus, through macroeconomic fiscal-monetary policies, macroeconomic consolidation can be achieved and, against the backdrop of macroeconomic equilibrium, wealth growth will be achieved. In this respect, it is proposed to stimulate private investment through active involvement of the state, i.e. by enhancing the projects in public private partnership and by state aids granted by the Government.

According to this regulation, the public-private partnership aims at the realization, rehabilitation, extension of a good or property belonging to the patrimony of the public partner and/or the operation of a public service. Its provisions are operable by the public partner for the implementation of a project if the project substantiation study demonstrates, in addition to the elements presented in Table 1, that more than half of the revenues to be achieved to the project company from using the good/goods or operating the public service that is the object of the project come from payments made by the public partner or by other public entities for the benefit of the public partner.

Table no.1. Key elements of the fundamenting study

No. crt.	Elements
1.	The project financing
2.	The economic efficiency of the project
3.	The risk distribution structure for each alternative project implementation option
4.	The degree of support of the project and the comparison of alternative contractual options/arrangements for project implementation
5.	The characterization of the project in relation to the public deficit and public debt, calculated according to the methodology applicable under the European Union law

Also, **the mechanism of public-private partnership** is characterized by a **series of elements**, among which (EIB, 2017):

- *cooperation between the public partner and the private partner for the implementation of a public project;*
- *financing the project, mainly from private funds and depending on the situation, by pooling private funds with public funds;*
- *the relatively long duration of contractual relationships over 5 years, allowing the private partner to recover the investment and achieve a reasonable profit;*
- *distributing the risks between the public partner and the private partner, depending on each contracting party's ability to assess, manage and control a particular risk;*
- *achieving the goal pursued by the public partner and the private partner.*

The following **forms** are known within this partnership (The Government of Romania, O.G. 39/2018):

✓ *institutional public-private partnership* - is the one made under a contract between the public partner and the private partner, through which the two partners form a new company that will act as a project company and which, after being registered in the company register, acquires the capacity as a party to the respective public-private partnership contract;

✓ *contractual public-private partnership* - is based on a contract between the public partner, the private partner and a new company whose share capital is wholly owned by the private partner acting as a project company.

All public-private partnership contracts may also be concluded for the purpose of performing relevant activities in the public utility sectors provided by Law no. 99/2016 regarding the sector acquisitions, as subsequently amended and completed, as well as for the realization by a private operator of the community utilities services provided by the Community Public Utilities Act no. 51/2006, as subsequently amended and supplemented.

Regarding the **financing of investments under public-private partnership contracts**, this is carried out as follows:

- *in full, from financial resources provided by the private partner;*
- *from the financial resources provided by the private partner, together with the public partner.*

The private partner provides the necessary financing for the realization of the investments from own resources and/or attracted resources from the donors and the public partner can contribute to the financing of investments with public financial resources, including from external non-reimbursable post-accession funds and from the national contribution related to them the conditions laid down by national and European Union legislation. The contribution of the public partner to the financing of investment in a public-private partnership contract made up of financial resources other than non-reimbursable external funds and the national contribution to such funds may not exceed 25% of the total amount of the investment.

In table no. 2 the mandatory steps to be taken to conclude and commence the fulfillment of the obligations of a public-private partnership contract are to be presented.

Table no. 2. Stages covered in a public-private partnership contract.

No. crt.	Steps
1.	Making a fundamenting study by the public partner.
2.	Approval of the Government's substantiation study for central public administration projects or, where appropriate, deliberative authorities for local government projects.
3.	Examining the procedure for awarding the public-private partnership contract.
4.	Approval of the public-private partnership contract resulting from the finalization of the negotiations and initiated by the parties, by the Government for the central public administration projects or, as the case may be, by the deliberative authorities for local public administration projects.
5.	Signing the public-private partnership contract.
6.	Fulfillment of all the conditions of suspension provided for in the public-private partnership contract, including the financial closure.

Public entities wishing to carry out public-private partnership projects will organize and operate by decision of the head of the public entity, internal units for the coordination of public-private partnership projects organized as internal structures without legal personality dedicated to the preparation, assignment and implementation of the public-private partnership contracts or, as the case may be, the implementation of the contracts assigned by the National Commission for Strategy and Prognosis, which will be supported in carrying out the activity of technical, financial and legal consultants contracted in accordance with the legal provisions.

4. Considerations on the benefits and limits of a public-private partnership

Analysing the literature on this topic, we found that the institutional capacity to create, manage and evaluate public-private partnerships is essential to ensure that they become an effective tool for delivering important services such as infrastructure, which is best suited to such partnerships. Many economic analysts, especially Europeans, that pay more attention to public-private partnerships, consider that transferring management and private sector knowledge to the public sector can reduce the management gap in the public sector resulting from the fact that people who manage public resources, are not theirs, they do not assume any risk, often in conflict of interests or may be subjected to external influences or pressures, affecting the observance of the principles of economy, efficiency and effectiveness in the use of public funds.

Over time, the implementation of PPP projects has highlighted a number of *benefits* that refer to (Moldovan, 2017; Petrescu, 2010; Vertakovaa and Plotnikov, 2014):

- ✓ *better implementation of public projects from the point of view of observance of the execution terms and the fitting into the approved budgets;*
- ✓ *the allocation of financing costs both during construction and operation, with the effect of reducing immediate pressures on public sector budgets;*
- ✓ *providing easy facilities to attract additional resources in a specific area;*
- ✓ *reducing construction costs and improving quality by capitalizing on the efficiency and innovative potential of the private sector;*
- ✓ *ensuring attracted stakeholders to support all project-specific actions.*
- ✓ *stimulating research - development, innovation and sustainable development efforts;*
- ✓ *introducing new, more efficient and effective ways of achieving projects;*
- ✓ *the proper allocation of risks between the public and private sectors, resulting in a reduction in the overall costs of the project.*

Since public - private partnerships have a common goal in their creation and development, advantages have been identified by both parties, and they will be described in Table 3. As can be seen from the information below, the public sector is most helpful in implementing such partnerships.

At the same time, as for any other activity, also in the case of public - private partnerships, certain *limits* have been identified that cover a number of aspects (European Court of Auditors, 2018; Jomo et al., 2016):

- *responsibility and transparency in the provision of services is limited by the involvement of a private partner to whom the same obligations as the public are not subject.*
- *long-term partnerships may involve higher costs if the project is funded by the private partner through a private loan, with the risk of rising final costs;*
- *the existence of high transaction costs in the negotiation procedures, the financing needs being relatively large and the association agreements being carried out over fairly long periods. In such a situation, only a relatively small number of private or non-governmental partners will have the financial and institutional capacity to enter into such partnerships that will distort economic activity and will create competitive advantages only for a part of the economic partners.*

▪ *both partners must have the skills and capacities specific to such partnerships in order for a contract to be successfully assigned and implemented and the number of partners with such capabilities is rather limited.*

Table no. 3. Advantages of partnerships by sectors

Crt. no.	Public sector	Private sector
1.	Attracting private financial resources to finance public works or services.	Public Private Partnership is an excellent business opportunity for the private sector.
2.	Cost reduction.	It benefits from intellectual property acquired through the partnership project.
3.	Transferring a part of the project risks to the private partner or the risk of emergence of force majeure.	Project funding can be done not only from private funds, but can also include a component of public funds coming from non-reimbursable funds and the corresponding national co-financing.
4.	Increase efficiency of public projects by using know-how and private management in public projects.	-
5.	Less implementation time.	-
6.	Increased quality of public services provided to the population.	-
7.	The possibility of benefiting at the end of the project from the property right of the product made under the partnership contract, which is transferred free of charge and free of any tasks to the public partner.	-

According to the legal provisions and the literature (Pîrvu and Voicu Olteanu, 2009; Munteanu et.al, 2013), the **risks** of financing, obtaining permits, opinions, timely delivery of projects or activities are distributed between the two equitable partners, depending on their possibilities and expertise to deal with them, being generated by:

✓ *the absence of common goals and objectives for the partners involved in this form of collaboration can end up conflicts both during the project implementation and in the operational phase with negative consequences on the fulfillment of established indicators;*

✓ *the impact of the project on other services or projects, such as public transport-related transport infrastructure projects;*

✓ *the existence of differences in organizational culture between partners, accentuated in the event of difficulties during the project's realization;*

✓ *the lack of coherent national strategies on infrastructure development, a situation that does not allow for the correct estimation of the initial parameters of the project;*

✓ *the existence of a hostile economic and political environment that makes cooperation between partners unattractive.*

Public authorities in Romania consider that it is more profitable to finance public investment by accessing resources through the European Regional Development Fund than through PPP, with the exception of infrastructure investments where the concession's benefits may be higher compared to investments in other areas of public interest activity. Therefore, Romania's delay in implementing PPP projects may be motivated by inadequate legislation in this area and the lack of experience of the public authorities that should initiate these projects and the difficulty of completing them.

5. Conclusions

The utility of public-private partnership has proven its effectiveness in socially important areas such as education, health, services and transport systems development. These types of partnerships have an important growth in Europe, but with macroeconomic and systemic significance only in the UK, Turkey, Italy, France, Germany, Portugal, the Netherlands and Spain. In all other European countries, including Romania, the importance of investments through such partnerships remains low compared to traditional public investment procurement. For the Romanian public sector a particularly important aspect is the necessity of satisfying the public interest through appropriate public services as the main means of eliminating or reducing the factors of stagnation of the evolution of this sector and satisfying the social needs whose diversification requires finding new forms to provide public services through the public-private partnership, whose specificity is given by private intervention in public administration, under the control of public authorities. So we need a modern and flexible public administration that can manage the priority of public investment for development, which includes as a tool to implement these partnerships, which would prove useful for making public investments especially in rural areas, which increase the competitiveness of land use and improve the quality of life of the inhabitants.

Public-private partnerships are often accompanied by significant deficiencies in policy management and partnership implementation, as there is no interest in developing and promoting strategic priorities as well as in respecting important principles and criteria through a co-ordinated and cooperative system among all partners, and due to the fact that the legal framework is not clear and explicit for all situations that may arise, and no tools for effective management of these projects are developed.

The implementation of many public-private partnership contracts, with no performing results in favour of the people and public partner benefits, with the recovery of private-sector investment, is the result of an institutional framework with weaknesses in evaluating, monitoring, analysing, recording and reporting such contracts, generating inefficient functionality of the system.

Research has shown that these partnerships are more suited to economic infrastructures such as transport and electricity, where demand is relatively stable, and the impact on service quality is easy to assess and where better quality infrastructure can reduce costs at the stage operational. For public - private partnerships to become an effective tool for financing key infrastructure projects, our country needs to have the institutional capacity to create, manage and evaluate these partnerships.

Considerations on the Need to Implement International Accounting Standards for the Public Sector in Romania

Maria Ciurea^{a*}

^aUniversity of Petrosani, University Street, No. 20, Petrosani, 332006, Romania

Abstract

The current context of the globalization of the economy, the development of the capital markets and the accession of Romania to the European Union, imposed a series of measures regarding the introduction of accrual accounting in order to fulfil the assumed commitments. Therefore, Romania's primary purpose in developing the public accounting system was to harmonize it with national legislation, European directives and International Accounting Standards for the Public Sector. From the analysis carried out on the reform initiated in the Romanian public accounting system, it transpired that the national legislation was substantially improved by introducing specific elements for the accrual accounting. Regarding these aspects, the objective of this paper is to undertake an analysis of the implementation of the International Public Sector Accounting Standards by identifying those standards that can be easily applied and adapted to the specifics of the public system in Romania, given that the regulatory bodies recommended their application rather than their obligation.

Keywords: International Public Sector Accounting Standards (IPSAS), accounting harmonization, implementation.

1. Introduction

Accounting harmonization has made it necessary to adopt a common financial reporting language, which is achieved through the accounting normalization process. In this respect, the improvement and reduction of the differences between the national accounting practices and the international ones, aiming to develop principles and norms of a general nature leading to comparability of the information provided by the content of the financial statements of entities in the public sector. At the same time, the harmonization of rules is seen as the main means of ensuring the transparency and comparability of the information that leads to the optimization of the public sector decision-making process, from which interested parties can make an appreciation of the performance of different levels of this system. At international level, accounting harmonization at the public system level is guided by the International Public Sector Accounting Standards (IPSAS) developed by the International Public Sector Accounting Standards Board (IPSASB), a body that aims to evolve accounting standards to the highest levels, so that they can be used efficiently by public entities in the process of generating financial statements with a general purpose, which will lead to an improvement in their degree of trust and transparency. Thus, there are concerns both at the international level and within the European Union for the normalization and harmonization of accounting systems in order to create uniform procedures for the recording of financial transactions at the level of all states (Bellanca, 2015).

The integration of Romania as a full-fledged member of the European Union has led to multiple changes in the level of accounting for public institutions. In this regard, the accounting regulations for public institutions, approved by O.M.F.P. no. 2021/2013 are based on the international vision of public sector accounting and professional judgment. From this perspective, these regulations explicitly or implicitly include elements of the International Public Sector Accounting Standards (IPSAS).

Government adoption of IPSASs will improve both the quality and comparability of financial information reported by public sector entities around the world. It will also strengthen the management of public finances, which will lead to a better assessment of government resource allocation decisions, thereby increasing transparency and accountability (Tudor and Crişan, 2017; Dascălu et. al., 2006; Nistor, 2017; Ristea et.al., 2010).

E-mail address: author@institute.xxx .

In the current context at the European level, it is envisaged to develop a harmonized accounting framework that responds to the specific needs of the public sector in the Member States. From this perspective, the European Commission develops its own accounting rules, called the European Public Sector Accounting Standards (EPSAS), based on IPSAS. Given that Romania is a member of the European Union, it will have to comply with the European public accounting requirements as well. That is why accountants working in public institutions need to familiarize themselves with IPSAS specific accounting concepts and reasoning.

2. Legislative approaches regarding the evolution of public accounting in Romania in view of the transition to the adoption of IPSAS

Over time, our country's public accounting system has evolved in light of the changes that have taken place at certain times. All this was determined by the emergence of the market economy and the fall of the communist regime. A number of legal provisions constituted the cornerstone that revolutionized public accounting in Romania, namely: Accounting Law no. 82/1991, Order of the Ministry of Public Finance (OMFP) no. 1746/2002 and 1792/2002 on the hiring, liquidation, authorization and payment of expenses to public entities, GD no. 81/2003 and OMFP no. 1487/2003 regarding the revaluation and amortization of fixed assets held by public entities, OMFP no. 520/2003 on the organization and management of the budgetary revenues, but not the last of the OMFP no. 1917/2005 regarding the new plan of accounts for public institutions, which made a closer alignment to the entity's chart of economic accounts.

The adoption of IPSASs started in 2002, when the transition from the cash accounting to the accrual - based accounting took place, having as a legal document the implementation of OMFP no. 1746/2002, through which the methodology for organizing and managing the accounting of the public system, the chart of accounts and the accounting monographs used for the registration of operations was established. The basis for this regulation was a series of elements of the European System of Accounts (ESA 95), the Financial Regulation of the Council of Europe no. 1605/2002 or the Manual of Government Financial Statistics, prepared by the International Monetary Fund.

Also, the introduction of the new budget classification applicable from January 2006 through OMFP no. 1954/2005 was imposed by the necessity of its correlation with the National Accounts System and the 2001 Public Finance Statistics Handbook. The purpose of this order was to comply with the Standards of International Bodies on the Compilation and Presentation of Public Finance Statistics, in order to improve the structure and the transparency of operations carried out on public funds as well as our country's commitment to implementing the *acquis communautaire* in the field of public finances.

Later, after Romania's accession to the European Union, it was necessary to improve accounting in the public system through the emergence of new regulations at the national level through OMFP no. 2021/2013, applicable on 1 January 2014, and at European Union level by Regulation no. 549/2013 on the European System of National and Regional Accounts of the EU (SEC 2010) applicable on 1 September 2014, the date from which information was transmitted to Eurostat in compliance with the 2010 ESA rules. This sets out the accounting framework applicable at European level which gives the possibility of an analytical and systematic presentation of a country's economy, its main components and its relations with other economies in order to ensure international comparability, harmonization with other economic and social statistical systems, consistency, stability over a long period, focus on process description economically sound and easy to monitor; application capability in different situations and with different purposes. Consequently, the transposition of this regulation at the level of Romania was achieved through: OMFP no. 496/2014 for the approval of the Methodological Norms regarding the acquisition and withdrawal of the certificate of attestation of acquired knowledge in the field of the European System of Accounts and of the Law no. 270 / 2013 amending and supplementing Law no. 500 / 2002 on public finances.

Therefore, the progress made in our country's public accounting system for the implementation of IPSASs contributes to: the increase of the quality of financial reporting by the institutions, the credibility and transparency of the information provided, the achievement of comparability and a responsible evaluation at the level of all the managed resources, making accurate decisions, assessing the financial situation, financial performance and cash flows, good management and resource management, more detailed information on cost-effective management of results, performing more effective internal control and much more transparency regarding assets and liabilities (Deaconu et. al., 2011; Gisberto and Nisulescu-Ashrafzadeh, 2017).

All these aspects covered by public accounting have been and are still possible following the evolution of the national regulatory framework, with IPSASs main benchmark setting out how to recognize, evaluate, describe and present transaction information and events in general purpose financial statements.

3. The Current State of Implementation of the International Public Sector Accounting Standards

The world globalized economy and financial markets have contributed to the recognition of IPSAS as a common methodological basis for the preparation of financial reporting by the budgetary sector. The experience of other countries reflects that such features, such as intelligibility, relevance and comparability of information, are achieved through the direct use of international standards for the preparation and reporting of financial statements (Măcriș, 2015). At the public sector level, by introducing accrual accounting and waiving cash accounting was the first step and the

most important reform process of public financial management. On this basis, IPSASs are the main international reference that provides financial information to the public sector through the use of accrual accounting. International bodies contributed by adopting IPSASs to their legitimacy, this ample process having a particular impact on their implementation at the EU level for the Member States. The accounting harmonization imposed the need to adopt a common financial reporting language, which can be achieved through the accounting normalization process. In this regard, the improvement and reduction of the differences between the national accounting practices and the international ones, aiming to develop principles and norms of a general nature leading to comparability of the information provided by the content of the financial statements of entities in the public sector (Man and Ciurea, 2016 a, b). At the same time, the harmonization of rules is also considered as the main means of improving clarity and comparability, which will also lead to the completion of the wide public decision-making process, from which stakeholders can assess the performance of the different levels of this system. Public Accountancy Harmonization (IPSAS) has as its main reference the International Public Sector Accounting Standards (IPSAS).

The accrual-based accounting standards adopted for all areas of the public system at EU level are the best solution for public sector management and governance. In the public sector, accrual accounting is intended to increase the efficiency and effectiveness of the business, while providing liquidity requirements for optimal performance of this system (Pitulice, 2013; Tudor, 2010). In this context, IPSASs are the only tool for accounting for the public system that helps to manage it, according to clearly defined principles, which largely depend on information from managers providing information on the financial and economic situation and performance of it. This type of accounting is the only system for obtaining generally accepted information, which identifies the true, complete and reliable image of the financial situation and the performance of public entities (Nicula and Bragadireanu, 2017; Dumitru and Pitulice, 2014; Munteanu et. al., 2014). At the same time, this implies the recording of all transactions, not when cash is made, but at the moment when the economic value is created at the time when claims and obligations arise or turn out or when they record transactions when the amount is received or paid. In fact, accrual accounting can be considered as complementary to cash accounting and not an alternative to it.

Since 2012, C.E. through EUROSTAT initiated the process of setting up the European Public Sector Accounting Standards (EPSAS), which considered the fact that the implementation of the central EU budget made up of national budgets, requires common accounting tools to be harmonized and applied by all members. Therefore, IPSASs are the most appropriate reference framework for the future development of these European standards, called "EPSAS", whose adoption contributes to the broad process of meeting EU requirements, and will bring substantial benefits better governance, development of public management, accountability in financial management and transparency.

Based on the latest information made by visiting www.ifac.org, in the section for the public sector, we have found that new standards have been added, currently there are 41, of which 40 for accrual accounting and one for house accounting. Their inspiration came from IFRS and some of them have been tailored to the public sector. In this respect, the following standards may be mentioned: IPSAS 22 "Presentation of Financial Statements to the State Sector", IPSAS 23 "Income from Transactions other than Exchange Rate (Taxes and Duties)", IPSAS 24 "Presentation of Budget Information in the Financial Statements", IPSAS 32 "Service Concession Liabilities: Grantors", IPSAS 33 "First-time Adoption of the Undertaking Basis", IPSAS 39 "Employee Benefits", and IPSAS Standard "Financial Reporting according to Cash Accounting". Starting from the fact that the evolution and context of the act of the public sector activity is constantly changing, these standards are regularly amended and revised.

At the level of Romania, the institution with attributions in the field of public accounting regulations is the Ministry of Public Finance (MFF), which through the General Direction of Treasury and Public Accounting has as main duties:

- *studying and analyzing the European Directives, the International Standards and the Financial Reporting of the Public Sector, as well as other documents adopted by the professional bodies in order to achieve the convergence of these regulations with the national ones;*
- *ensuring that the annual and quarterly financial records required to provide information for the statistical reporting of EUROSTAT and other international bodies are improved and updated.*

The analysis of the specialized literature on the implementation of IPSASs in our country revealed that the opportunity for cooperation between the Court of Accounts and the Ministry of Public Finance was required to obtain certain assurances that all consolidated accounting reports are adjusted and meet the IPSAS requirements. Thus, in order to respond promptly to the international commitments assumed, this institution carried out a documentation that aimed at the evaluation and the stage of implementation of IPSASs. In this regard, a number of issues have emerged, related to the fact that:

- ✓ *did not exist at M.F.P. any collaboration with another specialized structure regarding the implementation of IPSASs;*
- ✓ *at the level of Romania, an interdepartmental committee was not established for the implementation of IPSAS, although it was adopted in 2017, Order no. 928 on the approval of the Organization and Functioning Regulation of the Public Accountancy Council, it should have been the main independent supervisory body to ensure the convergence of national regulations and practices in the field of public accounting with the regulations applied at the E.U.;*
- ✓ *no implementation timetable for IPSASs was established because it was not a request from the European Commission (E.C.), although the International Monetary Fund and the World Bank requested information on their applicability;*

✓ the completion of the transposition process of all IPSASs has not been accomplished as new developments of the E.C. are expected;

✓ the following standards have been implemented only partially: IPSAS 1 "Presentation of Financial Statements", IPSAS 2 "Cash Flow Statements", IPSAS 4 "The Effects of Changes in Foreign Exchange Rates" IPSAS 5 "Borrowing Costs", IPSAS 11 "Construction Contracts", IPSAS 12 "Inventories", IPSAS 13 "Leases", IPSAS 17 "Property, Plant and Equipment", IPSAS 19 "Provisions, Contingent Liabilities and Contingent Assets", IPSAS 23, "Transactions other than exchange transactions (taxes and charges)", IPSAS 24 "Presentation of Budget Information in Financial Statements", IPSAS 31 "Intangible Assets".

Table no.1. The current state of implementation of IPSASs in the Romanian public system

Crt. nr.	Name of standards	Full implemen- tation	Partial implemen- tation	Non- implementation
1.	IPSAS 1 „Presentation of Financial Statements”	-	X	-
2.	IPSAS 2 „Cash Flow Statements”	-	X	-
3.	IPSAS 3 „Accounting Policies, Changes in Accounting Estimates and Errors”	-	X	-
4.	IPSAS 4 „The Effects of Changes in Foreign Exchange”	-	X	-
5.	IPSAS 5 „Borrowing Costs”	-	X	-
6.	IPSAS 6 „Consolidated and Separate Financial Statements”	-	X	-
7.	IPSAS 7 „Investments in Associates”	-	X	-
8.	IPSAS 8 „Interests in Joint Ventures”	-	-	X
9.	IPSAS 9 „Revenue from Exchange Transactions”	-	X	-
10.	IPSAS 10 „Financial Reporting in Hyperinflationary Economies”	-	-	X
11.	IPSAS 11 „Construction Contracts”	-	-	X
12.	IPSAS 12 „Inventories”	-	X	-
13.	IPSAS 13 „Leases”	-	X	-
14.	IPSAS 14 „Events After the Reporting Date”	-	X	-
15.	IPSAS 15 „Financial Instruments: Disclosure and Presentation”(superseded by IPSAS 28 and IPSAS 30)	-	X	-
16.	IPSAS 16 „Investment Property”	-	-	X
17.	IPSAS 17 „Property, Plant and Equipment”	-	X	-
18.	IPSAS 18 „Segment Reporting”	-	-	X
19.	IPSAS 19 „Provisions, Contingent Liabilities and Contingent Assets”	-	X	-
20.	IPSAS 20 „Related Party Disclosures”	-	-	X
21.	IPSAS 21 „Impairment of Non-Cash-Generating Assets”	-	X	-
22.	IPSAS 22 „Disclosure of Financial Information About the General Government Sector”	-	X	-
23.	IPSAS 23 „Revenue from Non-Exchange Transactions (Taxes and Transfers)”	-	X	-
24.	IPSAS 24 „Presentation of Budget Information in Financial Statements”	-	X	-
25.	IPSAS 25 „Employee Benefits”	-	X	-
26.	IPSAS 26 „Impairment of Cash-Generating Assets”	-	X	-
27.	IPSAS 27 „Agriculture”	-	-	X
28.	IPSAS 28 „Financial Instruments: Presentation”	-	X	-
29.	IPSAS 29 „Financial Instruments: Recognition and Measurement ”	-	X	-
30.	IPSAS 30 „Financial Instruments: Disclosures”	-	X	-
31.	IPSAS 31 „Intangible Assets”	-	X	-
32.	IPSAS 32 „Service Concession Arrangements: Grantor”	-	-	X
33.	IPSAS 33 „First-time Adoption of Accrual Basis IPSASs”	-	-	X
34.	IPSAS 34 „Separate Financial Statements”	-	X	-
35.	IPSAS 35 „Consolidated Financial Statements”	-	-	X
36.	IPSAS 36 „Investments in Associates and Joint Ventures” which has replaced IPSAS 7 and IPSAS 8	-	-	X
37.	IPSAS 37 „Joint Arrangements”	-	-	X
38.	IPSAS 38 „Disclosure of Interests in Other Entities”	-	-	X
39.	IPSAS 39 „Employee Benefits” which has replaced IPSAS 25 with application since 1.01.2018	-	X	-
40.	IPSAS 40 „Public Sector Combinations,” to be implemented with 1.01.2019	-	-	X
41.	IPSAS „Released to Improve Financial Instruments Reporting”	-	-	X
	TOTAL STANDARDS = 41	0	26	15

Also, there are standards that are not found in the Romanian regulations at all, it is the case with the following standards: IPSAS 11 "Construction Contracts", IPSAS 16 "Real Estate Investment", IPSAS 27 "Agriculture" and IPSAS 32, "Commitments concession of services: concessionaires", etc. In the table no.1. the present situation of the implementation of IPSASs in the accounting of the Romanian public system is presented.

From the analysis of the information presented above, it resulted that 29 standards were partially implemented and 12 of them were not implemented at all. Thus, it can be estimated that the implementation rate is 63.4% at the level of 2018. If we refer to the grouping of these standards used to present the financial statements, revenues, expenditures and financial position, we will find that the highest degree of implementation have those relating to the presentation of financial statements, followed by income and expenses.

4. Conclusions

The global financial community, and in particular the European one, agree with the need to implement consistent, high-quality, high-quality counterparts. The need for a common language at the international level in the context of contradiction is very important because it provides a horizon for the professional debate. As a result of the changes in the Romanian public contingency, especially since 2016, when the approved regulations contain concepts and definitions from the International Standards for Public Sector Compatibility. They also recommend the possibility of selecting a contradictory tract to the application of a stable policy through professional judgment correlated with the requirements of the norms. All standards are an indisputable reference for the establishment of new EU-wide public sector accounts.

The conclusion drawn from this analysis is that the implementation of IPSASs is a process that has been successfully launched in only one EU member state, namely Spain, and in other countries this process has been difficult to achieve because of the very large differences between IPSASs and nationally applied standards. Many of the obstacles to the implementation process have been generated by high costs or the need for substantial legislative changes. In Romania, the implementation of IPSASs has been achieved only partially, and the legal regulations in force at national level have and have inspired these standards, but without direct reference to them.

Increasing the efficiency of public administration activity in administrative transparency, the use of modern communication tools and the transmission of information are major objectives that are permanently found in their strategies. One of the tools to implement these goals is to use the FOREXEBUG system that allows for standardizing the reporting and transmission of 15 types of financial statements for each public administration entity versus 43 physical forms that were completed before using the new system. These situations are transmitted in electronic, standardized and secure format, which has allowed the confidence of data collected through cross-checks with system data to be increased. Therefore, the major advantage of using this system is that it allows for electronic monitoring and control of legal and budgetary commitments, with a direct impact on improving financial discipline and preventing the build-up of public institution arrears.

The planning of business processes in undefined condition of oligopolistic market

Alexakhin A.V.^a, Zaytsev I.M.^a*, Sala D.P.^b

^a NUST MISIS, Russia, Moscow

^b AGH, Poland, Krakow

Abstract

Methodology – we have carried out a review of the current state of the market secondary metallurgy of precious metals. The basic tenets of the theory of antagonistic games and show their application in an oligopolistic market recyclers of electronic scrap. It is shown that decision-making in the field of business process is advantageously carried out on the basis of market monitoring and behavior of other contracting parties, in particular, to their pricing decisions.

Originality/value – The models, which can formalize the behavior of companies in an oligopolistic market and find a solution under conditions of uncertainty. The proposed rules non-cooperative interaction and competition rules are making management decisions on planning business processes, in particular, to ensure the natural resources of the enterprise.

Findings – Improving the competitive strategy of raw materials procurement is possible through the use of guidelines defining their behavior in a competitive environment that include elements of game theory. Non-cooperative game models of interaction and competition can be used in the planning of business processes. Application management advice supply of raw materials necessary to make now can be used to implement the ability to manage the volumes supplied raw materials to attract more number of suppliers in the development of business processes, in particular in the field of planning, supply of raw materials on the basis of long-term relationships.

Keywords: macroeconomics; game theory; oligopolistic market; decision making under uncertainty; management

1. Main text

Many authors in their articles describe undefined conditions in some business [1,2,3,4,5,6,7] and in different regions [8,9,10,11,12,13,14]. To ensure a stable position in the market, the enterprise needs to improve approaches related to strategic management, in particular, to develop a competitive strategy for providing resources using specially created economic mechanisms. One of the areas for improving the strategy can be the application of a scientifically based management system to ensure the process of rational procurement of raw materials, which will enable detailed planning of the business processes of the enterprise. Managing the process of rational procurement of raw materials of the necessary composition is expedient to implement, using elements of game theory.

The game is a mathematical model of the conflict situation. The model of the behaviour of persons in the form of a game can be used when several firms try to win the most advantageous place in a competitive market, or, for example, if several people (companies) wish to divide a certain amount of the product (resource, funds) among themselves so that everyone gets It is possible more. The theory of games is the mathematical theory of decision-making in conflict situations [15]. Players in conflict economic situations modelled as a game can be industrial and non-productive firms, banks, individuals and other economic agents. For games, the outcome (outcome) is uncertain. Uncertainty is of strategic origin: the player does not know what kind or mode of action his opponent holds, that is, the uncertainty comes from another person. The corresponding games are called strategic games.

In Russia there are more than 100 enterprises that have registration certificates of the State Assay Chamber of the Russian Federation for the right to collect and process secondary raw materials containing precious metals. The largest of them, capable of processing large amounts of raw materials, include the following: OAO Kirovograd Copper Smelting Plant; JSC "Prioksky plant of non-ferrous metals"; JSC "Krasnoyarsk Plant of Nonferrous Metals named after

VN Gulidov"; JSC "Shchelkovo Plant of Secondary Precious Metals»; OOO Mosexpo-metal. Consider the application of the theory of games in a conflict situation, when several enterprises of the secondary metallurgy of precious metals are interested in purchasing a batch of raw materials, that is, electronic scrap, that has arrived on the market. At present, throughout the world, including in Russia, the volume of electronic scrap, suitable for secondary processing for the purpose of extracting precious and non-ferrous metals, is growing at a fast pace. This is due to the technical re-equipment of industries, the modernization of the fleet of computers and other electronic devices at enterprises, organizations and military units. The extraction of precious metals from recycled materials is part of the problem of using returnable resources. The formed wastes, on the one hand, cause great damage to the environment, on the other hand they represent the most valuable resources, in terms of the content of useful components hundreds and thousands of times superior to natural sources. The rise in gold prices observed in recent years and the consistently high prices of other precious metals such as silver, platinum, palladium make it economically advantageous to process electronic scrap.

The competitive environment is fairly homogeneous. The aforementioned plants have the technical capabilities to process a wide range of raw materials, except for computer equipment of domestic and foreign production (personal computers, workstations, servers, general-purpose computers, peripheral facilities), electronic, radio electronic and electrical equipment, Ashes of porcelain manufactures, sludge of gold electrolysis. The range of services and price lists for all plants are approximately the same. Since enterprises capable of processing large quantities of any raw materials in the secondary processing of precious metals are few, and each of them, having a certain influence, is forced to reckon with the presence and behavior of other counterparties, the secondary metallurgy market belongs to the oligopoly. The behavior of firms in the oligopolistic secondary metals market of precious metals is strategic, as each of them is compelled to take into account the possible retaliatory actions of competitors. The strategic interaction of firms under oligopoly conditions takes place in two main forms: in the form of non-cooperative interaction (when firms compete with each other and conduct more independent policy on the market) and in the form of cooperative behavior (when firms agree on joint actions and can act on the market "United front"). In the market for the purchase of electronic scrap as raw materials for processing, the interaction of enterprises occurs as a non-cooperative interaction: if a large batch of electronic wastes enter the market, then each firm is interested in obtaining it, and if one plant buys a particular lot, the other is deprived of this opportunity. Justification of recommendations for carrying out its policy on attracting suppliers is proposed to be obtained with the help of mathematical theory of games. The ability of an enterprise to determine its strategy can be achieved through the use of models of non-cooperative behavior, namely, models of antagonistic games. The antagonism of interests creates conflict, while the coincidence of interests reduces the game to pure coordination, accordingly, such situations can be reflected by non-cooperative or cooperative games. In a conflict situation, decisions are made not by one individual but by several participants, and the winning function of each depends not only on its strategy, but also on the decisions of other participants. If the players are two, and their interests are opposite, then the game is called antagonistic. The basic concepts of the theory of antagonistic games were introduced by E. Borel [16, 17].

We consider a model of a finite (in terms of the number of players and their strategies) games with complete information, in which two parties with opposite interests participate. This game is usually called the ultimate game of two persons with zero sum or antagonistic. At the disposal of each player there are many strategies. The antagonistic game is given by the aggregate $\Gamma = (X, Y, F(x,y))$, where $X = \{x_1, x_2, \dots\}$ – set of strategies for the first player, $Y = \{y_1, y_2, \dots\}$ – Set of strategies for the second player. A strategy is understood as a set of rules (principles) that determine the choice of an option for each personal move of the player, depending on the situation. Player 1 chooses strategy x from X , player 2 chooses strategy y from Y . The normal form of the game implies that each player chooses his strategy independently, not knowing the choice of partner. $F(x,y)$ – The payoff function of the first player, defined on $X \times Y$. In a zero-sum game, the first player's $F(x, y)$ win is the loss for the second player. The second player's win is therefore $-F(x, y)$. The first player's goal is to increase his winnings $F(x, y)$, and the second goal is to decrease $F(x, y)$.

The strategic behavior of firms buying electronic scrap can be considered as a model of game dynamics, when the game is repeated at certain points in time and the state of the economic environment is changing. Models of this type are constructed as an alternative to static optimality principles, such as the Nash equilibrium and dominance solution. Consider the situation on the interaction of competing enterprises in the market for the purchase of electronic scrap, when a large consignment of raw materials enters the market. This situation can be considered as a conflict, since there are several participants in this market, each of which pursues opposite goals, and the result of the event on each side depends on the actions of the competitor. It is assumed that the operation (game) is conducted against a reasonable opponent (competitor), pursuing its own goals and consciously opposing the achievement of the goal by the other participant. So, if a large consignment of raw materials comes to the market after the technical re-equipment of some large organization, then each potential processor tries to acquire it, thereby counteracting the acquisition of this party by another participant. The result of the game is victory or defeat, which in some cases can be conditionally expressed in numbers, for example: 0, $\frac{1}{2}$, 1. The conflict situation in such a market is determined by the following features: the presence of 2 or more parties to the conflict, in this case, the enterprises-processors of electronic scrap; each participant has a set of strategies $X = \{x_j\}$, $j=1..m$; increase or not increase the price of a certain kind of raw materials in relation to equilibrium prices. each participant has information about the set of strategies of others, but does not know which strategy will be adopted by either of them; the effectiveness of the actions of any participant is determined using the

efficiency function E ; the effectiveness of each participant's actions depends not only on his own, but also on the strategies chosen by other participants. All these features are inherent in the oligopolistic market of this industry. It is believed that oligopolistic relations are antagonistic. If the effectiveness of each activity is evaluated as a function of E_1 and E_2 , then $E_1=f(X,Y)$, $E_2=f(X,Y)$, where X and Y are sets of strategies of conflicting players, then condition $E_1 = -E_2 = E$. If one of the oligopolists buys a batch of raw materials, the other loses this opportunity, so this conflict situation can be described as a zero-sum game model, when one of the players wins as much as the other [18].

The development of the game in time is represented as a series of successive "moves". The moves can be conscious and random. A conscious move is a player's choice of one of the possible options for an action (strategy) and making a decision about its implementation. An antagonistic game is called a matrix game if the sets of player strategies are finite: $X = \{x_1, x_2, \dots, x_m\}$, $Y = \{y_1, y_2, \dots, y_n\}$. The possible variants (outcomes) of the game are reduced to a rectangular table - a payment matrix in which the lines correspond to the different strategies of the first player, the columns to the strategies of the second player, the values in the cells are called the price of the game. Element of the matrix u_{ij} - player 1 win if he applies the strategy x_i , and his opponent is a strategy y_j . In the game of two persons with zero sum, as in any other strategic game, the outcome depends on the behavior of both players. The goal of the theory of games is to develop recommendations for the different behavior of players in a conflict situation, that is, to choose the optimal strategy for each of them. To find the optimal strategy, it is necessary to analyze all possible strategies and to expect that a reasonable opponent for each of them will respond in such a way that the other player's winnings are minimal [19]. If player 1 does not know how his opponent will act, then, acting most expediently, not wishing to take risks and believing that the enemy will also act expediently, he will choose a strategy that guarantees him the greatest of the smallest wins for any opponent strategy. The preferred, or cautious strategy for the first player is to select the maximum value from the minimum in each line: $\alpha = \max \min u_{ij}$, where α - maximized winnings, and the corresponding strategy is maximin. If you stick to the maximin strategy, then for any behavior of the competitor the first player is guaranteed a win, in any case not less than α . Therefore, α is also called the lower price of the game, or abbreviated to maximin. This is the guaranteed minimum, which can be provided with the most cautious (reinsurance) strategy. In turn, player 2, acting rationally, will choose a strategy that guarantees him the smallest possible loss for any opponent's actions. It must select the minimum value from the maximum in the columns: $\beta = \min \max u_{ij}$, β - Minimax loss, the corresponding strategy is minimax. Adhering to the minimax strategy, the second player will lose at least β , β is called the top price of the game or the minimum. The numbers α and β are respectively the maximum guaranteed payoff of the first player and the minimum guaranteed loss of the second player. They are connected by inequality: $\max \min u_{ij} \leq \min \max u_{ij}$. If the equality $\max \min u_{ij} = \min \max u_{ij}$ if the equality = C , that is, the lower price of the game equals its upper price, then C is called the price of the game or the saddle point. If a strict inequality, then it is considered that the game has no price. Finding the solution of the game consists in choosing a pair of maximin and minimax strategies that are optimal, since any deviation from these strategies leads to a decrease in the first player's gain and an increase in the loss of the second player compared to the game price. In an antagonistic game that has a solution, the components of the saddle point are the maximin and minimax strategies of the players and, conversely, any pair of such strategies forms a saddle point [20].

For games with zero sum, a pair of optimal strategies is a saddle point. The key characteristic of zero-sum games is the existence or absence of the price of the game. If the game has a price, then the optimal strategies exist and are defined equivalent in two ways: in isolation (as cautious strategies) and simultaneously by both players (as saddle points). However, there are two zero-sum game matrices for which $\alpha \neq \beta$, that is, the saddle point defined above is absent. The outcome of such a game is harder to define, because there is no one, the so-called pure optimal strategy for any player. In such cases it is said that there is no solution to the game in pure strategies, and they consider the so-called mixed expansion of the game, the solution of which is sought in mixed strategies. A mixed player strategy is a random variable whose values are its pure strategies. The task of the mixed strategy of the player is to indicate the probabilities (frequencies) with which his initial (mixed) strategies are selected. It is assumed that the game is repeated many times.

For a matrix game $m \times n$ denote by $P = (p_1, p_2, \dots, p_m)$ mixed strategy of player 1, where $p_1 \geq 0, p_2 \geq 0, \dots, p_m \geq 0, \sum p_i = 1$, across $Q = (q_1, q_2, \dots, q_n)$ mixed player strategy 1, $q_1 \geq 0, q_2 \geq 0, \dots, q_n \geq 0, \sum q_j = 1$. Here p_1, p_2, \dots, p_m - the probability of using the player 1 in the mixed strategy of his pure strategies x_1, x_2, \dots, x_m ; q_1, q_2, \dots, q_n - the probability of using the player 2 in the mixed strategy of his pure strategies y_1, y_2, \dots, y_n . The expectation of player 1 win: $M(P,Q) = \sum \sum x_{ij} p_i q_j$. A mixed strategy that guarantees the player the greatest possible average win (or the smallest possible average loss) is called its optimal mixed strategy, and the strategies from which the optimal mixed strategy is formed are defined as profitable strategies. Let P^* - mixed strategy player 1, Q^* - mixed strategy player 2. The situation (P^*, Q^*) , with which $M(P,Q^*) \leq M(P^*,Q^*) \leq M(P^*,Q)$, the saddle point of the mixed expansion of the game, and the mathematical expectation of the gain $v = M(P^*,Q^*)$ - at the cost of the game, always $\alpha \leq v \leq \beta$.

Consider a single repetition of the game, that is, the actions of competitors in the field of pricing when purchasing one indivisible batch of raw materials. Suppose that the supplier's preferences depend only on the price offered by the enterprise - scrap recycler. In this case, the game is antagonistic, because the interests of the players - scrap buyers are opposite. Each enterprise, aware of the intention of the provider to sell a certain amount of electronic scrap, is interested in the given batch of raw materials being supplied to it, rather than to another enterprise. This game makes sense in case of players' knowledge of the actions of competitors. In the event that one of the players is aware of the prices offered by the second, he can raise his price, of course, if he has the financial means to raise the price. If the 1 st raised the price,

and the second one does not, then the "played out" consignment of raw materials is more likely to enter it. Otherwise, if the price is raised only by the 2nd player, the consignment of raw materials will go to it. If both buyers offer equilibrium prices, then raw materials with equal probability can get both the 1st and 2nd player. Let's designate as 0 the result of the game, when the plant 1 does not buy the given amount of raw materials, 1 - buys and $\frac{1}{2}$ when the given batch with equal probability can arrive both at the plant 1 and at the plant 1.

In an antagonistic game, the principle of equilibrium is consistent with the principles of optimizing the players for their guaranteed results. If the players, that is, the enterprises that purchase raw materials, have chosen the components of the saddle point as a strategy, then each of them does not benefit from deviating from the chosen strategy. The saddle point is a formalization of the concept of equilibrium in the game. But if one of the players does not benefit from equilibrium, he will deviate from him. With reserves to increase purchasing prices, one of the enterprises can offer the seller a higher price than the competitor, thereby deviating from the optimal strategy and breaking the price equilibrium.

If the prices are balanced, the supplier's preferences depend on other factors, such as-the possibility of processing a large volume of electronic scrap; possibility of processing any types of electronic scrap; the magnitude of the transport tariff, the distance from the buyer to the seller; transport accessibility of the enterprise - processor, possibility to accept the cargo, arrived by the railway; the supplier's knowledge of extraction technologies used in a particular enterprise; the relations between the supplier and the processor; the speed of calculations. When considering the continuous activity of enterprises, the conflict situation is described by a game with finite sets of strategies, and the game is repeated at times $t = 1, 2 \dots n$. Before the sale of the next batch of raw materials, the potential supplier collects information on the prices offered for this type of raw materials, on the enterprises located in the scrap collection area, or in nearby regions ready to receive this raw material, on the possibility to take scrap at a certain time, on insurance costs and On the other criteria listed above. If it is possible to send the goods by mail with a small amount, the seller takes into account the speed of delivery. Enterprises that are informed of the arrival of the next batch of raw materials can choose their strategies from a finite set of strategies: to offer higher purchase prices compared to competitors, or to interest the seller with other conditions.

The process of finding a solution to a game can be considered as iterative, when players choose their strategies several times according to certain rules. Such a process is called the Brown's iteration process or the Brown method [2]. It consists in repeatedly playing a matrix game, in which players, according to certain rules, choose their strategies. At the first step, players randomly choose strategies, at + 1 step players choose strategies as the best response to the corresponding move of the partner. If there are several best answers, then any of them is chosen. Each player has at least one optimal strategy. The decision of the game, that is, the equilibrium situation, is when the difference between the two following values becomes less than a certain number ϵ . In this case, the strategy of the first player will be maximized, and the second - minimax. In the Brown method, the limit points of sequences of strategy use by players are optimal mixed strategies. In addition, the limit point of the iterative process sequences is the equilibrium situation of the game. If the sets of player strategies are finite, then the mixed strategy is defined as the probability distribution, i.e. The probability of choosing one strategy as a real one. The equilibrium situations in such a game are called mixed Nash equilibria. In any game with finite sets of strategies, there is a mixed Nash equilibrium [3]. If, with a cumulative approximate equilibrium of other conditions, one of the enterprises will consistently increase purchase prices, then the other should pursue the same policy, and eventually the equilibrium will be established at a different level.

A rational approach to finding the price of a game assumes that each player forms his or her assumptions about the behavior of the rest and builds the best answer based on these assumptions. These principles of decision-making require for their implementation a full awareness of players about the conditions of the game (that is, with respect to the sets of strategies and functions for winning all participants). Players must be rational in making their own decisions and assume the same rationality from their partners. An infinite sequence of situations is called a process trajectory. Each participant chooses a pricing strategy - to raise or not raise prices - to the next step, based on the history that has developed by this period. The strategic decisions made today depend on the previous games or at least on the initial position. This behavior is called adaptive, its meaning is that the player predicts the probability of implementing partner strategies based on the background, and maximizes his own winnings based on such a forecast. In this case, the adaptive process converges to the equilibrium situation.

The considered models of single and multiple repetition of the game assumed the same level of awareness of players about the actions of competitors. In the oligopolistic market for the purchase of electronic scrap as raw materials for subsequent processing to extract gold and other valuable components, an asymmetric distribution of information naturally arises. Such a situation is described by the model "behavior like leader-led in the game of two persons." Each player, having received information about the strategy of another player, forms his best answer. The best answer for each player is to maximize your winnings. But at the same time one of the players is the market leader and has information about its winning function (the result of applying its strategy) and about the function of winning a competitor. This information he uses to predict the reaction of the second participant. The second player (slave) perceives the strategy of the first player as given exogenously and maximizes his own win, believing that the strategy of the first player is fixed. Thus, player 1, having the first move and foreseeing that player 2 uses one of the best answers to the behavior of the 1st, will find the optimal solution. This situation is called the Stackelberg equilibrium. The use of the Stackelberg balance requires cooperation from players, which is not always possible.

In this situation, one of the firms is stronger than the rest and has the opportunity to dictate its price to the market. Such a game is a struggle for leadership: if players are informed about each other's preferences, then it turns out to be beneficial to have the first move and force the other player to take the position of the slave [4]. The leader in the procurement of raw materials can be an enterprise that has significant production capacity, cost advantages, and also has a qualified PR-service to collect and process information necessary for the procurement and production.

In the Russian market, purchases of raw materials for the production of secondary precious metals have the greatest impact on the market by 5 large processing enterprises that provide services for the refining of precious metals. Each of them is characterized by significant production capacities and a constant specific cost of produced products, in particular, gold bullion. Scrap as raw material for processing is classified either by the percentage content of gold, or by its origin, depending on the sphere of production (in the jewelry industry, electronic, electrochemical, defense, radio industry, domestic waste). The percentage content of valuable components in various types of raw materials is established, and when receiving a specific batch for processing, the plant pays the supplier half of the value of gold contained in this scrap form according to passport data. For products in which there is no data on precious metals, a calculation is made taking into account the number of electronic components. For various types of raw materials, such as transistor glass insulators, printed circuit boards, IBM computers, scrap of electronic systems of airplanes and tanks, the generalized component composition of mixed scrap of electronic devices, there are equilibrium prices. But the increase in purchasing prices by one enterprise cannot but cause the reaction of other participants. If one of the enterprises has an advantage in costs, then it can become a leader in the industry and increase procurement prices, thereby violating the existing balance. Advantage in costs can be based, for example, on the use of technology for the integrated use of raw materials, that is, extracting from electronic scrap not only gold, but also other valuable components, which allows you to obtain additional profits from the sale of precious and non-ferrous metals and their products

2. Results

The models considered allow us to formalize the behavior of companies on the oligopolistic market and find a solution to the game in conditions of uncertainty. This will make it possible to develop recommendations for making strategic decisions from the point of view of the mathematical theory of games for providing raw materials with the necessary composition. Thus, the proposed rules of game models of non-cooperative interaction and competition are elements of the basis for planning the business processes of the enterprise and the principles of implementing a competitive procurement strategy, on the basis of which it is possible to implement long-term plans for an enterprise to improve the economic state.

^aNUST MISIS, Russia, 119049 pr. Leninskii,

Abstract

This papers aimed at the usage of automatic control systems by the financial situation of a company. The solution of this task includes three steps. The first step is the creation and the forecast of the integrated factor which define the financial condition of a company. Owner's earnings were selected as this factor. Then analyze the level of influence of the financial coefficients on the selected integrated factor. The second step is the creation of the estimated vector. The methodic of the assessment of company's financial position using the new characteristic – “the length of the integrated factor”, which defines by financial and statistical coefficients. The vector allows dividing the array of initial data into two parts related to satisfactory and pre-crisis periods of the enterprise that makes possible to build a separate forecast model for the main indicator for crisis data and for satisfactory data. Probability density functions were built for each group of data. The final step is the modeling on purpose to find the optimum value of owner's earnings of the company using a change of financial coefficients were recommended like as management decisions. Authors present the block diagram of the below steps for solving the task set: the creation of listed ratios, the calculation of the estimated vector and the determination of rational values of management decisions. Shows the results of two simulations experiments for Russian steel company – NLMK group.

Keywords: imitating modeling, owner's earnings, the sliding value of a vector of assessment of an economic situation; rational values of the financial ratios used as corrective actions

1. Main text

The need to develop new company management systems is conditioned by the fact that the existing methods of management of industrial enterprises on the basis of financial indicators, have a number of significant limitations:

- a) ignore or incorrectly assess the value of intangible assets of the enterprise;
- b) does not take into account the expectations of the main stakeholders of the company;
- c) late responds to changes in the external accident;
- d) do not allow to determine how this or that factor affects the results of the company due to the high aggregation of indicators used.

If we consider an integrated industrial structure as an object of management, it will be a complex system, which according to the theory of systems, has a goal and objective function, elements and links of elements of control links, the result of the system and the system effect. In Russia, for many years it was believed that the main motive of the company is to make a profit, but in the foreign literature on management and finance for several decades, the criterion of profit maximization is recommended to use only for management decisions in the short term. Profit has several significant disadvantages that can distort effective financial management decisions in the long term. It can be noted its four basic drawbacks:

- 1) first, the profit is a static indicator, that is, the time factor is not taken into account;
- 2) second, it does not take into account risk, which is a critical category in financial decision-making;
- 3) thirdly, the profit is calculated accounting in nature, not monetary, therefore, in principle, any profitable enterprise might be financially untenable, as the cash could be insufficient to meet future obligations;
- 4) fourth, the calculation of profit is ambiguous, since it has many types-for example, gross, net, retained earnings, etc.

The effectiveness of the enterprise - a comprehensive multilateral concept. Depending on what theory underlies the management of the efficiency of the enterprise and different approaches to management.

Here are listed the main approaches and theories of enterprise efficiency management from the standpoint of their evolution.

1) Transaction approach. Can be considered historical one of the first methods. At the heart of this approach, the company is presented as a set of contracts. This particular type of contractual arrangement, combined with the coordinated use of resources, creates savings in transaction costs compared to the coordination provided by the market.

2) the Resource-based approach started to develop activities in the mid-1980s — early 1990s, at this time, the company is considered as a bundle of resources. The economic performance of firms operating in the same product market depends on the composition of the resources they have and use in their work.

3) The approach based on knowledge (PAHO), was also developed in the first half of the 1990s, the knowledge was regarded as the most important resource efficiency and competitive advantage of the enterprise. Now companies learn and develop the knowledge created by individuals. The company better than the markets organized a combination of knowledge, i.e. approved "atdependent" knowledge, whereas traditionally they were considered exclusively owned by individuals.

4) on the basis of the previous approach, the concept of dynamic abilities (CDU) was formed. An important branch of the knowledge-based approach (POS) is the dynamic capabilities of the firm (DS). Dynamic abilities of the company are changing internal and external organizational skills, resources and functional competencies that determine the direction of development of competencies formed under the influence of past experience. The object of analysis in the CDU are only those companies that operate in dynamic, innovative sectors.

5) the Entrepreneurial theory of the firm (PTF) focuses on the need of the business activities of firms operating in a global and dynamic competitive environment.

6) Process approach and behavioral theory of the firm. The term "process" has three different meanings in this approach: the first as the logic of causation linking independent and dependent variables; the second as the type of concepts or variables reflecting the actions of individuals or organizations; and the third as the chronology of events describing the change of things over time.

7) the Strategic theory of the firm (STF) is considered as "integrative", including all the set of theories of the firm that arose after the neoclassical - transactional, resource approach, the concept of dynamic abilities, etc. Note that if the previous theory took into account only certain parts of the company's efficiency, the strategic theory of the firm allows taking into account all the important factors. The formalization of the strategic approach is the concept of BPM - Business Performance Management (business performance management) or CPM — corporate performance management, EPM - enterprise performance management.

Since the term "efficiency" belongs to the economic category and is the "sister" of performance, the managerial category, it is important not to confuse these concepts. In a market economy, a prerequisite for effective functioning is the balance of interests of all business participants: owners, management and production workers. All members of the organization are interested in the effective work of the enterprise. The results reflect the key objectives of the organization based on the existing strategy. They are divided into economic and non-economic results. Non-economic results (for example, the result of work on environmental conservation) do not have effects in value form. If the result of economic activity exceeds the costs, then there is a positive economic effect, which for example can be considered as a profit; the otherwise-a negative effect, such as losses. The effect, as the difference between the cost of the product and the cost of its production, may appear, *ceteris paribus*, in two cases: the first-increases the product, or the growth of production; the second – when the cost of production of the product is reduced (saving resources).

There are four groups of performance indicators of the enterprise.

1. Indicators of efficiency assessment of economic (operational) activity of the enterprise. The ratio of the resulting parameters (profit, revenue) and the amount of used, applied or total resources (assets, equity, etc.) is estimated. Traditionally, it is believed that the main performance indicators are in this group, gradually this position loses its force.

2. Criteria and indicators of efficiency of investment activity of the organization. This group of indicators should primarily be linked to the interests of investors as a key stakeholder in capital investment in General and specific projects in particular. Calculation of economic efficiency of the investment project is a special category of financial and economic analysis of the company.

3. A group of performance indicators of certain types of resources used in business: labor, stock (capacity), financial. In this group, the bulk of the dual-use criteria that extend the boundaries of classical efficiency is concentrated.

4. Financial indicators of economic efficiency of production in the context of goods, works, services at the level of individual positions, production units, strategic business units.

For managers and owners of organizations has always been an urgent problem in determining the effectiveness of enterprises. All efforts were aimed at increasing revenues and reducing costs. However, the requirements for determining and improving the efficiency of the enterprise have become more stringent over time. There is a certain process of increasing the efficiency of company management. It includes the following steps:

- assessment of external factors that may affect the efficiency of enterprise management;
- identification and classification of necessary knowledge and skills;
- definition and analysis of requirements to the Manager;

- forecasting changes in management requirements in the development of the company and its environment;
- assessment of senior staff;
- approval of the most important tasks in the areas of production and management.

At the moment, you can see an increasing interest in the concept of management based on the value of the company, which has been actively developing for several decades abroad and relatively recently in Russia. In the modern concept of value-based management ("Value Based management") the basis for management decisions is the maximization of shareholder wealth, which means maximizing the net market value of the business. The model based on the Value Based Management concept allows transforming the system of drivers of the company's value growth into key performance indicators (KPI) for the company's management. Despite some differences in the construction of management decisions, all the main existing models are based on forecasting the current and expected cash flows of the enterprise, analysis of financial and operational risks, determining the cost of debt capital and growth potential for the company's business.

On the process of formation of the company's value is influenced by the factors of micro - and macro-levels. Therefore, events that occur both in the economy or in the financial sector, politics, and in the social sphere, can have an impact on the performance of the company, including – on the value of the company. In order to implement long-term plans, the company needs to correctly identify key cost factors and ensure continuous monitoring of their values. Factors or drivers of the company's value formation should show the level of efficiency not only at the current time but also show the prospects for growth in the long term. An important task is to determine the direct or indirect impact of the value creation factor, and to what extent.

Now the most important and common methods for analyzing the efficiency of the enterprise are economic value added, added value of cash flow, added shareholder value and return on investment and owner's earnings. In this papers we will look at and analyze owner's earnings. The first how started to use this indicator was an American business magnate Warren Buffet. Owner's earnings represent (A) reported earnings plus (B) depreciation, depletion, amortization, and certain other non-cash charges such as Company N's items (1) and (4) less the average annual amount of capitalized expenditures for plant and equipment, etc. that the business requires to fully maintain its long-term competitive position and its unit volume.

It is established that there is a very strong correlation between owner's earning to assets coefficient, turnover asset ratio (x1), current ratio (x2) and long term liabilities divided to assets coefficient (x3). Using the step-by-step regression analysis method, we received the most reliable variables of the following characteristics for forecasting indicator owner's earnings to assets ratio for Russian steel company – NLMK group:

Table 1. The results of regression analysis

	x1 * x3	x2
Regression coefficient	2,3529	0,2824
Standard Error	0,2842	0,0240
t value	8,2787	11,7570
Multiple R	0,9738	-
R square	0,9484	-

In the automated systems of management of economy of the enterprise the problem of finding in dynamics of rational values of the operating influences providing maximization, for example, the owner's earnings indicator needs to be solved with application of simulation. The General scheme of implementation of this procedure is as follows. After selecting the main economic indicator, we proceed to find the vector that determines its financial and statistical coefficients, the so-called estimated vector $y = (y_1, y_2, \dots, y_n)$. In particular, for the relative owner's earnings components of the estimated vector selected above financial ratios $x_1 = y_1$, $x_2 = y_2$, as well as the indicator $x_4 = y_3$. From statistics in these papers suggested to use sliding coefficient of variation: (Rozhkov et al, 2017).

$$y_3 = \frac{\sigma}{M_x}$$

σ – sliding sample average square deviation of owner's earning;
 M_x – its expected value;

Next determine the length of the estimated vector $\|\bar{y}\| = \sqrt{y_1^2 + y_2^2 + y_3^2 + y_4^2}$. The coordinates of the vector are ones and zeros, that is $y_i \in \{1; 0\}$. The number 1 is satisfactory situation of the company and the number 0 is unsatisfactory. Values of y_i determined from the following system of relations is determined by standard values established by the company management (Larionova et al, 2001).

Conclusions

An evaluation methodology was proposed economic situation of the company with application of the new characteristic is the length of the estimated vector. The methodology includes the following main stages:

- determination of a set of financial ratios and their standards characterizing the economic situation of the company;
- determine of the coordinates of the estimated vector, in which the corresponding financial ratio is replaced by 1 if it meets the satisfactory situation of the company and 0 otherwise;
- the calculation of the length of the vector;
- the separation of data into two parts: satisfactory and unsatisfactory state of the company.

The Substantiation of Cash Flows within a Business Plan

Ilie Răscolean^{a*}, Ileana – Sorina Rakos^a

^aUniversity of Petroșani, Street Universității, no.20, Petroșani, România

Abstract

This paper highlights some aspects regarding the substantiation of the cash flows within an economic entity. The main objective is to highlight the cash inflows and outflows and the cash flow during the investment project, as well as in the next period, when the company should carry out cost-effective activities to ensure reimbursement of the financing and obtain the necessary profit and the remuneration of shareholders or associates. Based on the literature, the authors present the structure of the business plan that should include: medium and long-term vision and objectives; business description and implementation strategy; SWOT analysis, human resources policy; description of the investment project, market analysis; financial projections and justification of the need to fund the project. The business plan is a predominant tool for managers - identifying funding sources, getting funding, or making partnerships with other companies. The business plan establishes the vision, objectives, implementation strategy and actions of the economic entities necessary to carry out profitable activities in the future. The authors try to contribute to the conceptual and empirical national and global framework on the substantiation of cash flows in a business.

Keywords: market analysis, cash flows; financing; business plan; financial projections

1. Introduction

In order to understand the concept of a business plan, we consider it useful to define the concept of a business, namely: an intention of a person (physical or legal) to undertake certain activities in order to obtain a profit. The theoretical and pragmatic approaches to the business plan differ from specialists to professionals, as evidenced by the existence, after the 1990s, of extensive literature in the field, as well as numerous issues published in various volumes, but also disseminated through the online environment, including guides to develop business plans in various business areas.

From the prestigious Harvard University, David Gumpert, (1990) realizes a realistic approach to the business plan that it is “a document that proves in a convincing manner that the business envisaged can sell enough products and services to produce a satisfactory profit and make it attractive to potential investors.”

The role of the Business Plan is to demonstrate that the business deserves to be funded and to guide the entrepreneur from the first year of operating the business, being in fact both an internal tool through which the manager manages and controls the entire process of starting an economic entity, as well as an external instrument that facilitates communication with the economic environment. The Business Plan establishes: vision, *mission, goals, strategy and action plans for carrying out a specific activity during a determined future period, history, management, human, financial, and material resources, current activity, market analysis, cost analysis operation, necessary investments, financial projections and appendices* thereto, including: *cash-flow forecasts; any other relevant financial information; detailed description of the product or service; plans and sketches for the technological process; a detailed list of equipment owned or to be purchased; description of the investment; Cvs of management; organization chart of the economic entity; brochures and advertising materials; copies of various contracts; support letters from future customers / pre-orders; suppliers' offers; results of marketing researches; operational plans; any other material that can provide relevant information to those who will read the business plan; a list of all the assets held*, adjusting this list according to the economic entity profile and the size of the investment.

* Corresponding author Tel: 0722782323
E-mail address: IlieRascolean@upet.ro

Thus, the Business Plan “transmits” to all those around the entrepreneur - customers, suppliers, strategic partners, financiers, shareholders, that the manager knows for sure what to do, and in a functioning market economy, serious business partners appreciate this and they will perceive the entrepreneur as a pertinent actor of the economic environment.

Schematically, all these aspects are shown in Figure 1.

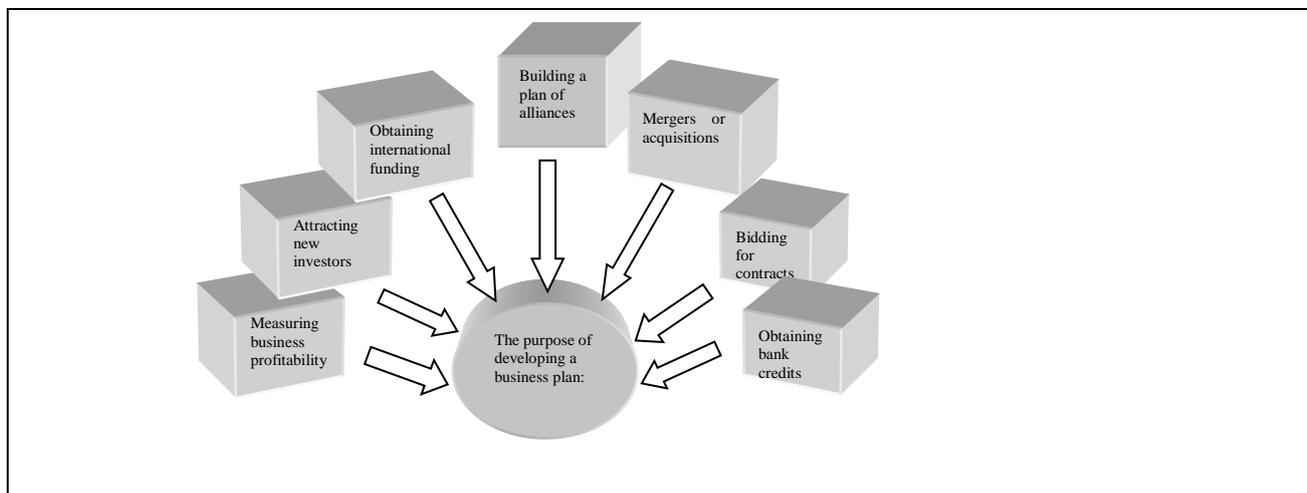

Figure no.1. The purpose of developing a Business Plan
Source: own projection

In addition to the business plan, a set of financial statements detailing cash flow is essential. This will give details about the actual amounts of money requested by an economic entity, each day, from one month to another, and from one year to the next. The needs of a business are constantly changing, and the cash flow will highlight potential shortfalls in cash that will have to be moved. Good cash flow management is essential to a successful business. It is necessary to carefully analyze the products / services offered, the competition, the necessary financial resources and other operational details. Also, the business plan is a working tool that is used to start and run a business that requires material, financial, and human resources. Through it, the experience and achievements of the past are used to design the future through the most appropriate methods of estimation and approximation. Implementing a Business Plan means control and adaptation - depending on real evolution. This control over the business will address all critical elements of the economic entity (inventories, production costs, quality control, sales, payments made, etc.). A realistic business plan always has two parts: a written part that analyzes the context (market, competition, trends) and a part that evaluates the operational and financial implications by preparing a future financial scenario (in an excel table). The Cash Flow is used to get the best value for money.

2. What is the cash flow?

The International Accounting Standard (IAS) 7 defines cash flows (also referred to as cash flows or cash-flow in some studies) as cash inflows or outflows and cash equivalents.

In business planning, the availability of money at the right time is a criterion that must first be taken into account when performing basic activities. The cash-flow of a business is one of the most important tools used by both managers and entrepreneurs, as well as by investors, in substantiating business decisions. Cash flow analysis is required in all economic forecasts, both for obtaining a bank credit and for financing a project through European or national non-reimbursable funds. The information provided by this cash flow analysis also serves specialists outside of the economic entity, such as:

- creditors - provide working capital and capital for investment, so they will be interested in recovering the borrowed funds;
- financiers - analyze the sustainability of the investment project over a certain time horizon, medium or long, being interested in how the company can sustain its activity without exhausting its financial resources;
- business consultants - will look at the evolution of the economic entity over a time horizon, medium or long term, being interested in all information regarding clear or estimated receivables and payments;
- investors - make the decision to attract participants into a new business, analyzing its ability to generate profit in the medium or long term.

In practice, the calculations are summed up on sources of income and costs, so if the revenue is higher than costs and profit is obtained then the investment seems appropriate. Practically, the cash flow is the clearest picture of the health of a business, showing both the earnings and payments a company has in a period of time. The longer the time horizon, the accuracy of the information will be lower, taking into account various hypotheses whose accuracy will be lower.

The most accurate information can be obtained over a time horizon of up to one year. When the analyzed time period exceeds 12 months, the accuracy of the information decreases, which makes this financial analysis tool not be sufficiently precise and real. Of the changes that may occur during a year, we can mention: the change in the VAT rate, the gross minimum wage in the economy, the tax rates and local taxes, the turnover tax rates or the income of the microenterprises, and the legislative changes this year are evidence conclusive in this respect.

3. Making a cash flow analysis

The main source for the analysis is the “Treasury Cash Flow Statement” prepared in accordance with the provisions of IAS 7, *mandatory* for large enterprises and *optional* in the case of small and medium-sized enterprises. The financial statement users include prospective and potential investors, hired staff, lenders, suppliers and other commercial creditors, customers, government and its institutions as well as the public. Regarding the “cash flow statement”, IAS 7 considers that it provides useful information for assessing the entity’s ability to generate cash, as well as its needs to use cash flows, respectively the timing and the safety of their generation.

The overall framework for preparing and presenting the financial statements of which the “*treasury cash flow statement*” also states that their objective “is to provide information on the financial position, performance and changes in the financial position of the enterprise that are useful to a wide range of users in making economic decisions”.

In Romania, the *treasury cash flow statement* is considered a component of the annual financial statements in accordance with the International Accounting Standards. Under the treasury cash flow scenario, according to the functional approach of the activities of an economic entity, the cash flow has three closely interconnected, so the result of one influences the others and, ultimately, the end result of the whole activity:

- the investment activity concerns the intention of the company to make new investments, acquiring goods and equipment, constructing, paying for software solutions etc .;
- the financial activity refers to the procurement of the money resources necessary for the realization of the investments: loans from associates, bank credits, own sources or non-reimbursable funds;
- the (operational) exploitation activity carried out by the company in parallel with the realization of the investment.

The duration of the economic forecast differs according to the destination that the cash-flow will have, the duration of the analysis may be limited by the repayment period of the credit, in the case of financing from national or European funds it is five years, and for internal use it is designed for one year, which ensures high precision. The cash flow is compiled for three distinct components: the investment activity, financial activity and operational activity.

The cash flow for the investment activity includes the following information: what are the necessary investments and what is their value? At what times will payments be made to suppliers? Will the investment be made within one month or is a breakdown needed over a longer period?

The cash flow for the financial activity refers to securing the financing sources from which the economic entity will support the investment. These sources can be: own financial sources when the entity is available from the prior period; loans or bank lines when the entity will lend the financial resources necessary to make an investment or to cover operational expenses; contribution of the associates or loans granted by them to the entity; European or national non-reimbursable funds when the company accesses such funding.

Often, the economic entities use a mix of four funding solutions. These cash inflows will also generate cash outflows: interest payments on contracted loans; repayments of contract credits; repayments of loans from shareholders.

The cash flow for operating activity is for the upcoming period, and it does not generate earnings or payments until the activity starts. If the activity is started, the cash flow will comprise two components, adding activities and the activity that is financed by the implementation of the investment project. This will generate a substantial increase in the company’s workload when the investment is made to expand the range of products, services. Operating revenue is: provision of services to the entity’s customers; the sale of goods and products; carrying out works. VAT must be calculated if the entity is VAT-paying.

Payments generated by exploitation are: for suppliers, for raw materials and material; for utilities; for the rent of the production hall or the office; for salaries and social contributions; taxes and duties owed to the budget; advertising and publicity.

The analysis of the cash flows on all three types of activities is useful for: correlating the profit (loss) with cash; the separation of cash-based activities from those that do not involve cash; assessing the ability of the entity to meet its cash payment obligations; cash flow assessment for future cash-flow activities. The usefulness of the analysis is given by the fact that the global variation of the treasury is evidenced by the treasury balance resulting from the real assets management (from operating activity) and from the capital-related investments and financing operations. When real and monetary flows do not coincide, as it actually happens, the treasury is provided by pay mismatches associated with these flows.

Each of the three categories of flows has an impact on a source or use of liquidity. While respecting the American accounting tradition, operating cash flows can be determined either directly or indirectly, and cash flows from investing and financing activities by direct method. According to the direct method, gross cash receipts and payments are used, and the peculiarity of the indirect method is that the net profit (or net loss) is adjusted with the effects of non-monetary transactions, deferrals or payment commitments or receipts in cash from past or future operations and the items of income and expense associated with cash flows from investment or financing activities.

Although they lead to the same results, IAS 7 recommends entities to present cash flows through the straight line method because it provides useful information in estimating future cash flows that the indirect method can not provide.

Therefore, the cash-flow can be positive or negative, which is explained as follows: if the money entering an economic entity is more numerous than the ones going out, then we are talking about a positive cash-flow. Positive cash flow is a very good thing for the entity and the only problem is managing this surplus. In the reverse situation, that is, when the money coming out of the entity is more than the one entering the negative cash-flow. The negative cash-flow can be caused - for example - by the timely non-collection of money from customers, in which case quick solutions must be found to avoid the company's inability to pay.

Also, making a cash flow analysis of an economic entity's business requires a thorough knowledge of the business and the collection of all necessary information on the proceeds and payments to be made in the future. The information to be collected is related to: the number of staff employed and estimated to be employed and the expenses of the entity are salaries and social contributions for both existing and those who will be hired during the analysis period; the structure and value of other business expenses (rents, utilities, raw materials, third parties etc.); realization of planned investments for the next period; the maximum production capacity of the entity and the degree of effective use of the entity; contracting of credits and conditions under which they will be repaid (interest rate, grace period, duration of credit etc.); - forming the sale price, the granting of volume or pre-maturity discounts etc.

For the collection of these data, a questionnaire will be made which will be sent to all persons able to provide the requested information, stating that the information can be extracted from the following documents: financial statements for the previous or previous months; staffing needs; revenue and expenditure budget for the following period; the investment plan; financial offers of equipment to determine the value of the investment; technical offers of equipment to determine future production capacity, energy consumption, fuel, etc. what these are supposed to do etc.

When calculating the cash flow, the amortization expense is not taken into account. This is not an expense involving liquidity outflows within the entity, being a way in which the entity may constitute the financial resources necessary for the future replacement of fixed assets at the end of the normal period of operation. In a cash-flow analysis, it is very important when the company collects receipts and when the company makes payments. For example, if an economic entity purchases raw materials with a negotiated three-month payment, cash outflows will not be evidenced at the time of signing the contract or at the time of delivery, but at the time of actual payment. This reasoning also applies to cash inflows from the sale of goods, provision of services, etc. A negative disposition at the end of a period (day, week, month, quarter, semester, year etc.) means that the economic entity does not have sufficient financial resources to cover current payments at that time. In this case, working hypotheses need to be redefined, taking into account the delay in paying suppliers or quickly collecting invoices issued to customers, while offering some trade discounts.

4. Case Study

A Limited Liability Company (LLC) is set up, with a share capital of 200 lei, with a single associate, also having the capacity of administrator. For the forecast period, the company falls into the category of micro-enterprises with incomes less than 1000000 euro equivalent in lei during a financial year. In order to start and carry out specific productive activities, the following sources of funding are sought:

- non-reimbursable funds partially covering the initial investment amounting to 150000 lei;
- a 5-year bank loan in the amount of 30000 lei with an annual interest rate of 10%;
- in addition, the single associate lends to the commercial company the sum of 20000 lei, and the loan is to be repaid from the liquidities generated by the profitable activity carried out after the commissioning of the investment project.

The initial value of the investment project is 200,000 lei, including the following: production hall, equipment necessary for the technological flow, provision of the necessary utilities, means of transport, offices for the administrative headquarters.

Funding sources provide funding for the investment project and cover current expenses for three months from the start of the business and partly for the next three months. Starting with the seventh month, the expenses will be fully covered by the proceeds from the sale of the production.

The cash flow for the first seven months of starting business and forecasts for the next two years are shown in the table no.1 below.

Tabel no.1. Cash Flow

Crt. No.	Explanations / month	PERIOD OF IMPLEMENTATION						PERIOD OF PROGNOSIS		
		L7	L8	L9	L10	L11	L12	2018	2019	2020

5. Conclusions

The cash flow forecasts are an important tool for leading an economic entity that can help in general business planning. In addition, the effort made to realize the forecasts will be useful as a good starting point for possible detailed discussions with the credit officer in the case of bank loan withdrawals. Without the cash there is a safe way of ending the activity of the economic entity and respectively towards insolvency, which is why it is necessary to give due importance to flows that represent cash inflows or outflows. The cash flow shows the cash movements of an entity over a certain period of time, this being the spring that makes the business go. A number of companies go bankrupt because they are not concerned about cash flow management so they can secure enough cash to honour their due obligations. Cash flow management means the tracking and forecasting of cash inflows and outflows so as to ensure the exact amount of cash needed to deal with outstanding payments at the time the payments become due.

It is important for entrepreneurs and managers to understand that focusing solely on sales volume DOES NOT ensure the sustainable success of the economic entity, which must be operationally effective and manage its financial flows with fairness. The forecasted cash flow involves estimating all the sources and future cash uses of an economic entity, depending on the strategy the entrepreneur proposes, namely: the target of increasing the volume of sales, the concluded business contracts and the payment terms, the policy the human resources, the location in which they operate, the financial resources they have or intend to attract, the seasonality of the business, the taxation, etc. It can be run monthly, quarterly, semi-annually or annually, and takes into account the trend in the past, the expected changes in the operational cycle, investment policy, financing contract features, seasonality, and last but not least, environmental changes business, politics or taxation. The fact that an economic entity is profitable is not a sufficient condition for the firm to remain solvent. A bad debt collection policy or an inappropriate managerial decision about continued output on the stock - may generate a profit accounting position, but lacking the cash needed to resume the production cycle and invest. When an economic entity does not have sufficient cash to honour its maturity, it becomes insolvent. The case study presents the cash flow for a newly established trading company that has three categories of funding sources: non-reimbursable funds, bank loans, and the single associate's contribution. The mentioned sources of funding ensure the realization of the investment project necessary for carrying out productive activities and covering some operating expenses in the first months of the activity. There is a positive cash flow generated by the profitable activity that makes it possible to make payments related to the exploitation cycle from the collection of the income from the sale of the production.

Essence and role of co-operation in regional development. RIS3 case study

Marzena Szewczuk-Stępień, Brygida Klemens*

Opole University of Technology, Economics and Management, ul. Luboszycka 7, Opole 45-036, Poland

Abstract

The paper presents the role and importance of co-operation in regional development. It includes the discussion on the essence of co-operation in modern economy and specification of its scope, forms and types. The deliberations on the role of co-operation are based on an analysis of regional innovation strategies which constitute one of the more important instruments for building innovation and improving the competitiveness of a voivodeship. The purpose of this elaboration was the determination of key definitions identified with the term of co-operation in Regional Innovation Strategies (the so-called RIS3) applicable in Poland until 2020. The study applied the exploratory data analysis, especially the *text mining* technique.

Keywords: co-operation, partnership, cluster, network, Regional Innovation Strategy

1. Introduction

A dynamic economic, political or social situation brings forth challenges for entrepreneurs and public authorities. Functioning in conditions of changes presents a series challenges for enterprises related to the need to quickly adapt production to market needs, whereas for public authorities this means, e.g. the need to propose other forms and rate of planning of pro-entrepreneurial activities. Entrepreneurs are increasingly seeking for opportunities to minimise the negative effects of their functioning in conditions of change. One of such opportunities can be co-operation and affiliation to various types of networks or organisations (Klemens, 2017). It is not a new statement that co-operation (regardless of the type of partners) brings substantial benefits for all parties involved. These can include financial, political, social and personal benefits. These types of benefits can also be defined in terms of regional development.

Taking into consideration the regional innovation policy in Poland, it is necessary to note that it is a relatively new area of activity of local government authorities, because regional innovation systems were started to be built only after regional local governments were appointed in 1999. Supporting innovation became one of the regional authorities' main tasks which intensified along with European integration processes (Heffner, Klemens, 2017a)

Activities undertaken in Poland in the last ten years to stimulate the development of innovation and entrepreneurship brought growth of numerous and varied in terms of their offer business support institutions, thereby creating business-friendly environment. Expenditure for research and development is increasing and employment in the private sector's R&D is also on the rise (Klemens et al., 2017). A stable regional and innovation development policy requires adequate tools, which include development strategies, among others. However, how do decision-makers understand the concept of co-operation between the main players of regional development? Which companies are willing to co-operate? The purpose of this paper is to attempt to answer the above questions.

The paper consists of three parts. This part presents the concept of strategic thinking and the significance of strategy in regional development. The role of innovation strategies in regional development are the main focus. The second part specifies the phenomenon of co-operation, its relevance, forms and types. Key definitions associated with co-operation are presented. The third part demonstrates the results of the conducted study based on analysing Regional Innovation Strategies in terms of use of the wording related to co-operation.

* PhD Marzena Szewczuk-Stępień, Tel.: +48 884 848 422; *e-mail address:* m.szewczuk-stepien@po.opole.pl
PhD Brygida Klemens, Tel.: +48 606 44 80 67; *e-mail address:* b.klemens@po.opole.pl

The article was developed based on a *desk research* analysis of secondary data (Polish and foreign literature analysis) as well as empirical studies (analysis of the contents of 15 regional innovation strategies with the use of the *text mining* technique).

2. Significance of strategy in regional development

Organisations plan their activities to achieve the assumed goals. The essence of strategic planning is to base activities on distinctiveness, unique advantages, individual way of viewing the surroundings, only then we can speak of building a competitive position (Obłój, 2014).

An organisation management system, e.g. territorial unit or economic sector, can also be used as an element of credibility or predictability. The potential for co-operation is also built this way: firstly, specification of goals authenticates the policy in the eyes of potential partners, and secondly, an established development policy allows for elaborating common fields of interest and combining efforts to ensure effective task execution (MRR, 2012).

The Cohesion Policy 2014-2020 was described in the Europe 2020 document. It is a strategy aimed at growth, which promotes a smart and sustainable economy favourable to social inclusion. These three complementary priorities can help achieve a high level of employment, efficiency and social cohesion.

In each of the above areas, the EU member states specified their own aims and developed a series of planning documents, including strategies towards smart specialisation (RIS3 strategies).

These strategies are integrated, local programs of economic transformation, which realise the following assumptions: a) establish innovation as the priority for all nations/regions; b) orientate support within the policy and investments towards key challenges and needs to ensure knowledge-based development; c) utilise strengths, competitive advantages and the nation's/region's potential for excellence; d) support innovation and striving to stimulate investments in the private sector; e) involve partners and encourage innovation and experimentation.

The premises of the RIS3 policy include series of elements that emphasise the key role of co-operation, including sharing experiences, uniting as part of a shared vision (networks of co-operation), openness to external relations (e.g. knowledge triangle, clusters), related activities with higher added value (collaboration, co-operation, partnership, consortiums), achieving synergy (common fields of interests, combining efforts), among others (Guide, 2012) (Foray et al., 2009). The vast majority (15/16) of Polish regions possesses their own RIS3. Only the Pomorskie voivodeship abandoned developing the document, however the essence of the addressed notions was included in the Pomorskie Voivodeship Development Strategy 2020 elaboration (due to the adopted research assumptions indicating to the analysis of the RSI document, the aforementioned strategies were not taken into consideration).

The RIS3 documents were developed in 2010-2016 with an expiry date of 2020 to support an effective implementation of the voivodeship development strategies in terms of innovation, research, development and entrepreneurship. The concept of smart specialisation emphasises development based on R&D works and innovation and uses the region's endogenous competitive advantages. In general, the documents were developed in accordance with the recommendations of the European Commission, which emphasises the development of knowledge-based economy requires determination of the so-called smart specialisations.

3. Concept of co-operation in regional development

The analysis conducted in the latter part of the paper uses wording (and its variants) that most often concern the essence of co-operation of various regional development players: golden triangle (triple helix, quadruple helix), synergy, cooperation, partnership, complicity, network of co-operation, clusters, producer groups, consortium, co-competition, co-opetition, collaboration, co-production, combining of efforts.

The co-operation of various regional development actors is often described in subject literature by using symbols of the so-called golden triangle or triple helix. Regardless of the symbol used, its main components include: private sector, public sector and the R&D sector (including universities). Gorzelak et al. (2006) points out a somewhat different division in which the golden triangle's composition consists of enterprises, R&D field (universities, technology parks, business incubators) and supporting institutions banks, *venture capital*, local government units, regional development agencies, among others). Independently of the components, the golden triangle concept balances itself with the structure of regional innovation systems, because both of them feature interactions in the region players' environment, which provide good conditions for the creation and stimulation of innovative processes (Głuszczyk 2011, p. 110).

H. Etzkowitz and L. Leydesdorff (2001) used the triple helix model to present various behaviours in economic, social and cultural networks, and particularly demonstrating cluster networks. The triple helix is also visualised as three overlapping circles (private, public sector, R&D) and their common section presents the scope of the trilateral co-operation network (Etzkowitz, Leydesdorff, 2000). This system is a balanced configuration, in which universities become partnered with industry and the public sector, and sometimes become the leader of various types of initiatives (Ejsmont et al., 2016, pp. 13-14). Due to the fact that there are many regional development players, the triple helix model has evolved in time. Currently, we can encounter the Quadruple Helix (Carayannis, Campbell, 2011), Quintuple Helix (Carayannis et al., 2012) or even Hexagon Helix (Frankowska 2012) concepts.

When considering co-operation with the widely understood business, we cannot omit the phenomenon of synergy, which is broadly described in subject literature. It points to the ability of co-operating entities to create higher value than each of them would be able to achieve by acting independently (Jonek-Kowalska 2007).

Co-operation is the ability of creating relations and collaboration, ability of executing tasks as a team, working to solve common problems and achieve mutual goals. Co-operation is a condition required for effective functioning of entities on the market. When considering co-operation, we must not only consider the entities that realise it, but also their market situation, quality of co-operative relations and mainly the effect of synergies created as result of their mutual activities. In subject literature, it is possible to find many types of co-operation, however regardless of its type (a popular form includes consortiums which are established to achieve a particular goal, do not require formal registration, but only conclusion of an agreement by its participants) numerous experiences show that relations and contacts between entities nullify the limits in knowledge access, allow for using good and reliable solutions, which in turn contributes to the generation of new ideas and improves the entities' global competitiveness (Szewczuk-Stepień, 2014, 175-176), (Szewczuk-Stepień, Dymek, 2015).

Regional policy conducted based on strong co-operative systems favours improving the quality of life of citizens, supports entrepreneurship and strengthens the region's reputation. Weakness of the system also weakens the region's position. On the other hand, it is possible to observe that a better economic growth of a region makes the formation of regional networks of relations and creation of partnerships between organisations easier. Vice versa, the lower the growth rate, the weaker the relations between organisations. The relations are also more individualised and are often characterised by lack of trust or hostility (Górzyński 2006, p. 8).

Global economy imposes the need to function in various types of networks associating various economic or regional development players. In subject literature, Castells is viewed as the precursor of contemporary network relations. He observed that the current economy should be viewed as a network affected by attitudes deriving from social, economic and technological changes (2007, p. 267). The aspect that distinguishes business co-operation networks is the unlimited number of members, territorial range or organisational and legal form. A network also becomes core of an innovation system, because it provides good conditions for creating innovation (Herliana 2015, pp. 151-160).

A co-operation network can be understood as a specific form of relations between economic players, based on co-dependencies, co-operation and trust. A well operating network generates a series of advantages for its members, i.e. increase in mutual trust, deepening of social capital, mitigation of social and economic tensions, provision of legal and organisational aid, transfer of knowledge and information (Klemens 2015a, pp. 46-61). A network's characteristic feature is its long-term pro-partnership approach which exceeds the field of single transactions (Ratajczak-Mrozek, Herbec 2014, pp. 30). Nowadays, it is impossible to function outside of a relation network. The process of building an effective co-operation network requires active engagement of its members, which is why understanding the importance of this phenomenon by public decision-makers is so important. Their representation in strategic documents suggests that the decision-makers are aware of the role and significance of creating a positive environment for developing co-operation and make all possible efforts to create favourable co-operative activity conditions for establishing relations and creating values impossible to achieve in case of isolated entity activities.

A characteristic co-operation network form is a cluster which is characterised by spatial concentration and strong co-operative relations. Clusters are a phenomenon formed mainly by the market, by their creation or development can also be stimulated by a suitable policy of supporting such structures (Klemens 2018).

A specific co-operation network form are producer groups which concern collaboration in agriculture and are created to adapt the sales of one's food products to the demand requirements through, e.g. organising supply, common use of machinery, searching for common distribution channels (Wiatrak 2015).

Another related phenomenon is collaboration which plays an increasing role in economic and regional development, including international and trans-border terms. It can be understood as the entirety of understandings concluded with other organisations with simultaneous maintenance of one's independence. It ensures the coordination of common goals, thereby allowing to complete the executed tasks (Ejsmont et al., 2016).

Bengtsson and Kock define co-opetition as a process consisting in a simultaneous clash of two opposite streams of relations: competition and co-operation (2000), in which the parties are competing with each other despite the co-operation (Lado et al., 1997). However, the longer their relations are, the stronger their inclinations towards co-operation and the better the advantages (Cygler 2013).

Collaboration brings a series of advantages, as it provides the possibility of exchanging information, mutual problem solving or mutual learning, among others. It also means that various stakeholders achieve their own goals or common goals in agreement with one another by coordinating their decisions, attitudes and behaviours. Due to the above, collaboration in strategic management is viewed as a mean to achieve the organisation's goals. Collaboration is based on the assumption that given organisation members can achieve goals that are impossible to achieve by each of them individually (Stanienda, 2012).

Co-production is a specific form of co-operation based on the production (at least to a certain extent) by local community members of public services and providing such services independently of various levels of public authorities, with simultaneous maintenance of public financing and legal regulations (Pestoff et al., 2006). The main axis of existence of co-production is the understanding that without the citizens' active participation, the capabilities of public administration to ensure access to adequate quality of public services are substantially limited. For the local

government, co-production becomes the possibility of building the desired social attitudes, i.e. more openness, better communication, mutual trust, willingness to co-operate or pride from engagement in the region's development. It is therefore a specific form of co-operation (Heffner, Klemens 2017b).

The forms of co-operation presented above seem to be key in terms of regional development, because they favour effective knowledge transfer and contribute to the proliferation of innovative activities (Szewczuk-Stępień, 2016).

4. Data analysis

In the *text mining* process, data is extrapolated from text documents written in the native language. In order to conduct a text analysis, documents should be developed in a specific format. Information acquisition mechanisms are based on the attempt to match the models determining the type of sought content to particular text fragments. The easiest model is the collection of key words. During next step - document browsing, the researcher uses automatic finding of the inflection base, i.e. bringing forms and inflections of a given word to its basic form. In this case, it is necessary to have a list of synonyms with the same or very similar meaning, but not directly derived from the same basic forms. The effect of document browsing is the generation of the number of terms present in the given document. The analysis of the number of terms in documents features the creation of a term frequency matrix (Kuligowska, 2008).

The extraction of information conducted as part of the study was based searching for a specific set of terms identified earlier as key words exhibiting the concept of co-operation (they are presented in the paper's paragraph 3). Each of the 15 strategy documents was browsed with consideration of the inflection base, forms and inflections of the 14 terms specified above. Then, we noted the number of terms present in each document and created the term frequency matrix.

The following terms were the most common: co-operation (1981), clusters (839), co-operation network (682), partnership (505) and collaboration (317). The following terms were poorly represented: consortium (141), synergy (68), collaboration (35) golden triangle (14), producer groups (11), complicity (5), combining of efforts (1). The terms of co-opetition and co-production are not present in the analysed documents. For the purpose of further analysis, we evaluated the studied population (RIS3 documents) with reference to the average frequency (assumed value of 307 terms) and presented the collected results on a radar chart (Fig. 1).

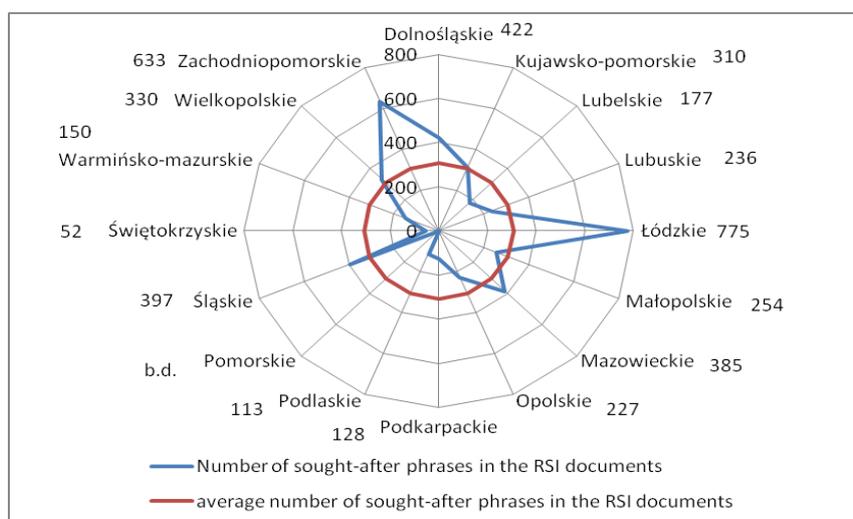

Fig. 1. Comparison of the presence of sought-after phrases with the average value calculated for all documents
Source: own elaboration

When comparing the number of sought terms in particular RSI documents with the average value estimated for all documents, we observed that 7 out of the 15 analysed documents are characterised by higher frequency of terms associated with co-operation. The ranking leader is the document developed in the Łódzkie voivodeship (775 terms), whereas the terms were least used in the RSI of the Świętokrzyskie voivodeship (52 terms).

From the 14 terms identified in the study as key words specifying co-operation, the five most common terms included the following: co-operation, clusters, co-operation network, partnership, collaboration. The detailed distribution of occurrence in the regional profile is illustrated on the chart in Fig. 2. It is clear that particular innovation strategies feature substantial differences in the frequency of terms referring to co-operation and the emphasis on its specific forms, e.g. clusters play a significant role in strategic thinking in the Dolnośląskie, Łódzkie, Mazowieckie, Śląskie or Zachodniopomorskie, and a smaller role in the Kujawsko-Pomorskie or Warmińsko-Mazurskie voivodeships.

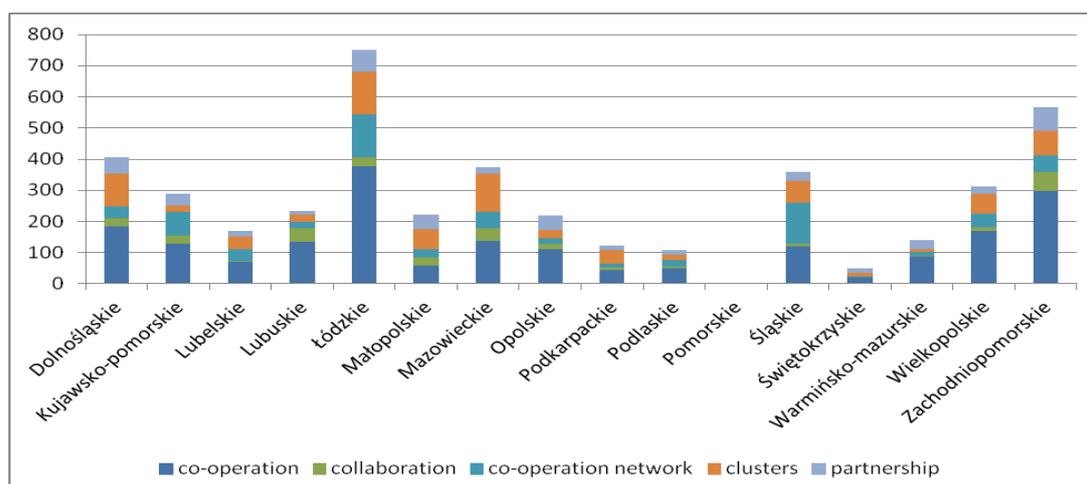

Fig. 2. Presence of sought-after words that are most common in the RSI documents
Source: own elaboration

5. Final conclusions and recommendations

The conducted analysis of the RSI documents in terms of the words referring to co-operation demonstrates that each existing strategy pays particular attention to this phenomenon.

However, we can observe substantial differences in the approach to co-operation. Firstly, the intensity of derivative words related to co-operation varies depending on the given document. It can be concluded that despite the fact that regional authorities see the need for and significance of co-operation, they view it with various intensity and the meaning of this phenomenon varies depending on the region. Secondly, co-operation is well represented in strategies, but in terms of derivative or supplementary phenomena, the following phenomena are well recognised: clusters, networks of co-operation, partnerships, whereas the following are weakly identified: consortiums, synergy or producer groups. The fact that not many documents refer to the phenomenon of a golden triangle, which is important from the point of view of co-operation, is especially disconcerting. The terms of co-opetition or co-production, based in the broader range of terms characterising co-operation, were not used at all.

Currently, intense work is underway on the development of strategic documents for the next EU programming period (2021-2027). It is a good time for decision-makers to verify the current approach, surveying the entire spectrum of terms associated with establishing co-operation and consider including a wider range of co-operation forms by specifying them directly in the strategic documents. Precise entries and explicit indications will surely translate into specific programs, projects and tasks in regions. Co-operation (regardless of the type of partners) brings substantial benefits for all parties involved, consequently the creation of conditions for establishing, strengthening and developing co-operation should be an important part of regional development programming.

Managerial Concerns for the Exit of 1929-1933 Economic Crisis in the Jiu Valley Coal Mining Industry

Mircea Baron^a, Oana Dobre-Baron^{a*}

^a*University of Petroșani, Str. Universității nr. 20, 332006, Petroșani, Romania*

Abstract

We are trying to present in this study some of the preoccupations existing in the Jiu Valley so that the coal mining from this region to effectively respond to the challenges of the economic crisis of 1929-1933.

We are observing, from a management point of view, the application of the principles of “rationalization”, many of the taken measures being dictated by the more or less subjective capacity of Romanian society to absorb the basic production of mines, coal and the necessity of dealing with the income-expenditure ratio, without which the largest part of production capabilities could not maintain its activity.

“Rationalization” has entailed an intellectual and material effort and has consequently created a modern technical basis and, implicitly, the continuation of mining activity in this region and the establishment of the Jiu Valley as the most important carboniferous basin of Romania until the 1990s.

Keywords: Jiu Valley; coal mining; mining companies; economic crisis; rationalization

During 1929-1933 the global economy would be traversed by an economic crisis of overproduction which would also manifest in the Romanian economy. Mining in general, with the significant exception of gold and silver mining, would enter a crisis, the mining industry and, implicitly, Jiu Valley mining supporting the consequences of imbalances produced in the Romanian economy.

The crisis in the mining industry begins as early as 1927, in the following conditions: the Romanian economy, being in a recession, was incapable of absorbing the entirety of coal production, and the main consumer, Romanian Railways, would reduce its demand for coal and, at the same time, acquire increasingly large quantities of lignite and brown coal, to the detriment of Jiu Valley superior coal; competition with other energy sources manifests itself: petrol (heavy fuel oil (HFO)), natural gases, wood and hydro power, being either less polluting or cheaper, or easier to use; the carboniferous industry is incapable of finding, with notable exceptions, far larger domains which utilize its product and the need to develop technologies which increase burning efficiency etc. (Analele Minelor din România (further A.M.R.), XII, 1929, nr. 5, p. 224-225)

Industrial carboniferous mining in the Jiu Valley, which has its beginnings in the end of the 1860s, the first known production, of 853 t, being obtained in 1868, 150 years ago, would reach maturity in the interwar period.

In the first interwar years, together with the achievement of the Great Union of 1918 and the incorporation of Transylvania in Romania, with geostrategic and legislative changes of 1923-1924, a process of “nationalization” of foreign capital is created in Jiu Valley mining, which determines the creation of new mining companies, in which Romanian capital comprises a majority: the “Petroșani” Company, in operation from the 1st of January 1921, having a social capital of 100 million lei, rising in succession up to 820 million lei in 1927, through the reevaluation of capital, and which overtakes the Jiu Valley actives of the “Salgótárján” Company; the “Lupeni” Company, which started operating on the 1st of January 1925, with a 400 million lei capital, which rose in 1927 to 590 million lei, formed mainly from Jiu Valley actives of the “Uricani-Valea Jiului” Company; the “Valea Jiului de Sus” Company, property, in equal proportion, of, from now, the “Petroșani” and “Lupeni” Companies. At the same time, through the application of the provisions of the Law regarding commercialization and control of State enterprises of the 7th of June 1924, Lonea State Mines are commercialized and, from the 1st of January 1926, the “Lonea” Company would be created, with a 180 million lei capital, of which 150 million lei are State shares, and 30 million lei are private capital, mainly the one involved in the creation of the “Petroșani” and “Lupeni” Companies. Furthermore, on the 1st of July 1926 a small mining company would be created, the “Sălătruc” Company.

Table 1. Romanian Railways fuel consumption during 1926-1934

Year	Energy source						
	Coal			Total	% Jiu Valley coal from total	HFO	Wood
	Jiu Valley	Pit coal	Lignite and brown coal			t	m ³
1926	1.292.385	10.060	775.072	2.077.517	62,21	295.804	387.446
1927	1.400.625	1.968	835.552	2.238.145	62,58	263.615	185.998
1928	1.350.610	4.411	781.383	2.136.404	63,22	286.203	176.570
1929	1.332.368	574	770.071	2.103.013	63,35	287.476	152.261
1930	1.046.573	-	546.025	1.592.598	65,71	299.997	98.613
1931	952.974	37.252	451.595	1.441.821	66,09	295.556	60.695
1932	822.201	36.388	293.531	1.152.120	71,36	325.498	32.003
1933	780.897	23.782	326.166	1.130.845	69,05	295.997	21.800
1934	777.953	36.383	505.881	1.320.217	58,93	239.170	19.584

Source: Lăzărescu I.M., *Întrebuințarea cărbunilor la C.F.R.*, Miniera, XVIII, 1943, nr. 3, p. 80

As was previously said, the economic crisis, with all of its consequences, would affect coal mining in the Jiu Valley, but what must be emphasized is the fact that, beyond problems of a social nature, which have created a major discomfort to an important part of the workforce, we are currently observing the most important transformations of an organizational, and especially technical and technological nature. These transformations, some which started before the economic crisis, and others which were continued after 1933-1934, and which were thought out and realized by management which has proven itself knowledgeable and performing, would define coal mining in the region for a long period of time, and are contained in what in the era was called *rationalization*. Rationalization mainly sought to lower material costs through better organizing of work and through renewal of fixed capital on the basis of new techniques which allowed a rise in work productivity, and the mining companies of the Jiu Valley would be capable of conducting a policy of major investments.

Eng. Ioan M. Lăzărescu, talking in 1941 in his paper *Cărbunii în economia românească*, arrives at the conclusion that, “the problem of rational use of coal in Romania has been brought up since 1926, meaning in a period in which almost all coal producing nations in Europe went through an acute crisis. The Romanian coal industry, in particular, has been, over the past 15 years, in a unique situation, for it was competing with other fuels which were fairly widespread in the country: HFO, natural gases and wood. It had to make a large effort to sustain itself and to resort to a series of measures meant to ensure a return close to that of the other fuels: 1. Reducing cost price to a minimum, in order to ensure that diffusion is as high as possible in relation to HFO and natural gases in the industry and to wood in household consumption. In order to achieve this goal intensification of the mechanization of extraction, rationalization of exploitation and its concentration were resorted to; 2. Improving the quality of coal meant for consumption, improvements realized through plants for prepaning, sieving and washing, through modern agglomeration and briquetting plants; 3. Improving coal usage conditions at Romanian Railways – the main client of the coal mining industry – in industry and in household consumption” (Miniera, XVI, 1941, număr unic, p. 15-18).

Here we could add the steps relating to the concentration of capital, being created economic entities with a financial, material and human force capable of dealing with market competition and, why not, for cancelling competition which could become a disruptive factor, and not a stimulating one.

Even though we are talking about several mining companies in the Jiu Valley, the fact that they conducted the same type of activity, with the same finality, that they had similar internal organizational structures, that there were close relations between the companies through the origin of invested capital, through the presence of the same people in the leadership of the companies, and, last but not least, the need to efficiently respond to stimuli, especially random external and internal factors, would gradually determine a process of concentration in the entire basin which could ensure a larger return of capital and also an optimization of productive activity.

The artisan of this process would be Eng. Ion E. Bujoiu, CEO of the “Lupeni” Company from the 1st of January 1925 and of the “Petroșani” Company from the 15th of November 1927, his proposals regarding the fusion of the two companies being discussed inside the talks carried between the Romanian Group of shareholders, represented by the Romanian Bank, and the Hungarian “Salgo-Commerce” Groups and “Urikány-Budapest” of the shareholders. The talks would end favorably (Serviciul Județean Hunedoara al Arhivelor Naționale (further SJANHD), *Fond Societatea „Petroșani”. Direcțiunea Generală. Consiliul de Administrație*, dos. 2/1930, f. 23-24), permitting the closing at the end of 1930 of a principle accord regarding the fusion of the “Petroșani” and “Lupeni” Companies. As such, the idea that the fusion brought not only important savings in the total costs generated by the enterprises, through the removal of the different administrations, but also a reduction in return costs through the possibilities of a large merged enterprise to conduct studies and make improvements in the organization of extraction, was accepted.

From a technical point of view, the fusion presented the advantage of the adoption by all of the mining sites of principles proven to work in certain places, of standardization of working methods, of mutual help and of the organization of all principal and secondary mining sites; the mining sites could be reunited – closing some mines if need be – in a few mining groups, each group, built on geographical, geological and technical criteria, being considered a technical unit equipped with all necessary accessories for meeting production goals in good condition; supersized power

plants of the two Companies would be tied together, one of them being closed; an immediate concentration of far too large central workshops of the different groups, a unit named Petroșani Central Workshops being created, which should be able to produce mining machinery and tools; the electromechanical service and the construction service would be concentrated and the colonies maintained (SJANHD, *Fond Societatea „Lupeni”*. *Direcțiunea Minelor*, dos. 166/1930, f. 1-5).

In order to make the accord operational, an extraordinary general assembly of the two mining companies was held on the 29th of May 1931, in which it was decided that the “Lupeni” Company would be dissolved and fused (Monitorul Oficial, II, nr. 133/12 iunie 1931, p. 7481-7485).

The extraordinary general assembly of the “Lupeni” Company shareholders held on the 29th of May 1931, would unanimously approve: the fusion of the “Lupeni” Company with the “Petroșani” Company; the assets and liability of the “Lupeni” Company would be transferred through the effect of the fusion to the “Petroșani” Company, and personnel of the “Lupeni” Company would be transferred to the employment of the “Petroșani” Company, in the same conditions in which it is situated in the “Lupeni” Company; through the effect of the fusion with the “Petroșani” Company, the “Lupeni” Company would cease its existence from this moment (SJANHD, *Fond Societatea „Lupeni”*. *Direcțiunea Minelor*, dos. 169/1931, f. 1-2).

The extraordinary general assembly of the “Petroșani” Company shareholders held on the 29th of May 1931, would decide the fusion of the “Petroșani” Company with the “Lupeni” Company through the incorporation of the entirety of assets and liability of the “Lupeni” Company to the “Petroșani” Company, based on the balance sheets of the two societies at the 31st of December 1930; the growth of social capital of the “Petroșani” Society, from 820 million lei to 1.410.000.000 lei, meaning with 590 million lei, a sum which represented the “Lupeni” Company capital; the modification of articles 5, 6, 8, 9, 11, 13, 15, 25, 29 from the Statutes of the “Petroșani” Company (Societatea Petroșani, *Statute. Modificate în Adunarea Generală Extraordinară din 29 mai 1931*, Tiparul Românesc, București, 1931; Monitorul Oficial, II, nr. 133/12 iunie 1931, p. 7483-7484), and the modification of the statutes of the company’s Pension House (SJANHD, *Fond Societatea „Petroșani”*. *Direcțiunea Generală. Consiliul de Administrație*, dos. 1/1930, f. 5-6).

The newly formed “Petroșani” Company, having its social centre in Bucharest, would be the largest producer of coal of the country and, at the same time, the third largest industrial corporation by capital, initially having the following organizational structure: the General Direction, situated in Bucharest, led by the general director; Mining Groups: Petroșani, Vulcan, Lupeni; the Central Administrative Division of the Jiu Valley/The Petroșani Mining Direction; the Lapoș Mining Exploitation; the Sebeș Forest Exploitation; the General Services Direction (SJANHD, *Fond Societatea „Petroșani”*. *Direcțiunea Minelor. Serviciul Muncă și Salarii*, dos. 9/1932, f. 1-10).

Following the process of capital concentration, the “Petroșani” Company would purchase in 1933 the 10.000 shares of the “Sălătruc” Company, taking over its patrimony and transferring its social centre to Bucharest (SJANHD, *Fond Societatea „Sălătruc”*, dos. 35/1940, f. 556). This way, the “Sălătruc” Company is incorporated technically, organizationally and socially in the “Petroșani” Company and would continue with its support to carry on its extractive operation until January 1941 when an approval by the Ministry of National Economy to suspend mining operations is obtained (SJANHD, *Fond Societatea „Sălătruc”*, 28/1938-1942, f. 7-8).

The “Valea Jiului de Sus” Company would be absorbed by the “Petroșani” Company as well. Because after July 1931 the productive activity in the mining field of the “Valea Jiului de Sus” Company from Vulcan would cease, in November 1942 the General Assembly of the Company would decide the fusion of the “Valea Jiului de Sus” Company with the “Petroșani” Company, through the concession of capital and patrimony (A.M.R., XXV, 1942, nr. 12, p. 256).

In 1929, as a result of the teachings acquired during a study trip in the Ruhr mining region in Germany, Eng. August Buttu from the “Petroșani” Company elaborates a study named *Raționalizarea în coal mines with a few considerations on the opportunity of mechanization and frontal slopes* (the study will be published later in, A.M.R., XXIV, 1941, nr. 2, p. 27-35; nr. 3, p. 53-62), in which he proposes, among others, quitting coal layers and unprofitable mines and the methodical concentration of operations, possible, however, only after new stoping methods will be adopted. By this logic, the “Petroșani” Company would proceed to close the following mines: West Petroșani (30th of October 1928) (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 68 c/1931, f. 10-18); Dâlja/Petroșani (march 1931) (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 68 c/1931, f. 5); West Vulcan, East Vulcan, Dr. Chorin (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 99/1931, f. 13-24) and “Valea Jiului de Sus” from Vulcan (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 99/1931, f. 30) after July 1931 and temporarily suspend the activities of the East Petroșani Mine at the 29th of June 1937 (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 106/1937-1938, f.f.), which would then become a sector of the Petrila Mine.

In Lupeni, the program was based on intensifying the production of the Ștefan and Ileana Mines in the 3, 5, 8, 9 layers, after the depletion of higher layers of the Ileana Mine, the closing down of the Carolina and Victoria Mines during a 2-5 year term, meaning after the complete depletion of higher coal layers (SJANHD, *Fond Societatea „Lupeni”*. *Direcțiunea Minelor*, dos. 101/1928, f. 47-48; dos. 68e/1931, f. 13-14; dos. 9/1932, f.f.). Such a process would also occur at the “Lonea” Company. It was thought that the most logical solution regarding concentration would be at Mine III “Jieț” - Mine I Cimpa and II Lonea would be closed down from 1930 – because it presented the largest advantage that the majority of organizational operations were already under way, the coal layers permitting the

application of modern extraction methods, and the coarse coal was in a smaller percentage than in the other two mines (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 111/1931, f. 1-5).

Therefore, a process of reorganizing mainly surface activities is taking place, at the same time as the lowering of production capabilities, which has not, however, affected the possibility of satisfying the necessary amount of coal demanded on the market. Inside the "Petroșani" Company, the Petrița, East Petroșani, Aninoasa, and the Lupeni Group mines would remain functional after May 1931, with the present mines, at the "Lonea" Company, Mine III "Jieț", and there was also the small enterprise of the "Sălătruc" Company from Livezeni, so that, by the end of the interwar period, five mines would operate: Petrița, Aninoasa, Lupeni, Lonea and Sălătruc, the latter being closed down in January 1941.

It was thought that closing down these productive units would not affect the capacity of the Jiu Valley to provide the necessary amount of coal demanded on the market: Mine III Lonea could provide, work being done in two shifts, 500 t coal/day, so a 55% increase relative to May 1931, and the "Petroșani" Company could provide, through the Lupeni and Petroșani mining groups, 5.200 t coal/day, work being done in two shifts, so a 75% increase relative to May 1931. Furthermore, it was determined that, should the expansion of production be necessary, the following mines could be reopened: II Lonea; West Petroșani and Dâlja/Petroșani; East Vulcan; Victoria/Lupeni. It was determined that the existing features allowed the expansion of production capabilities of the Jiu Valley mines with 1.700 t coal/day as soon as necessity would demand it, keeping the advantages of surface concentration (SJANHD, *Fond Societatea „Petroșani”. Direcțiunea Minelor. Serviciul Tehnic*, dos. 1/1931, f. 1-3).

Concentration would make the "Petroșani" Company, which had in its activity, before this process, 15 mines and 32 pits, in 1943 to only have three mines in exploitation, where 14 pits were functioning, among which only four were extraction pits. The effects of concentration can be observed in the quantity of extracted coal/metre of tunnel: in 1928 there were 203,8 km of tunnels at annual production of about 132.355 t of coal, and in 1941, 101,7 km to 186.000 t, so 0,65t/m in 1928 and 1,82 t/m in 1941 (Buttu, 1943, p. 65).

Eng. August Buttu, in the cited study, has also regarded that, in order to optimise activities long-term solutions were necessary, which consisted of, among others: reestablishing discipline and order; lengthening effective work time; rational use of those who did not produce, elimination of those who were useless, unwanted, inadequate; increase and picking of good supervising and control personnel, for the workers as well as for the material and equipment; rising the value of workers through schools; protection of personnel through safety measures, medical service and welfare; equitable wages and bonuses; perfecting mechanical equipment, introduction and use of machinery in mines, applying the principle of: *don't let a man do what a machine can*; methods of general organizing and of exploitation with the application of a large-scale concentration policy, through the introduction of stopes with long fronts, large units of production.

Eng. Ion E. Bujoiu would understand that these measures had to be taken, especially in the increasingly harsh conditions which affected the mining companies in 1929, due to the tripling of mining tax, the lowering quantity of taken coal and the lowering of prices by 8% of supplies to Romanian Railways, the competition of other energy sources, and higher wages. At the made proposals, Eng. Ion E. Bujoiu added the obligation to obtain the amelioration of the amount of coal extracted through the removal of as much sterile as possible and reduction of the percentage of dust, in order to deal with consumer requirements.

From the amount of issues, we will choose just two plans of action: *a.* the introduction of new exploitation methods, based on augmenting mechanization; *b.* sustained preoccupation with ameliorating the quantity of extracted coal. The modernization of exploitation methods, like of the entire productive process of Jiu Valley mining, would obviously entail the development of mechanization, tools and machines being built which would operate underground using electricity and compressed air, being, at the same time, safe for the vicious medium, especially the one with methane, in which they operated.

If at the surface the spread of electricity was universal, three-phase asynchronous engine being an indispensable auxiliary for any machine, steadily electricity has entered the underground: centrifugal pumps; ventilation fans; locomotives with trolleys or accumulators; trolleys for inclines, and in the coalface: oscillating troughs; transporters with rubber bands or scrapers. Even though, in the coalface, pneumatic dislocation tools were prevalent – in 1925 624 pneumatic hole punchers, 38 stoping hammers, 19 hewing machines, 1509 m oscillating troughs (SJANHD, *Fond Societatea „Petroșani”. Direcțiunea Minelor. Serviciul Tehnic*, dos. 4/1925-1932, f. 1) - electricity tends to be used through electrical lighting of the workplace, using fans for secondary ventilation, centrifugal pumps, electrical boring machines, hewing machines, using asynchronous motors etc., such that, in 1929 the "Petroșani" Company consumed 19,9 Kwh/t of extracted coal, the Lupeni Group, which was the most electrified, consuming 34,4 Kwh/t of extracted coal. Furthermore, in 1931, after the Petrița and Lupeni Preparation Stations started their operations, the specific energy consumption of the "Petroșani" Company would be 27,8 Kwh/t of extracted coal. Of course the focus on mechanization and, implicitly, on the introduction of electricity, would favor an increase in the capacity of the Vulcan and Lupeni Power Plants the coal mines consuming a part of the production in order to create secondary energy with a large output (Georgescu-Gorjan, 1933).

The growth of mechanization would allow the introduction, beginning with 1927-1929 in Lupeni, along with the method of exploitation with stoping rooms, the method of exploitation with mechanized stopes with a long 80-120 m front in thin layers, method which would later be applied in the Petrila, East Petroșani Piscu/Aninoasa mines. The use in stopes with a long front from thin layers, of hewing machines, has determined a 50% growth in returns and a productivity of the hewing machine of 96 t/shift, with an 80 m long coal-face (Marian et al., 1969, p. 60).

During 1932-1933 experimenting was done in Lupeni, being later applied at Aninoasa mine, with the following type of exploitation: directional frontal stopes, in layer 3, using a pneumatic embankment, the long front being introduced in the main layer as well (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 62/1933, f. 1-3). From 1933, again in Lupeni, in layer 3 the method with transverse front and pneumatic embankment was introduced, followed in 1934-1935 by the selection of coal in the coal-face (SJANHD, *Fond Societatea „Petroșani”*. *Direcțiunea Minelor. Serviciul Tehnic*, dos. 45/1932-37, f. 180-182).

In 1936 the first horizontal frontal stope started operating in layer 3 at the Lupeni mine, with metallic support under an artificial ceiling made out of planks, the method being extended in 1937 in Lupeni at layer 5, in frontal stopes on the layer's slope. This type of support, with 70 kg metallic pillars supplied by the "Schwarz" company, semi rigid type, with planks, with a strength of 30 t/pillar (SJANHD, *Fond Mina Lupeni*, dos. 28-12/1937, f. 47), would be applied at layer 3 at Aninoasa mine in 1937 and at Petrila mine in 1938 (Giuclea and Opreșă, 1969, p. 114-115). It is worth mentioning that augmenting mechanization and introducing new methods of exploitation, which are based on technological progress, would cause advancing speeds in stoping and a growth in productivity, as expected - in 1928 the "Petroșani" Company had 9.926 employees, of which 2.525 were miners, output in the coal-face being 2,226 t, and in 1934 there were 6.484 employees, out of which 1.635 were miners, output in the coal-face being 3,988 t - however, the growth is not spectacular, and after peaking in 1933-1934, output started to visibly decline, which shows us that mechanization helps the effort of the people, but in mining deposit conditions definitively influence the output of machines and of people (SJANHD, *Fond Societatea „Petroșani”*. *Direcțiunea Minelor. Serviciul Muncă și Salarii*, dos. 2/1935, f. 16).

The second large direction which we were referring to would be represented by the sustained preoccupation for ameliorating the quality of extracted coal, through methods used in the mine: reduction of shooting, selection, manipulation, as well as especially its mechanical preparation. This direction would impose financial and technical actions to ensure a response to the "challenge" which coal buyers imposed and, at the same time, ensure its integral capitalization at a price which should be as convenient as possible (Baron and Dobre-Baron, 2004).

Romanian Railways, which used coal for the production of vaporized water in the locomotive's focus, was the main buyer of coal extracted in Romania and would impose its own policy regarding quantity and quality of the purchased product. Otherwise, the evolution of Jiu Valley mining companies would be decisively influenced by the purchasing policy of Romanian Railways and a part of the realized transformations, especially the qualitative ones, would owe to the requirements formulated and imposed by their most important client. The leaders of these mining societies understood that, in the conditions in which coal is not a renewable source, it is beneficiary that it be exploited rationally and, most importantly, be capitalized in a superior and profitable way.

1930 exploitation programs and the extraordinary operations program for 1930-1931 and 1932 of the "Petroșani" and "Lupeni" Companies provided the concentration of mechanical coal preparation activities in two modern and complex installations, using the "rheo-laveur" system, at Petrila and Lupeni, which would replace the old separations at East Petroșanit, West Petroșani, Vulcan, Lupeni: Victoria and Ștefan (SJANHD, *Fond Societatea „Petroșani”*. *Direcțiunea Minelor. Serviciul Tehnic*, dos. 25/1932, f. 1-97). The Lupeni plant with a washing capacity of 140 t/h, would be functional from the 18th of February 1931 (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 84/1932, f. 1-7), and the Petrila plant, with a washing capacity of 270 t/h, would be functional from the 12th of August 1931 (SJANHD, *Fond Inspectoratul Minier Petroșani*, dos. 54/1931, f. 32).

The beginning was continued and so, at the beginning of the 1940s, the "Petroșani" Company could boast about a complex of coal preparing equipment, unique in Romania, comprised of seven groups: washing plants; drying plants; flotations; water treatment; briquetting; low-temperature carbonization; auto agglomeration (Buttu, 1937, f. 1-26), and which allowed it to deliver a large assortment of coal to its clients (Buttu, 1937, f. 4).

All of these actions and achievements have not only had a financial and technical component, but also a social component. Through all that was achieved, the economic crisis was overcome and, especially, the maintenance of the Jiu Valley industrial complex and the underlining of qualitative competence, which allowed it to keep an economic, technical and social role in the Romanian economy. All of these would not have been possible without those who have been invested in leading the destiny of this industrial complex and who had the managing capacity of thinking about continuity through the imposition of transformations which overlooked all the components of this entity.

Optimization of business processes with the use of microlocation tools based on the Industry 4.0 concept

Janusz Wielki^{a*}, Przemysław Koziol^b

Opole University of Technology, the Faculty of Economics and Management, Opole, Poland

^b Algeco Polska sp. z o.o., Poznań, Polska

Abstract

The dynamic development of information technology enables the implementation of tools that improve business processes in enterprises with an unregulated flow path. The use of intelligent systems within the framework of the concept of Industry 4.0 makes it possible to monitor the resources and processes in real time in order to perform efficient inference and modelling of the workspace, shortening in this way the path of implementation. The aim of the article is to analyse the possibility of using microlocation tools in the optimization of business processes. The adopted method of the analysis of literature covering the field of the Industry 4.0 concept and the use of individual case method for Indoorway InSites 4.0 tools allow to present potential benefits for business while their extended recognition may become the basis for further research. Flexible shaping of workspace generates savings due to both the rationalization of the space utilisation and elimination of the phenomenon of hidden waste, which is particularly important for organizations with unregulated process paths. The synergistic benefits of lean management, Industry 4.0 and microlocalization tools are commonly used, and on the market are available intuitive, relatively cheap tools, the implementation time of which does not exceed several hours.

Keywords: industrial Internet; Internet of Things; location technologies; business processes improvement

1. The concept of Industry 4.0: the concept, characteristics and possibilities associated with it

When it comes to the very concept of Industry 4.0, it is possible to indicate quite precisely when it first went public. The term was coined at the Hannover Fair in 2011 and refers to the fourth phase of the industrial revolution (Schwab, 2016). Historically, the first of these phases (Industry 1.0) took place at the end of the eighteenth century (1784) and involved the introduction of a steam machine in mechanical production systems. The next phase of the Industrial Revolution (Industry 2.0) started at the end of the nineteenth century (1870) with the emergence of mass production systems based on the use of electricity. The third phase (Industry 3.0) started at the end of the 1960s (1969). It was associated with the use of electronics and IT systems in the process of further automation of production. Phase four (Industry 4.0) is associated primarily with the possibilities opening in the context of combining the real and virtual worlds, based on the use of cyber-physical production systems (Deloitte, 2015). Other terms used in this context are: Industrial Internet, Connected Enterprise, SMART Manufacturing, Smart Factory, Manufacturing 4.0, Internet of Everything, Internet of Things for Manufacturing or Digital Factory (Cotteleer et al., 2016; Geissbauer et al., 2016a).

There are various definitions of the Industry 4.0 concept. Baur and Wee understand this term just as the next phase of digitization of the manufacturing sector (Baur and Wee, 2015). In turn, according to Geissbauer et al., the concept of Industry 4.0 refers to over a dozen key innovations in the field of information technologies, which in recent years have reached the level of maturity, ready to transform such sectors as energy and production (Geissbauer et al., 2016). According to the PWC this term is to be understood as the end-to-end digitalization of all physical resources and their integration with digital ecosystems created with value chain partners (Geissbauer et al., 2016a). However, for Helbig et al. the essence of the term "Industry 4.0" comes down to incorporating the technical integration of cyber-physical systems into the manufacturing and logistics sphere and the use of Internet of things and Services in the industrial

* Corresponding author. Tel: +48-77-449-88-00; fax: +48-77- 449 88 16.
E-mail address: Janusz@Wielki.pl.

processes (Helbig et al., 2013). Deloitte, on the other hand, defines Industry 4.0 as a combination of physical and digital technologies that enables the creation of a digital enterprise that is not only completely connected but also capable of more holistic, informed decision-making (Deloitte, 2018).

According to the Deloitte consulting company, it is possible to indicate four features that characterize Industry 4.0. These are (Deloitte, 2015):

1. Vertical networking of smart production systems.
2. Horizontal integration via a new generation of global value chain.
3. Through-engineering across the entire value chain.
4. Acceleration through exponential technologies.

At the same time, it is possible to point to various factors stimulating the development of the Industry 4.0 concept. According to Bauer and Wee these are (Baur and Wee, 2015):

- Exponential growth in the amount of data available and the development of the Big Data phenomenon.
- Development of advanced analytics.
- The emergence of new forms of human-machine interaction, such as augmented reality.
- The advances in information flows between digital and physical world (*digital-to-physical transfer*), for example, 3-D printing.

Schwab, in turn, points to the three categories of *technological drivers* of the fourth industrial revolution i.e. physical, biological and digital. The first of these categories includes such technology megatrends as: autonomous vehicles, 3D printing, *advanced robotics* or new types of materials. In the field of biology, these are advances in the genetic research, *synthetic biology* or the use of 3D technology in medicine (*bioprinting*). As far as digital factors are concerned, these include such technologies as *blockchain*, the technology platforms for the development of the "*on-demand economy*" or the Internet of Things [Schwab, 2016, p. 18]

As mentioned above, the Industry 4.0 concept is based on the use of a whole range of digital technologies that have evolved over the years at an exponential pace and have reached the appropriate level of maturity (Davis and Schwab, 2018). According to the PWC these are (Geissbauer et al., 2016a): cloud computing, mobile devices, IoT platforms, location detection technologies, advanced machine-to-man interfaces, authentication and fraud detection technologies, 3-D printing, intelligent sensors, Big Data analytics and advanced algorithms, multilevel customer interaction and customer profiling systems, the augmented reality/wearables.

At the same time, the data and analytics are indicated as *the core capabilities*. PWC also points out in its report to the three essential possibilities related to the Industry 4.0 concept and "driving" its development. These are (Geissbauer et al., 2016a):

1. Digitization and integration of vertical and horizontal value chains.
2. Digitization of product and service offerings.
3. Digital business models and customer access.

2. The phenomenon of endemic waste in organizations with a unregulated flow path

Companies, in order to ensure the value desired by the customer, design and continually refine their business processes through, among others, identification and elimination of all forms of waste, which have an adverse impact on the flow and effects of work (Stenzel, 2007). In well organized enterprises that constantly optimize their flow paths (information, materials, semi-finished products and products paths), a defined process map makes it possible to identify both: the sources of the creation of value added product and waste. The advanced process awareness is characteristic for companies in the such sectors as: automotive, domestic appliances, electronic and electrical, FMCG and food sector. However, also in other branches it is possible to find companies that base their activities on the concept of lean management, usually being leaders in their industry.

Waste is defined as a broad spectrum of activities which do not bring added value to the customer and to enterprises with a unregulated flow path in which lack of lean culture waste is endemic. While in companies with advanced process awareness, the search, reduction and prevention of hidden waste is mandatory, in organisations with unregulated flow path this phenomenon is not unequivocally characterised and therefore subjective, and additionally it can have a decisive impact on the business profitability. Organizations that do not map their own business processes, expose themselves to process gaps, do not integrate their activities with the needs and requirements of the customer, prolong the flow time, and as a result degrade their own accounting liquidity. The lack of stabilisation of flow pathways is typical of enterprises with low level of standardization of operations, work at unstable rates with a small number of repetitive activities, with the need to pay attention to the details of the product, especially in companies where there is no rooted and developed lean culture, regardless of the field of activity. Of course, there are specialized solutions dedicated to e.g. piece- or small lot-producing companies that integrate flows through the use of ERP class systems, e.g. by processing data about the demand, the availability of materials, the technical and technological capabilities of machinery and equipment, and any other information necessary to provide an optimal production plan. However, systems of this class are often unattainable for many small and medium-sized enterprises and their implementation and maintenance is associated with significant costs. From this perspective, it is crucial that in the era of the development of

the Industry 4.0 concept, there are widely available IT solutions on the market that support organizations with unregulated flow path in business optimization by effectively reducing waste within the processes.

3. Application of the Indoorway InSites 4.0 platform for multidimensional motion analysis

One of the providers of smart building solutions in which object navigation and space mapping were used to optimize business processes and usable space, is the Indoorway company, the winner of the final of the national competition for start-ups: PowerUp! by InnoEnergy 2018. Indoorway's algorithms analyze data multidimensionally through the use of the company's location technology Indoorway Hive and a mobile application based on an accelerometer, magnetometer, gyroscope and beacons that enable precise navigation. Obtaining localization accuracy up to 20-30 cm makes it possible to use microlocation to optimize business processes and gives practically unlimited possibilities regarding traffic analysis and, as a result of this analysis - possibilities to shape the workspace. Indoorway company, in addition to comprehensive implementation of the multidimensional motion analysis service, provides a set of tools with the use of which the developers can create proprietary solutions based on indoor navigation. Scalability of the system allows the use of an IT platform in organizations of various sizes, and the authors emphasize that the goal of developing the solution was to create a fast, clear and logical implementation system that can realistically be implemented in several hours. The companies using the InSites 4.0 platform include representatives of the following industries: manufacturing, real estate, finance, transport, IT and others. Currently, the company's development is aimed at commercializing the platform, adjusting the analytics results from Ultra WideBand technology (UWB) to the largest customer groups and conducting the pilot implementations of the new technology.

IndoorS InSites 4.0 tools operate based on UWB technology and Bluetooth Low Energy (BLE) - Bluetooth version 4.0, which eliminates the problem of continuous operation of connected devices, and hence, rapid consumption of battery power from wireless devices. On the basis of BLE, the iBeacon protocol for devices called beacons was developed. Beacons are signal emitters containing an encoded identifier, which can be used by mobile devices (Łyda and Miłosz, 2017). The data from beacons can be used in a variety of applications in advertising, sales and services. Using them in the industry to optimize processes opens new possibilities for shaping space and organization of work. UWB broadband technology is based on sending short-term pulses at a fast rate. UWB devices work at a low power level which eliminates interference with other radiocommunication devices. Low energy consumption makes it possible to build a wireless location system for users. This technology has the ability to penetrate some construction materials (concrete, wood, glass) which is important for estimating the distance of objects and testing their location and tracking inside buildings. This property is also used for indoor positioning because it gives the possibility to determine the distance in the absence of direct visibility (Czopik and Kraszewski, 2014).

InSites 4.0 is a ready-to-implement set of tools based on an in-building location system that uses devices such as tags and hubs. Tags are transmitters, placed on vehicles or machines, and can be a part of the equipment of the employees. Hubs as receivers are mounted on the elements of the facility's infrastructure (walls, ceilings) to collect data about the location of the tested elements. Information about the traffic in space gathered in this way is presented in a user-friendly, online analytical panel. Due to higher reliability and accuracy, ultimately Indoorway solutions will be based only on UWB technology.

The InSites 4.0 platform provides data for multidimensional motion analysis in the following areas:

- traffic analysis,
- heat maps – a workload for working space,
- analysis of the distribution of employees (or guests) in the organization space,
- input/output analysis (room statistics).

Use of data from the above tools makes it possible to identify instability of the process flow, visualize its actual status and not only the hypothetical notion of the status, and constitutes a practical starting point for changing the process elements in order to optimize the process.

The system of control of the employees' movement, regardless of the tools used, arouses a lot of controversy and can be identified with surveillance. Apart from arguments regarding the safety of employees (in the event of evacuation from the workplace, faintness, etc.), microlocation tools can be used to optimize the organization of work by collecting and processing data on, among others, work time in and outside of the workplace and the distance the employees have to cover to carry out specific business processes. The analysis of these data is closely related to defining the process and revealing any traces of waste, especially the waste of motion and the waste of transportation, which in turn improves the functioning of the enterprise in a dynamic environment, increasing its competitive advantage.

Table 1. Time of implementation of platform InSites 4.0 divided into stages (source: own study based on the Indoorway company data).

Industry	Time of realization of the platform implementation						Total implementation time
	Design	Systems assembly	Service training	Modification and customization	Testing and quality control	Final acceptance	
Production	64	16	2	8	8	2	100
Finance & Banking	120	12	2	6	6	2	148
Real Estate (Implementation 1)	1.920	144	8	72	72	8	2.224
Real estate (Implementation 2)	960	72	4	36	36	4	1.112
Consulting for industry	16	16	2	16	2	2	54
Fitness	40	240	40	40	20	20	400
IT	120	12	2	6	6	2	148
Rail transport	8	8	2	4	2	2	26

As part of the analysis, the length of the process of implementation of the InSites 4.0 platform was measured, which affects the real cost of the project. It was found that it depends on the degree of specification of the potential customer's goals. The process proceeded in the following stages:

- customer's request for proposal,
- presentation of the system realizing the assumed goal,
- offers of a trial or end-to-end implementation,
- preparation of implementation (electrical installation, WiFi, server, tags and hubs, space map, infrastructure),
- implementation (map configuration, hardware placement, system commissioning, preliminary measurement),
- system operation tests,
- post-installation service and technical support,
- data analysis.

The above-mentioned stages were consolidated into groups: design, system assembly, training on servicing, modification and customization, testing and quality control, and final acceptance. For the implementations of the InSites 4.0 platform realised by Indoorway company, the implementation times for individual projects are shown in Table 1.

The benefits associated with the implementation of microlocation tools in process optimization include:

- acceleration of tasks realization by shortening paths and improving the effectiveness of the use of space,
- elimination of micro-downtime and reduction of endemic waste,
- quick access to current and actual information on the status of the machinery park, the movement of employees and transport equipment,
- increased security through the use of monitoring devices that inform about dangerous situations (lack of movement, potential collisions, etc.),
- the possibility of expanding the platform and adapting it to the company's dedicated needs,
- obtaining transparent and reliable data on the course of processes, delivered without interference caused by subjective notions,
- precise identification of the availability of equipment, premises, workplace, location of employees and transport equipment.

4. Modelling of the space of process execution based on the data from microlocation tools

It is characteristic for organizations operating in the spirit of lean management to constantly search for waste in processes. Typical for organizations with unstable flow paths is ad hoc, temporary and non-persistent workspace designing based only on current goals. Analysis of motion assisted by modern tools based on the concept of Industry 4.0, acting in the background of actions being carried out, provides a range of information that can be used to model the space of the organization without disrupting the already ongoing process.

Thanks to the use of the Indoorway InSites 4.0 platform it is possible to support the optimization of distribution of the means of labour by, among others:

- analysis of the flow paths and, in particular, the distances to cover in the executed process and the time of the movement constituting process waste, performed by mobile devices in a real enterprises environment,
- current and historical degree of utilisation of work zones, communication spaces, rooms, entrances and other elements of the organization's infrastructure,

- analysis of the activity of individual machines and devices, employees and all the company's resources that create added value in the processes.

The Indoorway's InSites 4.0 platform itself does not provide and does not impose ready-made solutions, but by presenting the collected data in an intuitive way, it can be an effective tool for optimizing business processes in the production, commercial or office space. Figure 1 presents one of many tools within the InSites 4.0 platform – a heatmap, thanks to which it is possible to analyse the degree of utilization of the space of business process implementation in the enterprise.

Fig. 1. Application of Indoorway InSites 4.0 heatmap for analyzing the degree of space utilization (source: Indoorway materials).

The data obtained thanks to the use of the IT platform allow for the analysis of processes in terms of their improvement and optimization. Typical examples of workspace reorganization, which at a relatively low cost often bring quick and visible effects, are, among others:

- application of visualization tools,
- use of supermarkets, consisting in organizing intermediate storage space, in which a constant level of stock of the selected assortments of goods is maintained. This approach, used when there are no fixed levels of orders, reduces the movement of workers to the main warehouse,
- reorganization of the workplace, consisting in changing the arrangement of machines and devices so that the path of the process is simple, logical and short,
- reorganization of the process, consisting in changing the order of performing particular operations, implementing standardization, systematics and segregation at the workstation,
- redesigning and change of spatial layout of workplaces, associated with the change of the location of infrastructure (toilets, kitchens, social rooms, etc.) and workstations in relation to each other, in order to shorten the distances that employees have to overcome to achieve their goals,
- process mapping, through the use of visualization of the course of the process, along with its internal connections, increasing the level of awareness about its shape and the resources involved.

5. Summary

According to Deloitte estimates, by 2022 at least 25% (currently 5%) of all microlocation applications will be implemented partly or entirely inside buildings. This increase will be the result of, among others, the emergence of new data processing capabilities that have a significant impact on increasing the location precision within the buildings. Deloitte states that the beneficiaries of these changes will be companies active in the beacons market, and their impact will be felt in all sectors of the economy, from government institutions to manufacturing companies and consumers around the world. Although microlocation is not a new concept, the development of interaction between the user and the application creates a new space for development. Among the active Polish companies in this industry, the most important are Estimote, Infinity, Kontakt.io and Linteri (Deloitte, 2017). Microlocation tools can have a critical impact on the optimization of the implementation space of the processes and on the shape of the business processes in organizations with unregulated flow path, which is the starting point for further scientific research. The subject of the authors' interest remains the in-depth analysis of the real benefits associated with the implementation of microlocation solutions and investigation whether relatively low implementation costs compared to potential revenues can be an incentive for further implementation of optimization platforms (such as Indoorway InSites 4.0) for small and medium-sized enterprises. The key to the change is the increase of the entrepreneurs' awareness that the financial result is influenced not only by the amount of generated revenue, but also by the level and structure of the organization's costs. Eliminating endemic waste is a challenge for all enterprises, and emerging start-ups provide modern tools to support this process.

Logistics parks – from theory to practice

Alexandru-Constantin Petrache^{a,*}

^aWest University of Timisoara, Faculty of Economics and Business Administration, Timișoara, 300115, Romania

Abstract

Logistics is a complex science through which thousands of tons of freight are moved around the world each day. Logistics means not only planning but also execution. Day and night an army of workers, means of transportation, freight terminals assures that loads are going from point A to point B. Near every city around the world were developed logistics parks, storage spaces and freight terminals. Through the following paper an analysis of the literature about worldwide logistics is done, the situation of a European market leader in logistics is shown and also will be presented the current situation on the transportation and logistics market from a Romanian county.

Keywords: transportation; storage; logistics parks; freight

1. Introduction

All over the world, the freight volume and traffic increased significantly over the last decades. Logistics parks are now significant nodes of modern logistics systems (Dai & Yang, 2013). When we talk about logistics, nowadays we need to consider not only the means and ways of transportation; either we speak about road, rail, water or air transportation systems, but also about the handling, storage and forwarding of the freight.

All the cities are connected through highways, railroads, ports or airports. The developed cities understood the future in logistics and all major cities have now spaces where the freight carried with the train, can be offloaded and then loaded in trucks, or airplanes in order to arrive to the final destination.

2. Literature review

The early concepts about logistics (Neeraja, Mehta & Chandani, 2014) considered only the main activities such as transport and storage. But today is also about intermodality (Záhumenská & Gašparík, 2017), and the concept of quattro modal freight hub (Hauger, et al., 2016).

With the increase of the freight transportation volume, the Logistics Service Providers (LSPs) dimension and their behavior changed (Rolko & Friedrich, 2017), in order to offer integrated services for customers. It's not only about transporting freight from one point to another, but also offering the customer the best solution to his problem.

Today, a logistics park is a place with a variety of logistics facilities, warehouses and storage units near a highway, railroad, port or airport. A logistic park can be operated by a LSP, or the LSP rents a warehouse where he runs his activities.

The theory also presents the key performance indicators (Záhumenská & Gašparík, 2017) or the criteria and measures (Akdoğan & Durak, 2016) used in the evaluation of a logistics park, but in the end it's all about the size, the storage capacity, multimodality and the location (either if we talk about a city or a way of transport).

Today, more and more it's about finding new ways for an efficient and effective transportation operation. The hub-and-spoke model (Crainic & Kim, 2006) from an airport business model seems to fit well also in freight transportation on road, railroad or water. For a better logistics planning in transportation, the best way is to gather all the freight in one place, then to prepare load units that are going in the same direction. It's all about the costs and timing.

3. European logistics leader

According to a document released by the economic development agency of the Federal Republic of Germany (Friedrich & Pfeiffer, 2010), the German economy is the world's fourth largest after the United States, China and Japan. This thing happened because of the European Union's eastward expansion. With this expansion more goods pass through Germany now than through any other country in Europe. That led to a significant boost in Germany's logistics sector.

The main concern in Germany's logistics sector was the linkage between numerous ways and means of transportation. Storage facilities and multimodal terminals were built along the main highways in Germany, and also logistics hubs and facilities were developed near the big cities in every region.

Regarding the innovation performance, Germany is classified as an innovation leader, according to Innovation Union Scoreboard 2014 (Maticiuc, 2015), and in addition with the information already presented, we can deduct that these logistics hubs from Germany can be considered logistics clusters, "Innovative forms of spatial organization, in order to ensure a more efficient and effective business by using the synergy between organizations" (Maticiuc, 2014).

Between the characteristics of a successful logistics hub and also the main functions that this logistics hub should fulfil, we can mention:

- Customized solution,
- Handling, warehousing and transfer of goods,
- Access and proximity to the market,
- Strategic location,
- Multimodality,
- Intermodal terminals.

With some of Europe's most advanced transportation networks, well-trained workforce and also a stable political and economic environment, Germany can be considered the best possible base for European and global logistics operations (Rolko & Friedrich, 2017).

The logistics infrastructure in Germany is so well developed that near every city logistics operations run day and night. We can see a connexion between two or more ways of transport in order to obtain efficiency and effectiveness. Key players use or operate intermodal hubs in order to store, ship and manipulate the freight.

4. Timiș county logistics situation

Timiș county, situated in west of Romania, with a population of more than 680000 inhabitants and a surface of 8700 km², is the largest county in Romania in terms of land area and on the border with Hungary and Serbia (Consiliul Județean Timiș, 2018).

With a population of more than 330000 inhabitants and a surface of 130 km², the city of Timișoara is an important economic, cultural and scientific center. Timișoara is an important commercial node, where many big companies from Europe and all around the world decided to invest here.

On the road, Timișoara is a node for important European and national roads. The Romanian Highway A1 passes NNE of the city, linking Timișoara with Hungarian Highway M43. On air, Timișoara is served by the third busiest airport from Romania, situated at about 12 km NE from the city center. On the railway, Timișoara has a direct link with Belgrade, Budapest and Vienna from the main railway station and also with the major cities from Romania (Primăria Timișoara, 2018).

The logistics market in Timișoara is quite developed from a storage facility point of view. In the last decade, around Timișoara were built true logistics parks.

- VGP Park Timișoara
- CTPark Timișoara
- Timișoara Airport Park
- Dunca Logistic Park
- Olympian Logistics Park

VGP Park Timișoara (VGP, 2018) is located 8 km ENE from the city center easily accessed from E70 and near "Traian Vuia" International Airport and has a built-up surface of approximately 70000 m² of warehouse, production and administrative space. This logistics park suits for production facilities and service companies, showrooms and headquarters, warehouse and logistics and it offers turnkey custom-made solutions.

CTPark Timișoara (CTP, 2018) is located 10 km E from the city center with fast access to the A1 Highway and close to "Traian Vuia" International Airport and has a total built-up area of 32000 m², and also a planned construction of 61000 m². This logistics park offers flexible, long term lease, proximity to highway and airport, turn-key, built to suit solutions to fit clients' requirements, flexible options for dock levelers and loading ramps.

Timișoara Airport Park (TAP1) (Invest4SEE, 2017) is located in the NE part of Timișoara between the city ring road and A1 Highway. TAP is a modern industrial park with over 102000 m² of industrial and logistics space.

Dunca Logistic Park (AIC Industrial & Logistic Development, 2018) is located in the N of Timișoara, between the city ring road and DJ691. This logistics park offers over 45000 m² of logistics spaces and around 8000 m² of offices.

Olympian Logistics Park (GVA Activ, 2018) is located 11 km E from the city center and has a direct access from E70 being also close to “Traian Vuia” International Airport. This park offers more than 27000 m² of warehouse space.

We can see that all major logistics park around Timișoara developed near the A1 Highway and the airport, mainly because in Romania most of the freight is shipped on the road despite the fact that since 2010 Timișoara city authorities are trying to build a Regional Intermodal Freight Center (Primăria Timișoara, Monitorul Primăriei Municipiului Timișoara, 2010), but with all the bureaucracy the project was put on hold. A lot of freight is also transported on the rail road, by the national railroad transporter (CFR) or private companies. But there is no intermodal hub to connect the road and railroad shipment.

All the major companies that rented spaces in the logistics parks around Timișoara use this space only to store their products in order to a further shipment to client. The main function of these logistics parks seems to be the storage, so from this point of view, if we speak about the logistics functions, the logistics market in Timișoara is not so well developed. We don't have LSPs who can offer a solution to companies. Either we speak about transport of freight, or storage, but there is no LSP to offer this combined service, and also the infrastructure is not developed to help LSPs to ship freight via railroad with lower costs, and only to or from client with trucks.

The main advantage of the logistics parks around Timișoara is the proximity of the A1 Highway. In this way, the city is connected with Europe, that's why a lot of companies decided to invest in Timișoara. Also DHL, a well known logistics company decided to invest in a small cargo terminal at “Traian Vuia” International Airport, because the airport infrastructure can allow here also cargo airplanes. This can represent a big plus for the logistics parks situated in the proximity of the airport.

Clusters – Value Added Creators for SMEs

Mădălina Dumitrița Maticiu*

Faculty of Economy and Business Administration, Pestalozzi Bd. 16, Timișoara 300115, România

Abstract

Clusters support the competitiveness of SMEs and they foster the growth of economies in transition and developing countries. They give enterprises the chance to gain experience and to improve the services they offer. Before forming strategic partnerships, SMEs should evaluate their capabilities and their potential, and should take into account the fact that, inside a cluster, SMEs can benefit from the synergy between members that fosters the individual competitiveness. The purpose of this paper is to review the existing literature on creating added value by clustering and to identify the main research tendencies in this area of interest. The study focuses on improving our understanding of the relation between value and capabilities in SMEs partnerships formation inside clusters.

Keywords: cluster, Small and Medium Enterprise (SME), added value, competitiveness, innovation

1. Introduction

Competition between firms has become more and more fierce in recent years following the globalization process. As a result, SMEs have encountered several opportunities but also threats. Opportunities aim at creating multiple chances to increase individual competitiveness by going through a process of change (Mariana Predișcan (2001) argues that „... organizational change is an action, a set of actions, a process that aims to change, partial or total transformation of an organization, of its component elements or of the processes taking place here, allowing the transition from the present state to a desired future state, which differs quantitatively and / or qualitatively from the first. The objective of organizational change is to establish a new state, instead of the existing one”) and the threats are created by the small size of SMEs, reminders that can bring remarkable competitive advantages if SMEs are to cooperate with other private and public representatives to achieve the synergy effect. In this regard, clusters have been created in many countries of the world to support SMEs in gaining competitive advantage by disseminating various resources (human, material, informational).

2. Challenges for SMEs

SMEs (Small and medium-sized enterprises) are defined by OECD in 2000 as „non-subsiary, independent firms which employ fewer than a given number of employees. This number varies across national statistical systems. The most frequent upper limit is 250 employees, as in the European Union. However, some countries set the limit at 200 employees, while the United States considers SMEs to include firms with fewer than 500 employees. Small firms are generally those with fewer than 50 employees, while micro-enterprises have at most ten, or in some cases five, workers. Financial assets are also used to define SMEs. In the European Union, SMEs must have an annual turnover of EUR 40 million or less and/or a balance-sheet valuation not exceeding EUR 27 million.” (OECD, 2000).

SMEs are very specialized in their specific activities. „This increases the importance of effective interaction with other firms and public research institutions for R & D, exchange of knowledge and potential for commercialization and marketing activities.” (Tal A., 2017)

* Mădălina Dumitrița Maticiu Tel.: 0040256592563 ; fax: +40-(0)256-592500.
E-mail address: madalina.maticiu@e-uvt.ro.

The current business environment in which SMEs operate is characterized mainly by a strong competition, both at national and at international level. „SMEs have gradually become the "engine" of the national economy and human resources occupy a vital position in developing activities.” (Demyen S., 2012)

The European Union aims, based on the Europe 2020 strategy and through policies and programs to support SMEs to create an attractive environment for their emergence and development so that the EU economy becomes „the most competitive and dynamic knowledge-based economy in the world”. As Günter Verheugen, European Commissioner for Industry and Entrepreneurship, said: „ Europe's entire force is involved in supporting SMEs by involving all Europe's resources to support small businesses in their day-to-day work and to pave the way for those who want to create more jobs and develop in Europe and not only.”

Competitiveness is a more and more used concept by economists, which involves the ability to increase market share, profit and value added (Ramasamy, 1995). The low competitiveness in some of the Eastern European countries can be explained by the many problems they face. Much of the products made in these countries are sold at very low prices, and they often resort to intermediate distribution channels, and these markets are rich in imported products. Even the labor force problem is not to be neglected, much of the population in these states is paid with low wages, which is why a part of the population reaches work in more developed countries. People are active in various fields of activity, being one of the basic resources of companies. The quality of human capital is generally the result of population education and qualification. The abilities of individuals are sometimes limited due to the lack of knowledge and education. In SMEs, there is often a tendency to engage family members, relatives, friends and acquaintances, although they lack the necessary knowledge for the posts they occupy. Although there are many cases where such companies have not been successful, there is the opposite side, where SMEs have been family-owned businesses passed on from generation to generation and have retained their success over time. Outside the big urban centers in developing countries, the issue of the labor force itself, and not its quality, is a real obstacle. Labor migration is a real phenomenon in some countries, and this is a real problem for SMEs too.

To preserve the competitive advantage, SMEs must cope with competition, not only in terms of quality and price for the services or products offered but from the point of view of knowledge and technology. This has gone from pursuing a traditional competitive advantage to a modern one, creativity and innovation. Competitiveness and implicitly economic growth have as main factor innovation, and this is not only specific to developed countries but has spread throughout the world economy. Including the OECD recognizes that "innovation (...) is faster and more intense, more closely related to scientific research" (OECD, 2000). Creativity has become an entrepreneurial performance, the strategic approach being focused on identifying resources, capabilities, skills and opportunities. In order for the SME sector to create greater added value in the economy, SMEs are committed to becoming more innovative by creating products with increased added value. Clusters can help SMEs by taking over production and the marketing of these products on a much larger scale, but all of this through the efforts of SMEs to develop their entrepreneurial skills.

3. Gaining added value with clusters

According to Michael Porter, clusters „are new forms of organization (...) that offer advantages in terms of efficiency, effectiveness and flexibility.” He was the first person who offers the first most complex definition of the cluster as „ geographic concentrations of interconnected companies and institutions in a particular field. Clusters encompass an array of linked industries and other entities important to competition. They include, for example, suppliers of specialized inputs such as components, machinery, and services, and providers of specialized infrastructure. Clusters also often extend downstream to channels and customers and laterally to manufacturers of complementary products and to companies in industries related by skills, technologies, or common inputs. Finally, many clusters include governmental and other institutions--such as universities, standards-setting agencies, think tanks, vocational training providers, and trade associations.” (Porter, 1998).

A cluster is a form of innovation in organizing the business space with the potential to add more value than companies adopt a simple collaboration relationship. One of the central processes of adding value within the cluster is the transfer of knowledge. The main purpose of cluster policies in all countries is to increase the level of innovation, R & D and to achieve the clustering benefits of SMEs, start-ups, improved efficiency and added value (EU Best Practice in Cluster Development Policies, 2012).

Separating the cluster term from innovation is difficult to achieve. Innovation comes inside the cluster as a way of expressing an unprecedented experience that can create the network effect in terms of creating added value. Within the cluster, innovative ideas are supported through cooperation and collaboration, often cooperative to create new value for all stakeholder categories. Innovation can often suffer some bottlenecks mainly because of the costs and accumulated knowledge. Developing countries often face problems such as: the promotion of guarantee instruments is often inadequate, the profit obtained is insufficient to guarantee bank loans and the high innovation cost. Also, within the cluster appears the exemplification of the concept of co-innovation that has become increasingly important in clusters, especially in the context of a very competitive market like the current one. As more and more people use social technologies to get what they want from other people, rather than through formal channels, such arrangements are missing among the less experienced people. Co-innovation is a platform where new ideas or approaches from different

internal or external sources are applied differently to create new value or experience for all stakeholder categories, including for consumers. The core of co-innovation includes commitment, experience and co-creation of value that is difficult to imitate by competition. The co-innovation platform is built on principles of idea convergence, collaboration agreement and co-creation of stakeholder experience (Lee, S.M., Olson, D. L., Trimi, S., 2012). Organizations find it difficult to survive for a long time if they pursue their own interest, not emphasizing shared value with stakeholders. In this context, we can talk about the commitment of all members, the acquired experience, innovative ideas, and of course the collaboration agreement between the cluster members.

SMEs involved in clustering must make real and useful decisions, considering the widespread availability of competitive and opportunistic information, the development of technologies and the speed of change that is the same for all competitors. To do this, businesses must have well-defined skills to identify, select, collect and process data and information, and transform them into knowledgeable decision-making. Companies also should have a tremendous anticipation capability in the complex and turbulent environment in which they work, proactivity being a challenge not only at the organizational and regional level but also globally.

One of the early forms of a cluster was the industrial cluster as a group of enterprises and non-profit organizations for which cluster membership is an important element of the individual competitiveness of each member firm.

Buyer-supplier relationships within the industrial cluster have led to the formation of the concept of a cluster based on the value chain. A cluster based on the value chain is an industrial cluster identified as an extensive chain of entry-exit or buyer-supplier. This includes final market producers and three levels of suppliers that engage directly and indirectly in trade, consisting of several sectors or industries (Roelandt, den Hertog, 1999). A cluster of the value chain is in line with an industrial cluster as defined by Czamanski and Ablas: "A subset of the industries of the economy linked to stronger flows of goods and services than their association with other sectors of the economy

national "(Czamanski, Ablas, 1979). It can also be defined as a potential where businesses can or cannot carry out commercial activities among themselves, but they may eventually take place in the future.

Where entrepreneurial culture is not well outlined, there is a low interest in innovative activities, research and development and partnership. At European Union level, it is trying to support scientific research and the implementation of results that have not been applied before, encouraging performance. Nadvi and Barrientos 2004, considered clusters as a tool for poverty reduction, especially in extra-urban areas where the informal economy predominates and where SMEs predominantly employ unskilled workers. In their conception clusters are dynamic and engage in increasing the degree of innovation of their products, in switching to activities and functions with higher added value and in disseminating the accumulated experience to increase the competitive advantage. „Fostering public-private partnerships and small-firm networks and clusters may be the most expeditious path to a dynamic SME sector... Clustering facilitates the exchange of personnel and diffusion of technology and creates new possibilities for efficiency gains.” (OECD,2000).

Surely the decision to be part of a cluster is not easy to take. SMEs typically use local resources, have developed a certain attachment to their local business partners. To join a cluster, SMEs can decide pooling resources acquired selectively or wholly, for example only a part of the value chain or the entire chain of the whole company. Depending on the size of the SME, they can contribute to cluster both with activities with high added value (such as research, development, design, after-sales service) and with those that have an added value lower in the value chain (such as manufacturing, processing and basic services). One of the benefits of belonging to a cluster is that low value-added activities are not outsourced to emerging economies and those with high value to more advanced economies. The small size of SMEs requires material profits not so substantial that does not allow them to create an experience of lending needed to develop, investments do not amount to sufficient values to improve existing technologies (often wear and tear and obsolescence) and not infrequently due a poor business culture is geared towards creating value-added products or services with little added value.

Once part of a cluster, SMEs benefit from a set of advantages given by what a large company is, namely everything that was considered a disadvantage due to the small size of SMEs is now becoming an asset because it is a part of a large company, and besides, it will not have to remove the two main advantages of a small company, namely specialization and flexibility. According to Schmitz and Nadvi in 1999 „clustering helps firms to ‘overcome growth constraints and compete in distant markets’”.

In its Communication COM (2008) 652 "Towards the setting up of the world level in the European Union - implementation of a comprehensive innovation strategy " the aim of EU is to support the development of clusters as a strategic priority for sustainable economic growth. The communication referred to several ways to promote clusters in the European Union by creating new policies and continuous improvement of existing ones, promoting national and international cooperation within the clusters and by fostering the integration of many small and innovative media in clusters. Through the same document, the European Commission is committed to supporting Member States in formulating clustering policies, ensuring communication infrastructure at European level, supporting cluster integration of innovative SMEs but calls on Member States to adapt national policies to European ones , to support the involvement of SMEs in clusters in line with the recommendations of "smart specialization" and to engage in ensuring synergies and complementarities between clustering policies.

4. Conclusions

Clusters are constantly looking for durable solutions for their businesses, interactions that go beyond the cluster value chain become evident. Of course, the specialization of a company in a particular branch may cause the need to identify another within or even outside the cluster if the entire economic agglomeration is focused on a single industry if the market requires integrated products and services. The ability of companies within a cluster to cooperate with the outside grows as there is easy access for outsiders to engage in cluster activities. Including public authorities, special attention has been paid to this type of cooperation not only at the national and European level. Collaboration between cluster members allows them to make innovations that would have been individually difficult to build. Thanks to the collaboration and physical and communication proximity between cluster members, it is much easier for them to do incorporate downstream or upstream knowledge into the value chain and thus bring competitive advantage within the cluster. The main advantage of innovation co-operation is given at cluster level precisely by the relations between the members, not only cooperating and in a competitive relationship, the desire to overcome the rivals' performances giving rise to cooperative innovation.

Analysis of companies' behavior in smoothing conflicts of interest

Tatiana Dănescu^a, Maria Alexandra Botoș^b *

^aUniversitatea Petru Maior Târgu Mureș, România

^bUniversitatea 1 Decembrie 1918 Alba Iulia, România

Abstract

Within corporations and large entities, some internal policies and practices are typically designed and regulated to prevent and resolve conflicts of interest. Multinational entities, especially those listed on the stock exchange market, elaborate codes of ethics or internal standards that guide all persons who have contact with the entity, including collaborators. Through this paper, we aim to identify the behaviour of the above-mentioned entities on an international level, regarding the conflict of interest and its risks.

The results presented are based on a quantitative and qualitative analysis of a sample of 177 multinational entities around the world. In order to achieve the purpose of this research, we took into account over 321 guides, manuals, standards and conflicts of interest policies that were made public by the entities in the selected sample.

Keywords: Conflict of interests; Risk management; Management; Companies' Behavior; Code of Ethics.

1. Introduction

The phrase conflict of interest is associated in particular with terms such as fraud or tax evasion, but according to some opinion it can only evolve in fraud and tax evasion if the conflict of interest is not effectively managed. However, non-identification and recognition of conflicts of interest may lead to risks that are closely linked to the reputation of the entity and the loss of public confidence; moreover, a decision based on a conflict of interest is in most cases vulnerable and can be challenged in judgment. However, it is worth mentioning that there are situations in which allowing the manifestation of conflict of interest brings a benefit to the entity, over the scenario in which it would have been prevented.

Thompson D.F. (2009) argues that the emergence of conflict of interest is due to a set of circumstances that are responsible for creating a substantial risk that the professional judgment of a person of primary interest is influenced by a secondary interest. This definition is included in the Report on Conflict of Interest developed by the United Kingdom Audit Office and is in line with international audit standards. The Romanian legislation defines conflict of interest as the situation or circumstance in which the direct or indirect personal interest of a contracted person is contrary to the public interest in such a way that it affects or might affect its independence and impartiality in taking decisions or objectively fulfilling the duties of the person.

Therefore, we consider the conflict of interest to be classified according to the entities affected by its manifestation in: Conflict of interests on the public environment and conflict of interest on the entity's internal environment. We define the first type of conflict of interest as the accumulation of intrinsic and extrinsic conditions that trigger an action to obtain a benefit, which is in detriment of a third parties' interest, anyone except the employing entity. The second type, the conflict of interest regarding the interest of the employing entity, we consider to be the accumulation of the intrinsic and extrinsic conditions that lead to the manifestation of an action for the purpose of obtaining a personal or professional benefit, which can affect positively or negatively the employing entity.

2. Research methodology

The process underlying this research is primarily aimed at identifying the risks posed by the conflict-of-interest behaviour of multinational organizations. The approaches that we have taken to achieve this results are: fundamental research, based on the theoretical documentation and critical analysis, carried out with the help of the professional experience and the previously accumulated knowledge from the field of ethics of behaviour and internal control; comparative research, between international frameworks in which conflict of interest is manifested; causal research based on qualitative analysis of multinational practices and policies; empirical research based on a combination of quantitative and qualitative analysis of the predetermined sample set for research.

The first stage of the research aimed specifically at identifying the practices and policies of entities, on conflict of interest, at an international level. The proposed objective was achieved through the process of documentation and comparative analysis of the existing framework at national, European and global level. The second stage aimed at presenting organizational practices and policies on conflict of interest resolution and prevention. This objective was achieved through the analysis of the information resulting from the documentation process.

Finally, the third stage aimed specifically at identifying practices and policies to smooth the conflicts of interest used by multinational organizations. The empirical study, that stood at the foundation of our efforts to identify practices and policies to mitigate conflicts of interest used by multinational organizations, was achieved through the quantitative and qualitative analysis of 177 entities selected from the 540 multinational list of Forbes International, the main selection criteria being financial indices: turnover, profits and total assets, and the disclosure of their conflict of interest policies on the public domain, such as government sites or sites of the entities being analyse.

3. Practices and policies regarding the conflict of public interest

From our professional experience, we have noticed two situations in which the conflict of interests is strongly associated with the decision-making process, namely: in the case of affiliated transactions and in the case of shareholder loans. Therefore, we have resorted to analyzing these two situations at an international level to observe the level of risk it presents. We consider relevant the comparative analysis of the legal framework in which the conflict of interest is present in the case of transactions between related parties, especially at an international level. In order to carry out this analysis, I proceeded to the elaboration of Table 1.

Table 1. Comparative analysis of the conflict of interest framework for affiliate transactions

	National setting	Other European countries	Other countries in the world
	Market Value and Price transfer Principles		
Legislative framework	In Romania, in commercial or financial transactions between affiliated parties, if the nature or characteristic of the transactions made, differ from those that would have occurred with another independent entity, any amount of profit that would have been realized by one party may be included in the profit tax base. According to the legislation, Romanian Law 207/2015, it is necessary to carry out the price transfer dossier, which is used as evidence for the tax authorities.	At European level in June 2006, the European Council adopted the Code of Conduct on Price Transfer. Entities in the Member States are obliged to apply both the code and the national legislation. There are also avoiding double-taxation regulations such as Directive 2011/96 / EU on the common tax regime applicable to mother companies and their subsidiaries in different Member States.	At international level, the Organization for Economic Cooperation and Development has contributed to the international harmonization process by providing a Guide for Price Transfer for Multinational Enterprises and Tax Administrations updated in 2017.
	At present, in Romania, the legislator encourages the creation of groups of companies, but profit tax determination is not acceptable based on tax consolidation system. This gives the group the opportunity to manipulate financial results within the group through transactions and transfers.	Fiscal consolidation In 2011, the European Commission drew up a proposal to implement a consolidated tax base, by this proposing a single set of rules for the whole Europe. The proposal was re-launched in 2016 but was not approved by the European Council.	In the USA and Canada there is a form of fiscal consolidation called formal distribution. Formal distribution is a method of allocating the profits of an entity or a group to a particular tax jurisdiction in which the entity is taxable, and by this there rest of the entities of the group are not taxed separately.

Source: Made by the authors based on information from the documentation process

The structure of the table being focused on two broad concepts that we have found as international practices and which, according to our professional experience and literature, are strongly correlated with the conflict of interest in the case of transactions between affiliated parties, namely: the principle of market value and price transfer and the consolidated tax base.

According to a theory developed by Hyde and Choe (2005) in practice, two types of price transfers are used: the taxable price transfer, used to obtain the most favorable tax result and the incentive price transfer, used to provide appropriate incentives for off-shore assets. As can be seen in Table 1., at international level, many steps have been taken to reduce the risk of conflicts of interest. Currently, we have identified two situations of affiliated parties' loans that are related to the conflict of interest and are being conducted at an international level, addressed in Table 2, namely: shareholders crediting the entity or shareholders loan and the entity loaning to the directors.

Table 2. Comparative analysis of the legal framework for the related parties' loan

	At an national level	At an European level	Worldwide
Legislative framework	Shareholders Loan		
	In Romania according to the present legislation, shareholders and associates are allowed to credit the entity by charging related interest with restrictions only in the case of cash payments, in which case the legislation permits transactions amounting to a maximum of 10,000 RON (national currency) between individuals and commercial entities in the case of loan.	There are no directives at EU level with precise specifications in this regard. Rules similar to those in Romania are also found in France. Meanwhile other states are legislating this case in the code of insolvency, for example England and Germany, where an associate loan is only accepted as to save the entity from bankruptcy.	In China, the loaning of the entity is often seen by tax authorities as a capital contribution which is not recoverable so fast as a firm loan, in order for it to be qualified as a loan, the entity has to provide a mortgage to the shareholder to secure the loan.
	Loaning to the administrator or directors		
	Currently, the Romanian legislation, Law 31/90, only regulates the administrator's loan by the entity. Under the law, loans to the administrator are forbidden unless their due amount is less than € 5,000 and if the lending terms are not different from the terms of credit to others or are not an exception to the entity's current activity.	There are no directives at EU level on this issue. In England, loans may be granted to directors with the approval of the General Assembly. In Denmark, credits to directors or associates are recognized as wage entitlements or dividends and taxes are charged correspondingly.	In the US, granting a loan to one of the shareholders is permitted provided that the interest rate is above the monthly rate set by the federation. If the interest is below the required level, the loan is given the name of "below market level loan" and becomes taxable. A similar approach is also found in South Africa, where loans that have interest below market level or other suspicious circumstances are considered to be dividends or wage entitlements and are taxes are charged.

Source: Made by the authors based on information from the documentation process

In Romania, the legal framework is more permissive in terms of loaning the entity and lending to its directors than to other countries in Europe or the world. In Romania it has become a trend for the money invested in the establishment of an entity to be considered credit provided by the associate and to be subsequently recovered as to cover absence of money from the treasury. In the literature, we have noticed this inclination to address only the situation of a shareholder loan if the entity is in a poor financial state or in the event of bankruptcy.

The scientific literature presents methods of identifying conflicts of interest relevant especially to the person who is the subject of this phenomenon. As follows a series of manuals and guides have been produced, but such techniques are also used to make codes of ethics of multinational entities for employees and management, this being more or less detailed. The general consideration is that under certain circumstances the act of declaring the potential or actual conflict is sufficient to adequately mitigate or manage the conflict of interest. According to a manual made by the Institute of Medicine there are two models of conflict of interest management, namely: the prohibition model, which specifically defines conflict of interest rules and the consequences of their violation; the model of disclosure and evaluation, which is taking into account guidelines mentioned in the previous paragraph.

Due to this we considered it relevant to classify the conflict of interest according to the related risks, stating that the number of risks is not limited to those mentioned in this classification:

- Financial conflict of interests: refers to the risk of financial loss that the entity may suffer, it can be more easily identified in comparison to the other categories, but the underlying reasons may not be the most influential;

- Professional Conflict of interests: refers to the risk that the trust and image of the entity in the collaborators and clients view may suffer;
- Informational Conflict of Interest: refers to the risk of loss of informational confidentiality.

4. Case study on the domestic practices and procedures of multinationals

In order to have a clearer picture of what the international conflict resolution behavior means and how it is manifesting, we appealed to the analysis of a sample of 177 global entities, chosen on the basis of three financial criteria; turnover, registered profit and total assets and the condition to have disclose public codes and policies on conflicting interests. The distribution of the sample by geographical area can be seen in Figure 1.

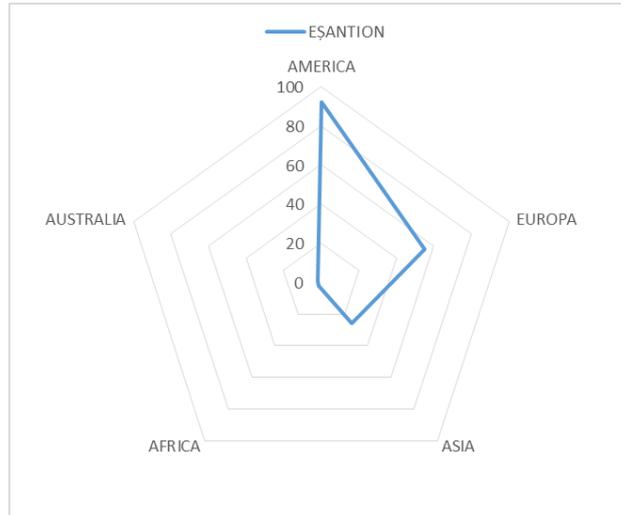

Figure 1 Batch distribution based on geographic areas

The first step in analyzing the sample was to identify subjects who published relevant conflict of interest information and whether they were updated over the past two years. Note that for the purpose of data processing, we used the IBM SPSS Statistics 25 program, and the Cronbach Alpha coefficient was equal to 2.88, certifying the consistency of the sample as an excellent one. We also mention that each subject of the sample has in some cases presented multiple manuals and guides on conflicts of interest practices and procedures, each of which is intended for a different category: employees, management, board of directors and collaborators. The analysis was extended to all identified conflicts of interest information, with a total of 321 manuals, policies and guides analyzed.

A second step in our research has been to identify the type of conflict management model used by each subject and whether there is a correlation between it and the staff responsible for conflict resolution and management of conflicts of interest. The analysis resulted, according to Table 3 processed by the SPSS Statistics 25 program, that 47.5% use the prohibition model by clearly specifying what is allowed and what is not allowed, in some cases with the indication that any employee who is unable to decide whether or not he is in a conflict of interest situation to address his superior or a named person. The 51.4% left use the disclosure model, referred to in the manuals sometimes as Whistleblower policy, in which case concrete examples of potential conflicts of interest are shown, so that the employees will understand what it signifies and so that they are motivated at any time if they realize that they are in a conflict of interests situation or are in uncertainty that they are, to address the person responsible.

Table 3. Analysis of the sample composition according to the management model

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	.00	2	1,1	1,1	1,1
	1,00	84	47,5	47,5	48,6
	2,00	91	51,4	51,4	100,0
	Total	177	100,0	100,0	

Source: Generated by the SPSS Statistics Program 25

In the research, we found that some of the subjects created special compartments for the management of compliance of employee behavior with the code of ethics, some assigning this task to management, and others did not mentioning who is responsible for this task. Therefore, we considered the SPSS verification of the correlation between the model used and the existence of a special compartment dedicated to the compliance of the employees' behavior with the code of ethics. According to Table 4, as can be seen, the bivariate correlation is 0.37 greater than the recommended limit of 0.01, therefore it is significant. We find that subjects using the prohibition model tend not to mention who is responsible

for the task of managing employee behavior compliance with the code of ethics, and those using the disclosure model assign this responsibility to management and the Compliance Bureau at an equal level.

Table 4. Bivariate correlation between the model used and the department responsible for managing the behaviour of employees in the code of ethics

		Model used	Responsible
VAR00009	Pearson Correlation	1	,372**
	Sig. (2-tailed)		,000
	N	177	177
VAR00008	Pearson Correlation	,372**	1
	Sig. (2-tailed)	,000	
	N	177	177

** . Correlation is significant at the 0.01 level (2-tailed).

In addition to the quantitative analysis, we present the following practices identified in conflict of interest codes and practices that have been noted and considered relevant to the study:

- Some codes specifically mention the fact that it is forbidden to grant loans to employees and executives employed, to avoid conflicts of interest;
- A significant number of entities state in the Code that if conflict of interest cannot be avoided, it should be treated fairly while others state that in some cases, if possible, the person concerned will be required to cancel or remedy some actions;
- Certain entities such as Bank Rakyat, British American Tobacco and Brookfields are annually requesting their employees' reports on the conflict of interest from the previous year;
- Citic Securities mentions the use of the Chinese wall method to prevent conflict of interest, which is to restrict the flow of information from one department to another, in particular due to the financial and confidential quality of the information. Restrictions including physical (geographic location) and digital restrictions, employees are not allowed to communicate by e-mail.
- Dai-ichi Life have created special roles for monitoring conflict of interests, they are called group monitors, and the person who is in this role has an obligation to report any apparent or possible conflict of interest;
- Some entities such as Boeing have presented questionnaires by completing of which employees can see whether they are or not in a conflict of interests;

Following the qualitative analysis of the above mentioned codes, manuals and procedures, we identified the following risks, which are advisable to be considered in the future:

- Risk of non-identification:
 - Considering the Chinese wall model used by some companies, we express a reservation on the guaranteed functionality of the conflict of interest method, and we want to emphasize that the isolation of departments can lead to a difficult identification of conflicts of interest by the management or department responsible;
 - Most entities rely totally or to a certain extent on self-identification and self-declaration in the event of a conflict of interests by employees, in our opinion this method is not guaranteed and needs a solution to complement it.
- Risk of noncompliance:
 - Considering that employees complete some questionnaires and reports at the end of the year, the risk that they are not in line with reality is very high due to the lack of a verification and control system;
 - Also, due to the limitation of this study, we emphasize the possibility that the practices and procedures elaborated in ethics codes and guides may not be implemented in the entities is very high, due to the fact that there is no evidence of this process.
- Conflict risk:
 - Because of the Whistleblower policy, there are risks of creating conflicts between employees. Considering that each of them has to declare apparent conflicts of interest, without the need for evidence to underpin their claims;
- Risk of no conformation:
 - By observing the prohibition model in ethical codes, we have identified a very harsh and rigid language and that it contains all the interdictions that employees have in their personal lives and the consequences that they might suffer in violation of these regulations. We believe that such an approach is inefficient especially for young and non-conforming employees.

5. Conclusions

We conclude that there is currently no certainty that existing practices ensure transparency and disclosure of conflicts of interest. Consequently, the entities behavior of conflict resolution is difficult to track and test, but from the analysis we identified the following types of risks that arise from current practices:

- According to the analysis of scientific literature: financial risk, professional risk, risk of confidentiality of information
- According to the analysis of the study sample: the risk of non-identification, the risk of noncompliance, the risk of conflict and the risk of no conformation.

However, we would like to mention that this list is limited to the sample studied and the information obtained from the analysis process and we do not consider that the risks of conflict of interest are limited to it. In addition to this study, in the future we take in consideration to conduct an analysis of the situation of entities in Romania and their behavior regarding the management and resolution of the conflict of interest.

Analysis of managers' behavior in Industrial Companies in the North West Region

Alina Natalia Pop*, Gabriel Rus

Technical University of Cluj-Napoca, Faculty of Engineering and Management Romania,

Abstract

Managerial analysis is an important element in the development process of any organization, bringing to the fore the human resource and the results obtained by it.

The behavior of each manager depends on three characteristics that are determined by heredity, education, and mentality. Managers need to adapt their behavior to the group or team of employees they lead in industrial firms to create a pleasant and effective workplace atmosphere, and it is necessary to adhere to certain rules of behavior towards subordinates.

Managerial behaviors analyze leadership styles, differentiated by human resource categories, into authoritarian, democratic and laissez-fair styles. One of the characteristics of efficient managers is their flexibility, due to the continuous flow of major changes in industrial firms and technologies.

The behavior of the manager can often be influenced by his membership of a particular organization. Some organizations have rules so strict that the manager can not put into practice his own leadership style. In this situation, personal preferences are not taken into account, only what the organization considers to be fair behavior is accepted.

The rich and continuous data flow of information that is absolutely necessary for decisions is inconceivable in conducting activities in an industrial firm as well as solving problems. Managerial behavior means knowledge, experience, data and ideas about business opportunities.

Keywords: consumer, competitiveness, the human resource, industrial firms

1. Introduction

Man's ability to know is inseparable from his ability to evaluate, making selection and systematization of information possible. Whether it targets goals, phenomena or processes, placing a certain scale on a certain position usually determines attitudes, decisions and actions.

This spirit of innovation and entrepreneurial spirit, driven with integrity, devotion and ethics, was part of the vision of management within industrial firms.

Industrial firms are distinguished by ethical relationships within existing networks, being a strong feature distinguishing themselves from other companies.

Industrial firms believe that their results are incontestable due to their basic rules, of which the most important is ethics. Doing business properly is the motto of industrial firms, and each employee, managerial, has the responsibility to read and understand the principles of the Code of Ethics: law enforcement, integrity of registration and reporting of financial results, proper maintenance, accurate and complete records financial compliance, respect for human rights, quality delivery through quality services and products, ethical competition - competitive advantage through superior performance, respect for diversity and fair employment practices, avoiding conflicts of interest - avoiding relationships or behavior that could compromise judgment create apparent or real conflicts between personal interests and loyalty within them, protecting goods and information, confidentiality of information and data about employees, integrity,

compliance with laws, rules and special regulations that relate to government contracts and relationships with government personnel, the environment, health and safety becoming global leaders in defending the health and safety of our employees and protecting the environment.

2. Problem Statement

The assessment of the managerial activity results within the industrial firms, the objectives and the relations developed, is a condition of managerial adaptation. The evaluation allows for the correct identification of the deficiencies and the means that led to their realization, as well as the possibility of improvement of each evaluated person. The performance appraisal system must always be linked to the company's specificity as well as to other human resources policies. It will not be considered as an activity in itself, but should be related to the identity of the industrial firms of certain organizational aspects: structure; values; benefits of evaluation, organizational development measures; training system, development of career plans; promotion and relegation system, etc. (Pânișoară, 2017).

Most of the time, when we think about the role and impact of evaluating managers' performance on the other components of human resources management that they are developing, we ask ourselves the following questions: How should I make the assessment?; Where should I start?; Where do I need to go?.

In order to get answers to these questions, it will start from Ralph W. Tyler's analysis, which involves highlighting an axis that has the conception of activity at one end, and at the other end the objectives of the industrial firms.

From this point of view, we notice that in practice we will meet five types of balance between the goals of the firms and the results obtained by the manager.

The ideal model, results and goals are equal, the companies has proposed something, and the manager has achieved the following goals:

- a) The ratio in which the objectives of the industrial firms are much higher than the employee's possibilities.
- b) Report against the previous situation.
- c) Intersection model - when the employee achieves only some of the objectives required by the cluster, but there are goals obtained outside the employer's requirements.
- d) The least desirable case - the ratio of the industrial firms' objectives and the employee's results are zero. (Pânișoară, 2017).

In order to make these equilibrium patterns easier to remember, they are shown in figure 1:

Fig. 1. The five types of balance between the objectives of the industrial firms and / or the department and the results of the employee (Pânișoară, 2017).

Feedback can be considered as having only an evaluation purpose of the performance of individual attitudes and behaviors, but can also serve as a way of streamlining communication within the organization (setting goals, feedback, drawing up the action plan, implementing the action plan, evaluating results) (Bocean, 2015)

3. Research Questions/Aims of the research

The notion of personality is all-encompassing, referring to the individual's behavior and how this behavior is organized and coordinated in the interaction with the environment.

The personality of the manager is involved in all the hypotheses and roles within the industrial firms. It gradually builds, over time, effective practice with a particularly important role in shaping and finalizing it.

There are two categories of requirements requested by the manager:

- 1) Personality requirements: Constitution and temperament of the subject; Physical environment; Social environment; Habits and skills gained under the influence of previous influences.
- 2) Requirements relating to intellectual qualities: Intelligence; Ability to recognize; Ability to accept and apply the new one; The ability to think clearly; Memory; Imagination; Predictability; Practical thinking; Theoretical thought. (Gabriela and Cibela, 2009).

The performance of industrial firms is the result of mobilizing the resources they have.

The characteristics of this assessment that distinguish it from the rest of the traditional assessments are:

- Operates with a set of evaluation samples.
- It can only be made by people or firms specializing in this.
- Assumes collaboration between the employee and the evaluator.
- The evaluation activity has a permanent carcass.
- Ensures interaction with the outside environment by reporting employees' performance to those profile firms.

Position analysis in a small and medium-sized enterprises appears in four assessment situations:

- 1) When defining the need for personnel of industrial firms.
- 2) For promotion policy within industrial firms.
- 3) When preparing the training plans.
- 4) To re-establish the salary scale. (Dorel U, 2001)

These principles are the directions of action to be followed throughout the performance management process, defined as follows:

1) Excellency of services - each employee must contribute to the improvement of services and to the satisfaction of internal and external customers by identifying their needs.

2) Improving the quality and safety of work - each employee must be based on maintaining his / her activities of quality and security.

3) Support and development - each employee must have the resources to meet his / her goals within the industrial firms, be provided with the necessary assistance and support to continuously improve the results.

4) Responsibility - Every employee must use the resources he / she has in an efficient and timely manner.

5) Involvement - Every employee must continue to achieve the organization's goal. (Bocean, 2015)

Performance evaluation is two ways:

1. Non-formal evaluation: whether or not it is necessary, the daily relationship between the manager and the employee.

2. Systematic evaluation: it is required to take place at certain intervals, once or twice a year. This type of assessment involves direct contact between the manager, eventually assisted by a human resources and employee, the recording of impressions and remarks on the performance of employees is done in writing. (Liviu G. and Maria G, 2004)

4. Research Methods

The APEX evaluation, reward and motivation model can be highlighted in Figure 2:

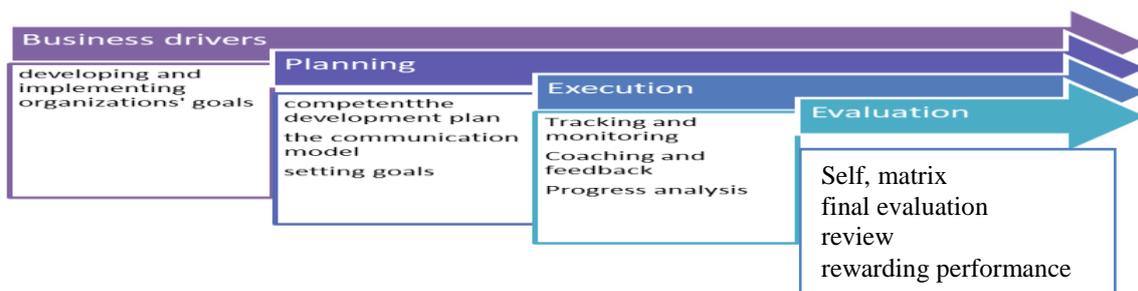

Fig. 2 APEX process; Source: own processing APEX

Coaching and continuous feedback

Business initiators: Planning - Execution - Evaluation - Excellent performance; Developing and evolving, organizational goals are the initiators of the business

Planning: November – January 1. Goal Setting 2. Competencies 3. Development Plan 4. Assessing the Leadership
 Execution: Throughout the year 1. Evolution and progress monitoring 2. Coaching and feedback 3. Verification of progress at the semester (June / July)

Evaluation - November - January 1. Own evaluation 2. Matrix and introduction of level 2 managers, 3. Final evaluation, 4. Evaluation session 5. Performance reward.

By using the APEX program, managers and employees plan and manage their performance so that they can achieve excellent performance from "do my job". Performance management and success in industrial firms.

Apex will help us: To be more valued on the market. This vision is determined by:

- What customers say: We want to do more business with this company
- What the shareholders say: This company is one of my best investments.
- What the employees say: I am proud to be part of this team.

Companies select the best and take responsibility for the quality of everything they do. Removes all barriers to achieve goals, to accomplish them quickly and efficiently, without compromising quality: Health and Safety; Excellency; Involvement; Communication; Remuneration; Study, Responsibility; Innovation; Commitment.

The basic steps for evaluating APEX include:

- Setting and tracking objectives;
- Choosing the necessary skills;
- Creation of the development plan;
- Granting and accepting coaching & feedback;
- Completion of performance assessments.

Evaluation results Apex MFG 2017

- Approximately 1250 direct and indirect employees (SCMs) were assigned and evaluated (including calibrated).
- Most supervisors have subordinated dozens of employees who received the objectives, were evaluated, calibrated, completed the evaluation sheet, brought to the knowledge, provided the copy of the card.
- Distribution of quotations received after the evaluation was:
- The quotations received after the evaluation was:

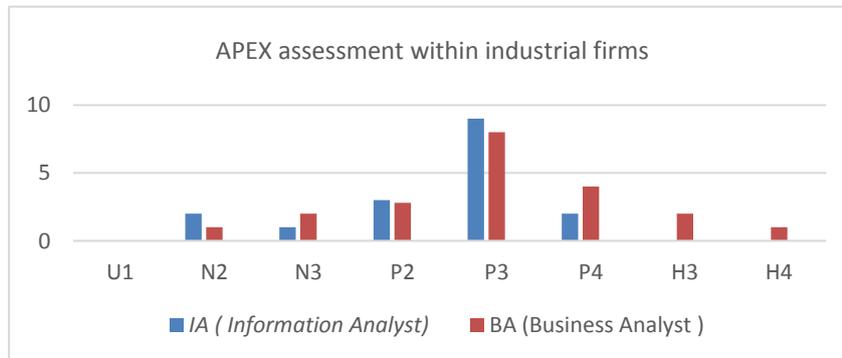

Fig. 3 Apex MFG 2017 rating; Source: own processing

Categories of objectives offered

- Health and safety (wearing protective equipment all the time and reporting at least a near miss or observation)
- Quality (constructive participation in maintaining the rebuttal in the set target)
- Productivity (compliance, achievement of the individual efficiency indicator)
- Lean (respecting and supporting Lean tools applicable to the workplace - SW, TPM, improvement ideas)
- Customer Satisfaction (Ensuring good production flow, timely and correct materials preparation for internal and external customers to reduce the number)

Requested skills:

- Professional knowledge (knows the process and working well, does not require guidance, can work on several phases of work)
- Involvement-orientation on individual and team goals (most often agree with overtime and change of work)
- Labor discipline (complies with the rules, does not have disciplinary sanctions)
- Communication and teamwork (communicates well with positive relationships with others, helps when needed)
- Learning and development (maybe and wants to learn, ask questions, make an effort to learn)

Improvements to the process:

- Introduction of the Lean objective.
- Closer (individual) expression of objectives.
- Reforming skills descriptions to allow employees who know how to work on multiple work phases.
- Provide a copy of the 2017 Employee Assessment.
- Delivering goals to indirect workers from production

Findings:

- Offering new employees' goals, returning or changing jobs and joining another type of employee - within 30 days of hiring.
- Enhance the familiarization of employees with the objectives and skills required, their reminders at any occasion, given explanations and examples.
- Encourage employees to report near miss misses and ideas for improvement.
- Establish measurable indicators for assessing objectives and competencies.

Employees are assessed through APEX, the formal process of process performance management that supports the growth and progress of society by setting measurable goals, honest discussions and performance feedback. This annual process consists of ongoing performance feedback and performance coaching as well as a half-year performance discussion in the form of an assessment of progress and an end-of-year evaluation. APEX users are rated with a double performance rating, consisting of an alphabetical score for results and a numerical assessment for the leadership and demonstration of functional competence.

Evaluating the performance of the companies managers is done according to the APEX process. Managing individual performance is important for corporate success and is practiced by everyone starting from the general manager to the last worker. Performance means both things, namely, how and how everything is done.

Responsibility implies acceptance of objectives that are challenging as well as open and constructive feedback.

- Whoever needs development, anyone!

Developing is not just the problem of those experiencing difficulties in achieving performance or those who want to promote in leadership positions.

Creating an annual development plan helps to focus on study and continuous performance improvement.

- APEX manager tasks
- Set cascade goals for everyone in the team.
- Explain what is expected from employees, emphasize the goals to be developed.
- Ensure coaching and continuous feedback.
- Identify remarkable contributions.
- Ensure that you have development plans that meet the highest level of satisfaction, contribution and give the team added value.
- Ensure at the end of the year a comprehensive assessment and performance appraisal that will be discussed with employees at a meeting.
- Finalize on time through the APEX process.

APEX means achieving the goal, performance and excellence.

By using the APEX program, managers plan and manage their performance so they can get excellent performance from "do my job".

- Basic steps include: Fixing and tracking goals; Choosing the necessary skills; Create your development plan; Granting and accepting coaching & feedback; Finalizing performance appraisals.
- Objective: The results for which they are responsible: They are measured and evaluated at the end of the year; It helps to distinguish between good performance, a good one or a higher one.
- Task: An activity that is required to achieve a goal; It is just "a way to end," not a plus of value in itself; It has no unit of measure; It is not included in the on-line personal evaluation form; Task setting in APEX is optional.
- Measure: What measures or checks will be undertaken to ensure that the target has been successfully achieved. They can be both quantitative and qualitative.
- Scope: Fix monthly, quarterly, or half-timer interim endorsements to help track the progress of a measure; Goal setting in APEX is optional; Competencies define the "how" of performance

A. Assessment of attributed competencies

- Employee individual competencies are important for the successful completion of any activity carried out in industrial firms.
- Competencies of senior management are important for successful completion of any management activity in industrial firms and will be automatically selected for managers and managers who have at least one employee subordinate. Competencies include the four dimensions of the leadership model:
 1. (Linke Dreiecksseite) Think & Act Strategically - Business Spirit; Vision and goal; Intellectual rigor.
 2. (Rechte Dreiecksseite) Get Results - Successful Skills; Change and adaptability; Effective use of resources.
 3. (Dreiecksbasis) Structuring the organizational capacity - Managerial Courage; Responsibility; Developing and motivating staff.
 4. (Rechteck unter dem Dreieck) Demonstrates leadership skills - Talent in interpersonal communication; Professional estate.

B. Apex Evaluation Process

- Achievements: Excellent; Extremely powerful; Performance; Requires improvement; Unsatisfactory.
- Conduct: 5 excellent skills - good model to follow; 4 very competent; 3 understands expectations; 2 proof of unconsciousness; 1 low –problematic.

C. Matrix of double evaluation

O1	O2	O3	O4	O5
H1	H2	H3	H4	H5
P1	P2	P3	P4	P5
N1	N2	N3	N4	N5
U1	U2	U3	U4	U5

Fig. 4. Matrix of double evaluation; Source: industrial firms

O - Outstanding - Excellent Achievement of Service Obligations. Achievements and Outstanding Achievement Outcomes.

H - Highly Effective- Extremely efficient in performing service tasks. Taking into account the degree of difficulty of the objectives, the available resources and the changes made during the year, had an irreproachable conduct.

P - Performance - Good performance in fulfilling the responsibilities of the service to find ways to 'overcome standards' of their own performance (on in-service training) and taking into account the difficulty of the proposed objectives, the available resources and the changes that occurred during the year, achieving the objectives were particularly satisfactory.

N - Need Improvement - Needs improvement with regard to continuous service tasks and / or needs for improvement and achievement of objectives. She can be responsible, but she needs to come up with more initiative and find a way to continually improve. It could be improved through coaching, feedback and a refinement plan.

U - Unsatisfactory- Unsatisfactory - it has shortcomings in terms of performing the service tasks and / or obtaining results. It is strict, requires a long-term improvement.

5. Conclusions

Within industrial firms it can be noted that the level and training of human resources is very important for a good day-to-day process. Their assessment of both employment and well-defined time is essential. Emphasis is placed on both the professional qualities and the character of the staff, trying to create a favorable climate, considering that, in a pleasant environment, favorable results are increasing.

The evaluation method used is Apex. This was chosen due to the potential of establishing the evaluation criteria.

The study highlighted the fact that a function should be evaluated in its entire complexity, each feature being extremely important for a company to function properly in terms of its structure.

Motivation and attitude towards work is of individual importance, reflecting his attitude towards work, but also at a collective level, which must be an example in this respect.

In conclusion, the method and way of assessing human resources in industrial firms are chosen in order to facilitate the execution and management processes, following the personal and professional development of their employees, in order to benefit from the highest level of performance.

The goal of performance management within Romanian industrial firms is to achieve better results for the organization by improving individual performance.

Performance appraisal within industrial firms is one of the most important parts of performance management.

The performance appraisal system must always be linked to the company's specificity as well as to other human resources policies. Managing individual performance is important for the success of industrial firms and is practiced by everyone starting from the general manager to the last worker.

Proposals:

Introducing a feed-back questionnaire on employee expectations related to the work of general manager and management team, if they are in the company's new philosophy, if they think they are heading for a good direction.

Utilization of “Value Analysis” in determination of competitiveness level with in S.C. EUROSPORT DHS SA

Guță Anca Jarmila *

**University of Petroșani, Petroșani, 332041, Romania*

Abstract

The value analysis is a method of competitiveness which aims at increase of products value by a systematic procedure with the object of obtaining optimum solution. The paper proposes to present, using the value analysis with in the company S.C. EUROSPORT DHS SA, on the basis of a questionnaire the degree of satisfaction of the customers concerning the products of the company taken for object of research.

Keywords: company, customers, value analysis, competitiveness level, degree of satisfaction, products range, EUROSPORT DHS

1. Introduction

The value analysis is:

- An organized and creative competitiveness method aimed at meeting the needs of the user through a specific, functional, economic and pluridisciplinary approach (French NF X 50-150)
- Method of conception or reconciliation of products and services to meet the user's needs at a reasonable cost.
- Organized procedure to identify unnecessary costs (L. D. Miles).
- Organized procedure for identifying unnecessary costs in multi-component products, using Functional Analysis to define the problem and group creativity to solve it (W. L. Gage).
- Method of increasing the material production by reducing manufacturing costs, while improving the quality of products, acting at the stage of constructive design (P. Orănescu).
- Method of conducting material production.
- A series of system processes geared to delivering the necessary functions at a minimal cost, without neglecting quality, reliability and delivery.
- A method for increasing the value of both products and services or technological processes, by means of which a systemic procedure tends to obtain optimal solutions.
- Research method - systemic and creative design which, through a functional approach, seeks to ensure that the functions of the studied objective are conceived and achieved with minimal expenses, in a quality condition that satisfies the needs of the users, in accordance with the socio-economic requirements.

The objectives of the Value Analysis are: cost reduction, quality improvement and required services, innovation, conquering new markets, adapting to external developments, ensuring sustainable competitiveness. The Value Analysis object forms its activity, product or components. Only the product is a value carrier and the subassemblies or parts contribute to the usefulness of the product.

The Value Analysis Directorate is Functional Analysis. Starting from the idea that a product is bought because it does something that corresponds to a buyer's need, this property has been named its principal function. In order for the main function to be fulfilled, a series of secondary functions need to be added to the product, which is of interest only if it contributes to the normal function of the main function. It is estimated that, in general, only 20% of the manufacturing costs of products are caused by the main functions, and 80% of the secondary functions.

2. Presentation of the company subject to the study

A Chinese math teacher, Yang Xi, left her native country in 1996 with her husband, Niu Guanghui, to start a business in Romania. They chose Petrosani, where they built the foundations of a bicycle factory in 1999.

The choice of location was based on two reasons: unemployment in the Jiu Valley, which guaranteed its availability on the labor market, and the second fact that at that time the Jiu Valley benefited from the status of the disadvantaged area. Ten years later, Yang Xi succeeded in inaugurating a second bicycle factory in Deva. The bicycle factory is located near the town of Deva, the central-western part of the country and is the country's largest bicycle manufacturing facility. Eurosport DHS is China's largest investment in Romania. Up to now, around 20 million euros have been invested here.

PROPHETE GMBH, Germany's number two bicycle manufacturer in Germany, bought 30 percent of EUROSPORT DHS shares with capital and at the same time gained 100 years of experience in Germany. In 2006 EUROSPORT DHS invested in the new production plant in Deva, more than 6 million EURO and with a production area of more than 17,000 square meters. In June 2006, Prophete GmbH entered into a partnership with Eurosport DHS SA bringing in this partnership both the capital and 100 years of experience in the production of bicycles at German standards. In July 2006, the massive investment of approximately 300,000 Euros in an automatic technological line for the assembly and centering of bicycle wheels (6 wheel adjustment equipment purchased from the French manufacturer Mach1, a company specializing in the production of bicycle wheel construction equipment .), and by acquiring automated assembly lines in the Netherlands that guarantee the quality of products as European standards, the company's production has grown to 500,000 units per year.

This investment was made taking into account the opportunity for bicycle production in Romania. The bikes produced here are sold throughout the European market since January 2007 when Romania became a member of the European Union. Eurosport products have some very important features: good quality and low prices thanks to the low cost of local labor.

The wide range of products and services, together with the long-established professionalism and reliability, have put Eurosport DHS S.A. among the first companies in the country. To prove this, the company holds numerous diplomas and awards. The National Council of Private Small and Medium Enterprises ranked Eurosport DHS S.A. for the third consecutive year in the first place in the category "Bicycle production".

In 2009, Chinese managers began building a new production hall, in which they invested another 2 million euros.

3. Determining the level of market competitiveness of S.C. EUROSPORT DHS SA

The proposed questionnaire is the following:

Company Name: _____

Date: _____

Your Name: _____

Your function: _____

Customer Satisfaction Assessment Questionnaire

1. What is the most important reason for working with Eurosport DHS?

- a) Seriousness
- b) Promptness
- c) Product design
- d) Rate
- e) Quality

2. How do you qualify your relationship with the sales department?

- a) Very good
- b) Good
- c) Normal
- d) Weak

3. Is the best way to promote DHS products?

- a) Banner
- b) Poster
- c) Catalog
- d) Media
- e) Flyers

4. Are your preferences about the 2017 product range?

- a) Impulse
- b) DHS
- c) Trekking
- d) DHS Kids
- e) Kreativ

5. The most sold product in the 2017 season was?

6. Was the 2017 service activity?

- a) Very good
- b) Good
- c) Normal
- d) Poor

7. Is your opinion about Bike Fest 2017?

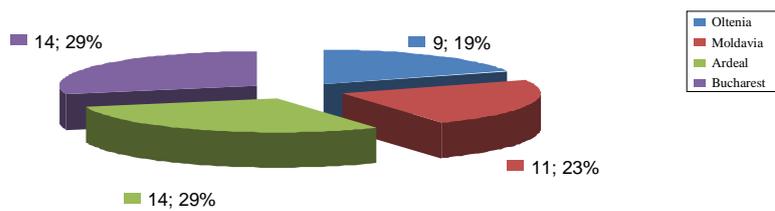

- a) Very good
- b) Good
- c) Normal
- d) Poor

Interpretation of results:

1) *What is the most important reason for working with Eurosport DHS?* This question seeks to determine the factor that most influences the collaboration with SC Eurosport DHS SA. This is a closed question with five variants of answer, of which the respondent chooses one.

In the following graph are presented the results of the analysis of the data obtained by this question. It is noted that most respondents, ie 58% of the respondents, consider seriousness as the most important factor that may influence the collaboration with Eurosport DHS, half of them, that is, 14, are from Bucharest and the rest of Transylvania. Only 19% of the respondents from Oltenia and 23% of Moldova consider the company's seriousness as the most important factor influence.

What is the most important reason that influences the work with Eurosport DHS?

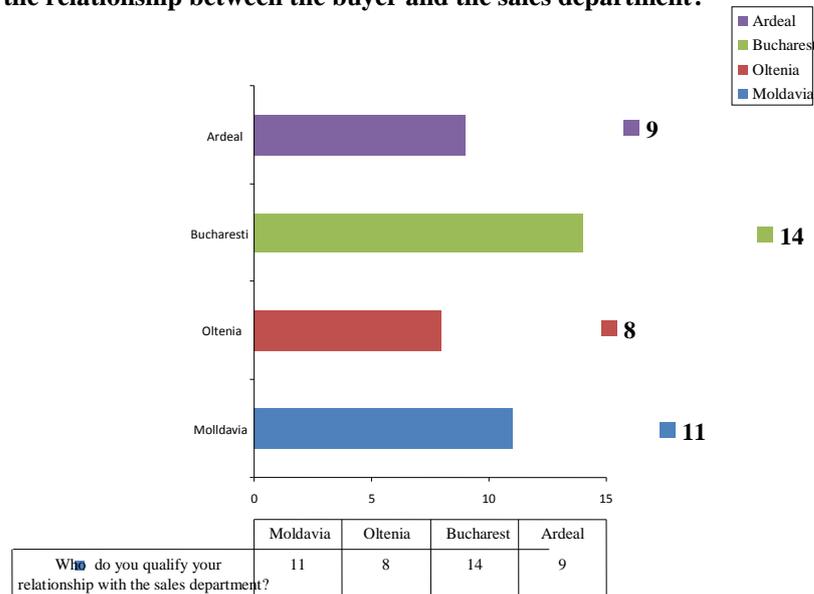

Scheme 1 - "Rated Deriousness"

2)

How do you qualify your relationship with the sales department? This question seeks to establish the type of relationship between buyers and the sales department. That question is closed, metric scale type

The type of the relationship between the buyer and the sales department?

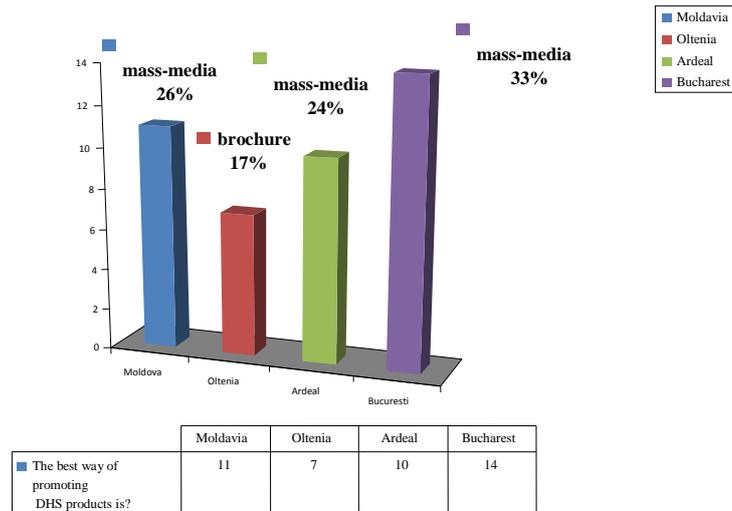

Graph 2- Rated "Very good"

From the above figure we can see that the area where most of the respondents qualified the relation with the sales department as being very good is Bucharest with 34% (14 persons), followed by Moldova with 26% (11 persons). Only 9 respondents from Ardeal consider that their relationship with the sales department of the company is very good (ie 21%), and in the Oltenia area, 19% of the respondents gave the same answer regarding their relationship with the sales department of the firm.

3) Is the best way to promote DHS products?

The role of this question is to determine the best way for the respondents to react and stimulate them to buy or at least to visit the Eurosport DHS store. This is a closed question with 5 variants of respondents that respondents can choose one.

The way of promoting DHS products

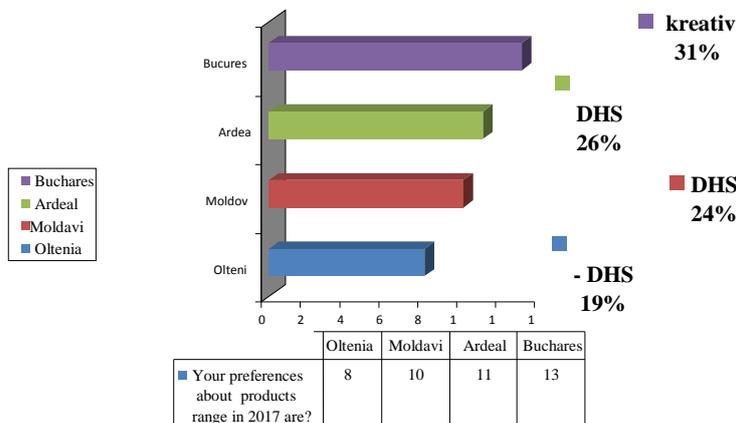

From the graph above, it can be seen that 33% of respondents in the Bucharest area, namely 14 persons, consider that the best way to promote DHS products is mass-media. In addition, the Moldovan and Ardeal regions are added with a 50% cumulative share (11 persons surveyed from Moldova and 10 from Ardeal), who opt for the same promotion of products as those in Bucharest. 17% of respondents in Oltenia state that the best way to promote DHS products is the catalog (7 people).

4) Are your preferences about the 2017 range of products?

The role of this question is to determine the preferred product from 2017. It is a closed question with five variants of answer, of which the respondent chose one.

2017 preferred products by the buyer ?

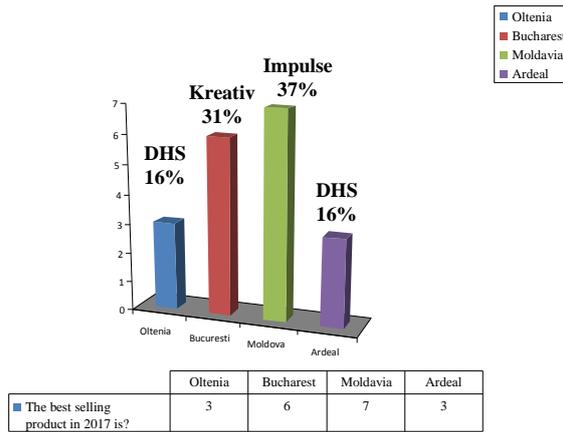

From this chart it can be deduced that the preferred product of the buyer in 2017 is DHS, accounting for 69% (11 persons from Ardeal, 10 from Moldova and 8 from Oltenia respectively) compared to Kreativ that was voted by 31% (ie 13 persons) of respondents in the Bucharest area.

5) The best-selling product of the 2017 season is?

The role of this question is to determine the best-selling product of 2017. It is an open question for the respondent to write which is the product that had the highest earnings in the year 2017.

The best selling product

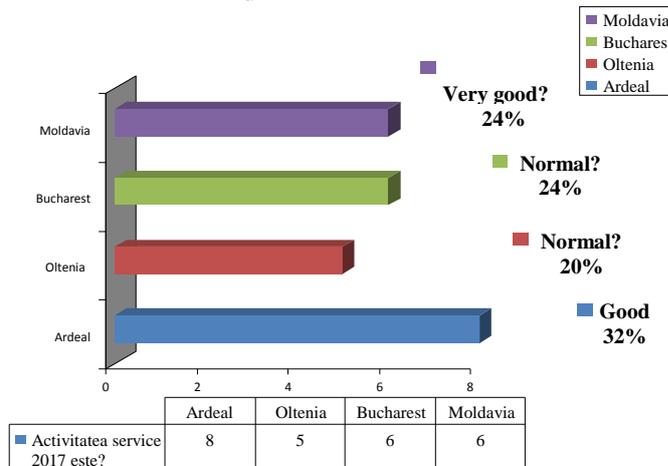

The graph above shows that the best selling product in the area of Moldova is Impulse with a weight of 37%, followed by DHS with a cumulated weight of 32% in the Oltenia and Ardeal areas. 6 of the people surveyed liked Kreativ as the best-selling product in 2017 in the Bucharest area.

6) Is the 2017 service activity?

This question is aimed at identifying how the service activity was qualified in 2017. It is a closed question with four variants of answer from which the respondent can choose one.

The service activity in 2017

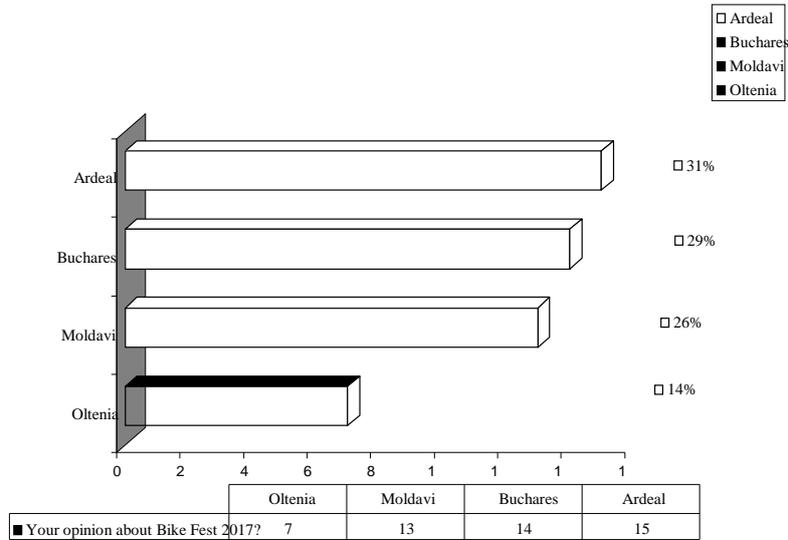

From the above graph we can see that 24% of the persons surveyed in the area of Moldova consider the service activity from 2017 to be very good, unlike the Bucharest and Oltenia areas which claim that the service activity was normal in 2017, thus registering a weight of 24% (6 of the persons surveyed), respectively 20% (5 persons). Transylvania registered 32%, ie 8 people claiming Eurosport DHS's 2017 service was good.

7) Is your opinion about the Bike Fest 2017?

This question seeks to determine customer opinion on Bike Fest 2017. It is a closed question with four variants of the answer that the respondent chooses one, ending the collaboration with it.

Bike Fest 2017

Quoted "Very Good"

From the above graph it can be concluded that among the people surveyed the most, who had a very good opinion about Bike Fest 2017, are from Ardeal, with a share of 31% (15 persons respectively). București registered a 29%, that is, 14 people interviewed, in this area is the Bike Fest of 2017 was a success with a very good opinion. Of the respondents in the Republic of Moldova, only 13 have this opinion (26%) and Oltenia, 14% meaning 7 persons.

3. Conclusions

The reaction of the customers entering the store, the ease with which the company's website can be accessed, or the way the seller comes to the customers are things that, although seem insignificant, make a vital contribution to the future of any business.

Adequate feedback is also a motivating force for employees, which strengthens self-confidence, commitment to the organization, and increases professional satisfaction.

The customer can choose from a wide range of products or may propose their own models to be produced at the factory in Deva. In the latter case, the customer benefits from the exclusivity of the models he has created. The company is very competitive in terms of prices due to the low cost of labor in Romania.

DHS has not only limited to bicycle production, but has continued to produce bicycle components, such as aluminum rims and body painting.

DHS directors contribute to "locating" EUROSPORT DHS products, meaning maximizing the use of components produced here. DHS acquired Italian painting equipment for the cadres, including this process in processes in Romania. This reduces the volume of imports but creates new jobs.

Abstract

This study is mainly based on the question; does Malaysian government support enhances the quality and positive contribution of Amanah Ikhtiar Malaysia (AIM) on the women self-sustainability? Thus, article attempts to examine the moderating role of governmental support regarding the effect of AIM on quality women self-sustainability. Therefore, using survey questionnaire data only collected from three hundred and eighty (380) female clients of AIM in Kedah and Perlis. Results confirmed that AIM has vital contribution while government support plays significant moderating role in increasing women self-sustainability in selected regions. Therefore, government support is major contributors toward quality of women self-sustainability among the female clients.

Keywords: Amanah Ikhtiar Malaysia (AIM); Government Support; Microfinance; Small Loan; Women Self-sustainability

1. Introduction

Women self-sustainability is known as the process of equipping women to be economically independent, self-reliant, having positive esteem which allows them to defend any challenging circumstances and contribute to various development activities (Kapila *et al.*, 2016). Women are the integral part of every society as women has major influence on economy (Ekpe *et al.*, 2010). However, cultural issue, beliefs and gender discrimination decreases the women sustainability level. This gender discrimination is still existing in Malaysia. In various sectors of Malaysia still inequality exists between men and women. For instance, at managers position men earns RM5080 (=€1075) and women earns RM4500 (=€952). Moreover, in craft and related trade men earns RM1330 (=€281) and women earns RM879 (=€185), and so on in all various fields (Department of statistics, 2015). Therefore, women salaries are less as compared to men salaries. In such occupations women participation is only 38.22%, however, men participation is 61.78% (Department of statistics, 2015). Therefore, this unequal distribution effect negatively on women self-sustainability. Furthermore, in labour force participation, female-to-male ratio is 0.59, professional and technical workers this ratio is 0.77 while in estimated earned income female-to-male ratio is 0.51 (Buang *et al.*, 2015). These issues are more in Kedah and Perlis states of Malaysian. That is the reason, level of poverty is more in Kedah and Perlis has high poverty.

Kedah state has 5.3% and Perlis state has 6% poverty (Department of Statistics, 2015). Commonly, females have higher unemployment and stagnant performance (Lewandowska-Gwarda, 2018). Nevertheless, through research and development, the labour productivity can be improved in long-term (Dubauskas, 2018; Stoklasova, 2018). However, in this situation, AIM is playing vital role with the to decrease the poverty level and gender discrimination while enhancing the level of women self-sustainability (Amanah Ikhtiar Malaysia, 2014). It provides various services such as small loan and training to promote women micro enterprises along with self-sustainability (Al-shami, Razali, & Rashid, 2018). Additionally, the role of Malaysian government for supporting women self-sustainability through micro credit programs is important by distributing funds through several ways for supporting poor people (Sriram & Mersha, 2006). Firstly, the

* Corresponding author. Tel.: +48 34 3250 330;
E-mail address: beata.slusarczyk@wz.pcz.pl

current study contributes by introducing government support as a moderating variable to enhance women self-sustainability and to enhance the positive effect of AIM. Secondly, this study covered Kedah and Perlis which is not formally documented by any study for examining the relationship of AIM and women self-sustainability.

2. Literature Review

The aim of various microfinance institutions and AIM is to reduce the poverty level by facilitating economic activities of poor people (Misnan, Noor, & Ramli, 2017). Micro enterprise generates income which enhance the women self-sustainability. Successful entrepreneurs have distinctive common attributes (Alroaia & Baharun, 2018). It also creates decision making power which enhance the social empowerment (Faizan and Haque, 2016; Mayoux, 2005). Thus, micro enterprise as a mediator has a major role to reduce poverty and enhance women empowerment. AIM provides various services such as financial services (small loans) as well as non-financial (training program) services to facilitates women micro enterprise for utilizing credit in better way (AIM, 2014). Through these financial and non-financial services, AIM tries to empower women community and increase quality of women self-sustainability. The combination of both loan and training is most important to run micro enterprise (Hameed et al., 2017). Loans help in establishing firm while training helps in effective running of micro enterprises. However, sometimes, credit/loan shows negative consequence when poor people use it unproductively (Hameed, Mohammad & Shahar, 2018a). Nevertheless, sufficient loan supports entrepreneurial performance (Gatewood et al., 2004; Ojo, 2009). Interestingly, loan aids entrepreneurs, especially women by often increasing income, investment, output and welfare of entrepreneurs (Kuzilwa, 2005; Peter, 2001). Thus, it has significant contribution in quality of women self-sustainability. Furthermore, credit has a positive impact on performance across the world (Hameed et al., 2017). Positive performance through loan from AIM enhances the income of women which ultimately increases the economic and social empowerment of women along with powered decision making (ibid). Thus, loan from microfinance institutions enhance the women social and economic empowerment which is positive indication towards women self-sustainability. Moreover, training is another aspect but in 1990, very little was offered to microfinance beneficiaries (Nieman, 2001). Nowadays, it is a significant tool adopted for enhancing micro-enterprise as it has significant positive relationship with micro enterprise success (Hameed et al., 2017). Nevertheless, there are failure in business due to the lack of skills (Radipere & Van Scheers, 2005). Microfinance institution's clients are unable to use microfinance factors properly because they do not have unique abilities (Karnani, 2007). However, training programs through AIM are most important to develop a reasonable level of sustainability among women community in Kedah and Perlis.

Government support has significant positive association with the attitude towards entrepreneurship (Sadeghi et al., 2013). Different agencies in Malaysia are now concentrating to distribute funds in different ways (Sriram & Mersha, 2006). In literature, the government roles as well as various activities towards encouragement on entrepreneurship are significantly related (Carayannis et al., 2003; Klapper, 2005). Therefore, government support is most influencing factor towards women self-sustainability. In this study, government supported is used as moderating variable between AIM and women self-sustainability. Based on literature, theoretical framework of this study is developed.

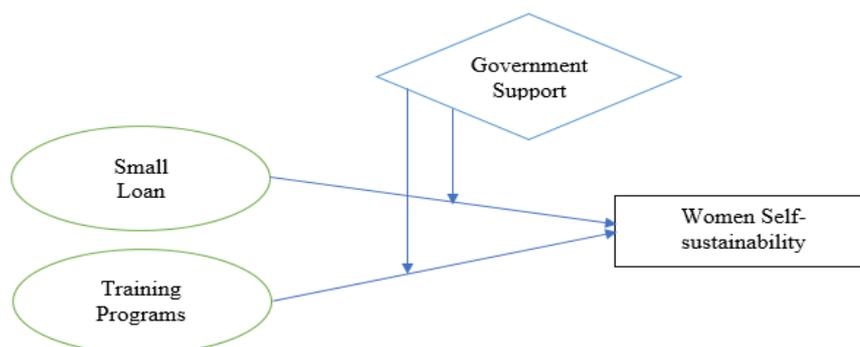

Figure 1. Theoretical Framework of present study

- H1. Small loan has significant positive relationship with women self-sustainability.
- H2. Training programs has significant positive relationship with women self-sustainability.
- H3. Government support has significant positive relationship with women self-sustainability.
- H4. Government support moderates the relationship between small loan and women self-sustainability.
- H5. Government support moderates the relationship between training programs and women self-sustainability.

3. Research Methodology

Research developed critical realism ontological stance as the study falls under the scientific research paradigm using quantitative analysis. Since, the research revolves around microcredit organization therefore the primary data is gathered from the beneficiaries of AIM using credit and training related services. The research design is cross-sectional

as data is collected in one-time interval (Haque, Aston, & Kozlovski, 2008; Imran, Aziz, & Hamid, 2017; Imran et al., 2018). For the determination of sample size, the approach of Krejcie & Morgan (1970) table was adopted to calculate a sample size for drawing logical conclusion. Total beneficiaries of AIM in Kedah and Perlis combined (28,039 + 22,212=50,251) is target sample while the women participants are 60% of total. Thus, the total women beneficiaries are (50,251*60%) 30,151. According to Krejcie & Morgan (1970), the sample size should be 380 when population is in range of 30,000 and 40,000. Hence, the adequate sample size is 380 beneficiaries of AIM are studied. Moreover, area cluster sampling is used to reach 380 target audience as it is suitable technique when the population spread on a wide area especially, non-availability of sampling frame then area cluster sampling is acceptable (Sekaran & Bougie, 2012). The questionnaire is adapted from previous studies hence, reflecting the reliability of research instrument. For women self-sustainability (dependent variable) scale items are adopted from Gangadhar and Malyadri (2015). For independent variables (small loan, training programs) scale items are adopted from Bernard, Kevin and Khin (2016). For moderating variable (government support) scale items are adopted from Kgagara (2011). Using PLS 3, measurement model assessment and structural assessment was done through factor loading, Cronbach alpha and composite reliability while Average Variance Extracted (AVE) was carried out for internal consistency and discriminant validity for external consistency. Minimum threshold was attained as the incurred values were above 0.7 value while square root of average AVE is greater than all incurred values therefore discriminant validity is attained, further confirmed by Heterotrait-Monotrait Ratio.

4. Research Result

Hypotheses was tested in structural model using SmartPLS bootstrapping technique while t-value (minimum 1.96) was examined to reject or not the hypotheses. Moreover, the relationship direction between variables of interest was examined through path coefficient. Table 1 shows the results of structural model assessment that the independent variables (a) small loan (SL) and (b) training programs (TP) have significant relationship with women self-sustainability (dependent variable) (TP t-value = 4.065 > 1.96; SL t-value = 2.314 > 1.96, Table 1). Furthermore, from the government support has also significant relationship with quality of women self-sustainability.

Table 1. Structural Model Assessment (Results without moderator)

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (O/STDEV)	P Values
GS -> WSS	0.246	0.238	0.078	3.141	0.002
SL -> WSS	0.242	0.252	0.105	2.314	0.021
TP -> WSS	0.447	0.451	0.110	4.065	0.000

Considering moderating role of government support between AIM and women self-sustainability, it is found that it has significant influence on the relationship. Table 2 revealed that the moderating effect in both cases; small loan and training program in relation to women self-sustainability are significant (SL = t-value 1.970 > 1.96 and TP t-value = 4.451 > 1.96).

Table 2. Structural Model Assessment (Moderation effect)

	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (O/STDEV)	P Values
SL* GS -> WSS	0.146	0.142	0.074	1.970	0.049
TP* GS -> WSS	0.202	0.208	0.045	4.451	0.000

Since R^2 value is 0.745, confirming that 74.5% variance in women self-sustainability (endogenous latent variable) is due to government support, small loans and training program whereas Table 3 showed effect size (f^2). According to Cohen (1988), effect size (f^2) 0.02 is small, 0.15 is moderate and 0.35 is considered as strong. In the current study small loan and government support has small effect size, however, training programs has moderate effect size.

Table 3. Effect Size (f^2) of variables of interest

	f-squared	Effect Size (f^2)
Small Loan (SL)	0.090	Small
Training Program (TP)	0.234	Moderate
Government Support (GS)	0.079	Small

Finally, the quality of model was assessed through predictive relevance (Q^2). From Table 4 confirmed the predictive relevance (Q^2) is more than zero. As Henseler *et al.*, (2009) stated that the value of predictive relevance (Q^2) should be more than zero. Hence, the current model has attained the required level of quality.

Table 4. Predictive relevance (Q²)

Total	SSO	SSE	Q ² = (1-SSE/SSO)
Women Self-Sustainability (WSS)	546.000	338.282	0.380

5. Discussion

The findings revealed that AIM is one of the most significant institute for women self-sustainability as its financial and non-financial services are most crucial for enhancing women self-sustainability, particularly in Kedah and Perlis. These services are key to the success of women micro enterprise. Results confirmed that small loans (financial services of AIM) has significant contribution to empower women community through income generating activities. Increase in income contributes towards enhancing the women self-sustainability, therefore, our finding is aligned with work of Mayoux, 2005 as evident that credit has significant contribution to empowerment and self-sustainability of women. On the other hand, training programs (non-financial service of AIM) has also significant positive contribution in women self-sustainability. Increase in AIM training activities will directly influence women micro enterprise programs, leading to generate income and eventually increasing quality of women self-sustainability. Thus, our finding support work of Mayoux (2005), Hameed et al. (2017) and Hameed et al. (2018a). These financial and non-financial services have direct effect on income generating activities, which has positive influence on women empowerment leading to women self-sustainability. Therefore, we support work of Hameed et al. (2018).

Figure 2. Government Support’ moderating effect between small loan and women self-sustainability

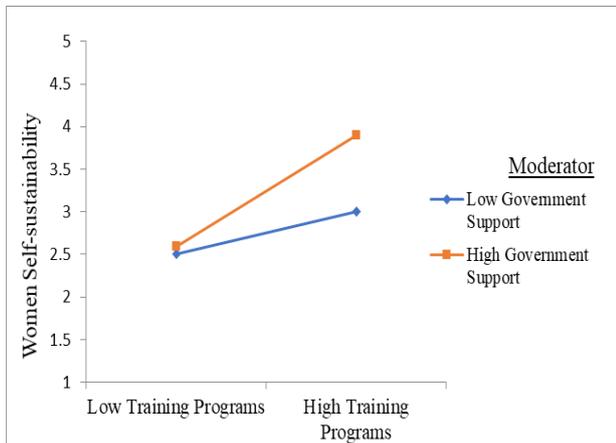

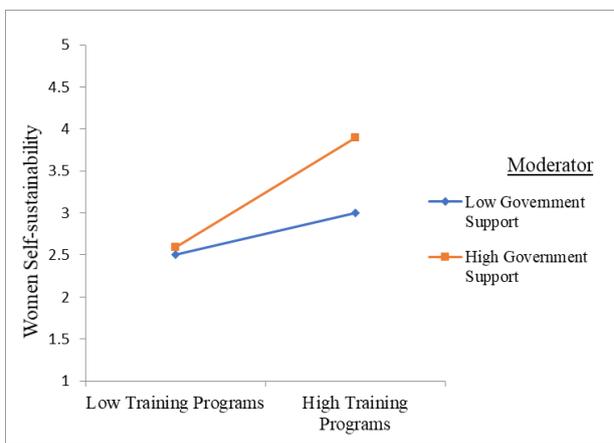

Figure 3. Government Support’ moderating effect between training program and women self-sustainability

Moreover, regarding the moderating role of government support, it is found that Malaysian government support has significant positive influence on the relationship between AIM and women self-sustainability. This argument is also supported by prior study of Carayannis (2003) that government roles and various activities towards encouragement on entrepreneurship are significantly related. The moderating effect of government support is shown in Figures 2 and 3. Figure 3 shows that government support strengthens the positive effect of small loan on women self-sustainability while Figure 2 shows that it also strengthens the positive effect of training programs on women self-sustainability.

6. Conclusion

Based on the findings, it is concluded that AIM programs have effect on the quality of women self-sustainability in Malaysia. Additionally, the research majorly investigated and found the role Malaysian government in creating positive effect of AIM on Malaysian women community. Results confirm that AIM programs for poor people has great importance in empowering female community by reducing the poverty level and gender discrimination. In the past, AIM proved to be one of the major elements in poverty reduction and women self-sustainability. Nowadays, AIM is extending the services all over the Malaysia. Small loan facility (AIM service) is most important to run micro enterprises. Moreover, training programs enhance the women ability to utilize loan in effective manner by educating them to use it productively. Moreover, Malaysian government support has pivotal part in enhancing the positive role of AIM towards women self-sustainability. Various government programs and funding to AIM has decreased the poverty while automatically enhancing the women self-sustainability, particularly in Kedah and Perlis. Having said that, AIM could be vital program for the other governments, especially for emerging economies in the reduction of poverty. The microcredit organizations could be instrumental in empowering masses and promoting entrepreneurial ventures. As the social capital is most significant and its vulnerability should be reduced and increases the positive effect on poor women. It is recommended that the future researchers should add other services of AIM, such as saving products,

insurance products and SHG - Self-Help Group (social capital development activities) to current framework in order to further expand in multiple dimensions. Furthermore, the comparative analysis should be drawn to measure the role of AIM in improving the contrasting genders' performances.

Adapting leadership methods to global challenges: interactive leadership

Mohammad Jaradat^a, Sergiu-Dan Iurian^{a*}

^aValahia University from Targoviste, Bd.Carol I St., No.2, Targoviste 130024, Romania

Abstract

Globalization is a driving force that can change the whole concept of leadership because it's ever changing variables. Human resources are probably the main direct beneficiaries of the process, therefore leaders cannot and should not ignore the needs of the ones they lead, especially in an evolving society. The purpose of the article is to demonstrate that leadership methods have shifted their attention and goals in the last years, due to globalization of the management of human resources, but also as part of the changing needs in the global economy, and thus the emerging of a new type of leadership: interactive leadership.

Keywords: leadership; globalization; human resources; challenges; technology.

1. Introduction

Leadership – is the process through which a person influences other persons towards achieving a common goal and guides the organization so that it can achieve cohesion and a higher level of coherence. (Northouse, 2000)

Globalization has proven itself as being the most important challenge for both an organization and its human resource. In this context, organizations need to take into consideration two crucial aspects (McChrystal, 2016):

- having the most talented asset at the exact location, moment and with the lowest cost;
- creating the best plan/product/service in the smallest amount of time, at the right time and with the lowest cost.

2. Managing human resources as part of the process

In the recent years however, due to the intense globalization, managing human resources has suffered major changes. Because of the branding process of the international organizations, whether its public or private sector, people are more and more attracted to work for them, to play their part into developing global brands, and thus international organizations have the advantage of hiring the most qualified labor force, to the detriment of small, local organizations. (Duret & Vladimirescu, 2014)

Global leadership principles must be applied flexibly, taking into consideration the context of each country. The rising interest for cultural diversity can be explained through the following mechanisms: urban areas have become inhomogeneous from a cultural aspect, due to migration and mobilization of labor force and the rise of the global organizations during the 80`s and the 90`s which were using various labor force and were developing in vast cultural regions. (Duret & Vladimirescu, 2014)

Managing diversity thus becomes the key point of leadership. The shape that some behavior features take is the result of mix cultural teams. In some cultures, work is viewed as a task rather than the result of teamwork therefore relationships between staff are viewed as a sign of weakness, thus strong leadership can reflect either a sign of strength in some cultures and weakness in others. When working teams manage to deal with their cultural differences it can often lead to having strong groups with an infinite potential of work. There are two major aspects that can ease the achievement of high performances regarding global teams (Goffe, 2010):

* Corresponding author. Tel.: +40-723-353-466
E-mail address: jaradat_hadi@yahoo.com.

- team selection

Consists into choosing wisely the employees with the right skills, purposes and knowledge, but also it consists into knowing how to evaluate them, knowing how to eliminate organizational barriers and obtaining high level of cooperation between their leading staff. Another key factor regarding team selection consists into managing to convince team leaders to get involved more often, being able to get proper feedback from each team member, but also knowing how to prepare and support them, by clarifying their task, deadlines and responsibilities. (Adler, 2010)

- team leading

Team leading must start slow and finish with strength. More than that asking for support can sometimes facilitate some team behaviors encouraging participation and collaboration among individuals, but also highlighting the differences between them enabling discussions that can lead to a clear analysis regarding the key factors that contribute to the success of a team.

It should be recommended that within an organization there should be a clear set of basic rules that serve as assets into the cultural difference harmonization process.

It is important to acknowledge cultural origins and respecting them because it might fuel the performance of the organization accepting that each person can be different, accepting their cultural heritage, the fact that differences regarding personality and abilities might be more important than differences among cultures and last but not least eliminating critical views regarding stereotypes, can all assure the long term of an organization. (Adler, 2010)

3. Interactive leadership influences organizations in a new global economy

Because of globalization we can no longer ignore the cultural sign of leadership. That being said there are vast differences between the styles of leadership that are accepted in some cultures and rejected in others.

If we look at different models of leadership but also at the differences between cultural rules, we can conclude that in this global world more and more often we see new tendencies emerge. Global leaders are the ones that act into a multicultural environment and could use some skills and attributes such as: charisma, skills for teamwork, openness to change, interest toward the political life but also to the socio economic state of their country. Abilities to develop good relations with humans belonging to other cultures, adaptability to new situations and abilities to work into a multicultural team can also be part of the skills and attributes of the global leaders. (Schraa & Trompenaars, 2006)

Even though some personal qualities might increase their chances of succeeding as global leaders, there is also a specific set of organizational qualities that are at the base of success of an organization. Generally speaking an organization with a huge international success has the following characteristics:

- a large number of employees of different nationalities than the one of the organization itself
- huge investments outside the country of origin
- an extensive decentralization of power among international subsidiaries
- well-represented managers in the board of directors of the organization
- vast experience into developing activities abroad, experience belonging to members of the organization
- members of the organization that have international experience as a foundation stepping stone in their career path (Covey, 1990)
- the openness of the organization regarding the quick promotion of employees of different nationalities

For testing the skills of different candidates for foreign job openings there should be procedures more or less formal that test their openness towards a global multicultural organization. Often candidates are selected based on their performances within the organization that is based in their home countries, but then find themselves into difficulty when working in an international environment. Candidates should go through a professional training program before being sent abroad. This professional training program should teach them about organizational culture and the ways that a global career might help their advance, especially when working into different cultures and environments.

Leaders must create multicultural communities establishing an organizational culture that extends beyond barriers that the differ people and they must be able to offer guidance signals towards values and skills that can be easily understood by different cultural groups among staff.

Interactive leadership mainly refers to confirming the assumption of external influences on the structure of the organizations. Organizations can adapt to external changes which therefore develop structural characteristics such as:

a) organizational complexity – is defined as the number of occupations within the organization and their level of professionalism. It is a structural feature that is connected with the capacities of an organizations to adapt to environmental changes. Leaders permanently look for changes in the external environment and try to adapt. (Slater, 2009)

b) decentralization – employees of inferior rankings which are often more aware of the need to change are in fact excluded from the decision making process which should take into consideration their opinions as well.

Authority centralization in the superior rankings of the organization can be an obstacle in the way of change.

c) flexibility – when a major part of the activities develop among the organization are based on strict rules, adapting becomes more slow and more difficult to achieve, opportunities of change are no longer correctly received. A high level of task regulation can be a obstacle for change.

From the analyses of the way that structures can adapt to environmental conditions, we can review of the definition itself of the organizations, viewing them as a conglomerate of jobs, activities and roles that articulate themselves around two key functions implementing the most advanced professional technology regarding the organization and the environmental challenges of the outside of the organization. (Mardar, 2013)

Therefore, old leadership methods are no longer adequate for the new situations in which organizations find themselves into. New aspects redefine leadership such as:

- 1) its essence – what should leaders do?
- 2) its processes – how should leaders do it?
- 3) its purposes – why should leaders do it?

1) What should leaders do it?

Three main facts affect what leaders do:

- a) the need to control change in parallel with the day to day leadership of the organization

For most of the leaders finding success formulas has been a constant difficult path especially when it comes to developing well harmonized policies. Nowadays this becomes more difficult because leaders must still keep their organizations walking but at the same time, as much as possible, they need to transform them. This requires a vision and a profound understanding of internal and external forces that can represent either serious threats or new opportunities for the organizations. This transformation implies the mobilization of the whole organization towards finding new competences and resources available in the future. Therefore, leaders must offer new advantages that will both help their organizations succeed and help transform it to a new one.

- b) the more and more rising influence of technology

The impact of technology is limited mainly to increasing the level of productivity among organizations.

- c) the concern for a larger and more fair leadership of processes and competences

The old role of leadership required that each compartment of an organization should function as the global strategy of the organization dictates it. Therefore, both integrating processes “part by part” but also integrating process as a whole had a major importance. The new leader must do the same things but viewed from two different perspectives:

- the first one is being able to manage more efficiently the processes that come together from different functions.
- the second major change refers to competences, because today efficient developing of each function is just a part of the daily activities, the main part becomes developing competences for the businesses of tomorrow, the future of the organization that basically makes it more competitive in a changing environment.

2) How should leaders do it?

There are generally three forces that influence the leadership process:

- Developing new organizational systems of leadership with reduced hierarchies

The diversity and complexity of the new organizations, together with the need of taking quick action measures more rewarding have diminished in a great way the importance of hierarchic leadership based on command. More and more often the mission of the new leaders is to prepare the grounds for the exercising the leadership among long ranking levels of the organization.

- Raising the number of alliances and unofficial networks

Leadership must also function in the new structures and unofficial extend allegiance from the need of adopting new methods of competitive approaches, solutions and technological requirements that define the competitiveness of an organization. The difficult task of leadership in their case consists into finding common grounds for a common purpose in defining a common strategy and engaging into common actions.

- The constant modifying of public values and claims

The general values and claims of the public have shifted their goals in time. At first there was tendency to evaluate by size rather than performances, then the attention shortly took a shift towards performances, but finally the public attention was oriented to decisive performances that meant clear needs towards either products or actions of a decisive nature, so that the public can be witness to transforming of something.

3) Why should leaders do it?

Leaders should want to find themselves into a new era because the general population is on a rise. Therefore, their task is constantly oriented into managing two major requirements from the global system:

- -creating new sustainable long term jobs
- -contributing to the social integration of their workforce – as shown above, cultural differences might be an obstacle but they can surely be an asset if managed properly. Multicultural teams can be very productive and efficient, therefore society plays a role into shaping the individual, but also individual plays a role into shaping society.

Finally the “what”, ”how” and “why’s” are the basis for resolving each plan of action but the leaders difficult task is to anticipate, to adapt and to foresee the variables the might influence their organizations short and long term plans.

The technological changes from the last decades have lead to a more interdependent world with a fast growing rhythm. This fact has created a state of *complexity*. Complexity produces a situation that is fundamentally different than the complicated challenges from the past, complicated problems that required a great deal of effort, but, eventually, that lead to predictability.

Complexity means that, despite all of our skills, despite all the high number of possibilities of tracking and measuring something, some sort of situation, it still is much less predictable. This unpredictability is fundamentally incompatible with reductionist managerial models built around planning and around predictions. The new environment requires a new approach.

In regards to the fundamental distinction made above, we can therefore apply this differences when it comes to human resource managing different fundamental structures that separate hierarchical structures in the way they deal with teamwork. The old ones have roots into the old way of predicting things which can be useful when executing a plan a applying procedures that were planned in advance, but which become less efficient and less adaptable.

The modern way of dealing with things in regards to human resources is to offer a higher level of connectivity based on trust and mutual purpose, creating teams that have the ability to resolve problems that could not have been anticipated by a single person (manager), solutions being provided as a result of interactions and being offered from bottom up than the other way around. Teams are not the only response into dealing with the current leadership challenges, cooperation between the different compartments of the organization, but also allegiances playing their part as well.

Conclusion

Adapting leadership methods to global challenges require interactive leadership, but interactive leadership is not an easy process to handle even though it might look simple at start. Like proven above the society needs have changed from being volume oriented to being effective quality oriented. For effectiveness to go hand in hand with interactive leadership there needs to be a synergy oriented shorter plan that helps leaders transmit their visions and goals to both low and high ranking employees, from different cultures in a short amount of time. A rather increased level of freedom of action among employees is also recommended, because it increases the chances of cooperation, together with a little bit of guidance towards global acceptance of different cultures as new environments to work in, or different teams of different nationalities that need to achieve better results through cooperation.

The importance of cultural marketing in evaluating creative personnel

Sergiu-Dan Iurian^a, Mohammad Jaradat^{a*}

^aValahia University from Targoviste, Bd.Carol I St., No.2, Targoviste 130024, Romania

Abstract

Culture is known as the product of human activities and thinking, therefore culture consist into various numbers of concepts containing science, beliefs, arts, customs, etc. Thus unlike any other domains, culture needs a specific type of marketing that is adapted to its special cultural products and services. In the cultural businesses the most important role goes to the creative personnel, therefore this special type of personnel will require special means of evaluation. The present article aims to demonstrate the importance cultural marketing in evaluating creative personnel, because creative personnel acts like both productive personnel and marketing staff at the same time. Thus evaluating creative staff should take into consideration their ability of promoting culture.

Keywords: culture, cultural marketing, creative personnel, evaluating creative personnel, creative mindset.

1. Introduction

The term culture refers to a complex concept that leaved through the ages due to various interpretations that gave different opportunities of growth. Ever since Cicero and later on Voltaire, the term culture was perceived as “valorization specific to the human spirit”, but also as a term referred to as something that describes “cultivating” or “growing”. (Gauntlett & Thomsen, 2013)

The definitions of culture widely refer to this word as being the result of products and services given by human thinking.

A first definition of culture would have to recognize both the abstract and material elements of culture. Culture influences attitudes, values and personalities around the world, religious preferences sets borders between individuals and between they will act, think. We can therefore refer to these aspects as being cultural rules. (Gauntlett, 2011)

The need of engaging people into cultural activities becomes the basis of human development, and it comes as a package deal with the need of correctly evaluating them once they become part of the cultural process.

2. The importance of culture as science

As previously discussed culture can be understood as a learning process, in which individuals voluntarily take part and one that gives perceptions, preferences and behaviors’ either through different groups (e.g.: dance crews) or social institutions (e.g.: museums).

Culture is passed away from one generation to another, it’s adaptive, it can be tangible or intangible, and it’s usually transforming as it evolves.

The content of culture will materialize under the form of either material culture creations (usually tangible creations) or immaterial culture creations (abstract creations such as: ideas, knowledge, opinions, values, rules, symbols, etc.). (Hawkins et al, 1983)

Culture can be understood from two different perspectives:

- one perspective that refers to culture as a service delivered to society;
- culture can also be understood as complex system with variables as the ones shown above, a system that encourages creative activities and their promotion to a public through an organization, making it a cultural product.

E-mail address: iurian_sergiu@yahoo.com.

Fig. 1. A model of culture (adapted from Sørensen et.al., 2010)

This adapted model shows culture as being at the center of four major characteristics of society such as:

- **being** at the core of :
 - a) traditions;
 - b) identities;
 - c) roles.

This means that culture *plays* a major role in the individualization of each nation, religion or ethnicity. Culture can also be individualized based on the cultural institutions it refers to. This also means that cultural people (as in people who are involved in the promotion of culture) are the ones that have to *think* the ways in which culture can be an entertaining and useful experience.

- **knowing** the full history of:
 - a) experiences;
 - b) knowledge;
 - c) meaning

This translates into the fact that culture is a result of the historical evolution either upon a group of individuals, or upon individuals seeking to contribute to the cultural heritage. Each individual sometimes expresses directly or indirectly his meaning on this world through culture. Whether we refer to an individual, or a group of individuals, they all possess the ability to develop knowledge, experiences or new meanings that will affect the cultural heritage in one way or another. Culture thus becomes a platform for social heritage.

- **having** different:
 - a) environments;
 - b) materials;
 - c) media access.

This means that culture is an expression of the *making* process. In other words, culture is an translation of knowledge through different platforms such as environments, materials or media. Having culture is one thing, but being able to share it is a completely different discussion

- **doing** things that will involve *sharing* culture such as:
 - a) activities;
 - b) developing relationships;
 - c) practices

This means that culture need to be shared in order to be perceived as something that identifies individuals, objects, groups of individuals, nations etc. Therefore, the process of being, knowing and having has a certain ending, by passing on knowledge. Sharing culture ultimately means sharing the cultural products. It can also be viewed as the beginning of

the process, if we perceive doing all these activities, relationships and practices as a source of origin for the cultural movement.

As a science, culture becomes extremely important because it does not only develop and transmits means of developing cultural products such as art works, but it also can be a science that can offer more understandings towards what are the characteristics that define a certain area, or group of people, whether we refer to an ethnic group, or a nation as a whole etc. Culture becomes thus a binder between different individuals, a science that can offer an infinite amount of understanding on how society works and interacts.

From a legal point of view these cultural institutions are to be understood as “a public or nonprofit organization that is engaged into cultural enriching, intellectual, scientific, environmental, educational or artistic enriching within communities. Cultural institutions also can consist into aquatic organizations, botanical, historical, preserving patrimony, public libraries, museums, artistically associations or zooidal ones.” (Oregon juridical dictionary)

Cultural institutions can be classified from various perspectives depending the context or their activities, however understanding the way human resources function within this type of organizations means understanding both the definition of the term culture and the way human resources management works (by the importance of the creative personnel).

3. The importance of cultural marketing

Cultural marketing is a widely referred to as a special domain of marketing that has emerged due to the extensive development of culture and in order to promote the cultural products and services.

Cultural marketing will assist any cultural organization into achieving its mission. Cultural marketing is also known as “marketing of arts”. This process need to be adapted from one organization to another, from one type culture to another. Therefore, the main organizations which this process can be applied to are (Pride & Ferrell, 1985):

- religious organization;
- research and education organizations (cultural ones, which different from the specific educational organizations);
- NGO’s specialized in promoting cultures (foundations which have special purpose into promoting culture);
- museums, memorial houses;
- libraries, archives;
- publishing houses;
- theatres and operas;
- cinemas;
- expositions and special institutions organizing cultural events;
- arts manufactures and traditional arts associations;
- individual artists or special artists’ associations;
- bands and other forms of artist groups;
- in the new modern times we live in, culture has been given an important commercial meaning.

This means that in order to survive a cultural organization of any kind needs to address itself to a specific type of consumer and needs to adapt itself to a very complex process that involves a high number of variables. For instance, cultural organizations need to be perceived as being contributors to (Miyata, 2013):

- education – by transmitting the main instruments for understanding and appreciating culture;
- the institutionalization of the ways for spending free time – this means that nowadays people are very selective when it comes to spending their free time, because of the various ways of doing it. Culture plays a huge part in this process because it can both influence it, or give options to individuals acting therefore as a supplier of products and services;
- technical support for the mass distribution of the cultural products and services.

Cultural marketing operates thus into various fields with a large number of opportunities regarding the satisfying client needs.

Regarding client needs it is very important to understand the concept of being a culture client, which means being either a spectator or directly involved in the cultural process.

The creative personnel involved into cultural process has also double role, being both creators of arts, and, at the same time, being the main ambassadors for this process.

Creative personnel, being involved into the marketing process need to take into consideration the consumer needs and motivations regarding culture such as:

- renowned creators or band or artistic company;
- the pleasure of listening to music;
- the desire to relax;
- advertising made for the show;
- recommendations made by parents and friends;
- favorable art criticism;
- the desire to go out with your parents and friends to the show.

All cultural organizations are faced with the difficult task generating new marketing strategies due to the change of the environment in which organizations prosper:

- the consumer has diminished his leisure time;
- expanding options for consumer diversification;
- the wider global exposure of cultural products worldwide;
- changing public funding methods;
- the distinction between popular and supreme culture is increasingly blurred;
- organizations are at the end of their lifecycle.

4. The importance of creative personnel

The importance of creative personnel in culture can be specially defined by the importance of organizational culture in arts. Being able to build an organizational culture for a cultural institution consists into creating a cultural product or service. This process has a specific original nature when it comes to culture. The cultural product or services are designed into a special environment which has its own history, values, boundaries and ultimately affects the way the organization understands and appropriates a specific system of values. (Runco, 2013)

In the center of this processes, the one of creating value and the one of creating an identity for an organization, stands a specific type of personnel. It is easily to be understood why this type of staff is a creative one, made of people with a high level of cultural understanding. Creative staff members have difficult tasks of:

- understanding client needs;
- anticipating client needs;
- creating products and services;
- understanding the environment in which their organization operates and creating added value;
- promoting cultural products and services;
- evaluating themselves in order to either improve what can be improved, or dispose what is disposable.

Creative personnel thus have to manage a difficult process between the needs of being an artist, and the expectations of the general public, (consisting into public actors – trustees; consumers). (Donald, 2013)

Managers of creative personnel have the difficult task of being leaders of this complex cultural process and specific type of staff. Their work consists into being able to give stimulants and performance bonuses to their personnel, a work that is generally not easy because it needs to satisfy both financial and nonfinancial rewards that creative personnel need.

Leadership into cultural organizations needs to address the main goals that each creative individual has which can be defined as Maslow states into five basic needs:

- psychological needs;
- security needs;
- social need of belonging to a group;
- esteem needs of respect and trust;
- personal development.

5. The importance of evaluating creative personnel

The necessity of a creative mindset especially when it comes to culture is undoubtedly high. The creative mindset has been during ages the main thing that has made the human race evolve or even survive. Therefore, stimulating a creative mindset especially to cultural activities, is a luxury that human race must entertain. (Runco, 2013)

This comes with a package deal of certain level of ease when it comes to the pressure of generating results. A creative mindset only prospers in certain environment where all its need and desires are fulfilled and where the level of pressure is relatively low.

Managers cannot force creative mindsets into generating products and services especially when it comes to cultural ones thus evaluating the creative personnel requires first and fore most evaluating their needs, the way in which the cultural organization can fulfill them and only then the results generated can be submitted to evaluation.

We can then easily pick different ways of evaluating creative personnel by their success, or more exactly by the way their work is being perceived and understood:

- on one hand we'll have a scenario where evaluating creative mindsets is done by the perspective of success triggered by their results;
- on the other hand we'll have a scenario where creative personnel hasn't been generating the results which the interested parties were looking for;

This also means that the marketing aspect of the creative work plays a huge part because maybe a cultural product or service has been created properly, but, from a various numbers of reasons, hasn't been transmitted properly to the clients. Cultural marketing therefore offers an alternative to cultural managers into evaluating creative personnel, because it operates as "the last stand" between successful cultural personnel and unsuccessful. Sometimes a good

marketer can hide its lack of creativity when it comes to their products or services under their great ability of communicating and promoting something that doesn't necessarily added value.

It is thus that cultural marketing can make the difference between the success or the failure of a cultural institution.

Evaluating the creative mindset should focus on (Gauntlett & Thomsen, 2013):

- seeing whether the individual's attitude towards the world is defined by curiosity, essential questions desires to share, to produce, or to play. Children usually have these attributes, therefore a creative mindset should be able to sustain them, to constantly nurture, or keep the flame of the "inner child" active.
- seeing whether the creative mindset is still active. This means that a creative individual never loses interest in their creative subject, it can reduce its intensity towards it, but lose it. This is why evaluating creative personnel should focus on seeing if the curiosity level is only at a low point or whether it has disappeared.
- seeing if the creative mindset has a high level of a playful behavior. This means that creative individuals are usually tempted to spend their free time into the same world creativeness regarding their designated subject. They tend to find different approaches towards the designated subject and approach them with a playful behavior.
- seeing if the creative personnel is able to fuel their desire to learn with expert help or by self-education. This means that even though creativeness might be understood as an individual process, nevertheless it is far from being so. Creativeness must have a knowledge basis which is defined by expert help, thus one cannot be creative regarding culture unless he/she has a certain knowledge and understanding about their designated cultural process.
- seeing if the creative personnel works in an environment that promotes creativeness, risk taking and also collaborative activities. This means that a creative mindset will usually look for an environment (space or a group of people) which stimulates its creativity knowledge regarding their subject and thus has an open mindset. This also can be translated through the idea that culture rarely was born from a cave, but from an open mindset that prospered into a rich (full of potential) environment.
- seeing if the creative personnel has generated more than one scenario where their idea might prosper. This means that in order to be successful a creative mindset must be open to the idea of trying, even with risk of failing, therefore creative personnel should be evaluated by their ability of trying more than once.
- seeing if the creative mindset is able to accept diversity. This means that creative personnel can prosper only when they are able to identify their consumers and in order to do so they must first cope with the challenge of understanding diversity, accepting it and knowing who to address and how to do it. Thus creative personnel should have a high level of acceptance regarding society.

All the aspects explained above could be evaluated from the different quantitative and qualitative approaches. Nevertheless, the results should be the same, in other words each of the points shown above should have high levels among creative personnel. If the levels are low in either of the cases shown above, there is a risk that the creative personnel is not as efficient as should be and therefore immediate action is required, if not the cultural institution risks failure.

However as shown above cultural marketing plays a huge role and comes as a helping tool for those (either staff or managers) who can or want to hide their lack of creativity behind a well-constructed process. Or on the other hand, cultural marketing can be an obstacle for a creative cultural mindset that is not able to communicate its work. (Durkheim, 1938)

Thus cultural marketing should also be considered as an attribute of creative cultural personnel and included in the process of evaluating the creative mindset of the cultural personnel. (Gauntlett, 2011)

Acknowledgements

Culture is an abstract term used to define a number of values and contributed to the evolution of mankind. Culture can also be viewed as a science seeking to offer solutions towards understanding and improving the social heritage, offering solutions towards understanding the cultural products.

Marketing plays a huge role in promoting culture. Cultural marketing is based on the ability to promote but also to understand the needs of artists and expectations of the public.

When it comes to culture, creative personnel plays a huge part in developing new products and services of culture. Creative staff members usually have certain needs in order to offer results. Creative personnel is defining for cultural institutions, but this does not mean that the creative process works into an absolute free environment.

Evaluating the work and the abilities of the creative personnel is a difficult task which should be made regarding certain key points, one of them being the ability of the creative personnel to promote, to present their work. The way the evaluation is made, ultimately affects the way creative personnel works and generates results.

The future will give us more and more ways of spending our free time. This means that cultural institutions will be working into environments more and more in a hostile environment, thus, the abilities of creative personnel become highly important because the quality of cultural products and services need to be better and better in order to compete with other ways of spending free time. Evaluating the creative personnel and cultural marketing become two imperative aspects that cultural managers must not ignore.

Dimensions and indicators of quality management assessment in the context of sustainable development

Monica Aureliana Petcu^a, Iulia Maria David-Sobolevski^a, Irina Daniela Cişmaşu^{a*}

^aThe Bucharest University of Economic Studies, Bucharest, Romania

Abstract

Sustainable business development, in an environment marked by strong dynamics that leads to changes of paradigms and meanings of the evolution of various components, generating constraints and multiple risks, is decisively conditioned by the quality of their management. Quality is a complex concept that can be defined by a series of quantitative and qualitative indicators adapted to the specificity of each entity's activity.

In the context of this paper, in the perspective of the sustainable development of enterprises, a brief presentation of the characteristics of the management quality assessment was considered, as a process with dynamics connected to the environment, with complex approach dimensions that imply specific reasoning, circumstantially relativized measurement and interpretation techniques, especially with benchmarks in maximizing the satisfaction of all those interested in their work, including communities, as well as environmental protection.

The research undertaken for this purpose has been finalized by proposing a set of indicators to provide, from the perspective of each stakeholder, sufficient arguments in the proper assessment of the quality of management and in making appropriate strategic decisions in the context of sustainable development

Keywords: sustainability; quality; management; performance

1. Introduction

Accelerating the changes in all environments, from the natural to the economic and social ones, and the prolonged economic and ecological crisis lead to connecting all the companies to the complex problems of sustainable development of their own activities, in the conditions of globalization. At the same time, the dynamics of the expectations of the stakeholders (clients, partners, investors, employees, community, etc.) requires continuous improvement of the quality of products/services, the efficiency and effectiveness of processes, the reduction of non-quality losses.

Between the arguments of any actor on the market, regardless of the size or area in which it operates, quality and innovation, especially eco-innovation, are required as fundamental factors of sustainable development.

As a vector of business excellence and a decisive factor in competitiveness, product quality is a fundamental business objective: "Quality of the product is not everything, but everything is nothing without quality" (Peters and Waterman - "In Search of Excellence") and the result of an integrated quality management system. The integrated approach to quality implies: the quality of products/services, the quality of processes, the quality of management, the quality of the workforce and the working environment, the quality of the results, the quality of the partnerships, etc. In this integrated system, the role of management is decisive, noting the dialectical interdependence between quality management and management quality.

* Corresponding author. *E-mail address:* irina.cismasu@cig.ase.ro

2. Quality of management - content and assessments

The definition of quality implies certain difficulties due to the need to interpret a formalized system by another formalized system, this interpretation depending on the analyst's ability to find objective operational terms as appropriate as possible and their measurable levels. It is also necessary to delimit the intangible dimensions of quality by its tangible attributes.

In an integrated system of assessing the quality of management, particularly important are the ways of approach, taking into account the following:

- the quality of management is the result of a continuous upgrading process aimed at maximizing the satisfaction of stakeholders with specific benchmarks of evaluation;
- the evaluation of managerial quality from the perspective of the sustainability of the activity carries out a complex approach in relation to the holistic subsystems in this approach, for each of which there are certain qualitative and quantitative indicators;
- the quality of management lies in the quality of products/services, results processes and partnerships, across the value chain, each having its own reference system;
- the diversity of the system implies the correlation of economic, financial, social, cultural, ecological dimensions.

From the economic and financial perspective, the quality management assessment involves both qualitative analyzes, through which systems are approached, elements, their structural and conditioning relationships, are identified, and quantitative analyzes that allow relevant quantification. Consequently, the assessment of the quality of management on this important level with certain assessments, through usual indicators that reveal the performance of the enterprise with repercussions on the satisfaction of stakeholders, has been considered satisfactory to date, when the issue of sustainable development and the creative-innovative dimension, eco-innovative are becoming key factors in assessing the quality of management.

From the socio-economic perspective with complex socio-cultural dimensions, including consumers, employees and the community, management quality assessment implies specific reasoning, based on derived indicators, own measurement and interpretation techniques, involving subjective relativisms and interpretations.

From the customer's point of view, the quality expresses the benefit of consumption, compliance with its needs, the reference value for the buyer consisting of its maximum expectation, within its own budgetary constraints, and the value of the product/service as such is given by the degree of utility in meeting a need, depending on its budget constraints (utility/cost grade). From the point of view of the manufacturer/service provider, the quality expresses the attributes, the essential features that define the product/service, respectively the function it performs, giving it the capability to use and the costs involved (degree of function/cost) satisfaction. Exceeding consumer expectation, correlative with the provider's capabilities fitting, ensures quality management and business excellence.

A particularly important area, in terms of sustainability, is the ecological one. Strict adherence to environmental standards and the sustained effort of eco-innovation are stringent requirements that give quality to the managerial process, even if the economic and financial results appear modestly and gradually.

From any perspective or within any holistic subsystem, the quality of management is addressed, the key is to use a complex system of indicators to enable it to be valued in relation to stakeholders, including the community and environmental protection, as a circumstances for the sustainable development of the enterprise.

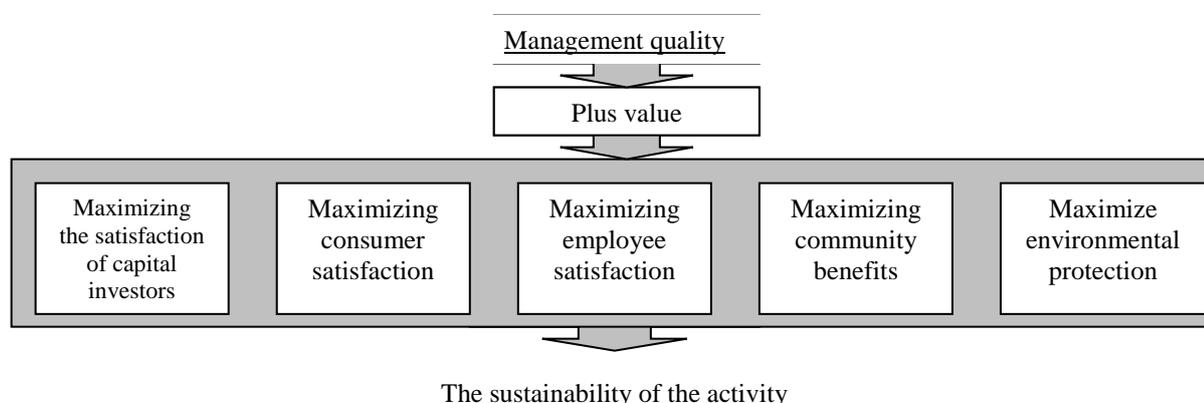

Fig.1. The approach of the quality management assessment in a sustainable perspective

3. Sustainability Performance Indicators

In a brief approach we present a series of indicators for the management quality assessment under the imperative of sustainability, structured in the presented context of the stakeholders:

- at the level of the capital investors

indicators	meaning
Specific indicators	
investment in scientific research and information technology	The orientation of investment efforts towards scientific research, in all its dimensions (from the fundamental one, to the application in production), and the information technology provide the premises of the adaptation to the dynamics and general progress, and at the same time its catalyst. The research results are generating superior added value, improving product and process quality, improving resource efficiency, with ecological valence.
innovative capacity	Stimulating the innovative capacities of human capital, expressed through the registration of trademarks, patents, licenses, product/ process innovation, with a high level of competitiveness and a sustained rhythm of technical progress, is a vector of sustainable development.
Support indicators	
turnover	A growing sales volume reveals the performance of the production and marketing activity by recognizing the value of the product/service offered by the consumer. Increasing sales, with an appropriate mix of quantity and price, is a condition for sustainable company development. The significance of the company at the level of the industry is appreciated by the size of the turnover. Companies with high market share ensure their sustainability in a dynamic, highly competitive environment.
profit	Achieving a significant and growing profit ensures self-financing of investments and increasing the indebtedness of a firm. This creates the financial resources needed to invest in projects with a high technological level, innovative, linked to the dynamics of the research in the field, which is the basis for a sustainable development.
return on investment	The decision to invest in a dynamic, complex, highly competitive environment requires, to ensure the capacity to capitalize on opportunities to maximize earnings and reduce risk, focus on investment project portfolios. A high return on capital invested in each project amplifies the synergistic effect of strategies, ensuring sustainable development.
the liquidity of the invested capital	Rapid recovery of invested capital allows the exploitation of new opportunities, synchronizations and even advancements in the rhythm of development of the industry, the elimination of opportunity costs and, implicitly, resources for the sustainable development of the firm.

- at the customers' level

indicators	meaning
Innovative products / services offered	Achieving innovative products/services with superior levels of value and expectation is an effect of management quality and the premise of sustainability.
Customer Satisfaction Score	Determination of satisfaction and changes in consumer satisfaction provides important information on the positioning of its products/ services in relation to consumer expectations and trends, which are milestones in substantiating sustainable development strategies.
Net Promoter Score (NPS)	Customer satisfaction assessment indicator, NPS is a reference in substantiating company strategies. A value tending to 100% reveals a maximum degree of customer satisfaction and their willingness to recommend the brand/product/service/store to others. Providing valuable products / services that exceed consumer expectations leads to increased demand, ensuring the potential for sustainable growth.
Customer Effort Score (CES)	A value in the proximity of the unit reveals great efforts in getting the product/service offered by the customer. The proximity of value 5/10 reveals the facility of acquiring the product, which will allow time and financial savings that will lead to customer loyalty. Increasing accessibility of products/services implies the imposition on the market, increasing sales, with consequences in the ability to sustain sustainable development.

industry benchmarks Evaluating the position of the brand in relation to its competitors allows us to obtain relevant references in substantiating the company's strategies, putting the focus on efforts to gain competitive advantage over the whole value chain. This implies the implementation of quality management systems. Validating the brand's superiority on the market is an essential element of competitiveness as a condition for sustainable development.

brand attributes The convergence between customer expectations and brand/ product/service attributes is a decisive factor in asserting them on the market and strengthening the market position of the firm. The similarity of perception of brand attributes at company and consumer level ensures customer loyalty, transformation them into promoters and sustainable development.

- at the level of employees

indicators	meaning
the optimal environment for using its own capabilities	The convergence between job requirements and individual capabilities is a condition of harmonizing employee interests and aspirations, with beneficial effects on innovative, efficient and sustainable company development.
fair compensation	Providing salary packages to satisfy the effort, being stimulating through the value generated individually, supports the effectiveness of the creative potential and the empowerment of employees as a sustainable competitive advantage.
safe working conditions	Job security enhances employees' involvement by eliminating absenteeism from focusing on physical integrity and improving work quality, focusing their attention on the production process. This is reflected in increasing productivity, capitalizing on creative and innovative skills, lowering the cost of accidents at work, staff litigation, with favorable effects on the sustainability of the work.
pleasant work environment	A pleasant work environment ensures physical, emotional and cognitive involvement. Reducing workplace stress is a prerequisite for increasing work productivity with effects on company performance. Happy employees have a creative, positive attitude and contribute to making team work more efficient. Pleasure to work in the right conditions favors employees' involvement, ensuring business success. At the same time, a pleasant work environment reduces the fluctuation of employees, with the company benefiting from the learning effect.
career development	The inclusion of employees in continuous training and professional development programs is the premise of increasing adaptability, creativity, innovative capacity, sine-qua non conditions of sustainable development.

- at the community level

indicators	meaning
the ratio between sponsorship and donations and turnover	Awareness of the need to engage in solving problems or in developing community projects, that exceed its resources, in ensuring a high level of welfare in the society in which it operates ensures the premises of an environment conducive to sustainable development.
investment in public-private partnerships	The development of public-private partnerships to achieve general interest objectives creates stimulating synergies for sustainable progress.

- from the ecological perspective

Indicators	meaning
eco-inovation	The creation of eco-innovative products/services and the innovation of processes with ecological valences are essential concretizations of management's concern in sustainable development.
efficiency of rational use of resources	The efficient use of resource ensures increased economic stability by reducing volatility in essential resource markets; limiting the risk of deficits and increasing competitive pressure; improving the economic health of key sectors enhancing long-term economic competitiveness. The efficient use of natural resources requires ecological fairness and sustainability.

the degree of environmental pollution

Reducing carbon emissions, increasing waste collection, making more use of renewable energy, efficient use of resource contribute to the prevention of dangerous climate change and are imperative to contemporary society circumscribed by the need for sustainable development. A priority objective in company strategies is to avoid natural imbalances, preserve the integrity and nature biodiversity and restore ecosystems, reducing vulnerability and increasing their resistance in a fair and sustainable development process. Reducing the anthropogenic pressure on biodiversity is now not only a condition for the sustainable development of enterprises, but also for the whole of humanity.

Conclusion

Sustainable business development is influenced by the quality of its management. Driving efficiently processes, obtaining quality products/services, stimulating creativity and innovation, reducing pollution, converted to maximizing the satisfaction of stakeholder, are fundamental management responsibilities.

The dynamics of environmental changes and the imperatives of sustainable development require a permanent process of strategic approach and holistic planning with milestones in the quality of management assessment, with an ongoing progress. In this context, the assessment of the quality of the management is also a dynamic process in relation to the conditionality of sustainable development and the maximization of the satisfaction of the stakeholders. Identifying a system of performance indicators adapted to the specifics of the enterprise and linking to the dynamic imperatives of sustainability will provide a solid foundation for assessing the quality of management and strategic decisions in this area.

The assessment of the quality of leadership as a resource for sustainable development

Vasile Robu^a, Irina Daniela Cişmaşu^{a*}, Alma Maria Petcu^a

^aThe Bucharest University of Economic Studies, Bucharest, Romania

Abstract

The constraints of sustainable development in an environment marked by high dynamics of the volume, diversity, and magnitude of the changes with a particularly high degree of risk have led to the reorientation of management research towards an inexhaustible cardinal resource: human creativity. The purpose of this research is to highlight the importance of leadership in creating the vision and the team able to implement it, in converting the potential of each member into creative efficiency, in the stimulating synergy of the people to achieve excellence in business and ensure sustainable business development. Also, the main differences between leadership and management, as well as the fundamental qualities that define the leader have been identified. The quantitative research has led to identify on the selected sample the differences in the perception of leadership quality on three dimensions considered relevant: focus on the client, focus on the team, and focus on the results.

Keywords: sustainability; quality; management; leadership

1. Introduction

Globalization has created conditions for business location in the most cost-effective environments, but also for the proliferation of large corporations with rigorous management, structures and procedures based on a permanent process of research and improve in the field, in an extensive development process. Reducing growth rates, falling labor productivity, environmental imbalances in the economic and social sphere, increasing the cost of resources and internal holistic of these areas imply major challenges that exceed the possibilities of adapting of a management that remains in the limits of conformism of some procedures even scientifically elaborated and routine.

The research undertaken at the level of many companies has revealed that the sustainable development of an entity is determined by the quality of its management. At present, businesses that are looking for sustainable development are pursuing excellence in business. Management research has led to the development of business excellence models: the Australian Business Excellence Framework, the Malcolm Baldrige National Quality Award (MBNQA), the Canadian Business Excellence Model, the **European Foundation for Quality Management, and the Japan Quality Award**. One of the determinants of business excellence, common to all models, is leadership. After extensive research on company, J.Collins states that "Excellency is not circumstantial", that the strategy itself, no matter how well defined, as technology or technology change or compensation systems, top-class membership or scouting famous managers, etc. did not mark the difference between "good" and "excellent" and that the most important lever to reach this level is "fit people" and "level 5 leaders".

In the literature, we find numerous definitions of leadership:

„A leader is one who knows the way, goes the way, and shows the way." by John Maxwell.

"Leadership is lifting a person's vision to high sights, the raising of a person's performance to a higher standard, the building of a personality beyond its normal limitations." by Peter F. Drucker.

"Innovation distinguishes between a leader and a follower." by Steve Jobs, 2013.

"True leadership lies in guiding others to success-in ensuring that everyone is performing at their best, doing the work they are pledged to do and doing it well." by Bill Owens.

* Corresponding author. *E-mail address:* irina.cismasu@cig.ase.ro

In this context, the authors believe that the leader is the one who has a coherent vision of business and results, is able to assess the necessary resources, the stages of its realization and to create the team that adheres creatively and performant to this vision.

Leaders and their appropriate teams that address change and issues as opportunities and challenges for new approaches, new solutions, those who open up new perspectives and convert risk and danger into development and efficiency vectors, those who ensure the creative, innovative use of human potential, are, in the current situation, a decisive factor of sustainable development.

2. Leadership and management

Changing the management paradigm by moving from setting objectives and controlling their approach to a complex approach that includes all stakeholders in a business as well as dynamically amplifying the changes in the environment in which the firm operates, in conditions of increased competition, have forced new directions in the research of management and essential reconfigurations in this system. The researches have highlighted the importance of creative, innovative involvement of leadership and team in the company's sustainable development. In this context, leadership has been defined as a component of management systems that provides sustained competitive advantage.

In defining the notion of leadership, features that differentiate between the leader and the manager are distinguished some of the following:

leader	manager
Ability to develop and communicate visions, inspiring employees	Ability to build structures, to delegate authorities and responsibilities
Ability to change	Ability to lead
Ability to challenge	Ability to create rules, standards
Focus on understanding and interpretation, team building, motivation and influence of employees	Focus on planning, organization, control
Exercising authority through vision and ability to find solutions	Exercising authority through the position in company
Leadership is art and science	Management is science
Evaluating team members through their potential and commitment to materialize the vision	Employee evaluation through professional training and work outcomes

The company's performance involves the interference of leadership and management, an over management as well as the absence of genuine leadership capping the creative potential that ensures sustainability.

3. The fundamental qualities of leadership

Introspection in the sphere of defining statements on leadership has facilitated the structuring of the main qualities needed by a leader, organized on the axis: has vision - has integrity, considering the ability to lead the team from the latent to the creatively effective, integrated with the others.

We briefly present the significance of these fundamental qualities identified:

- has vision - a leader must have a specific way of understanding the situation and the context, as well as interpreting things or phenomena, identifying, developing and exploiting opportunities, acting in an efficient way to achieve the goal. The ability to develop and execute a coherent vision, to project them in complete detail and to follow its step-by-step materialization, to the last man and to the last detail is essential for the leader;
- has the knowledge and skill that must be continuously developed by being permanently in touch with people who have skills and abilities in progress that they lead or with whom develop partnerships to produce goods/services that meet the expressed and latent needs of consumers. One of the leaders presented by J. Collins states that "I never ceased to try to become qualified for the job entrusted to me", which exemplifies the most suggestive need for permanent training and information in the field;
- is an example - leadership involves responsibility within a team, and it must be aware that it is considered as an example through the way of thinking, through innovative ideas, through proactive attitude, by way of action;
- is creative and finds solutions - a leader must be innovative and make the team always open to new, find solutions to overcome constraints, solve problems, exploit opportunities;

- cares about people - the leader must perceive himself as a member of the team and is dedicated to it. The diversity of individuals in a team, the different personality involving specific attitudes and motivations, must be understood and considered opportunities. Full team engagement, recognition of individuality, identifying what everyone likes and what one can do best, boosting self-confidence provide competitive advantages at the organization level. Leadership is not about the leader, but the people in the team;

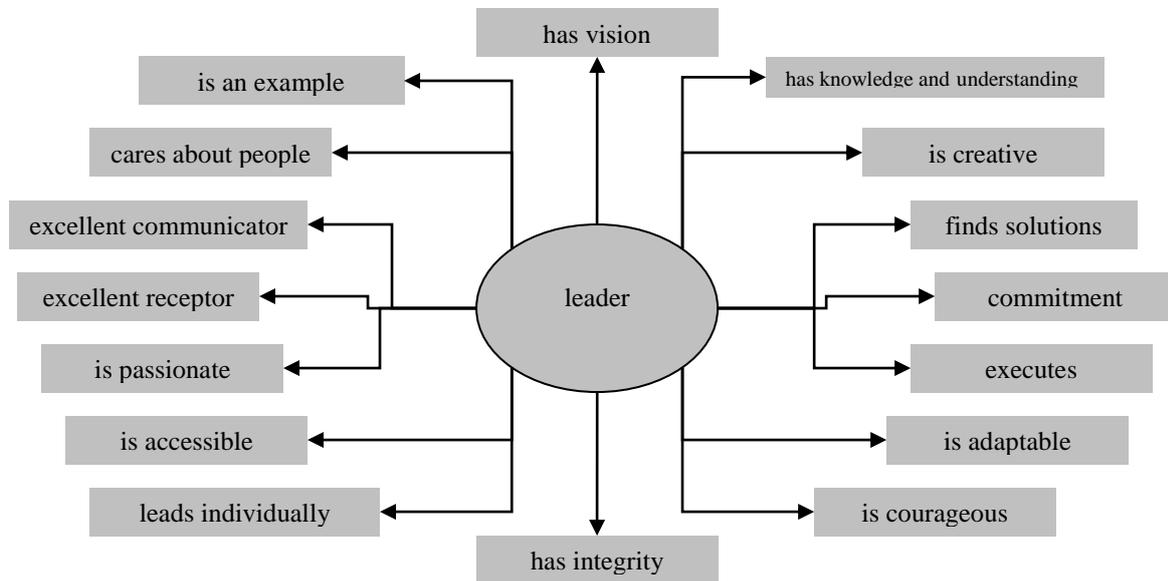

Fig.1 The fundamentals qualities of the leader

- is an excellent communicator and an excellent receiver - a leader must develop the ability to communicate clearly and concisely in the meaning of any person with whom they relate to in order not to create confusion and inaccuracies; at the same time, the leader must listen to any member of the team, partner, or other interested person, and to fully understand what is being communicated to make the most accurate decisions;
- leads individually - each member of the team is part of the joint effort, and the leader needs to know, guide and appreciate each person's work individually to make the most of their potential. The leadership translates the decision to the lowest level, considering as leader in its area of responsibility each member of the team;
- is accessible - resulting from communication and leading individually, accessibility becomes inherent, the quality of the messages and the time needed in the economy of the common project are to be appreciated in both directions;
- is passionate - leadership is art and science: for art you must have talent and passion without which you cannot have vision, you cannot act innovator, you cannot individualize yourself; for science you must always have up-graded knowledge, which again involves the passion and the constant interest in maintaining your right rhythm and preserving your quality of leader;
- engages himself and creates conditions for team members' engagement - engagement involves emotional involvement in creating value for the firm. In the context of assuming a common goal with the entire team, the leader must be proactive, point out the commitment of each member of the team or those who show inactive or even retroactive behavior. The art of engagement aims the decision regarding how to efficiently engage the team members. Commitment to the company goes to the preparation of equally visionary, passionate and involved successors. Precisely preparing such successors transforms a level 4 leader into a leader of level 5 and proves the involvement in the present and future company activity;
- executes - the leader has resources and must achieve results with maximum efficiency and effectiveness;
- is adaptable and courageous - an authentic leader needs to appreciate correctly what can change or when it is necessary to change himself and his team and have the courage to conform; an authentic leader views change as an opportunity for development and progress;
- his integrity - "The Supreme Quality of a Leader is Integrity" (Dwight D. Eisenhower); a leader assumes all decisions transmitted in their letter and spirit, does not admit ambiguity and inaccuracy.

The attachment to the company and its promotion to all team members accompanied by an extraordinary modesty and constant need to know all the aspects of the activities carried out, continually qualifying, but also the micro and the macro environment in order to adopt the most correct decisions, as well as the courage to accomplish them, regardless of difficulties, for the firm's sustainable orientation in the conditions of sustained growth of its performances are fundamental qualities of the leader at the top.

4. The analysis of the quality of leadership - case study

In order to analyze the perception of the quality of leadership, a study based on the evaluation of three dimensions was carried out:

- focus on customer - validation of the company's efforts is carried out on the market by the clients. Leadership orientation towards customer satisfaction is a condition of ensuring sustainable development. The main criteria for assessing the quality of leadership in this dimension are: product/service innovation, value creation, flexibility, training and changing attitudes and needs, assurance quality throughout the product life cycle, elimination of deficiencies, and defects;
- focus on people: the leadership efficiency can be considered integrated to the performance of the team, as one of the fundamental features of leadership is the orientation towards the person as a potential creator of value. The main issues addressed are: personal development by turning potential into effectiveness, re-enforcing goals, ensuring a working climate that encourages and stimulates commitment and creativity, permanent and reiterating communication of the vision and ideas;
- focus on results: the quality of leadership is assessed by the company's results, targeting three levels of interest - customers (customer loyalty, increasing the attraction rate of new customers, increasing market share, increasing turnover), employees (reduction of staff fluctuation rate, increase in productivity, negative correlation index) and investors (profit, stock exchange rate, capital investment liquidity, return on investment)

Data research and analysis instrument

Quantitative research to assess the quality of leadership is based on a survey of leaders and employees from 11 hotel units, based on a questionnaire structured on the three dimensions considered, containing a total of 21 questions, using a Likert scale with 5 steps. Depending on the specific nature of the work done by each employee and the considered dimension, 18 leaders and a different number of employees expressed their opinion: 290 employees, for the assessment of customer focus, 375 employees, in the case of assessment of the team focus and 22 employees in the case of assessment of the focus on the result. Data analysis was performed using statistical methods, using the Excel software, the Data Analysis module.

Dimension	level	average	standard deviation	minimum level	maximum level
focus on	leadership	22,56	2,21	13	25
customer	employee	18,43	2,98	14	23
focus on person	leadership	15,5	2,3	8	18
	employee	13,25	2,31	9	16
focus on results	leadership	38,89	3,41	16	49
	employee	38,23	3,92	22	45

From the analysis we find a difference in the perception of the quality of the leadership at the level of the considered sample. For all three dimensions, there is an overestimation of the leader level compared to employees' one. The differences between the minimum possible level and the effective minimum are superior to those between the maximum possible level and the effective maximum, which reflects a superior qualitative level of leadership. At the level of each dimension, the difference between the leader's and employee's evaluation, based on the average, shows different values: 4.13 for focus on the team, which highlights reservations in the relationship between leader and team; 2.25 for focus on the customer, due to a relative similar appreciation of this dimension and 0.66 for the focus on the result that involves concrete quantitative assessments, limiting the differences in perception in relation to the assumed objectives. There are close values of standard deviations of leaders and employees at each level, which reveals a relatively similar appreciation.

Conclusion

The complex of factors influencing the activity of an enterprise requires management to be at a higher level that transcends the rigorous scientific framework but relatively limited of the current approach in the field. It recognizes the need for leadership, leadership as art, visionary, and ability to adapt and solve correlatively the environmental challenges within an appropriate team that can transform constraint into opportunity and weakness in strength.

Leadership is equally visionary, creative, innovative lead, with firmness and determination, but also the ability to select and form a team where each member is a specialist, a leader in his area of responsibility. The ability to connect convergently and synergistically the creativity and effects of leaders at all levels is defining for leadership.

At the same time, leadership implies a deep attachment to the company for whose sustainable development his efforts are devoted in a permanent process of adaptive qualification to environmental change and conversion into the efficiency and effectiveness that the entire team makes. By affirming the leadership's supremacy, this leadership also affirms the essential role of the team in which each member is the leader in the assumed issues, under conditions of maximum responsibility.

Increasing the Quality of the Taxes and Fees Impact Assessment on the Romanian Economy

Loredana Andreea Cristea^{a*}

^aLucian Blaga University of Sibiu, B-dul Victoriei, no. 10, Sibiu, 550024, Romania

Abstract

The current market economy is characterized by a faster increase in resource requirements than the possibilities of obtaining them. Thus, it is crucial that any state address the problem in the most effective way, so that there is a balance between demand and supply (resources). The impact of taxes and fees on the development of the economy can be seen from the perspective of state incentives for investment and available financial resources. The two are in a relationship of dependence, saying that the lack of increase in the number of investments is a consequence of the additional tax, even with the aim of increasing the financial resources, but which still has daunting effects. In this context, this paper has as goal to set the basis for the development of a rigorous scientific research methodology aiming to bring more knowledge from the experience of developed countries in the researched field in order to identify proposals for streamlining the system of national taxes and fees, as well as adopting new methods and techniques for managing this complex system.

Keywords: quality; tax; fee; impact assessment; research methodology, finances, economy.

1. Introduction

Most of the state's financial resources are subject to mandatory levies, namely taxes and duties, which are income-generating sources and have a major impact on the functioning of the economy as a whole, in particular on the redistribution of economic resources. The tax and fees system is the main source of state budgeting, a budget without which the existence of a state is unthinkable. And depending on these additions to the state budget, it depends on the standard of living of all citizens, which materializes in the current state economy.

The actuality of the studied topic is conditioned by the need to estimate the impact and role of taxes on the formation of budgetary revenues, but also on the economy. Taxes have a decisive impact on the development of the national economy as they can be used as levers of economic and financial policy. In relation to the way the tax system is conducted within a state, it stimulates or inhibits the interest of citizens in carrying out economic activity, in consuming certain goods and / or services, but also in the commercial relations with the foreign partners.

It is also very important to ensure fiscal equity, which is only achieved when the tax burden is set and conditioned in proportion to the contributor's ability to pay. For example, if taxes are not too high and are optimal to be paid by all economic agents, an economy with fair competition unfolds, without appealing to tax evasion, and thus there is an interest in doing economic activity, resulting in the increase in payments to the state budget. An important effect of taxation is that it can affect a country's economic growth rate by deterring investors from investing in a country with strict tax rules.

2. Literature review

Concerns about the efficiency and optimization of the tax and fees system, both at national and international level, have generated numerous economic and financial studies, which have tried to provide solutions and models of action on the fiscal policy of states, having in view of the economic transformations over time (Cristea, 2017). The interests of

* Corresponding author. Tel.: 00 40 720 399 245.
E-mail address: crs.loredana@yahoo.com.

economists in the field of obtaining and use of public resources derived from the collection of taxes and duties have resulted in a significant number of papers that have addressed this issue.

The state of knowledge in this field highlights a significant number of papers addressing the efficiency, effectiveness and performance of the formation and use of public financial resources from taxes and fees, and for a more detailed analysis of this system are relevant the studies of Afonso (2008), Belean and Anghelache (2005), Brezeanu (2009), Dascălu (2006), Dobrotă et al. (2003), Drigă et al (2016), Moraru et al. (2011), Moșteanu (2008), Ungureanu (2010, 2013) .

Engen and Skinner (1992) pay increased attention to the relationship between the level of taxation and the rate of growth of gross domestic product, by increasing tax revenues and consolidating them at national level. Brașoveanu-Obreja (2007) outlines the relationship between taxes and the economy and observes that in practice, tax cuts have a positive but weak impact on a growing economy, thus leading to a change in long-term living standards. Arnold et al.(2011) concluded that a change that shows the biggest promise among taxes, both in terms of economic growth and economic recovery, is to reduce income taxes (including social security contributions) on those with low incomes. Kayaga (2007) concluded that the introduction of tax exemptions and deductions for essential goods and services benefiting the low-income population would not only bring tax benefits and other benefits to those with low incomes but would allow the government to offer some potential taxpayers who have hidden in the underground economy join the official economy.

Macek (2011) assessed the impact of different types of taxes on economic growth by conducting a regression analysis in OECD countries for the period 2000-2011, concluding that OECD countries should seek to reduce the corporate tax rate, taxes on personal income and social security contributions in order to be able to influence the economy in a positive way. Costi et al. (2004) argues that taxation can play an important role in improving the current situation and in ensuring a favorable environment for economic activities. Two different methods can be used, both with reference to how fiscal pressure is managed. Thus, it can appeal to a high fiscal pressure where the state builds a significant part of the gross domestic product at its disposal, thus limiting the financial resources that people can have. The second possibility is expressed by a reduced fiscal pressure. This has the effect of obtaining more financial resources from the population, and the state will collect a small part of the gross domestic product.

Mahdavi (2008), Castro et al. (2014); Bujang et al. (2013) and Stoilova (2017) are among the authors who studied the fiscal pressure of the tax and fees system and made comparisons in several developed and developing countries. They also attempted to show the connection between the fiscal pressure and the change in the economic indicators of the studied field.

Regarding tax evasion which is closely linked to the tax and fees system, Sabaini and Jimenez (2012) concluded that the benefits of improving tax administration can only be achieved under a number of conditions such as: a political commitment to the implemented reforms, the desire to abandon the old administrative practices and the desire to establish a formal plan with defined goals and costs for realistic time periods. They argued that only by establishing a high level of tax compliance will it be possible to implement reforms that involve the balance between direct and indirect taxes and thus, with regard to tax systems, to focus not only on the revenue target, but also on the objectives of efficiency and distributive equity so that tax evasion is at minimum levels.

3. Prerequisites for methodology development

The specialized foreign literature offers us limited scientific data, becoming restrictive due to the advanced degree of change in the field of research, without deepening and building up the economic dynamism through the system of taxes and fees. Given that this scientific research focuses on the close relationship between two disciplines with a strong influence on a state, *public finances*, namely the tax and fees system, and the *economy*, it is necessary to have a good knowledge of the specialists' concerns related to the improvement of these areas for the rational use of financial resources from mandatory levies, which have a positive impact on the economy.

The existing gaps between Romania and the developed countries in the world in general, and the EU states in particular, are mainly due to the lack of ongoing state reforms as well as medium and long-term strategies and programs in all fields, which make it necessary to study some possibilities increasing the efficiency of the system of taxes and fees, but also understanding its influence on the Romanian economy. The research theme involves tackling a very complex issue with many interdependencies, between mandatory tax deductions and the national economy.

In Romania's financial and economic research practice, scientific studies have been carried out on some aspects related to this research topic. However, these are not integral studies to address the issue of the tax and fees system and its impact on the national economy, in the light of several interdependent elements such as fiscal pressure, tax evasion, but also economic indicators which could highlight the close link with the main financial levers under market economy conditions. Taking into account this context, the hypotheses behind this research methodology are including:

- identifying proposals for streamlining the tax and fees system in Romania, possible by consulting and following the experiences of developed countries in Europe
- tax evasion, which is a barrier to a growing economy, can be diminished by adapting new techniques or methods of managing this complex system;
- the existence of a significant correlation between the tax and tax system and the economic impact indicators.

The **main purpose of the methodology** will be to identify ways to increase the efficiency of tax and fees system management by assessing the impact it can have on the economy, capitalizing on the experience of developed countries in Europe. In order to achieve the initial aim proposed in this research, the methodology will have to address the following **main objectives**:

3.1. Theoretical foundation of the tax and fees system

In order to have a basis for starting the research, the theoretical approach to the concept of fiscal system will be discussed, emphasizing the functions and role of its components, namely: *fiscal legislation*, which directly refers to the topic of this research theme, namely taxes and fees; *fiscal mechanism*, which means the techniques and procedures for organizing and managing the activity of tracking and collecting taxes and fees; and the *tax apparatus* respectively the institutions and the staff who act for the purpose of calculating, tracking and collecting taxes and fees. In order to highlight the opportunities for capitalizing the influence of the tax and fees system on the economy, a first step is to study the concept of a system of taxes and fees, how to organize it, but also to present it by emphasizing the features and functions detained.

Given that *taxes and fees* are components of tax revenues and are means and levers for budget revenue generation, a theoretical and conceptual approach is needed to understand how they are formed, the main features, and how effective management of these should occur, so as to reach a level of growth and socio-economic development. To conduct research on *budget revenues*, we need to know their content, structure and characteristics in order to be able to outline their complex effects on the economy. Of course, it is also necessary to conceptualize the taxes and fees by emphasizing their fiscal principles and their importance as financial levers and a means of stimulating the economy.

On the basis of the reports of the Ministry of Finance, as well as other data available from official sources, a study on the evolution of budgetary revenues will be carried out, focusing on Romania's tax revenues compared to EU Member States during the 2007 - 2018. Determining the place held by Romania within the European Union will be the starting point for the next comparative studies.

3.2. Influence on the economy framework of the tax and fees system, in European context

The conceptual delimitation of the *market economy* and the desiderata of *economic development* are necessary to outline the impact of taxes and fees on the economy, given that the market economy is the place where entrepreneurs operate freely, autonomously and rationally, in line with market requirements, to meet ever-increasing needs with limited economic resources. In order to give an overview of the fiscal pressure in the European tax system, a comparative study of Romania with the economically-financially developed countries and with the emerging countries will be carried out.

From the point of view of the impact of taxes and taxes on the economy, a correlation will be made between the level of income tax, profit, VAT level, excise level and customs duties and their influence on prices, demand for goods and services. A negative result of the high fiscal pressure is tax evasion, which can be considered a barrier to long-term economic growth. Tax evasion arises as a result of deficiencies in legislation and, on the other hand, due to the misapplication of tax evasion laws. An effect of tax evasion is the decrease in tax revenue collected, which leads to an increase in the budget deficit, having an effect on the overall balance of the economy.

3.3. Rational tax revenue management to improve and ensure a balanced economy

The fiscal policy promoted by the Government influences the formation of tax revenues, and the state can thus intervene through taxes in the way it desires by granting tax incentives to encourage and stimulate investments, by which to achieve export and import systematization, but also a tool to reduce inflation. In order to analyze and highlight the state intervention on the economy through the tax and fees system, a comparative study between Romania and Bulgaria will be carried out, assuming that both countries have joined the European Union in 2007. The analysis period will include both pre - accession and post - accession, up to date, according to the data available in the Ministries of Finance reports in both countries, as well as other official sources.

In analyzing the comparative situation between Romania and Bulgaria, it will be necessary to *characterize the tax and fees systems*, to highlight their structure in the two countries, by shaping the fiscal policy regarding the direct and indirect taxes. As tax revenues contribute significantly to the formation of the state budget, their modification would determine both positive and negative influences on the socio-economic situation in the country. Therefore, it will be necessary to highlight and outline an effective way of managing tax revenues, in order to ensure a growing economy.

3.4. Influence of the tax and fees system on the Romanian economy. Capitalization opportunities

Assessing a correlation between the main indicators with an effect on the economy (gross domestic product, inflation, unemployment rate, employment rate, public debt, income distribution, gross average earnings, etc.) and taxes

in Romania over the proposed period to be analyzed, respectively the last 20 years, will allow to highlight the influence of the fiscal revenues on the Romanian economy. Tax evasion, corruption, accession to the European Union and the economic and financial crisis that our country get over, have left deep fingerprints in the Romanian economy. Correlations should be made between all these aspects, using the SPSS statistical program, using mathematical modeling, but also by analyzing the resulting data and graphics.

To deepen the study, by means of the questionnaire addressed to the Romanian taxpayer, both to natural persons and legal persons will emphasize the perception of the need to pay the taxes and fees in order to determine the main causes of avoidance from their payment. The results obtained will highlight the importance of fiscal rules in *developing an effective tax and fees management methodology* to reduce tax evasion and economic growth.

It will be analyzed the situation of Romania by focusing the research direction on the main objectives of the Government regarding: the effective collection and use of mandatory levies - taxes and fees; how to implement the tax and fees system and how to manage them efficiently.

Examples of good practices in European countries can be milestones and starting points in developing ways to capitalize on the impact of the tax and fees system on the Romanian economy. In the context of these clarifications, the *main fiscal measures adopted by Romanian authorities* to support economic development will be identified to *develop tax policy recommendations* so that tax and fees collection can be efficiently achieved, to sustain economic growth and make tax evasion more difficult.

4. Developing the research methodology

The research methodology expresses a combination of methods to facilitate the understanding of the purpose of research and the interpretation of the results. There will be combined *theoretical research*, which will delineate the conceptual aspects of the tax and fees system, fiscal policies, budget revenue structure, with *empirical research* to analyze financial and non-financial elements directly related to the subject under investigation.

The methodology will have an interdisciplinary character, covering aspects that are found in the economy, public finances, economic-financial analysis, statistics and legislation. In order to achieve the objectives, the aspects will be treated in a deductive approach, from general to particular, combining quantitative and qualitative elements. Research methodology requires the use of various tools, techniques and methods, given the complexity and interdisciplinary character of processes. Combined and complementary use of qualitative and quantitative methods will be applied.

Quantitative approaches are based on the numerical measurement of some aspects specific to the phenomenon studied, with the aim of testing the hypotheses, and the *qualitative research* follows the comprehensive description of the phenomenon. Quantitative approaches allow the formulation of assumptions about a large number of variables with a higher validity.

The methodology will have to include:

- *Studying the general bibliography* (economics, public administration, legislation) and specialty literature (finance), respectively on national and international level, as well as EU reports, domestic and international governmental sources, as well as from the non-governmental sector and international financial institutions, for the scientific substantiation of further research;
- *Method of scientific observation* of the activity of formation and use of taxes and fees, by performing comparative analyzes on the situation existing in the E.U. and Romania, from the perspective of the influence on the economy and from the perspective of the system of taxes and fees as *a target group*;
- *Explanatory research method*, which seeks to find out the underlying causes of a particular thing by establishing a causal relationship;
- *Method of analysis and synthesis, induction and deduction* by which theories are verified, generating results that can be generalized, the *analogy*;
- *Interdisciplinary methods* for correlating economic, financial and legislative concepts;
- *Statistical methods* used to interpret the results obtained in empirical research, data analysis that can be performed using the SPSS (Statistical Package for Social Sciences) program, allowing the statistical analyzes required for the research work;
- *Case study* for a thorough and in-depth investigation of the implications of the tax and tax system.

The data collection techniques to be used are:

- Documentation will be an important step in the process of knowing the studied topic (legislation, guides, strategies, plans);
- Reports, studies, and syntheses on the subject of the study;
- Structured questionnaires;
- Official statistics.

With the help of the questionnaire, information will also be collected on the Romanian taxpayer's perception of the necessity to make mandatory payments and the determination of the main causes of payment forgery. Then, it will be correlated these perceptions with the results of the main indicators of influence on the economy and the study of the existing impact. Data analysis will use the SPSS statistical program.

The results of the research will be interpreted and presented in the form of conclusions that will come to bring added insight into the investigated field and may be the starting point for further research. As an expected scientific result of the future methodology, we aim at obtaining the Romanian taxpayer's perception of the necessity to make these mandatory payments and the determination of the main causes of payment forgiveness. It is also targeted the correlation of these perceptions with the main indicators of influence on the economy and the study of the existing impact.

Determining the impact of the tax and fees system on the economy, entails a number of advantages that are highlighted below:

- identifying the main financial elements that influence the Romanian economy;
- the possibility of developing a new way of implementing and designing the tax and fees system, taking into account good international practices where the impact on the economy is positive;
- relieving the importance of tax rules in maintaining / growing economic development through taxes and fees;
- finding ways to improve the tax and fees system by making comprehensive comparative analyzes of tax policies in developed EU countries as well as in neighboring countries to Romania and similar in terms of development;
- highlighting solutions to optimize the tax and fees system in Romania by making a comparison of the fiscal pressure at the level of the countries of the European Union, taking into account the structure of the tax revenues;
- developing effective tax management methodologies to reduce tax evasion;
- drawing conclusions on the correlation between the tax and tax system and the main indicators influencing the economy;
- Streamlining the fiscal revenues management with a view to improving and ensuring a balanced economy, also taking into account the perceptions of the Romanian taxpayer;
- Making proposals on simplifying the mode of charging taxes in order to relax the taxpayer.

All these advantages, derived from the proposed research, can lead to a set of recommendations and procedures that will help to increase the performance of tax collection so as to obtain a positive impact on the Romanian economy.

5. Discussion and conclusion

Given that tax revenue holds an important place in forming a state's public revenue, its importance is understandable. In order to have a well-established starting point for research, a unitary analysis of the components of the tax system, the way it is formed, and the functioning of the financial mechanism is needed. *Taxes and fees* have a complex role within any state, being a pillar that influences the economy, and therefore, through this research, we are aiming to study this in depth, since the system of taxes and fees is not limited to procurement and distribution of public financial resources.

Decision-makers can and should direct this system towards economic and social development of the country, and an important concern of the future methodology will be to find *opportunities to capitalize on the influence of the tax and tax system on the economy*. Tax revenues, namely taxes and fees, are influenced by the *fiscal policy* adopted and promoted by the government, but there are also economic factors that act on them. These factors of economic nature that determine the evolution of tax revenues can be represented by indicators such as: gross domestic product, inflation rate, public debt, population, income distribution, gross average earning, employment rate, but also the form of taxation of entities and facilities granted to them.

Account should also be taken of the *influence of taxes on the economic activity* of enterprises in general, as indirect changes may take place within the national economic structure. Thus, microeconomic taxes can play a role of development, contributing to job creation, balancing import and export operations, leading to inflation and unemployment cuts, but can also play a negative role, which discourages economic behavior. However, this depends on the tax rate and the economic agent's elasticity to tax. Through this research, we would like to emphasize these possible influences, to discover the correlations between the economy and the fiscal system, but also beneficial possibilities of its management, towards the creation of a positive economy.

Another concern of this research is the study of *tax pressure*. That is why, in order to deepen this element, we will use the study of the fiscal pressure at the level of Romania, but also at the level of the European states. This analysis, which should be drawn up in comparison with the fiscal pressure at the level of the developed EU countries, aims at deducting optimal solutions or ways of rationalizing fiscal revenues, which can be adopted through fiscal policies, so that fiscal pressure is at an affordable level for citizens.

Referring to previous research focusing mainly on the structure and weight of the tax and fees system within consolidated general budgets, and to the adequacy of these studies with the socio-economic environment, the relevance of the scientific outcomes of this research appears as a natural consequence of the fact that it is necessary to know and operate in order to make the impact of the system of taxes and duties on the economy more efficient, in the context of Romania, as an EU member state.

The Institutional Relations Between State Powers

Adelin Ungureanu^{a*}, Oana Răvaș^a

^aUniversity of Petroșani, Str. Universității nr. 20, 332006, Petroșani, Romania

Abstract

At central level between main country's institutions are established different relationships about exercising of powers and performing the tasks at each level of any central institution or in case of exercising of a special leverage, depending on constitutional provisions. Broadly, are envisaged reports of institutional between Parliament and Government, between Parliament and Judicial Authority, between Government and Judicial Authority, but also President's reports and tasks with each of three powers. Despite we take into consideration the division of power, according to the theory of their division, established in the supreme law, these are the powers of the same state, and for his uniform operation, as well as several another reasons, between the three powers certain operating mechanisms are created, and the President, in turn will exercise constitutional role of guarantor and mediator, developing different relationships with each power.

Keywords: President; Parliament; Government; The Theory of the separation of powers; Supreme Council of Magistrates; Constitution of Romania.

The theory that discusses the separation of powers received acknowledgement in recent years and was introduced in a lot of fundamental laws, in different countries around the world. It may be the case that is not the perfect mechanism for the organization and functioning of a state, but until now this system proved to be a democratic and efficient one, accepted and approved by citizens around the world. It represents a good way for the organization of a state, that respects the democratic values and principles, and even if it involves a certain separation (the separation of powers), the state remains a solid and unitary one.

The Romanian Fundamental Law acknowledged this principle, even from its early beginnings. Consequently, the state “*is organized according to the principle of separation and balance of powers – legislative, executive and judicial – in a constitutional democracy*” (Romanian Constitution, art.1, paragraph 4). The three powers are: the legislative power, the executive power and the judicial one, in the exact mentioned order, as it is stipulated in the Supreme Law' text.

These three powers are assigned as follows: the legislative power belongs to the Parliament “*The Parliament ... is the only legislative power of our country*” (Romanian Constitution, art.6, paragraph 1), the executive power belongs to the Government „... *that is responsible for implementing the internal and external policies and for assuring the general management of the public administration*” (Romanian Constitution, art. 102, paragraph1), and the judicial power which belongs to the judicial courts “*Justice is assured through the Supreme Court and through other courts that are established according to law*” (Romanian Constitution, art. 126, paragraph1). Some argue that the President also has one of the three powers, namely the executive power, of course, alongside the Government. In order to better understand this last statement, I go back to the fundamental law: “*...the President plays his role as mediator between state powers, as well as between state and society*” (Romanian Constitution, art. 80, paragraph 2). Considering this, the president would be unable to play his role as mediator between state powers, as long as he is part of one of these powers, namely the executive one. It's true that through his/her responsibilities, the President has some competences that are in line with state powers. Among these, one can mention for instance, in the case of the legislative power, the fact that the President takes oath in front of the Parliament and has the power to dissolve it, in certain conditions. In the same time, in case of vacancy of the presidential power, the interim is assured by a member of the Parliament, either the President of the Senate or the president of the Chamber of Deputies. In terms of the Executive power, the president assigns the person that could become the prime minister, as long as the person proposed, together with his/her team, obtains the majority vote in the Parliament. In addition, the President is able to revoke the ministers if the prime minister proposes so, and

* Adelin Ungureanu. Tel.: +400742005960;
E-mail address: adelin13ungureanu@yahoo.com.

can attend the Government's meetings. In terms of the judicial power, the President appoints and revokes magistrates, after a proposal that comes from the Supreme Court of Magistrates. Considering all these, one can conclude that the President has an active role in some aspects related to the three state powers, not only in terms of the executive one. In addition, the fact that he is responsible for mediating among these powers, excludes the possibility for the presidential power to be a specific one for only one power (namely the executive), as long as the president needs to play an equidistant role towards the other three powers. In conclusion, the President: represents the Romanian state, is a guarantee for certain values and principles (Independence, unity, territorial integrity), and watches over the compliance with the Fundamental Law, mediates among the state powers and is the Supreme Commander of the army forces (Muraru, Tănăsescu, 2016, p.261).

The acts issued by various institutions or authorities could be contested within an administrative appeal procedure, being subjected to legal control. Still, some sorts of relations, as the institutional relation between the Parliament and other public authorities are exempted from this type of control (Manta et al, 2014, p.242), in order to not block the activity of one of the main state institutions, as is the Parliament.

Even though we talk about the separation of powers and a President that mediates among them, they are all part of the same state, organizing and assuring the function of the state. Consequently, the three powers, even if they are separated, they all function in a unitary national system. The cheques and balances among them is assured through all sort of institutional relations that are regulated by normative acts and following a legal basis.

Certainly, the institutional relations are regulated through the existing legislation. Even though we cannot argue against these types of institutional reports, it was with the same reason of regulating the relations between people that the most ancient laws of humankind were written: the Laws of Mu in China, Ennuna Code in Mesopotamia, four thousands of years ago (Mihai, 2004, p.31). In addition, in a similar manner as we know them today, these institutional relations were included in Roman law, or in other judicial systems, like the German or the Anglo-Saxon (Dănișor et al, 2008, p.129) ones we all agree that the written form of these regulations confer more stability and judicial force.

1. The institutional relations between the legislative and executive powers

Firstly, one can talk about the institutional relations among two central institutions: the Parliament and the Government. Of course, the main types of institutional relations are at the level of these institutions, even though the entire public administration functions according with the normative acts adopted by the Parliament.

In addition, one can state that the Government exercises its power only after receiving the vote from the Parliament, following a procedure that includes also a decision from the President, before the final vote in the Parliament. Consequently, the structure of the Government, its members and the governing program receives a vote from the legislative power. The Parliament issues a substantive decision, in this case, without being forced by the Constitution to accept any proposal from the President for the future prime minister. The Parliament can either accept through a vote, as well as to reject the proposal. In case of a rejection, all the procedures, including that of the nomination from the President, are repeated.

In the same time, the Parliament can dismiss the Government through a vote, during its mandate. In this respect, it doesn't matter how much time passed since its nomination or how much time is left from its mandate. The legislative authority, through the adoption of a vote of non-confidence is able to dismiss the Government, if that is the wish. The non-confidence vote can be initiated by the members of Parliament and the Government has no possibility to intervene in this process. Actually, there are two types of procedures that enable the initiation and debate of a non-confidence vote. Consequently, during each session of the parliament, the members of the legislative body are able to initiate one non-confidence vote. Since the mandate of a member of Parliament includes 8 ordinary sessions, it means that the members of parliament, (especially the one in the opposition) during their mandate, can initiate 8 such votes that eventually can dismiss the Government. The other procedure can only be initiated by the Government. Therefore, it is usually initiated for fast decisions, or to avoid long lasting debates that can produce changes in the Government's proposals. In these situations, the Government can initiate the Government Accountability Procedure on a bill or a declaration. In this situation the Government chooses a quick way to pass laws. The Parliament can initiate a non-confidence vote, even if in that session there was another one already initiated. After the Government Accountability Procedure is initiated, in only 3 days, the Parliament can initiate a non-confidence vote and consequently dismiss the Government. If the non-confidence vote is not adopted by the Parliament, the Government continues its activity, since is considered that the Government still has the approval from the majority of Parliament, and the proposed bill, program or declaration are considered adopted. They enter into force only after all these procedures are finished.

The Parliament also has the power to ask the Government, or other institutions and authorities at local or national level, various information or other documents, due to the parliamentary control function that both of its chambers have. In addition, the Parliament can also organize special investigation committees, where the members of Parliament can ask for additional information, can hear different persons or collect documents that are issued by different bodies that are involved in public activities.

In the same logic related to the reports between the legislative and executive powers one can also mention the possibility of the members of Parliament to address questions or hecklings to all members of Government. These questions are addressed on different issues, and the members of Government, to which the questions were addressed,

are obliged to respond, according to the Parliament's regulations. Basically, this is a form of official informing, for every Member of Parliament, on various issues that are not necessarily related to the legislative activity but are related to topics that are related with their activity. Therefore, these questions are directly addressed to the ministers, based on the activity of the Ministry they are in charged with.

Another important aspect, related to the relation between the Parliament and the Government is related to the procedure for the delegation of the legislative power. As mentioned before, the Parliament is the only authority that passes laws. Still, through the institution of delegating the legislative powers, in some particular conditions, during specific periods of time, and with a very strict follow up and verification, this power is transferred to the Government. This special procedure for delegating the legislative power is done through two types of decrees: Government Decrees (OG) or Emergency Decrees (OUG). For the first category, the Parliament initiates a special law, for enabling the Government, in a limited period of time and in a certain field, to issue normative acts. In the same time, The Parliament could also ask that the OG be sent and confirmed by the Parliament, based on its statute, as unique authority for passing laws. The Parliament could also adopt, modify or reject the OG, even if this was already issued and even started to produce its effects.

Analyzing these aspects separately, one can easily say that there is a need for further discussion. In the case when the Parliament approves the OG, this is nothing else than a confirmation for the Government to continue its proposal. In the situation when the OG is modified, and it is not about some slight additions to the decree's original text, but it is about the rejection or the actual change of text, then we are in the situation where we have some judicial norms that already produce their effects without being approved and confirmed by the legislative authority. This situation is even more obvious in the case when the Parliament rejects entirely the government's decree. Consequently, the decree manages to produce some concrete judicial effects, similar to a law, even if it was issued through a different procedure, by the Government. This exception lies in the fact that we have judicial norms that are compulsory for the population, even though the Parliament never adopted them and is not adopting them, but basically decides on their later rejection. The reason for this possibility for delegating the legislative power, is that of the need for quick decisions, or when there is a need for decisions and the Parliament is in vacation. Still, starting from this, there are a lot of situations, at the borderline of this principle, when we have a lot of legislative acts that are implemented with clear effects without being approved by the Parliament, or with later rejection and elimination by the Parliament.

On the issue of Emergency Decrees, there is no need for a special delegation from the Parliament, but it needs to be used as a procedure in extreme situations in which the Government needs urgent legislative interventions. In these situations, the Government can pass laws but it is obliged to clearly indicate in the text the emergency that led to this legislative initiative. In addition, even in this type of decrees, following a certain procedure, and with very short deadlines, there is also a need for confirmation, modification or even rejection coming from the Parliament. These stipulations follow the same logic of the exclusive legislative competency that the Parliament has, even if there are some exceptions, in very specific conditions and circumstances.

2. The institutional relations between the executive and the legislative power

In order to exemplify this category of relations, I focus mostly on the type of initiative that thrives these relations. In the sections of this paper that I discussed above I introduced only those institutional relations that are initiated by the legislative power (vote of confidence or non-confidence for the Government or the legislative delegation for issuing governmental decrees). In the following section the focus will be on the three types of relations that are initiated by the executive power, namely the governmental authority. Even the issuing of emergency governmental decrees is probably better included in this section, then the previous one. This is the case because there is no delegation needed from the Parliament. Still, for a better understanding of the procedure for legislative delegation, it was included in the section above, together with the simple governmental decrees.

The legislative initiative is a common and very important procedure in consolidating the legislative system. The Government has the power to initiate laws in terms of both organic and ordinary laws. This initiative implies a few stages, including the preparation of the law, which is later on transmitted to one of the chambers of the Parliament, based on their competences. The final stages are that of debate and approval. This right of legislative initiative that the government has, is widely used. Basically, it means that almost all current laws were initiated by the Government. Once the Parliament receives the law proposal, it is not obliged to adopt it in that exact form that was sent by the Government. It usually follows a series of procedures, through which the proposal is either changed (it can be changed even substantially) or it is discussed and debated in the exact form in which it was sent by the Government. Eventually the proposal is adopted with the agreed changes or rejected by the legislative power.

Even in this respect, if we take into consideration the principle of cheques and balances, the above described procedure is debatable. Since there is a legislative power, as unique authority in this respect, why do we need another state power to initiate laws? In addition, if we also consider the highest number of laws are introduced through this type of initiatives, compared to the ones initiated by the legislative power, then the debate is even more interesting.

We are talking about the powers within the same state and even if they are separated due to certain regulations, the fact that they collaborate or even control themselves sometimes (e.g.: the vote for dismissing the Government, through a government decree), it does not mean that this separation of powers is not respected. It is most likely that the delegation

of the legislative power that we already talked about, with the Governmental decrees being rejected by the Parliament, is situated at the limit of this principle of separation. It is actually due to practical reasons, that the Government received the right to initiate laws, since it is better connected to the socio-economic realities of the country and the surrounding ones. Still, the Parliament has the last word, respecting the fact that it is a representative institution, elected by citizens.

Even though, in this paper, I've already talked about the Government Accountability Procedure as a procedure for initiating a bill, declaration, or a certain program, by the Government, this procedure should also be included in this section. The decision to start this procedure belongs exclusively to the Government that actually forces the Parliament to pass laws for the Government. In addition, the Parliament, through the vote of no confidence, has the possibility to revoke the Government. At first sight, it is probably considered as a worthless risk coming from the governmental institution. Indeed, having the right to initiate laws, it is pointless to risk its position through the Government Accountability Procedure. Still, using this procedure assures the adoption of a law in a matter of days in the exact form that the Government wants, since the Parliament has no possibility to change it. In reality though, the risk that the Government takes is only an apparent one. It's true that there could be some situations, in which through the Government Accountability Procedure the Government could be dismissed, but both Parliament and Government have political structures at their basis. Moreover, since the Government receives the confidence vote from the Parliament, usually representing the same political party, the majority in the Parliament has no reason to dismiss its own government, so the chances for this to happen are almost inexistent. Still, if the Government uses this procedure vastly, one can conclude that it cancels the main function that the Parliament has, surpassing, in the same time, the values and principles of the separation of powers.

3. The institutional relations between the executive and the judicial powers

As mentioned in the previous paragraphs, between these two powers there aren't many institutional relations, considering the judicial independence, as indicated before. When we talk about magistrates, we refer to the judges and the prosecutors. If in the case of judges, they are completely independent, based on the constitutional norms, the prosecutors are working, according to the constitutional norm, in a system of hierarchic control. This control manifests itself in a close loop, that of the State Attorney's offices, where no other power has access to the mechanisms for organising and functioning of its activity. Still, what leads to certain types of relations and reports is another constitutional norm, the one stating that „*the prosecutors are acting under the authority of the Minister of Justice*” (Romanian Constitution, art. 132), without having a clear explanation of what this function means. The opinions about this issue are different and vast. Some are arguing that starting from the idea that the prosecutors are a category of professionals that work under the principle of hierarchic control, this hierarchy goes directly to the minister in charge, namely the Minister of Justice. In the same time, others are arguing that it is only a matter of administrative control, which is consistent with the way the Public Minister is organized and functions, as it is stipulated in the supreme law.

Trying to analyse this from a strictly normative perspective, we take into consideration the terminology used in the Constitution, in chapter VI. Consequently, when using the term authority, this is used to describe the system – the judicial authority – but also to describe the activity of prosecutors – under the authority of the Minister of Justice. The fact that the judicial system represents a power and an authority in itself is unquestionable. Still, whether the authority of the Minister in relation to a category of magistrates, and whether this implies functional and professional functions or purely administrative, is a good topic for debate.

Continuing the same discussion on the relation between the judicial and executive powers, one needs to mention also the fact that a separate institution is in charged with the guarantee for the independence of Justice - The Supreme Council of Magistrates (CSM). This institution has 19 members, and one of the members is the Minister of Justice, therefore a member of the executive power. Even though we have the situation described above, this institution is not acting like a court, in the sense of running investigations or solving disputes, its responsibilities are more related to the management of Justice, or other aspects that are related to the constitutional guarantees of Justice.

Despite the relations that were previously expressed, one need to mention also the fact that the President of the country has some relations or activities/responsibilities that imply the collaboration of all three state powers. Therefore, being a mediator among these state powers, the President maintains some connections with these powers, as it is clearly stipulated in the fundamental law of the country.

4. The institutional relations between the Presidents and the Parliament

From the very beginning of its mandate, the activity of the President is in direct relation with the Parliament. The President starts the mandate by taking an oath in front of both chambers of Parliament, reunited in a common session. It is a very solemn activity that implies something that was very hard to achieve in history, namely a democratic transfer of the first position in a state. Usually, having such a solemn character, at this event, besides the members of Parliament, other personalities are invited, like the Chief of Church, former Presidents...etc. In doing this activity, the Parliament has no direct responsibilities, it only takes note of the President's oath and the beginning of his/her mandate. Based on the Revised Constitution of Romania, the mandate of our President is of 5 years and not 4 years as it used to be. The timing is clearly stipulated and cannot be exceeded, except the situation when the Parliament decides this through an

organic law. Even in this case, the procedure could be initiated in a particular context, like a state of war or other similar disasters. These particular situations are used to justify the necessity for prolonging the President's mandate. The decision belongs to the Parliament exclusively, and the Parliament has the possibility, not the obligation, to prolong the President's mandate, even if the country is in the case of war or other disasters.

Another institutional relation between the President and the legislative power is that when the President has the possibility to address some messages to the Parliament. These messages could touch various topics, situations, problems and decisions concerning the Romanian population. In addition, their role is rather informative and could eventually determine some legislative effects. Consequently, the legislative power, using the messages received from the President, can initiate normative acts, in order to offer legislative solutions to the identified problems. This could be predicted since the President is not able to initiate any ordinary or organic laws, the only prerogatives in this sense being the possibility to initiate some changes in the Constitution.

Since the President is not able to initiate laws, he/she has other rights and duties in the legislative process. Therefore, the President is responsible for enacting the laws. This activity should not be confused with the right to sanction laws or with a possible veto power that Presidents in other legislative systems have. Before our laws are made public through the Official Journal, basically before they actually start to produce legal effects, they should be enacted by the President, after already being approved by the Parliament. Basically, after the President receives the law from the Parliament he/she has 20 days to enact it. In the case when he/she considers the law should not be enacted in the form adopted by the Parliament, the President has the possibility to send it back to the Parliament, institution that is obliged to receive it and to put it back to the agenda of discussions and debates. The Parliament has the possibility to modify the law according to the remarks made by the President, or to adopt the law again in the same form that was initially sent to the President. After the law is adopted again, it is sent again to the President. Now, the President has only 10 days to enact it. In addition, the President cannot send it back to the Parliament for a new debate and has no other power to reject it. Separately, the President has another legislative procedure at disposal – the possibility to address the Constitutional Court, but only based on some aspects that are against the constitution, and not on the way the considered social relations are regulated. Of course, if the institution that has the power and competency to decide whether the proposed law is against the constitution, then the law will not enter into force and a further harmonization with the fundamental law is then necessary.

The President of Romania has the power to dissolve the Parliament. In this respect one could consider that the President has vast powers, since he/she has the possibility to entirely stop the activity of the legislative power. In reality, things are a little bit different. First of all, it is about a supplementary role: *The President...can*, that means is not obliged to dissolve the Parliament. In addition, such a decision would only be taken in a specific context that entails some specific conditions and deadlines. Indeed, it wouldn't be normal for only one person, even if it is the President, to have such great powers that could easily eliminate the Parliament, the most representative and democratic institution from our political system. Such a prerogative, that can easily dispose the faith of the Parliament in any context, even based on personal interests, is rather specific to authoritarian regimes. In terms of the specific conditions and deadlines related to the possibility for dissolving the Parliament, there are different possibilities that could easily become sources for future legislation. According to the current Constitution, the President is able to dissolve the legislative power, only if this last institution did not invest the Government and rejected at least two requests for governmental appointment. Another situation is that when more than 60 days pass after the first request to invest the Government (Romanian Constitution, art. 89). It is only in this context that the President can propose such an extreme measure. In addition, there are other aspects that need to be taken into consideration: the Parliament cannot be dissolved twice in a year and in the last 6 months from the President's mandate. Having all these in mind, and the type of institutional relations between the President and the Legislative Body, we can conclude that the conditions for dissolving the Parliament are very strict, making this possibility rather theoretical than practical and possible.

Since the President is able to initiate the organization of a consultative referendum, on diverse topics of national interest, in order to do this, he needs to firstly address the Parliament (Romanian Constitution, art. 90). Still, the Parliament has no power and possibility to stop the presidential initiative to consult the population through a referendum. In complex situations, like war for instance, the institutional relations between the President and the legislative power are different, as the deadlines and procedures are usually shorter and easier. In a situation, where the state is threatened with war or similar military aggressions, the President, in his quality of Supreme Army Commander, can decide on the army mobilization. The army mobilization could be either partial or total. In this sense, the President needs the Parliament's approval, before enacting the decree of mobilization. In some particular situations where there is an urgent need for decisions, this approval could also be obtained after the decree of mobilization was enacted (Romanian Constitution, art. 92). The cooperation between these two entities is vital, especially in these extreme cases, as army aggressions or actual war. The simplification of these procedural decisions as well as avoiding the overlapping of competences are important for creating a sort of freedom of acting and decision for being able to reject the military aggressions and to defend the country.

5. The Institutional Relations between the Parliament and the President

If the President can decide on dissolving the Parliament, in the above-mentioned conditions, The Parliament has also prerogatives for suspending the President. It is actually the case of suspension, since the decision regarding the remaining or the dismissal of the President does not belong to the Parliament but belongs to all the citizens having the right to vote. In this sense, all the citizens with the right to vote, through a referendum, organized in maximum 30 days after the Parliament decided on the President's suspension, decide whether to dismiss him or not. The reasons for this suspension should be the infringement of the fundamental law by the President, and this decision should be taken by both chambers in a common session. In terms of procedures, the initiative should belong to a third of both senators and deputies, and the suspension could be disposed with the vote of the majority of the members of Parliament (Romanian Constitution, art. 95). This type of institutional relation is extremely important. In theory, based on the existent doctrines, we can have three situations: one in which the Parliament can dismiss the President, the second one in which the Parliament could not decide on this situation in any case, and a third one in which the Parliament could only suspend the President. In the Romanian legislative system, the crafters of our Constitution opted for the third possibility. We should not forget that Romania is a semi-presidential republic, and that the types of institutional relations between the three powers are retrieved both from the parliamentary regime type, as well as from the presidential one. Consequently, if the President can decide on dissolving the Parliament in some specific conditions and with some specific limitations, the Parliament can also suspend the President following some strict procedures, but the final decision about dismissing the President is in the hands of all the citizens that enjoy the right to vote.

It is also the Parliament that can dispose another procedure for accusing the President of High Treason, a very serious offence, that attacks the fundamental interests of our country and that, of course, has serious effects. The decision to start the procedure for this accusation can be taken with a qualified majority of 2/3 from all the senators and deputies, reunited in one common session, called for this particular reason. The first effect of such a decision is the suspension of the President. Not even in this particular case does the Parliament have competencies to decide on the President's dismissal. In this situation, the competency for solving this situation belongs to the Supreme Court of Justice, as it is the only institution which can decide whether the President is guilty or not for what it's being accused off (Romanian Constitution, art. 96). Consequently, the possibilities when the Parliament has to sanction the President are rather limited and refer only to the President's suspension, and definitely not to the President's dismissal.

In order for the state to function in a predictable and balanced way, two general ideas should be respected when deciding the organization of state institutions and their competences. Therefore, the state powers should not belong to a single person and a single entity, this being very clearly stipulated by the separation of powers theory. In the same time, the means and competences that all these powers or state institutions have should not exceed those others have. More precisely, there shouldn't be left any possibility for creating a superpower. In this case, of course, we cannot talk about a real separation of powers, but rather a subordination of state powers.

Abstract

Globalization has become main trend, characterizing the development of modern financial market and affecting primarily the functioning of global banking system. Because of this process is distinguished banking globalization as a specific form of financial globalization. Banking globalization has specific issues. It is manifested by fundamental changes of global banking system functioning and elsewhere by modifying the quality of banking activity. It promotes the standardization of national banking systems and emergence of a single, dominant banking model. Banking globalization conduct a process of concentration and consolidation in banking sector that promotes the expansion of banking options. This process has both positive and negative aspects. Globalization banking contributes to strengthening global banking system, which takes place simultaneously with concentration of banking capital. In addition, unification standards occur, which runs simultaneously with deregulation of banking business and liberalization of financial markets. This erases institutional distinction between different types of banking and financial activities. Important aspects of banking globalization are deepening of banking competition and innovation process, which contributes to increase of banking services range and quality. It contributes to implementation of new technologies, giving opportunities to wide spectrum of banking products and their quality raising. Along with the above, it must mention that banking globalization causes a range of new problems, which constitute new challenges for regulators. The article will contain an analysis of all the basic aspects of financial globalization, as well as their conclusions.

Keywords: bank, banking globalization, transnational banks, banking technologies

1. Introduction

Banks have a dominant position in the financial market. That's why they become main participants in the process of financial globalization and exert an active influence on financial markets, stimulate their integration and modernization while simultaneously changing themselves.

Many researchers point to the fact that current trends in globalization of economy contribute to transforming the role of bank into economic system, becoming the important financial intermediary that provides all participants of international economic activity with necessary financial resources. As a result, banks not only carry out international financial activity as autonomous institutions but also contribute to international business of other economic entities.

The transformation of global banking system is a complex mechanism consisting of all the economic, social-economic, political and geopolitical problems that differ in their degree of mutual influence, combination and confrontation of evolution vectors. The controls on this system, on the one hand, are required to adapt to these processes and elsewhere to change them in their interests, but these processes can only be influenced by countries with a high potential and obvious competitive advantages.

Also, experts point out that in financial sphere globalization has determined the necessity of cardinal changes in banking market in general, as well as in foundations of commercial banks' activities, approaches and realization by banks of market strategies and change of corporate management in the field banking.

2. Banking globalization overview

2.1. Banking globalization definition

Banking system is the most flexible tool for capital mobilizing and, therefore, should be the most sensitive to any changes in the financial market. In the context of globalization as result of international nature banking system performs the link of global financial system, which is one of the first to feel the impact of financial globalization. (Davlatov, 2015)

Banking globalization is the stage where banking services have spread worldwide, becoming universal. (Savu, 2006)

It is a separate direction of economic globalization. As result of banking globalization change the nature and forms of competition on financial market. Banks are forced to compete simultaneously on many financial market segments, not only with each other but also with other financial institutions: insurance companies, investment funds, non-state pension funds and other financial companies. (Davlatov, 2015)

At the same time, banking globalization represents the highest degree of international banking development, which is reflected in the implementation of commercial banks transactions with foreign counterparts and on global financial markets. International banking business has developed along with development of world trade, international business of non-financial institutions.

Financial globalization also observed processes of deregulation of banking business and liberalization of financial markets, which has an impact on nature of international banking business. Institutional distinctions between different types of banking and financial activities are removed: commercial, investment, insurance and other. This leads to a change in nature and forms of competition in the financial markets. Simultaneously competition in many financial market segments is growing. Competitors are not only banks with other banks, but other financial organizations in a liberalized environment are both residents and non-residents. Liberalization also entails the extension of territorial diversification of banking business on global scale. It contributes to international banking business expansion.

Banking globalization has shown rises in following areas (Claessens, Marchetti, 2013):

- Increase in direct cross-border banking, foreign direct investment and other forms of capital movement, in particular portfolio investment in equity and bond instruments;
- Creation by banks of institutions with the participation of foreign capital, including banks, and activity in other states. Over the past decades, banks have widened their global presence by creating subdivisions of operations in branch and branch forms.

The notion of banking globalization is closely linked to *international banking*, which presupposes the existence of a wide network of credit institutions abroad, high proportion of foreign operations as well as high degree of dependence of size of their income from foreign sources. For international payments, banks use their foreign offices and branches, any correspondent relationships with foreign banks without establishing a legal entity.

Main forms of output of commercial banks to foreign market is opening of representative offices, branches, agencies, subsidiaries of banks and other, less common in organizational and legal terms of institutions. International banking activity without establishing a legal entity abroad includes conclusion of agreements on correspondent banking relationships, participation in payment and settlement systems (SWIFT-type), establishment of banks and other invisible forms. Increasing share of foreign operations in total volume of banking operations and services, they establish close correspondent relations with hundreds of thousands of banks in all parts of the globe, creating their own foreign vehicle, participating in bank consortiums and alliances allow qualified industrialized nations largest banks not only as universal, but also as an international. (*Международная банковская...*, n.d.)

Specialists in the field now apply the concept of *global bank*, which is linked to the installation of ultra-refined electronic systems and while engaged in transactions in dozens of centers throughout the globe. (Savu, 2006)

Formation of infrastructure of global banks requires a very large spending, which cannot bear only most solid groups. For centralized processing of huge volumes of transactions, providing wide range of services and information to meet the needs, big banks create one or more own specialized entities, performing an intense activity. (Savu, 2006)

The literature now uses the notion of *global banking* which implies the presence of powerful financial institutions in various world markets, as well as their knowledge of economic situation, financial services industry, state housekeeper sectors and cultural characteristics of each specific country in a given region. This suggests that global banks were able to provide a full range of financial products and services, the most suitable for a particular financial market, as well as offering innovative banking solutions for both local and for cross-border customer needs, which are often large multinational companies. Revenues of global financial institutions are relatively evenly distributed over geographic area and cannot be extracted mainly from any one market segment or region. (Zaitsev, 2010)

2.2. Global financial system evolution

According Wikipedia *global financial system* it „is the worldwide framework of legal agreements, institutions, and both formal and informal economic actors that together facilitate international flows of financial capital for purposes of investment and trade financing”. (*Global financial...*, n.d.)

Since emerging in the late XIXth century during the first modern wave of economic globalization, its evolution is marked by the establishment of central banks, multilateral treaties and intergovernmental organizations aimed at

improving the transparency, regulation and effectiveness of international markets. In turn, an important element of the global financial system is global banking system. (*Global financial...*, n.d.)

The *global banking system* is international economic category, which expresses the ratio of different interconnected banks and other credit institutions of different countries working in the framework of international financial system, on provision of banking services. (*Международная банковская...*, n.d.)

Global banking system is defined structure in modern literature as a system with a four-layer (Vasina, 2015), (*Классификация международных...*, n.d.):

- *Supranational banks and financial institutions*;
- *Central banks*;
- *Global transnational banks (TNB)*, which have widely ramified system of subsidiary banks, as a rule, much of TNB capital is withdrawn from jurisdiction of central banks governing their activities. TNB are largest banking institutions that have achieved a level of international concentration and centralization of capital, which gives them the opportunity to participate meaningfully in economic distribution of world market of loan capital and monetary resources (credit and financial services). They are the core of global banking system. They are carried out basic movement of international financial flows. They are major holders of foreign exchange reserves and is concentrated in countries where are present liberal tax laws and exchange rate regime for credit operations. (*Международная банковская...*, n.d.);
- *International commercial banks*, which international operations provide 5 to 10% of their income. To gain a competitive international reputation of such bank, this is clearly not enough. These banks are increasing their participation in international operations through creation of separate branches and representative offices in major international financial centers, performing wholesale monetary and credit transactions, including participation in various international loan agreements. Foreign network of banking institutions is subordinate and generally perform a passive role;
- *National commercial banks* with only one small foreign branch, which accounts for a small share of assets, revenues and personnel. Such branch finance trade agreements, non-recurring foreign exchange transactions, provide services using letters of credit to customers in host country, carry out limited correspondent relationships with other banks.

Thus, the global banking system is (Vasina, 2015):

- 1) *Complex*, consisting of many elements;
- 2) *Organic* - has a complete hierarchical structure created by development of world economic relations;
- 3) *Continuously evolving system* - transformed at certain stages of development history;
- 4) *Consisting of set of interacting elements in global scale* - international economic organizations, central banks, TNB, commercial banks;
- 5) *Increasing complexity in process of historical development* - elements included in new communication; in framework of integration process is modified financial architecture;
- 6) *Close interaction with environment* as subsystem of global financial system and, more broadly, world economic system.

At the moment, the world banking system is developing in following directions (Fetiniuc, Luchian, 2013):

- a. Unification, standardization, national legislation on banking activity given in conformity with the international standards of banking;
- b. Development at the international level in accordance with the Basel Agreement (standards) of common approaches to evaluation (analysis) the financial status of the commercial banks of banking supervision bodies;
- c. Creation a single management and regulation institution of banking activities in the face of a world Central Bank. A prototype of the global Central Bank is currently the European Central Bank (Frankfurt am Main), which in 1999 was due to the ongoing process of integration in Europe within the EU.

The transformation of global banking system is a complex mechanism consisting of all economic, social-economic, political and geopolitical problems that differ in their degree of mutual influence, combination and confrontation of evolution vectors. The controls on this system, on the one hand, are required to adapt to these processes and elsewhere to change them in their interests, but these processes can only be influenced by countries with a high potential and obvious competitive advantages.

Some authors point out that in financial sphere globalization has determined the necessity of cardinal changes on banking market in general, but also in fundamentals of commercial banks' activities, approaches and realization by banks of market strategies, as well as the change of corporate management in banking.

These transformations were determined by the following factors (Vlezkova, 2012):

- Increasing the dependence of national banking systems on international capital market;
- Strengthening competition on global financial market between both banks and banks with other financial institutions;
- Increasing the opening of national economy;
- Standardization of banking supervision;
- Development of information and communication technologies.

Roman investigator Savu (2006) indicate *banking alliances* as possible alternative to traditional farming methods, taking various forms of distribution agreements of financial products and services to create a new entity. They have multiplied, providing for specific advantages in relation to internal growth and restructuring.

The size of banking alliance determines the competitiveness backed by a diverse range of products, cost-effectiveness information related to financial activities and maintaining a global network of customer. (Savu, 2006)

Among advantages of banking alliance may be mentioned (Savu, 2006):

- Saving money and reducing their costs of penetration of foreign markets;
- When significant capital investment is making, all alliance partners are involved;
- Banks keep a relative autonomy and enable them to break the agreement;
- Bank may choose the partner for certain activities only;
- Alliance management is much easier to acquisitions or mergers;

Through alliance bank can penetrate a market where access is difficult.

3. Fundamental directions of banking globalization

3.1. Main features of banking globalization

According to some economists, banking globalization determines the transformation of banking business as follows (Samarina, 2011), (Vlezkova, 2012), (Davlatov, 2015), (Gabbasova, Mirzagaleamov, 2015):

- *Increasing share of international operations* in total volume of banking transactions.
- *Increasing influence of growing expansion of corporations* on national monetary policy (ie. central bank activity) has, banks and other financial institutions in global capital markets, including in direct investments sector.
- National banking systems, which are designed to accumulate and redistribute financial resources within national economic system, are *in ever-increasing dependence on international capital markets*, which in era of globalization has become an independent factor in development of world economy.
- Development of a network of transnational corporations and their affiliates around the world has led to increase in their need for adequate banking services and provoked *emergence of new non-traditional banking services*.
- Non-financial sector of economy, financial and banking systems of national economic systems are becoming more standardized at work in domestic and global markets. This leads to convergence of regulating rules of internal and external economic transactions. Process of financial globalization and formation of global banking industry promote the *standardization of national banking systems* and emergence of *single, dominant banking model*. It can also be about *standardization of banking supervision*.
- *Concentration of capital*, including the merging of insurance and banking capital, lead to formation of transnational financial corporations, which capital is spreading beyond national economies, size of assets of corporations is comparable with budgets of entire countries.
- It takes place *banking management objectives adaptation*. The main of which consists in to enhance market capitalization of the bank as a company. The increase of market value of bank and increase of capitalization of banking industry in general ensure compliance with their banking socially significant features that contributes to economic growth.
- *International portfolio investments is growing* which enhance active banking operations.
- Globalization is accompanied by *deregulation of banking business* and the *liberalization of financial markets*. This erases the institutional distinction between different types of banking and financial activities (commercial, investment, insurance, and others). Liberalization, on one hand, creates conditions for development of an overseas branch network of banks and formation of international banking business, which naturally increases the competition, but on other hand, at the same time activates consolidation of bank capital. This leads to increase of mergers and acquisitions number in banking sector, to expand and increase the diversity of banking cooperation between themselves and non-bank financial institutions, growth of bank alliances of all kinds.
- *Substantially change nature and forms of competition in financial markets*. Banks are forced to compete simultaneously in many financial market segments, not only with each other but also with other financial institutions (insurance and investment funds, finance companies, etc.) and in liberalized environment - not only with residents but also with non-residents.
- Banking, globalization is associated with the *reorientation of banking business from traditional to innovative*, reducing the share of traditional banking operations in favour of increase of new, qualitatively meeting of customers needs changing. Improvement of banking products and services, channels of their promotion on modern information and communication technologies, carrying out to achieve adequate compliance of banking business to changing customer demands.

Researcher Kozimenko (2002) is of opinion that banking globalization has some positive features:

- Using of high standards for the quality of services, information and reporting;
- Obtaining of additional funding for its own asset and liability management;
- Access to additional markets and capital flows;
- Introduction of new products;
- Independence from processes taking place in internal market;
- Increasing of diversification degree;
- Obtaining of sufficiently favourable liquidity;

- Availability of opportunities to better capital allocation;
- Application of professional risk management technologies, optimization of management systems, etc.

Under conditions of globalization, processes of banking activity deregulation and liberalization of financial markets are also taking place, which influences the nature of international banking activity. The elimination of institutional boundaries between different forms of banking and financial activity takes place: commercial, investment, insurance, etc., which leads to a change in the nature and forms of competition on financial markets. At the same time, there is competition on many segments of financial market.

Liberalization leads to the widening of territorial diversification of banking activity on a global scale and leads to amplification of international banking activity. At the same time, the elimination of entry limits on national banking markets for non-performing financial institutions has opened wide possibilities for development of banks' branch network abroad and the formation of international banking activity, which has strengthened and complicated competition.

The lifting of barriers to delimitation between different forms of activity and geographic regions broadly broadens the spectrum of services provided by banks and capital consolidation processes lead to formation of financial conglomerates with a complex structure.

As a result, banks face a large number of diverse financial and non-financial risks, which tend to diversify, which complicates the risk management system and raises the importance of financial management in banks.

The top management of banks does not always manage to properly assess risks of specialized activities even with modern risk management systems. That is why large banks are actively seeking new management models based on decentralization principles and at the same time refine strategic management approaches that become the determinant factor of future competition on international capital market.

An important feature of national contemporaneous markets development and of world economy is the increased concentration of capital and productions in different spheres of economic activity. Analyzing this issue, it should be noted that expansion of international banks, strengthening of non-banking financial institutions positions, formation of a strong segment of online and mobile banking services lead to a high level of competition and at the same time activate processes of capital consolidation banking, being motivated by tendency to preserve and strengthen competitive positions. In many countries, the number of acquisitions and mergers in banking sphere has increased, forms of cooperation between banks and the non-banking financial institutions have widened and diversified.

3.2 Globalization and new banking technologies

It should be noted that the latter factor has a crucial role in the processes of transformation on banking market:

- Development of information technologies contributes to efficient collection and processing of information and cost reduction of providing banking services.
- Due to information technologies, banks have gained 24/7 access to financial markets and have been given new opportunities to develop new banking products.
- Maintaining long-term relationships with customers of wide network of subsidiaries gradually diminishes their importance. The new generation of customers prefers growing use of banking product in cyberspace.
- New technologies reduce information asymmetry, increase market transparency, make customer information more accessible and, as a result, banks lose the benefits of exclusive business partners.
- Customers get the opportunity to choose convenient bank product offers.
- Based on new information technologies, some non-resident and non-banked non-bank institutions can provide some banking services (eg payments).
- Advancement of information technologies has created premises for development of banking innovations.

It should be noted that information technology, as well as globalization, changing conditions of competition in the banking industry, making it more hard for banks. They provide the transparency of market, enable customers to choose the most advantageous offer for their services. Also, based on new technology banking services (for example, payment transfer) may have organizations other than banks, including communication firms. (Vlezkova, 2012)

Hence, the characteristic tendency of global banks' activities which is to provide a new and expanding well-established delivery channels of banking products and services to customers. *Electronic banking* has significantly expanded the scope of coverage of consumer financial services, primarily limited by operations of traditional bank branches. (Zaitsev, 2010)

In connection with use of the Internet appeared the notion *virtual bank*. According Business Dictionary it "Internet based financial institution that offers deposit and withdrawal facilities, and other banking services, through automated teller machines or other devices, without having a physical (brick and mortar) walk-in premises". (Virtual bank, n.d.)

Another trend continues to be *outsourcing of certain functions and global banking operations*, which is logical, where these functions are routine, and some banking services have become a homogeneous product. As a rule, the main reasons due to which global financial institutions are outsourcing lie in desire to reduce costs, to replace permanent (fixed) costs variables, as well as to focus attention on running core business. According to experts, there are several ways in which global banks carry out outsourcing of their functions and operations. Firstly, an important role is played by geographical factor when banks transfer some of its functions in maintenance of outsourcing companies from

countries with cheap labor. Some data centers (processing centre) here serve one client, ie, one global bank, other - a few clients at a time. (Zaitsev, 2010)

Another notable trend in global banking sector is *further improvement of the integrated risk management (complex risk management)* as a way to identify, evaluate and control effect of internal and external factors, change of which may adversely affect value of portfolio or bank as a whole. (Zaitsev, 2010)

4. Conclusions

Globalization has become main trend, characterizing the development of modern financial market and affecting primarily the functioning of global banking system. This process is distinguished in such degree that at the moment we can talk about banking globalization that has a contradictory character. On the one hand it promotes the standardization of national banking systems and emergence of a single, dominant banking model. Banking globalization is accompanied by a process of concentration and consolidation in banking sector that promotes the expansion of banking options. In addition, globalization is accompanied by deregulation of banking business and liberalization of financial markets. This erases institutional distinction between different types of banking and financial activities. Important aspects of banking globalization are deepening of banking competition and innovation process, which contributes to increase of banking services range and quality.

Performing University Management - A Determinant Factor in Quality Assurance in Education

Roxana Plesa^a *

^a University of Petrosani, 20, University Street, Petrosani, 332006, Romania

Abstract

The quality of an educational system is reflected not only in the instructive performances of the educational actors, but also in the degree in which it ensures an adequate professional integration. The motivation of this research is closely connected to the improvement of the level of communication between the two aspects –the academic one, by its finite products, and the economic one, by job offer. The study set sights on over 29 of the most important employers from the Jiu Valley, and 39 of the graduates of the University of Petroșani. Data were collected in 2016 year, through a survey oriented as well as for the employers and graduates. The research based on the quantitative questionnaire was structured on 21 questions for the employers and other 25 questions for the graduates, of which 8 were common for the two lots of subjects, by which comparable results have been constituted between the requirements and expectations of the two parties involved in the labor market. Statistical data processing was done using SPSS program (Statistical Package for the Social Sciences).

Keywords: University Management; Employer; Graduate; Education; Quality; Labor Market; Skills

1. Theoretical Framework

Contemporary society is defined as a knowledge and learning society, an information society in which real flows of goods and services are replaced by information flows through a virtual economy in which the sustainable factor of progress is generated by the continuous improvement of human capital. The emphasis is on the quality of individual life, on major transformations of a qualitative nature of living standards. All this is only possible in those societies where the educational institution actually fulfills its social mission, assuring quality education, effectively contributing to the construction and affirmation of the new society. Taking into account social development, documents drawn up by the Ministry of Education and Research, in collaboration with the European Center for Higher Education and UNESCO, highlight: "Numerous demonstrations prove that today's developed societies and especially tomorrow's are more and more knowledge and learning societies. Procedure, transmission and application of knowledge in any field of activity are courts that increase productivity. Also, without lifelong learning, personal adaptability or individual way and style are poorer in content and performance, decreases the quality of life in terms of economic standards, the diversity and depth of cultural actions or experiences. Intelligence based on knowledge and professional competence constantly upgraded by assimilating new skills and knowledge is the sign of a personal quality of life capable of contributing to the development of the national and local community. "(MEN, CEPES, UNESCO, 1998 apud <http://www.preferatele.com/docs/management/noi/managementul-perform11206231719.php>).

1.1. Effectiveness of knowledge management

Given that the decentralization of the education system is becoming increasingly strong, the effectiveness of knowledge management increases substantially if the educational institution proves your concern for a careful analysis of the external environment, thus offering other information about their own activity. Decentralization of education implies involvement, responsibility, change of tactics approaching the educational process, strategies, a new management of that institution and a services offered by it. (Ciolca, 2012). This, especially given that the Romanian university system is obliged to adapt its educational offer to the current demands of the labor market. Otherwise, the

* Corresponding author. Tel.: 0744611230
E-mail address: rpmita@yahoo.com

number of graduates leaving the country will increase each year. Actions aimed at improving the management system of the school, as it is knowledge is integrated into this system, it mainly targets: conceiving the management system of the education unit and redesigning it on rigorous scientific bases; remodeling the school development strategies corresponding to the stage requirements the current development of the Romanian society, characterized by the transition to market economy and restructuring of the national economy; the decisive role of strategic and tactical decisions, risk and uncertainty, and those economic growth in rationalizing decision-making and accelerating profitability; training of educational managers according to the requirements of European education. (Ciungu, 2005).

Management of the system and educational institutions involves activities that make use of: clear formation of finality; designing the institutional network (types, profiles and specializations, location in the territory in relation to certain criteria); developing the content of learning (the official curriculum); ensuring the legislative framework necessary for the achievement school policies and financial resources; initial and in-service training of teaching staff; establishing evaluation techniques to optimize results. (Cristea, 2004). At central level there is a strategic management guiding, guiding and evaluating the entire system education, at the level of institutions is practiced one operational management to implement the strategy developed at a higher level. (Ghergat, 2007). An important indicator on the efficiency of the organization's educational management is the dynamism of the conception and realization of the actions, the entrepreneurial spirit that it is both the leaders of the institution as well as the teaching staff and the other employers. The beat accelerated changes in all areas of activity, the specific requirements of the economy market, require an increase in the response rate of all the factors that work in a learning unit. Initiation and dynamism have an increasing influence on the effectiveness of educational decisions and actions, being decisive in achieving a education which corresponds to the quality standards during this period of adaptation of Romania to EU requirements, which is based on the construction of a competitive type of economy in Romania which fast technical progress, the multitude of international contacts and profitability will be the main goals of the economic and social development of our country.

1.2. Managerial performance and performance management

Peter Drucker, a contemporary personality in the field of management, said: performance achieved through management is actually characterized and achieved in practice two dimensions: effectiveness and efficiency. Efficiency is the ability to choose the right and appropriate goals and reach them again efficiency is the ability to make the best use of the resources available in the process of achieving, respectively fulfilling the objectives. (<http://steconomiceuoradea.ro/anale/volume/2006/management-si-marketing/44.pdf>). In practice, managers need to balance the need for efficiency with the need for efficacy.

Educational management is a complex process of leading education at the level of the education system considered as a whole or at its structural levels and it includes the management of the educational act manifested under its informal and non-formal aspect. (Toca, 2002; Jinga, 2001).

Educational management combines the theoretical aspect (concepts, approaches) with the methodological aspect (information accumulation and processing necessary to carry out specific activities) with the appearance technologically (the concrete solution of different situations, processes, operations, stages) and managerial practice. (Orțan, 2004). Any institution or organization providing services education is included in a specific environment that condition and influence the managerial process. The three specific environments are: educational, social and economic. The activities carried out by the educational unit manager in these three listed areas need to be harmonized in a manner that ensures overall performance.

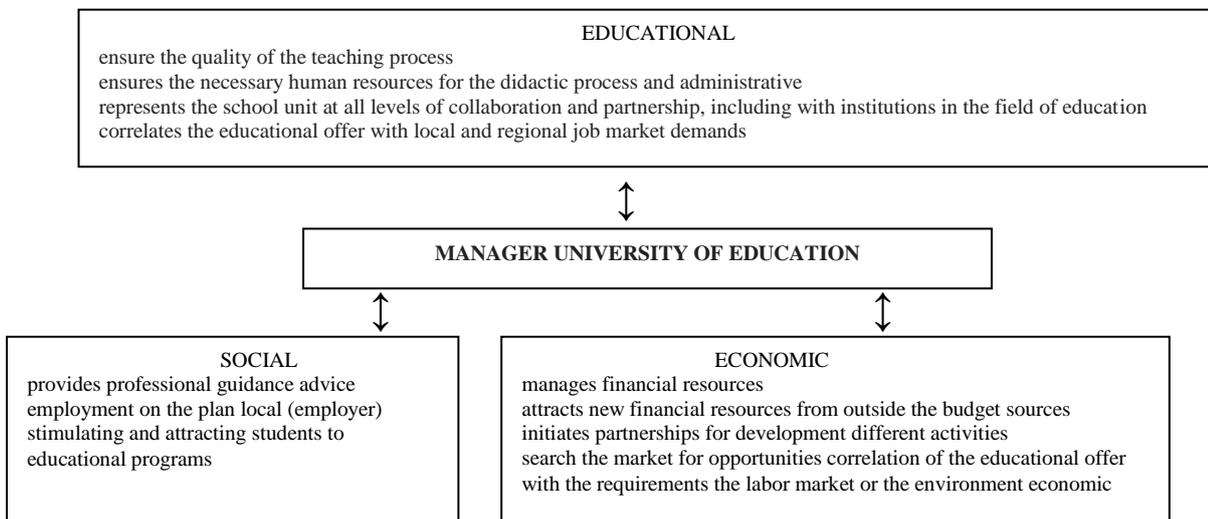

Figure1. Areas of activity of an educational unit manager

2. Results of the study

The socio-economic crisis that crosses the Jiu Valley in recent years, made the three important pillars in the development of this area - business, university and local government - to sit at the discussion table to determine which are business requirements in terms of human resource that provides university and how can local governments to support two media mentioned above, however the idea he wants to lay the foundations for sustainable development of the area Valley Jiu. The main question raised was that young people choose to leave this area to operate in other parts of the country. University requires from the businesses company owners, to create the conditions for young people to stay in Jiu Valley, and from the local governments the requirement was to create a conducive environment for investors that want to do business in this region.

The data presented in Figure 2 show the success of the action taken by the companies involved in the study, involving students interested in long-term internships, resulting in graduates with higher education, experienced in the workplace and motivated to remain active actors in the labor market work in the native country. In order to halt the emigration of young people with higher education, not only the labor market must be flexible and adaptable, but also the educational offer of higher education, the collaboration between the two environments being the essential condition for an adequate insertion on the labour market.

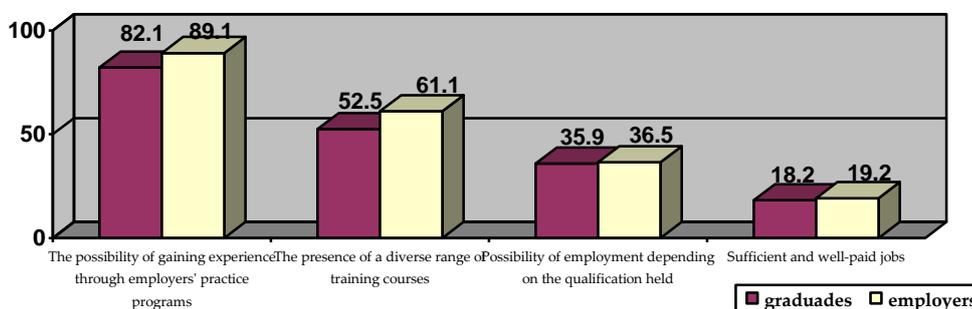

Figure 2. Labour market opportunities in the opinion of graduates and employers (%)

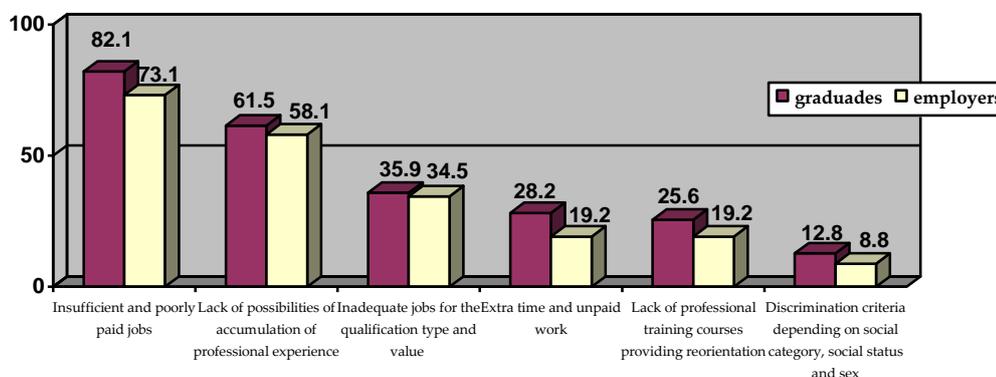

Figure 3. Labour market limits in the opinion of graduates and employers (%)

The comparison between the two lots of respondents points out a relative similarity of opinions regarding the limits existing in Romania's labour market. Thus, the variant with most of the choices, both of the graduates and of the employers, is represented by the problem of insufficient and poorly paid jobs. One should mention however, that with the graduates, among the aspects mentioned as limits of the labour market, we may also find lack of possibility of accumulating professional experience, a requirement that is absolutely necessary for hiring, but also the existence of jobs that do not match the value and type of qualification, an aspect which should be in the attention of the universities.

The comparison between the two lots of subjects of the study points out a perfect match of the hierarchy of activities intended to accumulation by the graduates of professional experience. Thus, in a percentage of over 85%, both graduates and employers rate first in the process of acquiring professional experience, entrepreneurial activities, which involve initiative and coordination of one's own activity or of a group, followed by activities involving interpersonal relationships, helping the others, educational activities, appreciated by more than three quarters of the respondents.

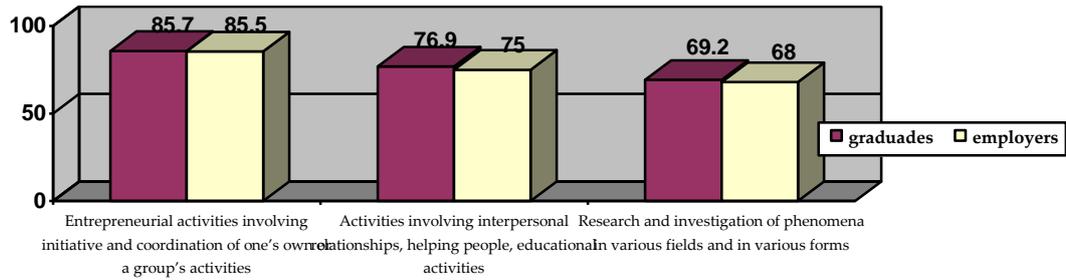

Figure 4. Importance of the following activities for accumulation of professional experience by graduates (%)

For the young at the beginning of their carrier, access to as much information as possible regarding the employing company, the expectations regarding the ideal candidate is important.

The same work experience is seen both by the graduates and the employers as key-element in carrier promotion and advancement, followed by the level of qualification attained, but also the existence of a personal and professional development plan, first of all by participating in training courses.

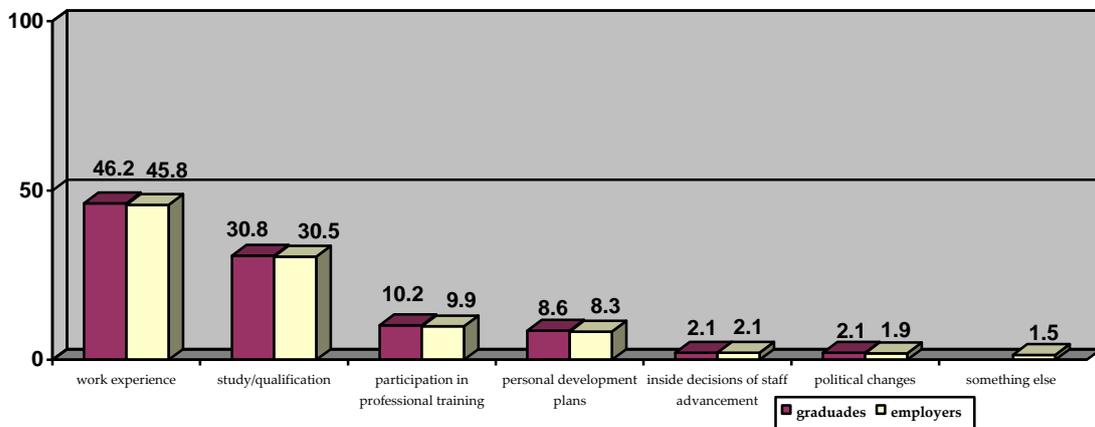

Figure 5. Carrier advancement possibilities, in the opinion of graduates and employers (%)

It is already known that when a university is graduated, the objectives in life are formulated generally, and the perception on the professional future is vague. Being in a continuous process of knowing their own selves, graduates will need instruments, strategies and methods that might help them discover themselves from a professional point of view, understand individual resources, but also their limits, so that they might build up medium and long term objectives, starting from these personal evaluations, being able to discover their abilities, but also their weak points in relation to a carrier they intend to develop.

Lack of self knowledge, of exploration of employment opportunities, preponderant centering on identification of a possible employer, without putting into balance one's own interests or values, make the entire decision process unsatisfactory. To this one might add the fact that most of the graduates put the responsibility for developing professional competencies on the University instead of their own person. The fact that the support in the professional course is done by academic means is a plus for the undergraduates, since it meets the needs and expectations manifested. Meanwhile, however we should take into account the fact that there is a risk of transforming the undergraduates into simple receptors. It is necessary to maintain the responsibility and confidence attributed to the academic environment, and meanwhile to encourage the development and assuming of one's own responsibility by offering practical exercises that might be achieved outside the academic environment, by orientation toward labour market, by support offered in developing a personal brand and training in social networks that might assist them in their professional course.

Table 1. Correlation between the importance given by the employer to the desire to investigate their own ideas or others and the need for higher education to improve other competencies

			The need for higher education to improve analytical thinking	The need for higher education to improve the ability to learn quickly	The need for higher education to improve the ability to open up for new opportunities	The need for higher education to improve the desire to investigate one's own ideas or others
Spearman's rho	The importance given by the employer to the desire to investigate their own ideas or others	Correlation Coefficient	,626**	,768**	,663**	,712**
		Sig. (2-tailed)	,002	,000	,001	,000
		N	19	20	19	20

** Correlation is significant at the 0.01 level (2-tailed).

Table 2. Correlation between the importance given by employers to analytical thinking and the need for higher education to improve other competencies

			The need for higher education to improve analytical thinking	The need for higher education to improve the ability to learn quickly	The need for higher education to improve the ability to mobilize the capacities of others	The need for higher education to find new ideas and solutions
Spearman's rho	The importance given by employers to analytical thinking	Correlation Coefficient	,616**	,597**	,717**	,597**
		Sig. (2-tailed)	,002	,002	,000	,002
		N	20	21	20	21

** Correlation is significant at the 0.01 level (2-tailed).

The pressure exerted at university level is also highlighted by the data presented in the correlation tables 1 and 2, obtained by calculating the Spearman correlation coefficient.

Conclusions

The hypothesis on which our entire research was based, namely “We estimate that there are no significant differences between the labor market needs and the outcome of the educational system”, has been confirmed.

University of Petroșani wants to become a bridge between business and academia, so students trained here, could find a place in the labor market, and this approach management has been declared through the official event organized on June 15, 2016 at the headquarters university. Higher education institutions that address holistic activities can be characterized as having a responsible way of action, ensuring a high level of long-term competitiveness. It is therefore advisable for university management to understand and take into account the strategic context, impact area, and the importance of social responsibility. Then it is necessary to clarify the university objectives and implement the principle of social responsibility, taking into account the specific problems faced by the institution as well as its opportunities.

In our opinion, when it comes to reforming education, we must mainly focus on the evolution of education time of each level, from preschool to postgraduate and analyzed strengths and weaknesses. Like suggestions reforming the educational system, we go on the idea of highlighting strengths and balance between practical teaching and theoretical methods, focusing on the practical side, the introduction of counseling programs to help each preschool, student or student in a direction appropriate to him, be helped to make the right decisions through clear arguments, taking into account their desires, passions and talents. Also, another point to be correlated with the above, we could talk about the efficiency and the way of teaching, which, in our opinion, should be dynamic, based on innovation and interactive methods.

Universities have the necessary capacity to develop the intellectual framework in support of practical applications on the concept of sustainable development. Higher education institutions, as academic leaders, have the capacity to agree on academic disciplines on large and complex issues, to mobilize resources, to create incentives and programs for skills development, and most importantly to lead by example in to promote and implement sustainable development education.

Techniques To Continually Improve Business Quality And Performance (I)

Ghicajanu Mihaela^{a*}

^aUniversity of Petroșani, Petroșani, Romania

Abstract

The continuous improvement techniques applied in quality management have their origins in the Japanese Kaizen philosophy which Deming simply described it as "Improving initiatives that increase success and reduce mistakes." Over the years, numerous continuous improvement techniques have been developed. These techniques represent a system that has evolved from a basic concept of quality or process improvement, or both, in order to reduce losses, simplify the production line, and improve the quality of the business in general.

This work consists of two parts, in this part I present the essence and the attributes of the continuous improvement, and in the second part I present a synthesis of the continuous improvement trends applied in various business environments. In these business environments, specific methods and techniques that belong to the Kaizen strategy have been successfully applied, such as: Lean, Six Sigma, Balanced Scorecard, Poka-Yoke, JIT, 5S and Kanban.

Keywords: management; quality; improvement; performance; techniques; business.

1. Introduction

Improving business processes in business management theory and practice represents an alternative, compared to business reengineering theory and practice. A company's strategic management can choose this alternative in order to obtain performance and achieve business excellence. Even more, in practice within a company, business redesign processes can be implemented, which can then be sustained and maintained by applying processes that are based on continuous improvement strategies.

Basic concepts, methods, strategies and techniques for improving quality and business processes have their origins in Japanese management approaches, based on the Kaizen philosophy, which essentially means continuous improvement. The Japanese philosophy is on the principle of progressing and gaining performance on a continuous, permanent basis, in small steps. This kind of thinking is called Kaizen. KAI = change; ZEN = good, for the better (<http://www.thetoyotasystem.com>).

Below I will present some of the main ideas of this philosophy taken from specialty literature, as well as a series of Japanese management techniques applied for increasing the quality of the products manufactured, especially the ones in the automotive industry.

Managing strategies based on the Kaizen philosophy has developed in Japan between 1950-1980, and this term was formally used in management by Japanese professor Masaaki Imai, who founded the Kaizen Institute in America in 1985 to support US companies facing the low-quality product crisis. Subsequently, in 1986 he published the book "Kaizen: The Key to Japan's Competitive Success" (Masaaki Imai, <http://www.kaizen-competitivity.ro>), which had an extraordinary success being translated into over 14 languages and published in over 30 countries. Masaaki Imai is the initiator of the Kaizen concept in Japanese management through the way thinking, speaking and doing, considered one of the leaders of the quality movement.

* Corresponding author. Tel.: +40722781313;
E-mail address: ghicajanumihaela@yahoo.com

Here is what Masaaki Imai said in his reference book: By definition, Kaizen means continuous improvement involving everyone without spending too much money (Masaaki Imai, <http://www.kaizen-competitvity.ro>), (<http://www.qualitydigest.com>, An Interview with Masaaki Imai, 1997) and that the implementation of the Kaizen principles incorporates TQM (Total Quality Management). Included here are all methods and techniques known in the specialty literature about quality management: methods to reduce defects to zero, reduce the costs, improve response times in the supply or customer JIT, TPM specific techniques - Total Productive Maintenance, "3S" and "5S" techniques or suggestions, etc. All these techniques, as well as others, are described step by step in another Masaaki Imai publication "Gamba Kaizen, A commonsense approach to a continuous improvement strategy" <http://pmworldjournal.net/>, Masaaki I., (2012) (2012 second edition). Gemba means the workplace where all the action takes place. In this book, the author points out the importance of Gemba Kaizen - continuous improvement of the workplace, where things are done. This principle can even become a lifestyle, and if it is applied correctly, excellent results can be achieved in quality and not only.

2. Definitions

Starting from Professor Imai's considerations, we understand through Kaizen - the process of continuous improvement for small increases that makes the process more efficient, effective, controlled and adaptable. Improvements are usually made without some sophisticated technique or expensive equipment. Improvement is done with the mind, not with money. The concept is based on simplification by dividing the complex process into smaller processes and then by improvement. By applying Kaizen-based methods to continuous improvement, process losses are eliminated through significant improvement, systematically using continuous observation and statistical data, continuously changing the tools and techniques used. Exceptional financial results can be obtained if the workers are also associated with these principles, which through training become more conscious and disciplined.

A definition that captures the essence of the improvement of this business process is: "It is a business process that allows organizing and managing product development, operations, relationships with suppliers and customers, that requires less human effort, less space, less capital and less time in order to produce higher quality products for well-identified customers, all these being in comparison with mass production systems" (Nicolescu, 1997)

Continuous improvement can be described as a culture based on the optimization of all systems and processes in an organization by gradually and continuously eliminating the losses or the waste.

Continuous improvement is a philosophy that Deming simply described as "Improving initiatives that increase success and reduce mistakes" (Juergensen, 2000: 3).

According to A.V. Todoruț and V.S.Tselentis, "continuous improvement is not only an important principle of quality management, but also an essential condition for the survival of organizations in a competitive environment" (Todoruț and Tselentis, 2011).

Although the term Kaizen is often considered to be the synonym of continuous improvement, Masaaki Imai asserts the existence of at least three types of Kaizen:

- Kaizen oriented on organization management
- Kaizen oriented on a group of people within the organization
- Kaizen oriented on an individual within the organization

Organizational management-oriented Kaizen is considered to be the most important, as it focuses on the company's strategy and it involves everyone in the company.

The group-oriented Kaizen in the organization is represented by Quality Circles that require the workers to form a team or circle in order to identify and solve the problems encountered in their daily activity without any interference with the company's management.

The Individual-oriented Kaizen in the organization is derived from a "top-down approach" in which workers provide recommendations on the issues they face. This theory has been successful in Japanese industries, given the fact that the employee works in the given ecosystem and knows the best solution to the problem. Some industries even have programs that want to stimulate workers, encouraging them to focus on problematic areas and find solutions for them in return for a reward.

3. Objectives of continuous improvement processes

These Japanese management methods and techniques were initially implemented and developed in production management, with improvements and goals being pursued:

- the maximization kind: on increasing product quality, safety and working conditions, increasing the existing capacity of utilization; in productivity growth, stock management, compliance with standards, and flexibility in production processes.
- the minimization kind: reducing manufacturing costs; in reducing manufacturing time, time cycle, or production time; in reducing space costs, in reducing production accidents that cause loss; in minimizing: manipulation of materials, distances, efforts, storage, use, etc.

The most important principle of Japanese management techniques, compared to the classical management style in which solutions come from top to bottom - from manager to the cleaning woman or security guard - solutions come back from bottom to top, that is from employees (gemba) to the manager. Employees have an essential role in the company. The general idea is that everyone is able to find solutions to improve the individual working process or the business process.

Improving product quality has become a top priority of the strategic management of a company or business. Quality management can be defined, from J.M. Juran's perspective, as "quality planning, quality control and quality improvement" (Ionică A., 2009:19).

On every Romanian company operates a multitude of factors that offer opportunities to be exploited, or which, on the contrary, generate restrictions that are need to be mitigated or eliminated. The factors that determine the need for sustained improvement in an enterprise's quality management can be both internal and external factors. These factors influence the activity of the organization directly or indirectly, causing changes of various natures and amplitudes. These changes can refer to the permanent adaptation to market requirements - to customer requirements first and to the attitude of the company in relation to suppliers, collaborators, and especially decisions and strategies taken in relation to competition. Here are some general factors:

- a first factor is the development of knowledge, generated by: the informational "explosion" that characterizes the current period;
- permanent training and improvement of the staff, becoming a strategic resource of the enterprise.
- increasing "immaterial" investment, with a tendency to equate the material investments.
- another factor that generates significant changes in the organization's environment is technical and economic progress.
- fast and substantial changes in products and services;
- essential changes in the company's management and economy;
- manifestation of a new attitude of the human factor towards some values, regarding the enterprise
- the emergence and consolidation of new values, like social equality, consumer protection, environmental protection
- a last factor is the internationalization of economies;

Among the basic objectives of improvement in quality management are (C. Oprean, 2008, pp. 68-69): Increasing the customer satisfaction; cost reduction; increasing the quality, increasing competitiveness, increasing productivity and profitability.

4. The essence and attributes of continuous improvement processes

Koan Zen (Japanese philosopher) wrote, "If you do not understand, nothing changes" Starting from this principle, the goal is to learn Japanese quality, considering that "Enthusiasm is not enough - you need knowledge too" - "Knowledge is not enough - you need in-depth knowledge." A Chinese wiseman, Confucius, once said, "Knowing without acting does not mean true knowledge.;" considering these lessons, as well as Professor Imai's viewpoints, we understand through Kaizen - the process of continuous improvement, gradually with small steps and increments, which makes the process more efficient, effective, controlled and adaptable.

Table 1. General features and attributes of continuous improvement processes

General feature of Kaizen improvement processes	Kaizen philosophy attributes
- gradual and continuous improvements, in small but fast steps	-Simplification or Division – simplified thinking, dividing the business process analysis
- the entire staff is participating, from director to simple employees (sometimes the best ideas come from those involved in the workplace – gemba)	-Continuous improvement – achieving sustained performance
- change and improvements are done through thinking, without costing too much	-Small growths – getting gradual results, step by step
- organization, perseverance and rigor in the working process	-Process – business process or work processes
- increased added value to the client and tracking the increase in his satisfaction	
- responsibility and discipline and the workplace; - diversity of methods, techniques and alternatives to applying them	
-the indicators are: efficiency(cost/benefit), effectiveness(object achieved in time), high quality, satisfied customers.	

Improvements are usually made without sophisticated technique or expensive equipment. Improvement is done with the mind, not with money. The concept is based on simplification by dividing the complex process into smaller processes and then by improvement. By applying the Kaizen-based methods, process losses are eliminated by significantly improving the process, systematically using continuous observation and statistical data, continuously changing the tools and techniques used. Exceptional financial results can be obtained if these principles are also associated with the workforce, who, through engagement and involvement, becomes more conscious and disciplined.

Table 2. Characteristics of continuous improvement processes

Characteristics	Improving business processes
1. The origin of the term	Japanese
2. The base principle	Continuous improvement of an existing process
3. Keywords (key concepts)	Simplification of thinking and acting; Continuous improvement; Results in small steps Business or industrial processes
4. Purpose	Performance, efficiency, efficacy
5. Participants	All those involved: workers, engineers, managers
6. Implementation time	It never ends, the processes can always be improved
7. Costs	Very low costs. One of the principles is that “ <i>improvement is done with the mind, not with money</i> ”.
8. Base methods	Methods of organizing continuous process flows: Just-in-time JIT, Taguchi method, KANBAN, HEIJUNKA, Bucket Brigades, JIDOKA Methods to reduce manufacturing change time: SMED method (Single Minute Exchange of Die), Total Productive Maintenance (MPT); Specific methods for controlling the processes: Six SIGMA, SPC Methods of analyzing and improving the processes: VSM Method (Value Stream Mapping) Methods for organizing the workplace: the method of 3S and 5S (suggestion systems) Methods of excellence for continuous process improvement: the Deming method (PDCA Cycle), Juran, EFQM of Excellence, Balridge of Excellence Methods to reduce costs and faults: Poka Yoke
9. Advantages	Low costs in general
10. Limitations	Results take time (done in small steps) Perseverance and rigor, daily efforts

5. Conclusions

In this paper I presented the theoretical foundations regarding the techniques for improving the quality and business processes, by the principles of the Japanese Kaizen philosophy and the thinking of Masaaki Imai, that have as keywords: division, simplicity, small steps, consistency, patience, loyalty, low costs, quality, work well done, processes. Initially the Japanese management methods and techniques have been applied to improve the maintenance of production, aiming targets relating to: increasing the product quality; in safety and working conditions; the increased use of existing capacity; increasing the productivity; inventory management; in compliance; the flexibility of production processes; in the reduction of manufacturing costs; reducing time manufacturing process, time cycle or the time of production; in reducing the cost of space; minimizing: material handling, distances, effort, disorder, storage, use, etc. In time, these principles were extended to all activities in a company from accounting, procurement, logistics, information systems, human resources in all business processes.

Techniques To Continually Improve Business Quality And Performance (II)

Ghicajanu Mihaela^{a*}

^a*University of Petroșani, Petroșani, Romania*

Abstract

Continuous improvement processes, based on Japanese management principles, organizational culture, or even their lifestyle, can be a way of organizing and managing business on principles of efficiency and efficacy. In the first part of the paper I presented the theoretical foundations regarding the processes of improvement in quality management and business management regarding: the concepts, objectives, characteristics and base principles of continuous business improvement processes - based on the Japanese Kaizen philosophy. In this part I present a synthesis of the continuous improvement trends applied in various business environments. In these business environments, specific methods and techniques that belong to the Kaizen strategy have been successfully applied, such as Lean, Six Sigma, Balanced Scorecard, Poka-Yoke, JIT, 5S and Kanban.

Keywords: management; quality; improvement; performance; techniques; business.

1. Continuous Improvement Techniques

Continuous improvement techniques have evolved from traditional factories with systems primary focused on production lines, reducing losses and improving the quality of the finished product, to hybrid techniques that focus on all aspects of the organization. Continuous improvement techniques aim at a wide range of organizational aspects and offer a variety of benefits, most of which are measurable in terms of quality, efficiency and speed (quality, cost, time).

The applicability of continuous improvement techniques within the different types of organizations has been widespread in recent years due to specialized firms and specialists in this field (providing advice, implementation assistance, training courses etc.). Over the years, many techniques for continuous improvement have been developed and they have been recognized as having some great contribution to: improving the products and processes of organizations; to increase efficiency and increase economic performance in industry, especially those related to production management and quality management. These techniques represent a system that evolved from a basic concept of quality or process improvement, or both, in order to reduce losses, simplify the production line, and improve quality. They were developed when there appeared a need for them, and the best known of these are: Lean Production, Six Sigma, Balance Scorecard and JIT.

2. Lean Production

2.1 Lean History and Description of the Technique

Henry Ford systematized Lean Production in the 19th century, when he implemented the concept of mass production within his factories. The term Lean Manufacturing was introduced by James Womack in the book "The Machine that Changed the World: The Story of Lean Manufacturing". However, it is said that Toyota Motor Company in Japan has developed Lean's type modern thinking, also known as the Toyota Production System. Lean type production is a systematic approach to identify and eliminate losses through continuous improvement by pursuing to attract customers through products that aim to perfection. Lean production includes practices such as JIT (Just in Time), cellular manufacturing and work teams, (Shah and Ward, 2003). The elimination of losses is the core of Lean production, and

* Corresponding author. Tel.: +40722781313;
E-mail address: ghicajanumihaela@yahoo.com

the goal is to eliminate losses on each part of production, including customer relationships, product design, supply networks, and production management. Examples of losses include human effort, inventory management, time for product development and storage. The ultimate goal is to become very receptive to consumer demands, producing high quality products in the most economical and efficient way possible. Usually, the transition to a Lean environment does not occur instantly. The mentality of continuous improvement must reach the general goals of the enterprise. The results of Lean type production are the ability of the enterprise to learn. According to Lean philosophy, mistakes are generally not repeated because they are exactly what is required to be eliminated.

2.2 Implementing Lean

Lean production can be applied to organizations that pursue a move away from traditional manufacturing vision and invest less in storage, reduce labor costs and speed up manufacturing processes. The basic ideology underlying Lean is to minimize losses and develop skills to change. The principles of implementing Lean thinking are: Specifying the value for each family of products, from the point of view of the final customer; Identifying the activities within the value stream of each family of products, eliminating as much as possible the ones that generate losses; Sorting the value-making activities in a clearly defined succession(stream) of steps, so that the product reaches the final client through a more continuous process, without too many interruptions, turns, stops and intermediary expectations; Once the value stream has been established and entered, any internal or external client can apply the “pull” type system in order to “pull” the product directly from the producer when he wishes, instead of placing the product on the market; Once the value, the identified activities of value creation, those that generate the eliminated loss, the stream of value specified and introduced have been established, they can move on to operationalize and perfect the process, until it reaches and optimal level, in which the added value is maximal and most of the losses are eliminated.

Implementation Costs. The cost of implementation depends on a number of factors such as: the size of the organization, the level of Lean technology the enterprise wants to adopt, and the available resources. Costs can escalate if a restructuring of the organization is required.

Implementation Period. The implementation of Lean Production from scratch in an organization will also depend on the size of the organization and its objectives, but also on its resources if internal human resources are to be trained through external consultants or training. The duration of implementation time in a large organization may reach even half a year.

2.3. Examples of companies that have applied the Lean technique

Table 1. Companies that have used the Lean Technique

Companies that have implemented Lean	Romanian companies that have implemented Lean
<i>The Boeing Company</i>	<i>Continental</i>
<i>Yamaha Electronics</i>	<i>Totalgaz Industrie</i>
<i>Fujitsu Component</i>	<i>Cersanit România</i>
<i>Bosch Braking Systems</i>	<i>OMCO</i>
<i>BASF Group</i>	<i>Dacia Mioveni</i>
<i>Parker Aerospace</i>	<i>Ford Craiova</i>

Table 2. Companies that provide Lean Consulting services

LEAN Consulting Companies	Romanian Lean Consulting Companies
<i>TMB Consulting</i>	<i>ALFRA Consulting</i>
<i>Simpler</i>	<i>Genium Trening and Consulting</i>
<i>Catalyst Connection</i>	<i>Enviso</i>
<i>Lean Plus</i>	
<i>AEM Consulting</i>	
<i>Manufacturing Success Consulting</i>	
<i>Granite Bay Consulting</i>	

Tools required for Lean implementation: 5S, TPS tools, and those responsible with the implementation must have knowledge about Lean philosophy and experience with Lean tools like: Kanban, 5S, Poke-Yoke and others.

3. Six Sigma

3.1. Six Sigma History and Technique’s Description

Six Sigma has its origins after Lean Production evolution, when Motorola developed a program called Six Sigma designed to achieve the goal of improving by a hundred times in 5 years. And it succeeded in such a way that the Six Sigma pioneers gained fabulous confidence in their product and delivered to customers without any prior control of the product. Six Sigma starts up as a means of measuring process quality using Statistical Process Control (SPC). The minimization of defects at a level close to zero was the basis for the methodology. Six Sigma has evolved into a much wider terminology that also represents a major opportunity to reduce costs. Since 1988, the impact on Six Sigma over the improvement of business processes has been so significant that today it is widely used by many top organizations.

Six Sigma has the ability to produce dramatic, measurable changes, reducing the cost and cycle time while improving product reliability, increasing consumer satisfaction, and delivering quality measurements that can be used throughout the organization, not just in the production department but also in design, administration and service areas.

Six Sigma is defined as a management technique that aims to improve business processes to create and deliver near perfect products and services (<http://www.trilex.ro/Metodologii/six-sigma-DMAIC.htm>).

It is defined by Pande as "a comprehensive and flexible system used to achieve, maintain and maximize business success. Six Sigma is driven by an understanding of customer needs, disciplined use of facts, statistical analysis, and careful management, improvement, and reinvention of business processes." (Peter Pande and Robert Neuman, 2000).

This technique, as mentioned above, is based on a statistical control process (SPC), which uses quantitative and graphical techniques to reduce the variance of assigned and variable measures of predetermined boundaries. The goal is set for a particular or variable part, along with the acceptable minimum and maximum limits where measures may be erroneous (standard deviation), and processes can be controlled using diagrams.

3.2. Six Sigma Implementation

Implementation Costs. The cost of implementing Six Sigma depends on the following major factors: The size of the organization (number of employees, its location); The existence of systems for improvement in the organization; Internal or external resources requiring training or employment;

The optimal time for implementation. The implementation period of Six Sigma is one of the most important factors for an organization and it depends on the following factors: The size of the organization (number of employees, its location); The existence of improvement systems in the organization; Commitment of top managers. The lack of this factor can lead to delayed implementation by not releasing the necessary funds and resources.

Duration of implementation. The entire implementation process in a medium-sized organization (500-1000 employees) can take between 6 months and 24 months, and for a large-scale organization (with over 1000 employees), implementation can take from 6 months to something more than 24 months.

3.3. Examples of companies that have applied Six Sigma Technique

Table 3. Companies that use Six Sigma

Companies that have implemented Six Sigma	Romanian companies that have implemented Six Sigma
<i>General Electric Company</i>	<i>Xerox Romania</i>
<i>Motorola Inc</i>	<i>Dacia Mioveni</i>
<i>The Boeing Company</i>	<i>Ford Craiova</i>
<i>NASA</i>	
<i>Honeywell International Inc.</i>	

Table 4. Companies that provide Six Sigma Consulting services

Six Sigma Consulting Companies	Romanian Six Sigma Consulting Companies
<i>Mulbury Consulting Limited</i>	<i>Six Sigma Consult SRL</i>
<i>Catalyst Consulting Limited</i>	<i>Enviso</i>
<i>The Athon Group</i>	<i>IGC Integrated Consulting Group</i>
<i>Ketch Consulting</i>	<i>Ascendis</i>
<i>Motorola University</i>	<i>SGS Group</i>

Regarding the duration of implementation, a small organization can usually complete the initial implementation model in a period of 4-6 weeks, compared to 12 to 14 weeks in large organizations.

Therefore, the fundamental idea of Six Sigma technology is that if the performance is improved, then the quality, capacity, time cycle, inventory levels, and other key factors such as loss reduction, energy sources, and environmental performance will also improve. Therefore, when these factors are improved, both sides gain, both the supplier and the customer experience greater satisfaction in business transactions.

4. Balanced Scorecard (BSC)

4.1. History and Description of the Balance Scorecard Technique

The Balance Scorecard technique was introduced to the world in 1990 and since then it has had a major impact on how organizations carry out their business. The Balanced Scorecard defines exactly what management wants to achieve when it comes to performance. It is a concept that allows balanced strategic planning at the level of an entire organization or its unit component. It is a system of management and optimization of the implementation of an organization's strategy, which allows it to achieve accelerated growth in operational performance and achievement of defined strategic objectives. Therefore, this technique can be used to translate the mission of the organization and the visions established in a set of objectives and performance measures.

"The Balanced Scorecard concept is a strategic planning and management system widely used in business and industrial organizations, in the public system and non-profit organizations around the world to align the activities to the organization's vision and strategy, improving internal and external communication and monitoring the organization's performance in order to achieve the strategic goals" (Balanced Scorecard Institute, <https://www.balancedscorecard.org/>).

The system consists of 4 processes: translating the vision into operational objectives; explaining the vision and linking it to individual performance; business planning; feedback, learning and strategy adjustment based on evolution.

It is generally used to: clarify the business strategy; keep everyone informed about the business strategy; it relates the organization's intentions within the annual budget; makes space for organizational change; increase acceptance of the vision and mission of the company throughout the organization.

The companies that use Balanced Scorecard are able to achieve their goals if the Balanced Scorecard is transformed from a measurement system into a management system. This technique covers the deficiency that many organizations have, namely when a strategy feedback is to be received. The implementation of a long-term strategy becomes a primary goal and a focus of the organization built around the Balanced Scorecard.

4.2. Implementation steps

Implementation of the system is only possible in relation to defining the vision, strategic objectives and general strategy of the firm. Determination of partial and derived strategies, setting of secondary and individual objectives, as well as establishing a hierarchy and prioritization is necessary to accompany the implementation process, (Stefănescu and Silivestru, 2012:25). Implementation of the Balanced Scorecard involves 2 phases, the planning phase and the development phase reflected in the following steps. Tools used to implement the Balanced Scorecard are: Brainstorming, Six Sigma tools, Lean Instruments.

4.3. Examples of companies that have applied the technique

Table 5. Companies that use Balanced Scorecard

<i>Motorola</i>	<i>Rompetrol</i>
<i>Royal Air Force</i>	<i>Bidefender</i>
<i>Kraft Food</i>	<i>P&G</i>
<i>Marriott</i>	<i>Guvernul României</i>
<i>Hilton</i>	<i>Transelectrica</i>
<i>UPS</i>	<i>Deloitte</i>
<i>Siemens</i>	<i>ING Bank</i>
<i>Cisco</i>	<i>Euralis</i>

Table 6. Companies that offer Balanced Scorecard consulting services

Balanced Scorecard Consulting Companies	Romanian Balanced Scorecard Consulting Companies
<i>Balanced Scorecard Institute</i>	<i>Ensiht Management Consulting</i>
<i>Hudson Associates Consulting Inc</i>	<i>Strategic Systems Consulting</i>
<i>Value Creation Group</i>	<i>Codecs România</i>
<i>Crescent Consulting</i>	
<i>Balanced Scorecard Collaborative Inc</i>	

5. Conclusions

In the last decades, comprehensive methods and techniques to achieve continuous improvement have evolved. The principles of these methods and techniques have begun to be applied not only in production activities but in all the activities within a company. The Japanese management techniques have become more and more present in Western and European business environments, based on the principle that: improvements that are constantly, persistently and speedily achieved, lead to results that are obtained over time in in terms of quality, profits and customer satisfaction.

Quality Supplier Response to Industrial Procurement Behavior on the South East European Metal Distribution Market

Székely Szilárd*, Adriana Benedek, Lucian-Ionel Cioca

Lucian Blaga University of Sibiu, Bdul Victoriei, no. 10, Sibiu, 550024, Romania

Abstract

Industrial marketing presents a list of peculiarities which differs from the “classic marketing” (the business-to-consumer). We can observe increased interactivity between selling teams and DMU (decision making units or buying centers). A good analyses and proper understanding of DMU’s behavior and needs give the opportunity to industrial supplier companies to offer a quality response and to obtain better commercial and financial results for mutual benefits, sustainable development and long-term success.

This paper presents multidisciplinary characteristics by mixing different approaches, solutions from industrial marketing, organizational (customer) behavior, sales management, management and digital marketing.

In this paper we shall analyze these peculiarities and processes by secondary market data analyses, professional in-depth interviews with members of DMU’s and selling teams from different countries, direct behavior observations from the market (industrial exhibitions or negotiations between sales representatives and buyers). One of the key area of the paper shall be the situation of the presented peculiarities on the (metal) semi-finished products on Romanian and South East European markets, in the era of digital marketing.

In nowadays industrial marketing, digital and traditional marketing concepts, instruments and tools are converging. The activity of sales forces are sustained by adapted marketing mix, digital tools and use of web based technology, strong long-term relations, automated processes, targeted communication to buying centers members, useful marketing and technical information, and customized services for key account partners.

Keywords: industrial procurement behavior, organizational buying behavior, buying center DMU, industrial marketing, semi-finished product marketing

1. Main features of industrial marketing

Industrial marketing or business-to-business marketing is many times treated like a down-graded version of the “classical” marketing, the business-to-consumer or the consumer’s goods marketing. “Marketing has its roots in understanding consumers, and because we are all consumers and business-to-consumer marketing (from communication to effective selling has more visibility) it has become altogether too easy to concentrate on using consumer-based examples and theories when discussing marketing concepts. However, business markets are far larger: businesses buy and sell more goods than do consumers, and the transactions that take place between organizations have a greater impact on the economy and on the welfare of people than do the transactions between businesses and consumers.” (Zimmerman A., Blythe J., 2004). However, B2C marketing has high visibility, starting from commercials in mainstream media channels to shopping malls, B2B marketing is most of the time more discreet, is taking place behind closed doors, at business meetings and nowadays online. In order to develop efficient industrial marketing strategies first we have to understand the similarities and differences between marketing to consumers and marketing to professional buyers from commercial or industrial organizations.

Continuing the parallel presentation of B2C and B2B, the first step is to understand our consumers, or in our case the industrial buyers (or as often called buying center or DMU – decision making unit). In order to be able to offer high quality services and to achieve sales or marketing targets our first duty is to deeply understand the way that our

* * Székely Szilárd Tel.:+40-740-210778;
E-mail address:office@astiadvertising.ro

costumers acts in a procurement process. In the present paper we'll make some comparison between the two major types (final consumer and industrial) of marketing and procurement, but the main focus well be on industrial markets and especially on the semi-finished metal products market in Romania and South East Europe.

The first issue that we have to focus on is the main purpose of companies acting on B2B markets: they have as main goal the profit and wealth growth. Company's interest is most of the time openly assumed based on rational decisions, also personal interactions and relations, reciprocal dependency at least for medium term are usual on this market. (Torocsik, M., 2007). The first impression when we talk about industrial marketing is that heavy equipment, production halls or even high-technology is involved. In this order marketing experts from this field need to have solid technical and economical knowledge.

David Ford focuses on three main directions: the features of the relations with suppliers, the volume and organizational infrastructure and the measure of relying on existing suppliers. (Ford, 2003). In his opinion, the most important task of an expert in business marketing is to give a quality support to the procurement process of the buyers.

One of the most accepted description of industrial buying features is given by Kotler. But first, we need to clarify the concept of organizational buying or procurement. Kotler refers to the Webster and Wind when defines the organizational buying as "the decision-making process by which formal organizations establish the need for purchased products and services and identify, evaluate, and choose among alternative brands and suppliers" (Kotler, Ph., 2002). So, a quality supplier response needs to follow the path described in this definition.

In the next table we try to offer a list of the most important peculiarities of industrial markets, based on the works of Zimmerman and Blyth (2004), Torocsik (1997 and 2007), Jozsa (2005), Kotler (2006) and others, which we adapted to the market of semi – finished metal products in Romania and South East Europe:

Table 1. Industrial markets' peculiarities adaptation on the semi-finished metal products' market

Industrial marketing features	How it appears of semi-finished metal market
Limited number of actors, market concentration	Less than 20 important producers and less than 100 resellers
Narrower customer base	From a few dozens to a few hundreds usual buyer
Derived and inflexible demand	Costumer market's demand influences, for ex. if people don't buy cars, on medium terms aluminum and steel sales decrease
Products are technically difficult to substitute	High quality products are important, but there are no big differences between products, complementary services do the difference
Importance of personal relations and sales force	Over 80% of sales are due to sales force and realized with long or medium term partners
Many sales visit (interaction) for one (first) transaction	For the first sale sales man pays many visit and changes lots of information through internet and phone
Internationally opened markets	International and multinational corporation appear on the market regularly as suppliers and customers, too
More formalized transactions	Transactions are based on price offers (request), contracts, orders, shipment documents, bank payment...
Additional services	Cutting to size, delivery routes, packaging, consultancy
Importance of buying centers or DMUs	(Design) engineers, plant managers, buyers, financial experts influence the decisions, at least at major negotiations
Many influencing factors on procurement	Product standards, price, reaction / delivery place and time, commercial credit, brand image, auxiliary services, relationship are also important
More rational decision	The above mentioned factors are quantified and weighted
Networking -clustering	In some subfields are important
Demassification	Every company has its needs and expectation—sometimes customization
Different segmentation	Segmentations by size, field of activity, volume of materials used, but also business style: willingness to risk, need for partnership and safety
Less end user info	Those who sales electrical, aluminum, steel semi-finished products don't really know in which way final costumers will use the product

For our paper the most interesting topic for the above list are those related to the behavior of the DMU's or buying centers: the importance of personal relations, more formalized transactions, more rational decision and many influencing factors on procurement.

2. Industrial procurement behavior (I.P.B. or O.B.B. organizational buying behavior)

Nowadays marketing experts and salesmen complain that consumers "behave in a strange way", "no one can understand what they want, how they make buying decisions". Understanding consumer's behavior, researching it, analyzing it became an important task of marketing departments. The same way that "classical" (consumer) marketing made the transition from production orientation trough product, then sales, and consumer focused marketing orientation till the actual societal marketing (Kotler, 2017), industrial marketing moved the focus from the product orientation to focus on the consumer behavior, in our case, the industrial buying (or procurement) behavior and relationship marketing. In the lack of dedicated space, we only mention a few concepts in this progress: the 4P (marketing mix: product, price, place and promotion) evolution to 7P (4P + physical evidence, process, people) or into 4C (consumers' needs, cost to satisfy, convenience, communication) etc. Or we can go further to the 4V concept, which focuses on the validity of the offer, the value, the venue and the vogue. One of the most interesting and complicated issue related to

consumer behavior analyses in industrial marketing is that industrial procurement is a **collective decision**, even if we can separate it into three levels:

- individual level – or interest;
- decision making units or buying center level;
- organizational level. (Torocsik, 2007).

Another aspect to clarify when discussing about industrial procurement behavior is that these companies use the procured goods for their business goals (Jozsa, 2005):

- users need the product (a machine, a tool) in the process of production of new products they sell to the market,
- buyers - producers, who build the goods into their own product (for ex. semi-finished metal bars for a car component). The US literature call them OEMs (Original Equipment Manufacturers),
- resellers – who don't use or change the products, they resell it in an unchanged form. Their customers are the previous two categories.

2.1. The process and participants to the industrial procurement

The process of decision making in industrial procurement is (similarly to individual or familial consumer behavior on consumer goods' market) is a multiple stage process. The number and the complexity of these stages vary influenced by many factors: the size of the company and the decision making units; the value of the acquisition; and the influence of the product (or service) on the activity and financial situation of the buyer company (from small spare parts to strategic industrial equipment or an ERP system). (Jozsa, 2005). Fill (2005) completes the ideas of Spekman, R.E. and Gronhaug, K. (1986) and identifies four groups of main influencing factors.

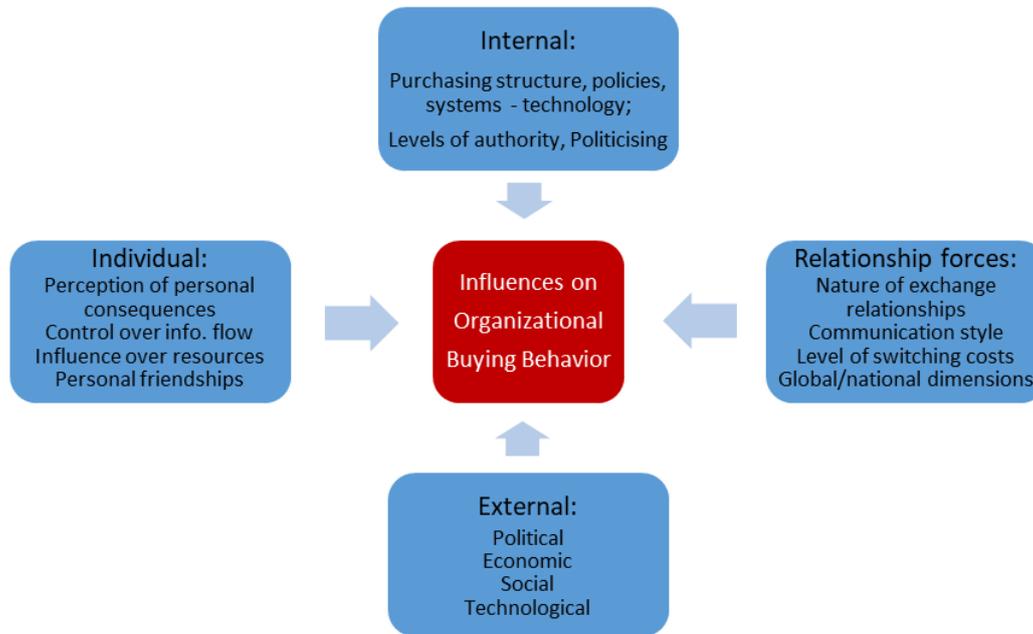

Fig. 1. Influences on O.B.B. (Organizational Buying Behavior) (adapted after Fill, 2005)

The classical stages of industrial procurement process are (Backhaus, 1997):

- identifying the problem, the need for a certain product, defining the value or volume needed to be procured
- searching for a solution, collecting product alternatives,
- assessing and comparing offer phase,
- negotiation – detailed discussion between seller and buyer (teams), comparison of offers (technical, financial, logistical and service aspects),
- decision making, order or contract signing,
- delivery stage, product using stage,
- additional stages: quality inspection, training, follow-up etc.

In case of complex products the offer, negotiation, decision making stages can have many other intermediate stages. Also the delivery and product using stage can suffer changes: testing, renegotiating, product – system development etc.

In present days, on the South East European metal distribution markets **sales force are still the dominating force**, but they became more and more **over-busy**, mostly because losing too much time and energy with small valued, transaction based selling, while not being able to properly serve the key account partners or focus on relationship marketing.

Cardozo (1980) found that industrial organizations tend towards one of two main strategies or directions in procurement. They are called the optimizers or satisfiers. The optimizers negotiate with a large number of potential suppliers and evaluate a list of proposals before selecting a supplier. The satisfiers prefer to have partnerships with familiar suppliers and sign contracts with the first company to fulfill the requested tasks.

In case of increased risks individual actions leave place to DMU-s, as Johnston and Lewin (1996) affirms.

The next question is, who is responsible for the above described process. As we already, shortly mentioned: the DMU (decision making unit) or Buying Center holds the responsibility for the whole project. This DMU is a complex team, with interesting models of functioning as you'll see in the next sub-chapter: DMU – Buying Center

Most of the researches, articles or educational resources focus on the group level, the decision making unit or the so called buying center. Probably the main reasons for it is that through analyzing DMU we can observe as well individual aspects and the same time with organizational features. The last 40 years, as industrial marketing reached a larger academic and industrial attention, many buyer behavior models were developed. We can distinguish partial and complex models. The partial models focus on analyzing one factor at one time, while the complex model aims to bring together all the main elements of organizational procurement behavior.

As Spekman and Gronhaug (1986) point out, the DMU is a 'vague construct that can reach across a number of different functional roles with any number of individuals participating or exerting influence at any one time'.

The dimensions and forms of Buying Centers are not stable. It can vary due to the complexity of the product to procure, the level of perceived risk in case of every decision taken by the organization. There is a need for special roles, because the procurement task is modified at every new procurement situation, (Bonoma, 1982).

Table 2. Procurement (buying) behavior models categories (adapted after Torocsik, 2007)

Partial models	Complex models
Buying center concept	Robinson Faris Wind – Buygrid model
Sub-division related to organizational power	Bonoma Zaltman Johnston
Sub-division related to reaction	Webster Wind
Focus on interactive communication	Sheth
	Choffray Lillien

3. Quality supplier response to the industrial procurement behavior

In these analyses we have to maintain focus on the basic principles on which companies activate: obtaining profit, sustainable development and increasing company's worth. So, **helping customer companies to obtain profit** by reducing acquisition (logistics, operational) costs and increasing sales are vital for suppliers.

The classical response to customers' needs in marketing was the **marketing mix**, or the 4P's: product policy, price policy, distribution or placement policy and promotion policy. And as the name suggest it is very important the proper mixing of these ingredients to a selected target (based on an STP strategy: segmentation, targeting and position). In industrial marketing some authors consider that the first two P's (product and price) have to be managed together as "offer policy": product and service range, prices, discounts on volume or value, payment conditions etc. Many times on metal markets the question „when to pay?" is more important than „how much to pay?".

The first aspect of analyzing seller-buyer interaction on industrial market are the relations between focusing on long-term relations versus individual transactions, and between focusing on individual customer versus on market segment, as you can see in the next figure. The study of organizational buying behavior needs to focus on developing and managing **inter-organizational relationships** on medium and long term. (Fill, 2004) The stronger the relations are the mutual benefits increase, including quality services are provided and both parties can be successful on long-term.

In industrial marketing many researchers affirm that relationship marketing is more important than the marketing mix. Knox (2000) suggests that there are three reasons why competitive advantage might be improved through **stronger relationships**. Systems cost reduction – cost savings from improved working practices: for ex. **improved order cycle times, reduced stock** and working capital, buyer centers already knows the products features, **delivery methods and time** etc. Increased effectiveness through innovation – as a relationship develops, more information is exchanged and suppliers become more willing to invest in the relationship (supplier holds on stock special semi-finished products for key accounts). Enabling technologies – electronic systems and communications help suppliers to **anticipate and understand the needs of their customers** (partner companies can set up common online systems for orders, payment etc. Suppliers become more able to evaluate the cost-effectiveness of their customer portfolios and to determine where to invest.

Fig. 2. Industrial market analyzed based on seller-buyer interaction (adapted after Jozsa et al., 2005)

Organizations work, wherever possible, to reduce uncertainty and risk. By working with others who are known and trusted, of whom the organization has direct experience, risk and uncertainty can be substantially reduced. So building relationship marketing approach is also a quality supplier response to industrial procurement behavior. Fill (2004)

It is vital for seller organizations to **identify members** of the buying center and to **target and refine their messages** to meet the needs of each member of the center, for ex. a design engineer needs information about the features of materials or semi-finished products, the logistical manager about the deliveries, the financial officer about price and payment methods etc. Fill (2004). Ronchetto et al. (1989) provide some insight into how influential members of a DMU might be recognized. Their research suggests that there are several criteria that indicate those members who have above average influence. In addition to those members who occupy particularly significant influential positions, they cite people who: work close to the organizational boundary; are near the center in terms of internal relations; has an active position in communication between the departments of customer firms; are connected directly to top management.

Quality auxiliary services are very important in many subfields, such as (cut to size) **service centers** for metal semi-finished products, **consultancy** related to use of products (including personal consultancy, or even online tutorial videos), **products presentation** workshops.

Useful marketing and technical communication at all time. This can be realized using the omni-channel approach, wherever the customer is looking for information (or product) the supplier needs to be there: Google Search by search engine optimization, web pages with text, infographic or video tutorial based frequently asked questions, e-mail, segmented – targeted newsletters, call centers, personal visits, even chat bots with artificial intelligence backup.

Use of web based technology – online technical and commercial communication, proper customer data base, CRM systems, EDI or ERP systems, B2B adapted e-commerce platforms, segmented and targeted newsletter communication etc. also increase the quality of supplier response to I.P.B. One of the first tools needs to be the use of search engine optimized web pages (for giving permission to customers to obtain information and contact suppliers), which are also filled up with valuable technical and commercial information and user friendly. Acquiring valuable data about customers and properly managing them (including CRM, ERP and on medium term big-data use) can increase the value of services provided to customers. A supplier needs to be everywhere where a (potential) customers is looking for information, products, services, advices (Fox, 2010). Organizations need to be sure that strategic relationships between suppliers and customers are protected and technology is used to complete long term partnership, not to jeopardize them, Fill (2005).

And finally, as Kotler (2017) suggested “technology convergence will ultimately lead to the **convergence between digital marketing and traditional marketing**. In a high-tech world, people long for high touch”. So, the same on the metal semi-finished products market, supplier needs to develop strong relationships with buyers using the personal high quality touch of sales force and also back-up from online (digital) technology. But regarding also the efficiency of serving markets sales force needs to focus personally on long term relations and key accounts while transaction type sales need to be automated. So, I propose a model with proportioned use of personal selling, the more important the customer and the relations are, the more personal involvement and customized services are necessary for a quality response to customers’ needs. The figure 1. presents the main influences and recommend supplier (seller) response.

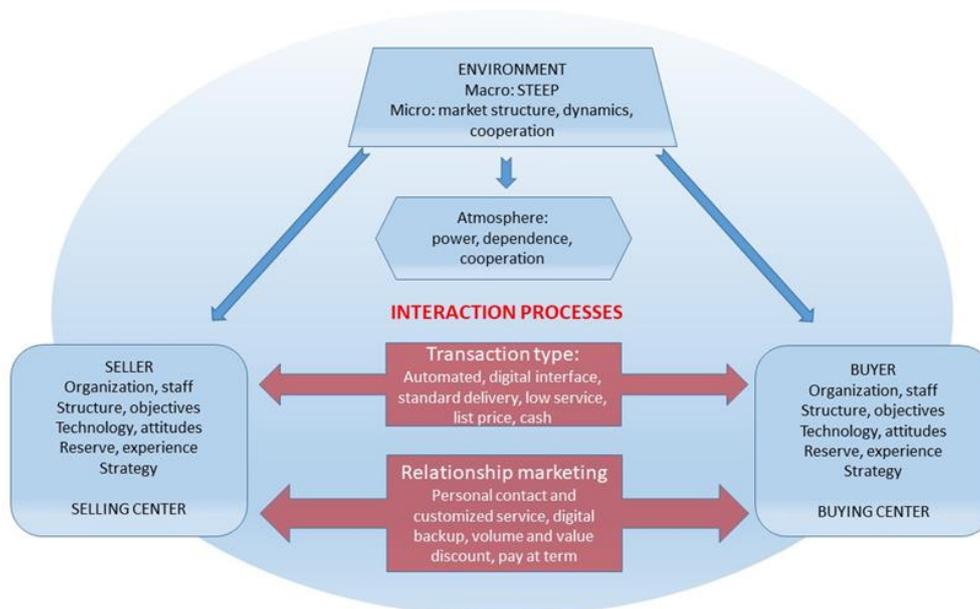

Fig. 3. Quality supplier response to industrial buying behavior in case of transaction versus relationship type interaction processes on industrial markets (Adapted after Turnbull – Valla, 1987 and personal researches)

In the case of transaction type selling the interactions need to be automated as much possible, standard, but quality delivery, list prices, without discounts and no payment at term. On the other hand, in case of long-term relations, with higher value of sales, selling center need to provide a more personal contact, customized services (which can be supported by business intelligence systems). Also volume and value discounts, and pay at term can increase the satisfaction of buying centers. The mutual benefits are the key to long term success.

Abstract

The increasing requirements of the local administrations, the challenges generated by the changes in the socio-economic environment, the technological progress, lead to the emergence of the difficult to manage situations given that sometimes the resources are scarce, the time of solving them is limited and even human resources are insufficient. In this paper we intend to show a model to be applied at local administration, proving its advantages, using the principles of sharing economy, this way aiming at coagulation of the capacities of an association of communities, in the interest of each individual.

Keywords: innovative; quality; management; IT; GIS; sharing economy;

1. Introduction

The improvement of the living conditions, the access to resources and to good quality services are desiderata that have become normality in modern society and they exist in all present and past government programs.

According to the current government program (Government) "There is no citizen who does not want a home with all the comfort (water, sewage, heat, electricity), who does not wish to be able to move safely and rapidly to work, ... " and "The answer is simple and at the same time very complex: the one who must take care of the needs of the citizen is the state by means of all its administrative structures."

The conclusion is obvious, the need to increase the quality of management in the administration is mandatory, no matter who governs it.

The methods of increasing the quality of management in the administration are diverse and we do not believe there is a unique solution, but they need to be adapted to the nowadays context and to the future perspectives. In accordance to this statement, observing these realities and understanding that the resources are limited, we try to prove the need of local administrations to use the sharing economy principles to perform in the work they must do.

2. Prerequisites of using the principles of sharing economy in administration

As Horton, John J., Zeckhauser, Richard J., Owing show in "Using and Renting: Some Simple Economics of the Sharing Economy," the notion of renting of goods underwent a development, moving from the situation where the owners own assets which they rent, to that where the asset holders use them for their own good but also for renting (Horton). It is this development the one that led to the notion of *sharing economy*, and the benefits were mainly given by efficiency. This model, which has come to be a practice presented in almost all sectors of the economy, with a size of \$ 15 billion in 2013, is estimated to reach 335 billion in 2025 (Cakravathi)

1.1. Sharing economy a sustainable perspective

Currently *sharing economy* is practically present in all economic sectors, as can be seen in Figure no.1.

Figure 1 Example of sharing economy (Chakravathi)

The subject is attractive for all actors involved in the market of goods and services and even for researchers. Andreotti shows that in the Eurobarometer 2016 questionnaire is presented the information that says that most of all Europeans respondents are aware of the existence of sharing economy but only about 17% declare that they have directly used the sharing economy. The pace of development of the sharing economy is high, because of the benefits, but also of the digital tools capable of supporting such development. Figure 2 shows an evolution of the financial dimension by domains.

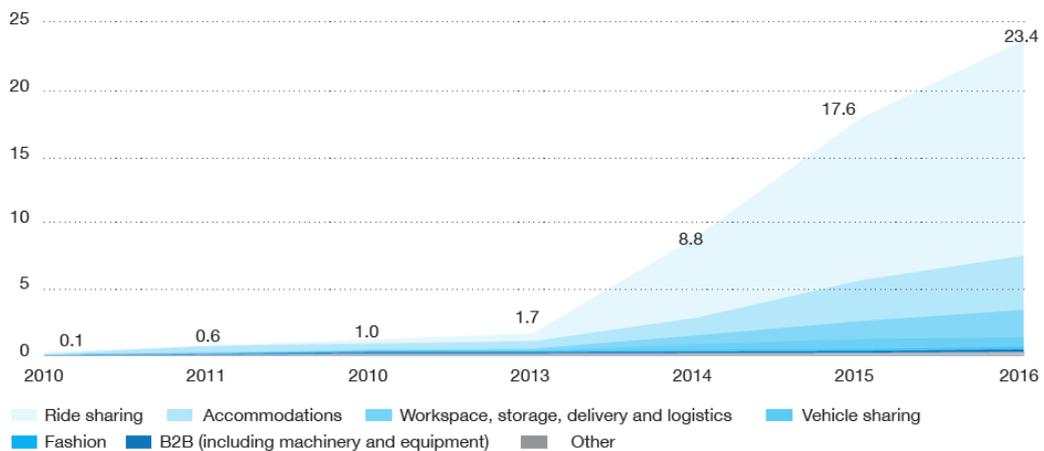

Figure 2 Evolution of financing the sharing economy on the domains (Future)

The advantages of sharing economy that offers attractiveness and viability are numerous and diverse being related to the customer’s requirements. Thus, Uber through its rating system, offers marks of reputation that stimulate the provider while offering confidence to the customer (Codagnone). Airbnb, with its double rating system, stimulates the provider’s attitude in relation with its customer (Andreotti). These arguments come as accompanying elements to what has already been clarified, starting from the possibility of renting, continuing with the need for a limited-term use and ending with the efficient possession of means.

The performed analyzes lead to a series of conclusions that show a sociodemographic stratification of sharing economy, proving unequivocally a link with digital stratification. Also, even if young users, higher-income users are more likely to use sharing economy, it is noticed that an analysis of sharing economy cannot be done in simple terms because it has influential factors and ongoing dynamics of digital platforms. Urban localization is also not a factor of influence (Andreotti). There are also significant implications regarding the component of the owners or of the future owners of goods who are to decide in accordance with the rental cost equilibrium (Horton).

Even if risks exist, such as the diminution of car sales, the increase of rents in some situation, as the case of Airbnb is now that is subjected to some interventions by some states where the listed properties are found, the efficiency of using goods, the rising of the consumption surplus, the high adaptability to the market needs, the customization of the offers and the coverage of the ignored market areas, lead to the conclusion of the viability of the sharing economy (Chakravathi).

1.2. Sharing economy in administration

In the group of examples in Figure 1 we cannot find city-halls, town-halls or other entities from the administration. However, does the local administration exist on the sharing market? Yes, it exists. The Future of Urban Development and Services Initiative at The World Economic Forum has conducted a study of 10 localities across the globe and a collaborative whitepaper from cities resulted: From Sharing to Sharing Economy, which shows how things are regarding this topic (Future).

In the opening word, one of the three speakers, Hazem Galal, Global Cities and Local Government Sector Leader, PwC, says that local administrations come to share the access to the municipal spaces and to other resources because of economic, social or environmental reasons. Local governments come to share their equipment, to collaborate to provide services to those targeted. (Future).

In the conducted study it was determined that the local administrations used to share the assets of the administrations, spaces and actives, services and competencies of the residents. As an example, a platform is created for goods, myTurn.com, that allows the trading of the offers of sharing. Regarding the spaces and the actives, for exemplification, the sharing allowed that through 596acres.org 200 locations to be transformed and 39 news community managed spaces to be created.

The state government in Alberta, Canada provides the framework and encourages municipalities from this state to collaborate with neighbors to work together to provide services by means of the Intermunicipal Collaboration Framework. The legal framework, with legislation that will come into force this year and will be effectively applied in 2020, is elaborated.

In Barcelona, through the "Program of Time and Caring Economy", it was made possible for an opportunity for people to help each other regarding daily tasks such as taking care of a sick child, reading books to the elderly, caring for domestic animals or plants, repairing things, or simply accompanying people on a walk, to be created.

The system functions as a time bank, the services rendered being considered as depositors, and citizens can redeem the time they invest for time from others to perform services for them. (Future).

2. Analysis of the need and availability of sharing economy in public administration in Romania

Although there is no public information in Romania confirming the use of sharing economy in public administration, there is a need and availability for use. To support this statement, I created a questionnaire by means of which we tried to analyze the state of digitization of spatial data, the future intentions regarding the digitization and the extension of the endeavor in the sense of the GIS implementation, endeavor that I submitted for completion at the ATU level in Hunedoara County.

We have collected information from 27 respondents, 11 cities and municipalities from 14, 15 villages from 55 of Hunedoara County. We have chosen to use this argument, because in the work paper "GIS, Integrated Solution, for Efficient Administration and Hunedoara County" (Jornea), published in 2017, we have shown the advantages of a GIS of such a scale.

2.1. The existing situation in Hunedoara County regarding spatial data

Romania, as part of the EU, is bound to implement the INSIPRE Directive, which is why it created a legislative framework registered in GO 4/2010 and in GD 579/2015. Consequently, at the level of each ATU, resources were allocated for the application of the legal requirements.

The question "At ATUs level, is initiated the procedure for the implementation of the requirements of the GO 4/2010 regarding the establishment of the National Infrastructure for Spatial Information (INIS) and of the GD 579/2015 regarding the establishment of the specific responsibilities of the public authorities, as well as of the technical structure for the implementation of spatial data themes and the approval of measures to share them?" had 24 responses as it can be seen in Figure 3.

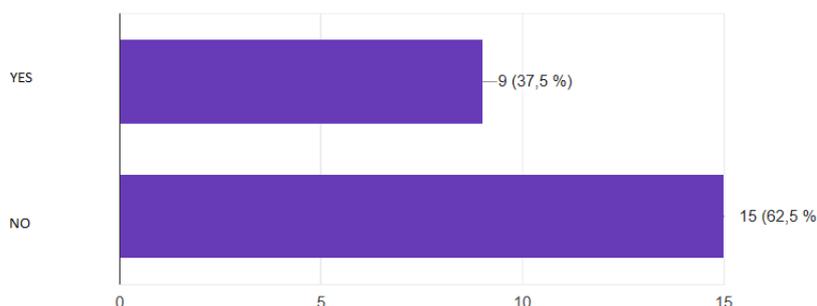

Figure 3 Implementation of the OG 4/2010 requirements

It is noticed that over 50% of ATUs have not yet begun to implement, and the main reason is the financial component, the lack of funds, the budget non-allocation. Nevertheless, 34.8% of the respondents stated that at ATUs level there are data sets related to them, with modest coverage, as shown in Figure 4.

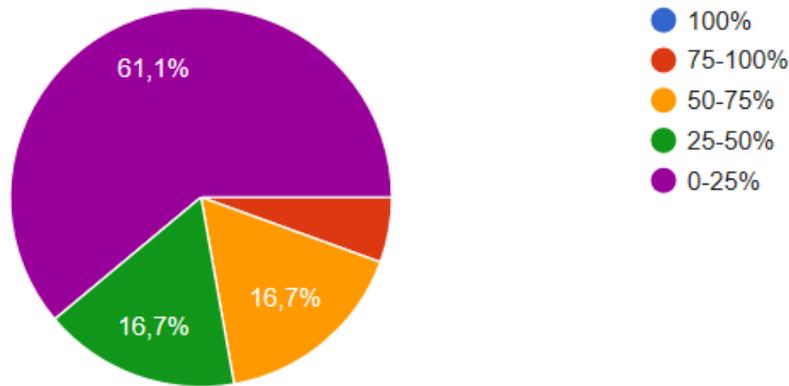

Figure 4 Degree of coverage of existing spatial data in ATU

Regarding the existence of dedicated IT tools, with the same motivation of the lack of necessary funds, a major lack of software can be noted. Even so, in the absence of software, with delays, including regarding the planning of the implementation of GO 4/2010, at ATU level there still is the intent to develop a GIS, at 52.6% of the respondents.

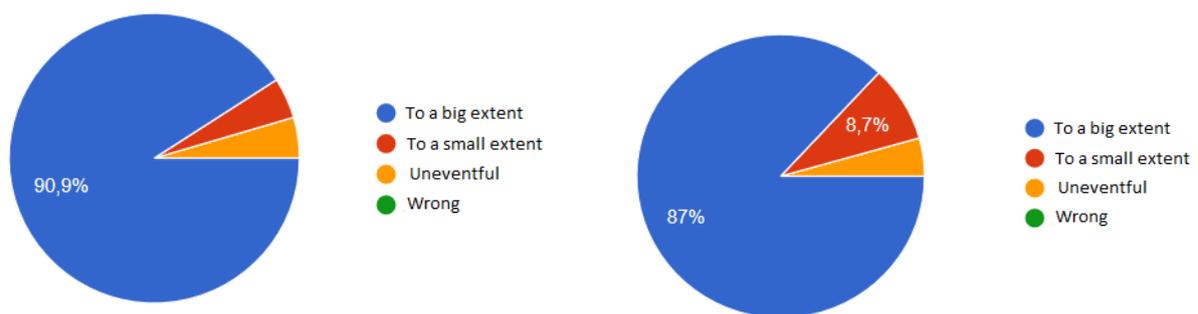

It is worth mentioning the fact that from 15 responses we received to the question "Have you started the implementation of a GIS? If so, at what level do you find yourselves?" 6.7% find themselves in the phase of up to 50% GIS implementation.

Undoubtedly, these elements clearly show the reduced capacity of ATUs to digitize spatial data and the remote perspective of implementing a GIS.

2.2. Availability and interest in shared use of a GIS

After collecting the information, using the created questionnaire, we concluded that there is a very high openness at the ATU level regarding the sharing of a GIS.

Figure 5, a shows the level of interest and one can see that 95% of the respondents are in favor of sharing of GIS.

a – interest in using of a shared GIS

b – utility in development using a shared GIS

Figure 5 Interest at ATU leve for a shared GIS

Figure 5, b shows that the interest is justified because of utility considerations, for the development of ATU.

Starting from the set of benefits identified by the respondent, such as the access to more and of a better quality information, simplification of data exchange between institutions, increasing the speed of solving many of the current problems, it is noted that 100% the respondents declare that a shared tool is a useful element in public administration activity, as can be seen in Figure 6, which shows the analysis of the answers to the question "Do you think that integrating a GIS with other systems (zonal or local such as of ISU, of CNADR, etc.) by exchanging information or by issuing notifications would be a useful element in your activity?" Regarding the manager and the coordinator of such a system, most of them appreciate as appropriate the location of it at the County Council or the ISU County.

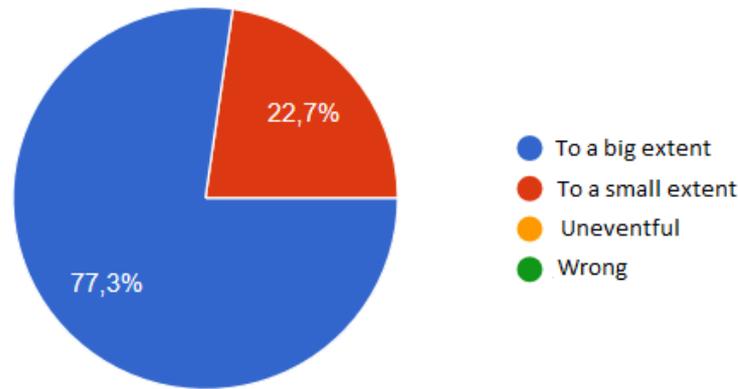

Figure 6 The utility in the activity of ATU through the integration of GIS with other systems such as ISU, CNADR

3. Possibilities of applying a sharing economy in a county.

Starting from the existing elements, meaning the stated need, the interest, the available resources and the existing circumstances, we identified two possibilities to be applied to achieve the goal namely the existence of a GIS that can be shared:

- The development of a GIS for the entire county, by the County Council, as we shown in the paper work "GIS, integrated solution, for efficient administration of Hunedoara County" (Jornea), with the right of the system to be used by all ATUs through a system of credits in which the unit of measure to be the money. Each ATU creates for itself a right of use, by contributing to the data of the system, contribution that is converted in money and then when use it, to consume as much as it accumulated. The proposition is to use the money as unit of measure, because this way the system would be an open one for the use for other categories of users, who, even if they could not contribute, could use it by paying with money. For ease of the system of use, the owner, being a state entity with coordination role, can generate a group of ATU in LAGs (groups with local actions) or other forms that allow the coagulation of all ATUs in several such entities and who might be users with a higher efficiency potential in using a GIS of such a scale. Currently, according to public information, in Hunedoara County, there is no such coagulation, even if many of the ATUs are part of the LAGs (List).
- The development of a GIS, for a powerful ATU or for an organized group of ATUs or even for the entire county, by a private player, in public-private partnership that to operate on the sharing economy principles, customized to ensure its sustainability and its development over time. When mentioning customization, we refer to the fact that if start is a powerful ATU, we must have into view the opportunity to expand it on neighbouring territories, the horizontal and vertical development and sustainability, and if it is about the whole county, then, we talk about vertical sustainability and development. The legal framework for public-private partnerships, described in GO 39/2018, makes it possible to clarify the responsibilities and obligations of the parties in all respects, without departing from the national security aspects.

José Manuel Barroso, in 2016, when he received the title Doctor Honoris Causa at West University of Timisoara, said, among other things, starting from the subject of Europe and of the European Union and mentioning that a student had said that when the pair EU – crisis was searched on the Internet, there was over one million results, that problem solving should not receive a punctual, short-term solution, but a long-term solution. His Excellency has shown that problems, seen in their solving as challenges, ensure progress (Agerpress). This approach is like our preoccupations in all the solutions proposed in the completed studies.

Conclusions

Starting from this particular case, of developing, implementing and maintaining a GIS, relying on the analysis of the needs of the communities and on the local, regional and national development directions, we can replicate the principle, we can develop the idea and this way we can build a platform or many of them to allow the sharing of resources of the local communities, whether that we talk about machines, territories, or even that we speak about people with useful skills in current or periodic activity.

Platform management responsibilities can, and must, be assigned to responsible entities that to ensure full transparency in what it is shared. This way we look at the attempts to develop local communities, management in public administration and the perspective of the consistency of progress, in the conditions in which the prosperity of the citizen is a central issue. We consider that any opportunity capable of increasing the quality of management in the administration, for the benefit of the citizen, is to be considered and used. We consider that our argument in favor of sharing economy, is only one part of the tip of the iceberg, the use being, as in the case of GIS, in the statement of Jack Dangermond from ESRI, limited only by the imagination of the user.

Innovation Management Correlated with the Models of Development of Technological Entrepreneurship

Amalia Furdui^{a*}, Eduard Edelhauser^a, Elena-Izabela Popa^a

^aUniversity of Petrosani, University Street, No.20, Petrosani, 332006, Hunedoara

Abstract

The paper presents the main features of the methods for the development of technological entrepreneurship, which could be correlate with the innovation management. The European Union promotes entrepreneurship as a key factor for competitiveness and underlines the importance of developing an entrepreneurial culture on a European scale. An important feature of the contemporary age is the development of the scientific and economic disciplines of the interface, an essential characteristic of the knowledge society, which attempts to respond to the growing complexity of economic and social realities, which requires interactive and innovative approaches.

Keywords: entrepreneurial; innovative process; competitiveness; models

1. Theoretical Framework

In the last decades after the manifestation of the economic crisis, the importance of the Entrepreneurship for the affirmation of growth and economic development at the global level represented a topic, which has captured the interest of researchers and practicing aspects of multidimensional relationships, because of the phenomenon, with implications in micro- and macro-economic.

The policy of the European Union (EU) in the field of entrepreneurship highlights the constant need to create the most appropriate micro and macro-sized to support the development of small and medium-sized enterprises and entrepreneurship (Román, 2013).

The studies in order to achieve innovation reflect the developments in the way of achieving innovation, the linear approach of the activities of research, development and innovation - with the sequence of activities carried out successively in the framework of the specialized structures of the company, at the complex interactive models, which requires a high level of collaboration, both within the organization and with other organizations (Tidd, 2006). The most popular theory in respect of models of innovation is assigned to Henry Chesbrough (2003), which presents new paradigms of innovation, compared with the traditional. "Open Innovation" (open) and "Closed innovation" - are assigned Chesbrough expressions of the two approaches.

Closed Innovation - defines the traditional achievement of innovation, successfully applied for a long period of time, Companies that exploit the results of research on its own have, become leaders on the market, but failed to anticipate the competition. The basic characteristic of this model is a greater degree of integration for research activities, development and innovation, both in order to generate new ideas and development

Figure 1 illustrates the innovation closed, characterized by carrying out the flow of research-development and innovation between the boundaries of the company. The process can be seen in the form of a funnel (innovation funnel), with a large number of ideas and concepts at the entrance, from which they are sorted and developed those which correspond most closely to the requirements.

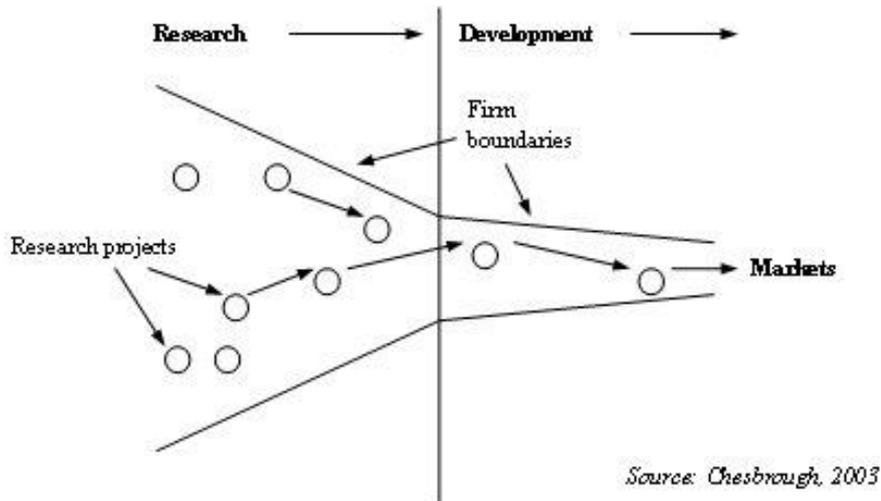

Fig. 1. Innovation closed

This model of the innovation is characteristic of the 20th century, has been deemed to be tacitly renewed, as the best route to bring new products to the market. Successful companies have played according to certain rules, the default settings. They have invested in research and development more than competitors. Those investments secured their leading position on the market with important profits and economic results, which enabled them to protect their creations by maintaining a real monopoly on their commercial exploitation.

Open innovation - defines a new philosophy of making the cycle research-development and innovation, which involves combining various sources of internal and external ideas, with the pathway of recouping on the market of new products and new technologies. This is the "Use of the inputs and outputs of knowledge in order to accelerate innovation, respectively, the extension of the markets for external use of innovation" (Chesbrough et al., 2006, p.1).

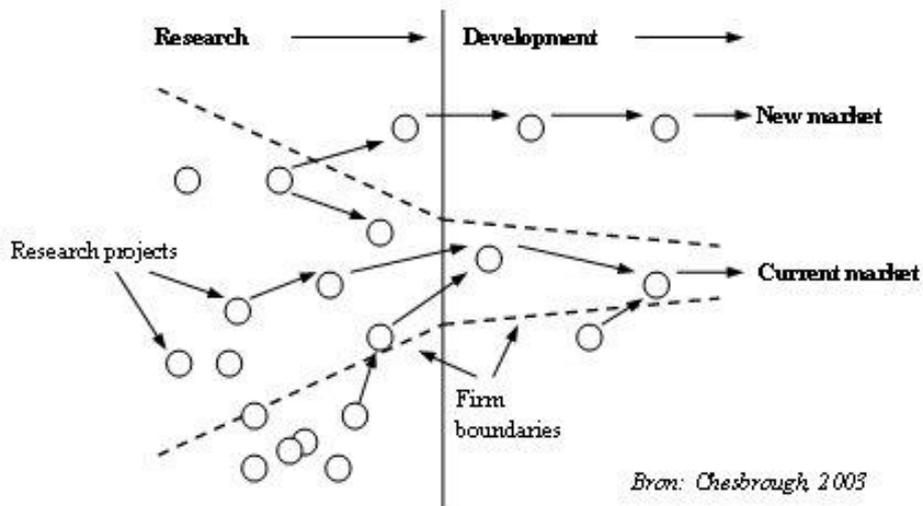

Fig. 2. Innovation open

The figure above illustrates the Open Innovation, characterized by complex flows of the activities of research, development and innovation, which integrates both internal processes and processes that crosses the boundaries of the firm. In essence, the innovation open presupposes the development of a system based on cooperation, including the possibility that a company to adopt different solutions for innovation (use of resources and internal creation, cooperation with customers, suppliers and competitors for the creation of added value for the consumer, developing partnerships and strategic alliances with other organizations in order to achieve some common projects for research-development and innovation, etc).

Open innovation is a model adopted by an increasing number of firms. Rules governing the actions were different from a company to another, and the new philosophy of innovation explains the success for small, surprising companies, which they managed to develop new technologies becoming serious competitors without having its own research laboratories.

The transition from the traditional innovation system to the new, open extended and collaborative innovation philosophy, has multiple causes. This transformation is the result of the changes that have occurred in the business environment and in society, in the conditions of sharpening competition and accelerating technical, scientific and social progress. Among the factors that contributed to this new orientation in innovation can be remembered: increasing R & D expenditure, the effort being hard to sustain even by large companies; growing complexity of the problems faced by mankind, imposing collaboration and convergence of forces to reduce risks and speed up the completion of R & D and innovation projects.

2. Performance evaluation of innovation and methodology of performance evaluation

The knowledge-based society, in the context of globalization, the approach of innovation in terms of the system has exceeded the boundaries of a country. The approach as a system of innovation is made at European level (Kaiser, 2005), respectively at regional level (Cook, 2003; Bruijn & Lagendijk, 2005).

At European Union level, the initiative of "Innovation Union" (a union of Innovation) establishes an integrated approach to innovation and strategic planning, the aim being strengthened by the competitiveness of the European economy. This Guideline is summed up in the strategies of the European Communities for the beginning of the century, the Lisbon Strategy (European Commission Directorate-General for Agriculture, 2000) and "Europe 2020" (European Commission Directorate-General for Agriculture, 2010).

An essential element of systems of innovation at national and regional level is the systematic assessment of the performance of the innovation, on the basis of specific indicators. In this context, the indicators represents data which reflect the fault of third countries in the field of science and technology development. That demonstrates the strengths and weaknesses, namely the changing trends.

The observation of those indicators allows measurement of the ripening system of innovation and may help to determine trends Seidel production (a.s., 2013). The most well- known system for measuring the performance of the innovation, is the following: the system of indicators proposed by the OECD in the eighties of the last century for performance analysis at the level of the country, region or sector, published in numerous reports under the name of "Frascati manual"; In the '90s, Eurostat started the publication of the report the European Parliament on the indicators for the assessment of science and technology, synthesized in the Workshop Oslo", by which the European Commission has created a basis for the development of statistics on science and technology.

Beginning in the year 2000, in the framework of the European Union was introduced a new methodology for the evaluation of the performance of the innovation, under the name of "European Innovation Scoreboard (EIS). This indicator provides a comparative assessment of the performance of the research and innovation of the EU Member States and third countries selected, as well as the strong points and weak points of their systems for research and innovation and help countries to assess the areas in which they must focus their efforts to improve performance in the field of innovation.

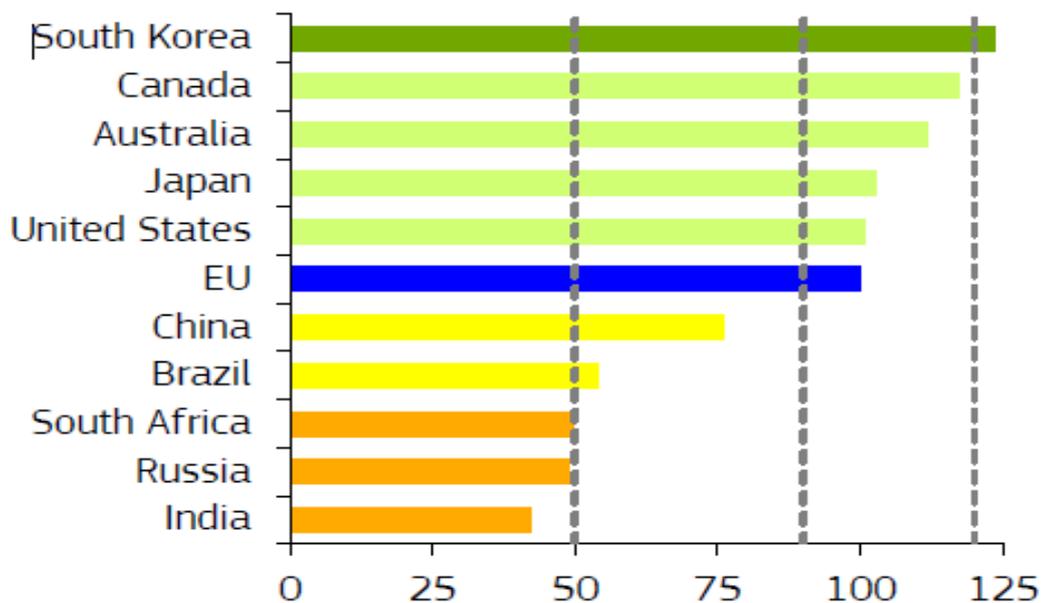

Fig. 3. Global performance /X axis (%) represents dimension composite innovation index calculated as the un weighted average of the re-scaled scores for 27 indicators within the respective dimension

At world level, the EU continues to improve its position relative to the United States, Canada and Japan. As regards South Korea, EU has fallen behind, but he expects a gradual process of alignment in the next few years. The People's Republic of China reaches up to three times the rate of increase of the performance of the innovation at EU level. The performance of the EU from Brazil, India, Russia and South Africa remains considerable. Barile shows the performance of the countries in 2017 compared with the EU in 2017. The dotted lines show the values of the thresholds of groups of performance in 2017.

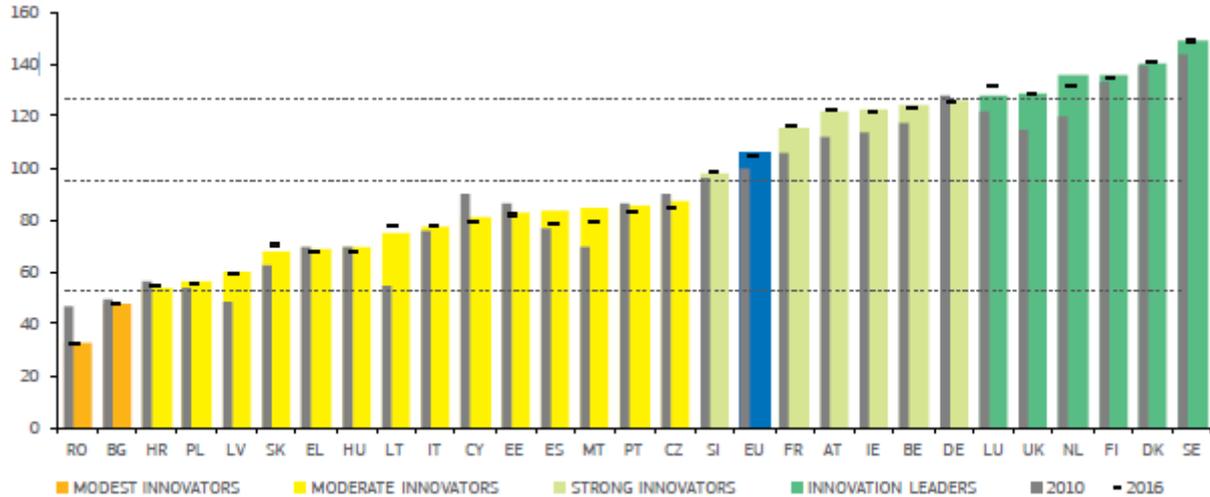

Fig. 4. Performance of EU Member States' innovation systems/ (X axis (%)) represents dimension composite innovation index calculated as calculated as the unweighted average of the re-scaled scores for 27 indicators within the respective dimension (Source: European Innovation Scorebord 2018)

Those 27 indicators relates three aspects: the drivers of innovation, business activity and innovation outcomes. Depending on the level of the SII (Summary Innovation Index), the Member States of the European Union fall into one of the following four categories: innovation leaders, innovation followers, moderate innovators and modest innovators.

The colored columns indicate the performance of the Europe States in 2017, using the most recent data for 27 indicators –, as compared to that of the EU in 2010. The horizontal lines show the performance in 2016, using the most recent data for 27 indicators, compared with that of the EU in 2010. Gray columns indicate the performance of the Member States in 2010 compared with the EU in 2010. For all those years same methodology of measurement has been used. The dotted lines show the values of the thresholds of the groups of performance in 2017, comparing the performance of the Member States in 2017 compared with the EU in 2017.

On the basis of average calculated performance of a composite indicator (index summary of innovation) Member States fall into four groups of different performance: Denmark, Finland, Luxembourg, the Netherlands, Sweden and the United Kingdom are leaders of innovation with the innovation performance than the EU average. Austria, Belgium, France, Germany, Ireland and Slovenia are innovators strong with superior performance or close to the EU average. The performance of Croatia, Cyprus, Czech Republic, Estonia, Hungary, Greece, Italy, Latvia, Lithuania, Malta, Poland, Portugal, Slovakia and Spain is below the EU average. Those countries are innovators and moderate. Romania and Bulgaria are modest innovators with performance with far below the EU average.

This year, the Luxembourg (formerly a strong innovative) join the group of leaders of innovation, while Germany (the leader of innovation), join the group of strong innovators. However, the differences between the overall performance of some leaders of innovation and the best innovators powerful are small.

Strengths and weaknesses of composite indicator:

- strengths (composite indicators are useful in summarizing information, composite indicators produce easy to read graphs, composite indicators reach larger public and thereby raise media)
- weaknesses (Composite indicators hide differences in underlying indicator performance, composite indicators can lead to wrong policy conclusions)

In conclusion, the annual evaluation allows the comparative analysis of the research and innovation performance of the EU Member States and the areas where they need to focus their efforts to improve performance. Romania has experienced continued economic growth and a positive evolution of most of the macroeconomic indicators in recent years, mainly due to investment and exports. However, Romania's innovation performance remains weak compared to other EU countries. In the latest EU innovation scoreboard, Romania has fallen well below the EU average for almost all indicators. The innovative profile of Romanian companies is still very low.

This is largely due to the specific economic difficulties of the transition period, where a very low level of innovation spending in enterprises has been aggravated by an insufficient level of public funding for innovation. The main economic areas with higher levels of innovation still belong to more traditional industries such as electricity and electronics, the food and beverage industry, furniture production, metallurgy, mechanical engineering, and transport and communications.

3. Evaluation of technological entrepreneurship at regional and global level

Understanding the essence of innovation management also involves benchmarking with entrepreneurship, a concept that has been known for over two centuries, which has been heavily promoted in academic and business environments in recent decades as a key factor in competitiveness and economic growth.

The last years marked the emergence of a series of indicators and indicators for comparative benchmarking of entrepreneurship in different countries, offering perspectives with varying degrees of exhaustiveness on the phenomenon investigated, including:

- Entrepreneurs International – OECD (Organization for Economic Co-operation and Development) - specific database, provides annual information on entrepreneurship
- World Bank - Indicators Group - World Bank's series of World Bank indicators and databases, geographically and temporally consistent, aims at developing business and the business environment in general, as well as entrepreneurship and small business Monitor
- GEM (Global Entrepreneurship - a large-scale project coordinated by the Global Entrepreneurship Research Association, which measures national entrepreneurship both on the basis of attitudes, perceptions, activities and aspirations of individuals, and on the views of experts on environmental factors and conditions affecting the development of entrepreneurship
- REDI (Regional Entrepreneurship and Development Index) - composite index developed at the request of the European Commission by four famous research institutions, assesses the development of entrepreneurship by region in the EU member countries
- GEDI (Global Entrepreneurship and Development Index) - the composite composite index developed by the Global Entrepreneurship and Development Institute (GEDI), evaluates individual, institutional and institutional entrepreneurial attitudes, abilities and aspirations

In contrast with indicators, indicators and databases addressing entrepreneurship in a sequential way, the need for this study is required by proposing a synthetic and complex model for entrepreneurship assessment, taking into account the specific requirements of the EU countries. The features of entrepreneurship are conceived through the construction of four pillars: the "Innovation" pillar based on The Global Innovation Index (GII) (Cornell University et al and the Summary Innovation Index (SII)), the "Change" pillar (with one explanatory variable) based on the Elasticity Index FM Global Resilience Index (GRI) (FM Global), the "Competitiveness" pillar (also with one explanatory variable) developed on the basis of the Global Competitiveness Index (GCI) (WEF, 2013).

Romania's results confirm the inefficiency of entrepreneurial education. But on the other hand, the lack of national entrepreneurship is recognized in Romania, so the first steps have already been taken in this respect, by facilitating procedures for setting up a new company (attractive startup conditions compared to other EU countries or the European average) and constant investing in entrepreneurial education.

4. Conclusions

Starting from the values of the EU countries, a few conclusions can be drawn, pragmatically reflected in the necessary directions for action at European level, for the assertion of competitive economies, sustainably based on supporting the entrepreneurial phenomenon. First, it is recommended to invest in the economic- as a basic condition and a prerequisite for the development of entrepreneurship. Secondly, the awareness of the decisive influence of culture on the national entrepreneurial character calls for increased attention to the economic and social factors that sustain or inhibit the maturity of the entrepreneurial mentality, and calls for a continuous correlation with entrepreneurial education and its role at national level and, third, only entrepreneurial education is not enough to add to the economic, administrative and cultural factors and its support is only an initial step taken at the beginning entrepreneurial development, which needs to be replaced by measures in the economic and administrative sphere.

Innovation is the key engine of growth in the market economy. The ability to innovate is crucial not only for the survival of individual companies but for the sustainability of the whole economy of modern society. The way innovation has evolved over time, the shift from "closed innovation" to "open innovation" being the most a popular theory about the changes that have taken place in addressing innovation.

Many countries still face major challenges in improving productivity and efficiency processes for emerging innovations.

Abstract

The study defines the concept of group development process as a set of phenomena occurring in groups and work teams as well as in all formal and informal social units. The various stages of team development are presented and characterized, including: dependence, differentiation, crisis of responsibility, attack on the leader, creativity and real capabilities of the team. The attention is paid to the inevitability of the existing group process mechanisms occurring always in a specific order. These mechanisms may have varying intensity and duration, and are dependent on the situation, group composition, behavior and decisions of team leader. For individual phases of the group development process, negative and positive actions of managers managing work teams were selected. The practical part of this study presents the results of research conducted among the managers of every managing level, referring to the knowledge, awareness and use of group development process phenomena in achieving the objectives of the managed employee group. The study finishes with the conclusions and proposals for future research in the field of discussed issues.

Keywords: group development process; management; work teams; quality of management.

1. Introduction

The basis for effective management of employee teams is knowledge and skillful use of processes taking place in all formal and informal groups. The group development process begins when a group of people meet to achieve a specific goal. This goal may be closely related to the company's operations or be an act in the sphere of privacy. It is important that the team created is effective and focused on achieving the goals set. Understanding the phenomena occurring during the formation and operation of teams allows them to consciously manage and react appropriately to emerging crises.

The group process was first described by Bruce Tuckman in 1965 and, according to the author, included four following phases: testing and dependence, intergroup conflict, cohesion, and functional roles. Further research led to the addition of supplementary phases in subsequent years. Currently, it is assumed that the group process has six phases, which include: dependence, differentiation, crisis of responsibility, creativity and real capabilities of the team (Andrew, 2012; Bonebright, 2010). The individual stages of the group process are described in the next chapter.

If we want to provide a synthetic definition of the group process, we can say that "the group development process is the stages through which a group of people goes through in order to form a team". It should be noted that the duration of the group development process is undefined and it can not be concluded that it has ended and is closed. The group process runs in a loop, which means that whenever there is a change in the team, the team formation process starts again. It should be remembered that in every repeated cycle the goal is to improve and we can achieve it only by controlling the process (Davis, 2016; Lee et al., 2016; Pachura and Hairul, 2018; Scherrer et al., 2016).

Properly used mechanisms of the group development process may be an internal determinant of improving the quality of management in the organization. This applies especially to intangible areas, i.e. improving the quality of team management and the best use of human resources available to the organization. As a result, there is an increase in the level of competitiveness of the organization and improvement of the quality of the offered products.

The aim of this study is to get to know the answer to the question, what percentage of managers know the concept of group development process and what percentage has been trained in this area. In addition, they wanted to know the opinion of the respondents on the usefulness of group processes training for more effective management of employee

teams. The utilitarian purpose of the study was to distinguish characteristic phenomena occurring while managing employee teams and to diagnose whether respondents apply appropriate solutions to the specific problems occurring in the various phases of group development.

2. Phases of group development

Individual stages of the group's development (the team of employees), which include: dependence, differentiation, crisis of responsibility, attack on the leader, creativity, real possibilities of the group occur after each other and the order mentioned here. They can have different intensity and duration, depending on the group's composition, group's goal, decisions made by the leader and many other factors. The group may under certain circumstances go back to the earlier phase or stop in development on one phase. In some specific situations, keeping the group longer in certain phases may be beneficial for the entire organization (Andrew, 2012; Bonebright, 2010; Pinto et al., 2018).

2.1. The dependence phase

This phase refers to the formation of a team or the emergence of a new leader. It is characterized by fairly high passivity in that members of the group listen to commands, do not contradict themselves, do not criticize and do not reveal themselves with their thoughts. At the basis of such behavior lies the fear of negative assessment and loss of acceptance of other group members and the leader. Improper conduct of the leader in this phase is the application of sanctions and penalties for lack of commitment, instruction, threatening, ridiculing and causing a sense of guilt among the team members. Positive actions are: clarifying the team's requirements, standards, values, motives and goals and attempting to integrate the team by ordering tasks for joint implementation. Good practices in this phase are also understanding the team's behavior and activating to independent initiatives (Andrew, 2012; Bonebright, 2010).

2.2. The differentiation phase

The differentiation phase is characterized above all by the fact that the members of the group perceive and emphasize the differences between themselves, have a need to stand out, make themselves known, are willing to participate in discussions and express their views (Bratu and Cioca, 2018). In this phase, violent and emotional conflicts may arise. This is due to the fact that the members of the group begin to compete with each other for the team's reasons and for the inclusion of specific group roles shaping the group's structure.

The wrong actions taken by the group leader in this phase are the attempts to silence the team, applying sanctions and penalties for chaos and lack of discipline and expressing negative emotions. Positive actions of the team leader at this stage include: adjusting to the energy and climate of the group, modeling constructive feedback, determining acceptable boundaries for individual behaviors, and insightful knowledge of the group structure for optimal use of the set tasks in front of the managed team.

2.3. The crisis phase of responsibility

In the phases of dependence and differentiation, the members of the employee team have a very positive opinion about the company and the way it operates. The next phase - the crisis of responsibility - is characterized by a gradual perception of shortcomings and negative aspects of the functioning of the organization. This manifest itself in complaining, criticizing all decisions and ideas, discouragement, criticizing working conditions. Team members usurp the right to greater independence, independence and trust with the lack of willingness to take on an adequate responsibility. In the long-term, this phase is harmful, it limits initiative and enthusiasm and demotivates the team.

Negative actions that can be taken by the leader in this phase include: an attempt to translate and convince that everything is fine, applying sanctions and punishments to critics and intimidating the team. The appropriate actions are: assigning independent tasks, inducing responsibility for the proposed changes and declaring support provided that subordinates are involved in the search for and implementation of solutions (Ihil and Hellya, 2017).

2.4. The phase of attack on the leader

The next phase, the attack on the leader, is an unconscious rebellion of the team, which is an emotional reaction to the frustration resulting from the belief that reality will not change for the better without the group's participation in bearing the responsibility and consequences of the choices made. The team's reactions in the attack on the leader include, among others: excessive and unjust criticism, accusations, claims and the pursuit of confrontation.

The wrong actions of the leader in this phase include: translation, polemic, dementing of charges, counterattack, dismissal of individual team members and, as a last resort, resignation from running a group. The right actions a leader can take at this stage are to wait an attack and talk about what the team should do in this situation. Then emotions fall and the attack phase on the leader goes by itself. It turns out then that the team is aware of the responsibility for the actions taken and does not avoid it (Hammar Chiriac, 2008).

2.5. Creative phase

A positive end to the attack on the leader phase evolves into the creative phase. This phase is characterized by the appearance among the team members of a sense of belonging to an extraordinary, unique group capable of performing very difficult and responsible tasks.

The basic mistake a leader may make in this phase is the conviction that such a state will be permanent. In addition, the leader should not present the team with a vision of above-average success in the future and raise the requirements in relation to the group. Positive action of the leader in this phase is the involvement of the team in solving particularly difficult and ambitious tasks (Farh and Chen, 2018).

2.6. The phase of the group's real possibilities

This phase is characterized by high responsibility and independence of team members. The group itself organizes, supports, distributes tasks and solves problems. It can be said that he understands fully his real possibilities, being aware of the advantages and disadvantages of the organization in which he works and the possibilities and limitations of his and the leader.

Improper actions of the leader in this phase are putting pressure on achieving unrealistic goals and constant and detailed control of the team's work. Positive activities include allowing the group to self-organize tasks and partnering with and appreciating achievements (Gren et al., 2017; Knight et al., 2016; Mason et al., 2016).

3. Research methodology

Questionnaire surveys were carried out from July 23 to August 14, 2018. Respondents were managers managing employee teams in production and sale departments in Poland. The condition for participation in the study was at least five years of experience in managing and managing employee teams. Taking part in the study was voluntary and preceded by the verbal consent of the respondent. 65 questionnaires were conducted, of which 62 questionnaires were classified after checking the correctness of the fulfillment, consistency and logic of the answers provided for further analysis. The questionnaire contained 12 questions. All questions in the questionnaire were closed questions. Five questions were one-choice and the other multiple-choice.

The aim of the conducted research was:

- Determining whether respondents know the concept of a group process;
- Obtaining knowledge whether the examined group had a training in the use of mechanisms taking place in employee teams;
- Separation of characteristic phenomena occurring while managing employee teams;
- Diagnosing whether respondents use the right solutions to specific problems occurring in individual stages of group development;
- Getting to know the opinions of the respondents on the usefulness of group processes training for more effective management of employee teams;

The test results are presented graphically or compiled in tables and analyzed in the chapter below.

4. Presentation and discussion of research results

The first question asked about the concept of the group development process. In the surveyed group of managers, 84% know this concept, while 16% indicated the ignorance of this concept. The results of the survey for this survey question are presented in Figure 1(a).

The second question was the question about training in the use of mechanisms taking place in employee teams. 55% of managers indicate that they had such training, while 45% said they did not. The results of the survey for this survey question are presented in Figure 1(b).

The purpose of the next question was to distinguish characteristic phenomena and attitudes while managing employee teams with which managers usually meet. The most responses were answered by: competition in the team, crisis in the team, as well as independence and responsibility. The least indications were: passivity of the team, creativity and irrational criticism, accusations and complaints. The test results for this part of the survey are summarized in Table 1.

The next question was to identify the right actions in the group development process undertaken by managers in the dependency phase. The respondents (94% and 84% respectively) correctly pointed out the appropriate actions, i.e. to explain to the team the requirements, standards and objectives, and to try to integrate the team by ordering tasks for joint implementation. Erroneous answers were given by 16% and 6%, respectively, indicating sanctions and penalties for not engaging and causing a sense of guilt among the team members. The test results for this part of the survey are summarized in Table 2.

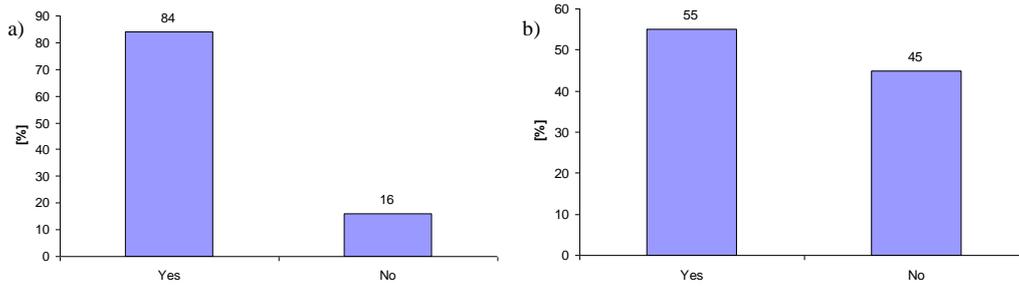

Fig. 1. (a) Knowledge of the concept of group development process; (b) Training in the field of mechanisms taking place in employee teams

Table 1. The phenomena observed during managing employee teams

Answers	Indication [%]
The total dependence of the team on the leader - the passivity of the team	42
Team rivalry - separating particular individuals	65
Crisis in the team - lack of independence and willingness to take responsibility by team members	61
Rebellion - unreasonable criticism of the leader, accusations and grievances	29
Enthusiasm - a sense of "power" in the team	35
Real possibilities of the team - getting to know their own skills, independence, responsibility	55

Table 2. Actions undertaken in the dependency phase

Answers	Indication [%]
Sanctions and penalties for lack of commitment	16
Explaining to the team the requirements, standards and objectives of the project	94
Developing a sense of guilt among team members	6
An attempt to integrate the team - ordering tasks for joint implementation	84

The next question was to identify the right actions in the group process undertaken by managers in the differentiation phase. After 84% of the respondents, as appropriate actions indicated the determination of acceptable boundaries for individual activities and learning the structure of the group and the optimal use of its possibilities. A relatively high percentage (26%) incorrectly indicated "silencing" individuality in the group and 6% for the application of penalties and showing reluctance. The test results for this part of the survey are summarized in Table 3.

Table 3. Measures to be taken in the differentiation phase

Answers	Indication [%]
"Silencing" individuality in a group	26
Setting of acceptable limits for individual activities	84
Applying penalties and showing reluctance	6
Knowledge of the group structure and optimal use of its capabilities	84

The next question was to identify the right actions in the group process undertaken by managers during the crisis of responsibility. Correct responses were given by the respondents indicating that the team was encouraged to take responsibility for what the team wants to change (61%) and to declare support provided that the team is involved (98%). Wrong answers were indicated: convincing the team that it was not bad (39%) and sanctions and penalties for critics (3%). The test results for this part of the survey are summarized in Table 4.

The next question was to identify the right actions in the group development process undertaken by managers in the phase of attack on the leader. Correct respondents indicated a conversation with the group (100%) and waiting out the attack (71%). Incorrect answers were given by 6% of managers, pointing to the dismissal of individual team members and the dementing of charges and counterattacks (23%). The test results for this part of the survey are summarized in Table 5.

Table 4. Actions undertaken in the crisis of responsibility stage

Answers	Indication [%]
Convincing the team that it is not bad	39
Inducing the team to take responsibility for what the team wants to change	1
Sanctions and penalties for critics	3
Declaring support - provided the team is committed to finding solutions	98

Table 5. Actions taken in the phase of attack for the leader

Answers	Indication [%]
Releasing from work individual team members	6
Waiting out the attack	71
Dementing of charges and counterattacks	23
Talking with a group - what the team is going to do in this situation	100

The next question was to identify the right actions in the group development process undertaken by managers in the creativity phase. 71% of respondents gave correct answers indicating the involvement of the team in solving particularly difficult problems and 84% indicating the use of the group's enthusiasm for new, ambitious tasks. 23% of incorrect answers were given with an indication of raising the requirements in relation to the team and presenting a vision of the team's above-average success in the future. The test results for this part of the survey are summarized in Table 6.

Table 6. Actions undertaken in the creativity phase

Answers	Indication [%]
Raising requirements in relation to the team	23
Engaging the team in solving particularly difficult problems	71
Presenting the vision of the team's above-average success in the future	23
Using the enthusiasm of the group for new, ambitious tasks	84

The next question was to identify the right actions in the group development process undertaken by managers in the phase of the group's real possibilities. The right answers were given by 100% of the respondents indicating partnership treatment and appreciation of achievements, and 55% indicating the group's permission for self-organization of tasks. Erroneous answers were given by 35% of managers pointing to constant and detailed control and pressure to achieve unrealistic goals (10%). The test results for this part of the survey are summarized in Table 7.

Table 7. Actions taken in the group's real possibilities

Answers	Indication [%]
Constant and detailed control of the team	35
Allowing the group to self-organize tasks	55
Pressure to achieve high and unrealistic goals	10
Partner treatment and appreciation of achievements	100

The last question was aimed at getting to know the respondents' opinions on the usefulness of group development processes trainings for effective management of employee teams. None of the respondents indicated that such training is useless or of little use. The subject training was indicated by 19% of respondents as being of moderately usefulness. On the other hand, 39% and 42% of respondents respectively indicated enough useful and very useful. The results of the survey for this survey question are presented in Figure 2.

4. Conclusions

The vast majority of managers participating in the study know the concept of group development process, and although only 55% declare that they have completed training in the use of mechanisms in employee teams, they are able to see the group process in practice and react correctly. The surveyed group of managers in most cases is able to properly identify the characteristic phenomena occurring in the group process. Most of them can also correctly indicate the right actions to solve problems occurring in each phase of the group process. Only a small percentage of respondents are inclined to use incorrect methods of solving problems in individual phases of the group development process. This is the result of the acquired knowledge and among people who have not completed the training it is associated with the experience acquired in practice. However, surveys have shown that a significant number of

managers are not aware that constant and detailed team control does not go hand in hand with partner-like treatment and self-organization of tasks by the team. This shows that training in this area should be deepened or repeated, paying particular attention to this aspect.

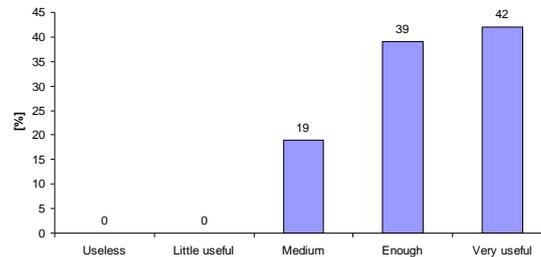

Fig. 2. Usefulness of group processes training for effective management of employee teams

The research also showed that the respondents perceive the benefits of training on group processes. All respondents indicated their suitability for more effective management of employee teams, what in the future can contribute to increasing the quality of management in the organization.

The intention of Authors is to conduct future research on group processes among team members headed by managers trained in group development processes as well as non-trained, and then comparing the results of research with the results presented in this study.

Analytic Dashboard, a Solution for Increasing Efficiency in Management of the Public Administration

Emilia Corina Corbu^{a*}, Eduard Edelhauser^a, Lucian Lupu-Dima^a

^aUniversity of Petroșani, University Street no.20, 332006 Petroșani, Romania

Abstract

The efficiency of public sector results from public resources and is calculated with multidimensional indicators, which can evaluate the effects through consume of resource units. Analytical dashboards visualize set data for certain purpose and enables users to see what is happening and to action. Our paper identifies actual situation of these indicators for Hunedoara district from West Region, Romania in EU-statistics. Then, we present the most utilized solution for analytical dashboards. In the final part, our study presents a part of research results, realized on local administration from local district in West Region, and also the best analytical dashboard for our public administration.

Keywords: management; analytical dashboard; analytics; business intelligence

1. Introduction

In the Top of Europe, in terms of government efficiency, Romania is placed on the last place. This position is given by the value of many indicators, used in World Bank assessments. This position is given by the value of many indicators that takes into account the capacity of central and local government. Comparing Romania with other countries, it is found that the value of many public administration indicators has not changed substantially in the last 7 years.

The objective of this paper is to understand and to support the design of dashboards for creating transparency and accountability, to identify benefits and principles for designing dashboards in the public sector. Following these principles can lead in realizing the benefits and overcoming the risks.

A cycle describing the data cycle of open and private data for dashboards is presented to show how value can be created. The dashboards identifies are most often referred as a tools for the improvement of processes and performance of organizations.

2. The efficiency in Romanian public sector

Afonso (2006) analyzed the most used methodologies like “raw” efficiency scores, Data Envelopment Analysis (DEA), stochastic frontier, explaining inefficiency, Tobit regression and bootstrap technique and concluded with the representation of these.

In the paper Public sector efficiency, it is proposed a methodology which measures the report between the obtained results and the resources used by the public administration, calculating the indicators for the principal fields like:

1. Administration: the level of International Transparency, the level of Doing Business Report, the Global Competitiveness; the underground economy (International Monetary Fund).
2. Education: the students that graduated superior institutes or university measured by Global Competitiveness Report.
3. Medical System: Global competitiveness Report, European Healthcare Consumer Index, The Health Consumer Powerhouse.
4. Infrastructure: the quality of the infrastructure – Global Competitiveness Report.
5. Distribution: the Gross Domestic Product GDP, the Poverty Rate (World Bank Report).
6. Stability: growth rate (World Bank Report)

* Emilia Corina Corbu. Tel.:+40767223677.
E-mail address: corina.corbu@upet.ro.

7. Economic performance: GDP growth, unemployment rate, public debt level in GDP (World Economic Outlook, FMI).

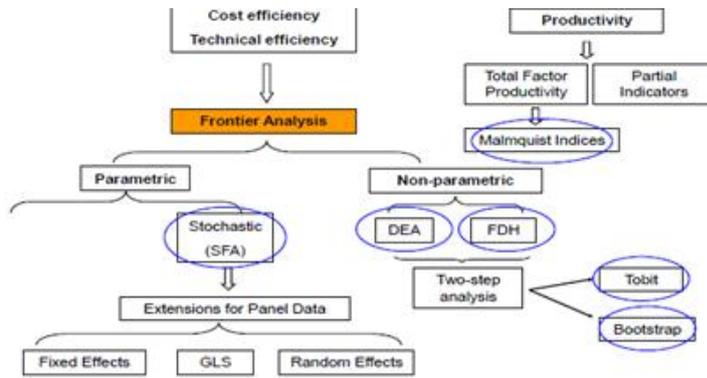

Fig. 1. Methods for measuring of efficiency of activities in public administration Source: Alfonso 2006

International Global Forum elaborate every year, The Global Report for Competitiveness, which evaluated the reforms, made for improving the efficiency in public funds. In this report is revealed that the consequences of the economic crises like, the economic growth remains low, persistently high unemployment are still felt throughout the world. Recovery was less robust than projected, while economic growth was reduced in the context of geopolitical shocks that had a negative impact on development sustainability.

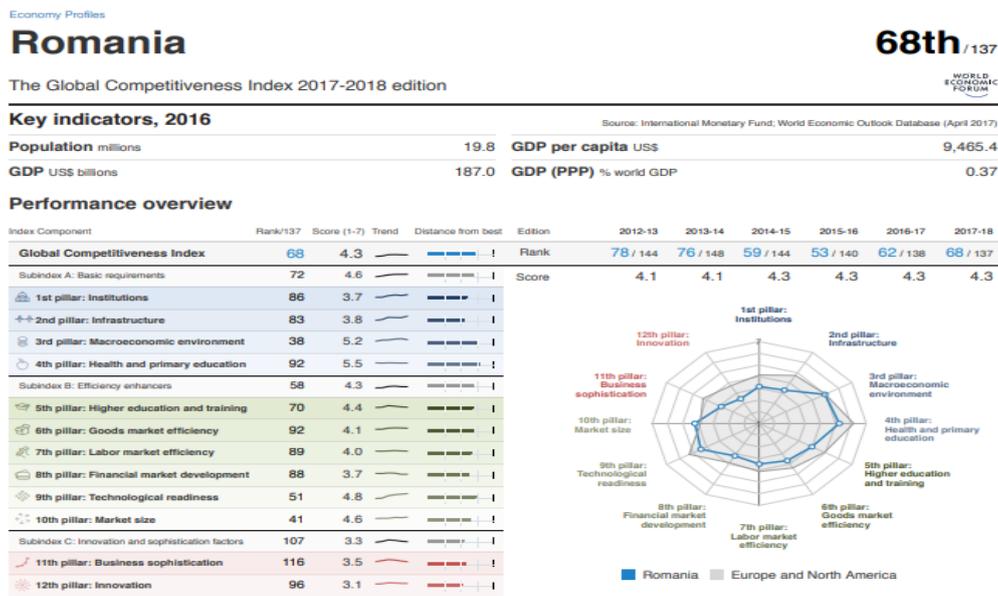

Fig. 2. The Global Competitiveness Index Source <http://www3.weforum.org/docs/GCR2017-2018/05FullReport/TheGlobalCompetitivenessReport2017%E2%80%932018.pdf>

The Global Competitiveness Index of the above-mentioned Report places Romania on the 53rd place (2015) of 140 countries for which such assessments are made. Compared to 2014, Romania advances six places (59th place) (in the previous years, 2013, 2012, the occupied places were 76, respectively 78, showing an improvement of the overall competitiveness of the country). In 2017-2018, the Global Competitiveness Index places Romania on 68th place (2016) of 140 countries.

The Global Index is based on four Pillars: Quality of Institutions, Infrastructure, Macroeconomic Environment, Primary Education and Health. The evaluations made place Romania in the Top World (140 countries), as follows: Place 86 at Pillar 1 - Quality of institutions; Place 83 at Pillar 2 - Infrastructure, Place 38 at the Macroeconomic Environment Pillar; Place 92 at Pillar 4 - Primary Education and Health.

As regards Pillar 1 - Institutions - the global assessment shows that Romania is ranked 51th for the investor protection component, 100th place for Ethical Behaviour of Companies, 113 for Public Trust in Politicians, 116 for Favouritism in Government Decisions and on 124th place at Burden of government regulations. The last place (115 out of 140) is held by Efficiency of Government Spending.

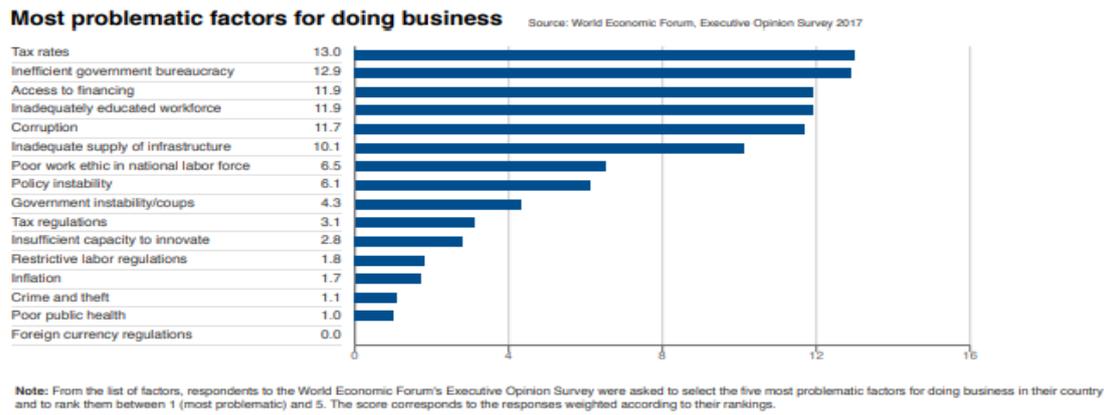

Fig. 3 Most problematic factors for doing Business in Romania
 Source <http://www3.weforum.org/docs/GCR2017-2018/05FullReport/TheGlobalCompetitivenessReport2017%E2%80%932018.pdf>

Most problematic factors for doing business in Romania are Tax rates, inefficient government bureaucracy, Access to financing and inadequately educated workforce. The report states that both economic issues, as well as falling consumption and political uncertainty, lead to increased inequality in income.

So, we consider that we can contribute in two ways to correcting and improving this situation. One practical way of improving the quality of life is based on accelerating public-private collaboration through better stakeholder information through the adoption of Corporate Social Innovation by the private sector.

3. Dashboards in public sectors

To visualize the data in dashboards is an important area of Data science. Cleveland 2001 argues that data science consists of multidisciplinary investigations, models and methods for data, tool evaluation and theory. Data scientists need in-depth knowledge of data analytics for analyzing data as well as knowledge on the use of techniques and instruments for predictive purposes and to visualize the results. Data science is essential area for public administration. (Janssen, Matheus, & Zuiderwijk, 2015) Analytic dashboards can collect a lot of data in various areas like geographical, traffic, social security, energy etc.

Brown, Fishenden, Thompson, & Venters, 2017 concluded that can be created platforms to share data. Dashboards can be used to release information for governmental decision-makers, but also for the public to scrutinize government actions, to engage in the decision-making processes and to improve decision-making. Dashboards should help to facilitate transparency, governance, trustworthiness and enable citizens' to participate in decision-making in smart cities (Allio, 2012).

In the last years, dashboards for the public sector have gained more attention. In 2009, for example the US federal government developed dashboards with federal stimulus funding aiming and accountability of national economic recovery policy (Ganapi, 2011). Another example is the Dutch government which uses dashboards to enable the monitoring of large IT-projects by the public (www.rjksictdashboard.nl).

In Rio de Janeiro, Brazil, The Smart City dashboards were created to solve problems related to public transportation and traffic. For this, were created an infrastructure, a dashboard, a data portal, related databases and APIs for real-time use (www.data.rio).

The dashboards created by the group Pensa have the objective of putting key organizational elements into a consolidated format using several visualization tools, gauges, graphs, charts, and pictograms (www.pensa.rio).

4. Analytic dashboards. Benefits and data cycle

4.1. The benefits of dashboards

The dashboards are becoming an important means of communicating and interacting with the public to create transparency and to achieve accountability. The benefits of the dashboards are classified in strategic benefits and operational benefits. The dashboards permit flexibility to create various types of overviews at glance. Also, the same flexibility allows to overview and can be used to drill into detail for any event. During the monitoring a certain process, it is possible to zoom in on a certain point of interest.

Creating views at a glance with dashboards, it means that this provide transparency. Also, enabling the creation of customized views, provide information to people at the time and place they really need it. Anomalies and patterns in data can be used to detect corruption by showing them in dashboards combined with data analytics.

The information presented in dashboards concerns the trends or issues in the city, county or region. Like operational benefits are: better and faster decision and policy-making, mobilize external knowledge, improving the effectiveness

and efficiency of operations, disclose relevant information to people, and enable participation, public participation in service improvement.

4.2. Data cycle for dashboards

The main phases often followed by data scientists are data capturing, data storage, data searching, data sharing, data analysis, and data visualization (Bizer, Boncz, Brodie, & Erling, 2012). In our case, our analytical dashboard should include five different phases Data collection, Data processing, Data analysing, Data visualization, and Data. The step 'data usage' is introduced, as a value can only be created from data when it is actually used (Janssen, Estevez, & Janowski, 2014). Figure 4 shows the main information flows in the cycle. One flow is used for creating a dashboard for internal use by the government to support policy-making, whereas the other dashboards are aimed at creating transparency and accountability for the public.

Fig.4. The phases of a data cycle for analytical dashboard

A first flow included in Data Collection comes from sensors, forms by the government or generated by citizens. In Data Processing, is made a division between the Database with Public Private Data (PPD) and the Database with Public Open Data (POD). PPD cannot be shared with external parties, due legal reasons such as privacy of personal data (names, nicknames, geographical positions etc.) and confidentiality of strategic governmental data (strategic plans anti-terrorism, emergency plans, etc.).

For these reasons, a normalization and standardization is conducted on the PPD to create the POD. The two databases POD and PPD enable the creation of two different flows with different objectives. While the PPD helps government to create internal strategies for public policy, the POD can be freely used by individuals and enterprises by accessing the Open Data Portal.

The governmental flow of information public flow of information go Data Analysis. Data Analytics Processes either manually performed by data scientists or automated. The statistical analysis and geographical analysis enable Data Visualization. This stage combines results from statistical and geographical analysis into a dashboard to present for internal and external audiences. The cycles in Fig. 4 suggest that dashboards need to be continuously updated. One cycle opens data for citizens, which should result in higher levels of transparency. For citizens, various views and visualizations can be created. Due to privacy issues and for other reasons not all data might be indiscriminately shared. The second cycle opens data for a limited group of policy-makers.

5. IT Trends in Territorial Administrative Units of Hunedoara County

5.1. Research methodology and results

We achieved the results in the virtue of the questionnaires. In order to analyze the statistical connections, we used correlation analysis for the intensity of the connections between the variables and regression analysis to estimate the value of a dependent variable (effect) taking into account the values of other independent variables (causes). One part of our research was to carry out a multiple regression analysis in order to identify the effect that implementation of IT tools in Territorial Administrative Units (TAU) of Hunedoara County, has over the population. (Edelhauser, 2014).

Another part of our research was to identify the stage of IT trends in TAUs of Hunedoara County and if there are conditions for implementing an analytical dashboard like a solution for increasing efficiency in public administration.

The instrument used for collecting data is a quantitative questionnaire. We used the questionnaire as a technique for investigating the territorial administrative units in Hunedoara County regarding the IT level. The questionnaire used was focused on the level of IT using 25 questions.

The study set sights on over 11 territorial administrative units from Hunedoara County, and data were collected in 2018 year. The survey led us to identify, based on the processing of the data gathered through the questionnaires and on the statistical data existing at national and county level, some trends in IT, trends that led us to a set of measures that we will propose to the decision-makers at county. (Edelhauser, 2012).

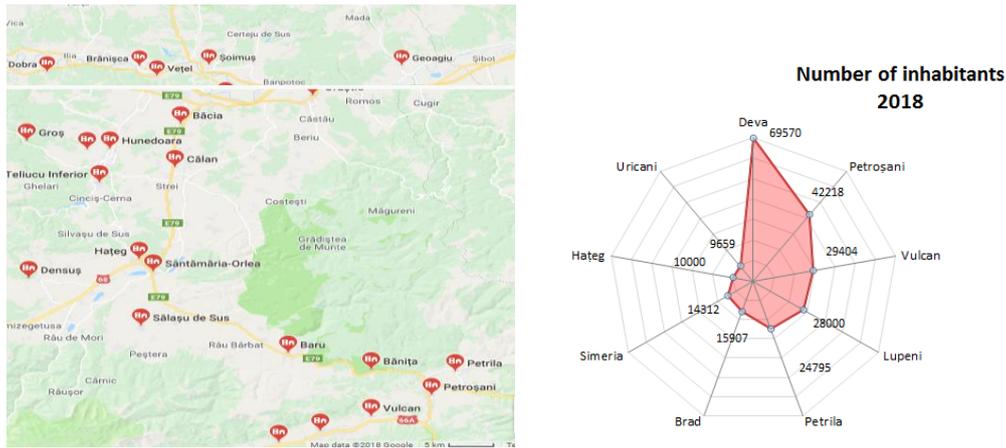

Fig. 5 (a) Territorial administrative units of Hunedoara County; (b) The chart of the number of urban population

Data were collected from 11 territorial administrative units from Hunedoara County (Fig. 5a), but these are representative for the year 2018 IT level, because there were selected from the 14 cities and municipalities of the county, and represent 74% of the urban population.

5.2. Findings and discussions. Graphical results

The 9th pillar establishes the clear link between Technological readiness and availability of latest technologies. So in figure 5b we determined the numbers of used computers in TAUs of Hunedoara County and from which are servers (figure 5c).

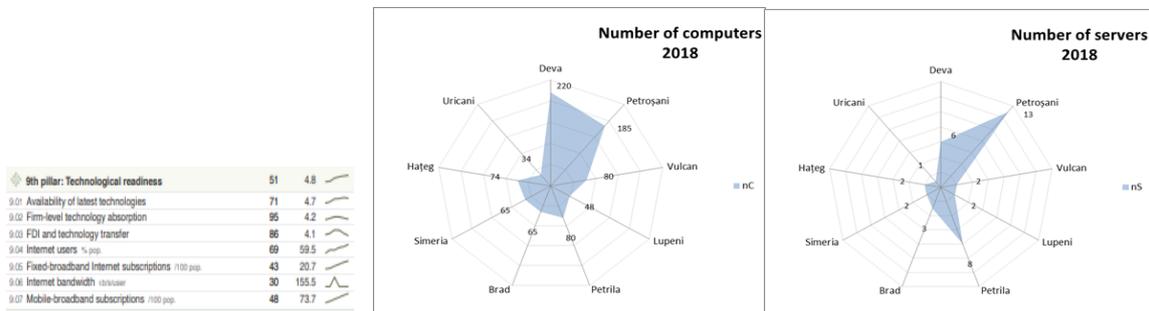

Fig. 5 (a). 9th pillar: Technological readiness; (b). Computers used in TAUs of Hunedoara County; (c). Servers used in TAUs of Hunedoara County.

Also, to another relevant question focused on the personalized access of the citizens to the public data, we observed that only 36% of TAU’s are using the full benefit of the Internet. But the future is optimistic because 64% of the respondents consider that it will be useful to offer the personalized access for the public to data.

A first conclusion can be reached. Hunedoara County is prepared from the point of view of the IT infrastructure for the implementation of the Data Collection phase of an analytical dashboard. In addition, Petrosani through the presence of the trained personnel as well as the IT endowment from TAU’s, can be the ramp of development of the following phases of the dashboard namely Data Processing and Data Analysing.

6. Conclusion

Currently, it is believed that a modern public sector is the one that provides opportunities for innovative information and information technology, accelerates strategic performance and human resources, allowing the administration to perform efficiently to raise living standards.

The quality of public administration is an important driver of national competitiveness. The conditions for an effective public administration are the focus on performance, the focus on quality services and products, institutional reorganization and adaptation, efficient human resource management and innovation of governance techniques and methods, including eGovernment.

Moreover, the tools currently used by Romanian public administration do not support a high public value of services and goods, leading to higher levels of bureaucracy and corruption. Therefore, it is necessary to improve all the constituent elements of the public sector so that it is able to fully support national and regional competitiveness, but economic growth as a whole.

Aspects Concerning the Quality of Management Projects Designed for Restructuring the Economy

Eugenia Jornea^{a*}, Eduard Edelhauser^a, Amalia Furdui^a

^a University of Petrosani, Universitatii street, No. 20, Petrosani, 332006, Romania

Abstract

Half a century ago, Hunedoara was one of the most industrialized county in the country, and the main cities of these county based their economy on large enterprises, the metallurgy and mining industries. Due to the dependence of the population on the extractive and metallurgy industry, this territory was identified as fragile area characterized by industrial decline. The statistics of the last years show that Hunedoara's County economy is 10 times weaker than in 1985. According to the "Projection of the main economic and social indicators in territorial profit until 2019", drafted by the National Prognosis Commission, Hunedoara County will have an economic evolution relatively positive. At the county level, it is necessary to develop a general medium-term development plan that would provide a starting point and to set out the development principles of Hunedoara County, namely by attracting investors, which can would contribute to the restructuring of the economy by replacing dependence on the mining industry as a result of creating a variety of sectors, businesses and qualifications. In order to achieve these objectives, an important role in the implementation of projects is the quality of management, which involves the processes necessary to ensure that the project will meet the needs for which it has been undertaken. Project quality management includes all the activities of the general management function that determine the quality policy, the objectives and responsibilities they implement within the quality system by means such as: quality planning, quality control, quality assurance and quality improvement.

Key words: organisational culture; improvement; management; performance; change.

1. Introduction

Project Management is defined by the Project Management Institute as implementing the project-specific knowledge, skills, tools and techniques to meet or exceed the expectations and requirements of those involved in a particular project (Oprea, 2011). Authors Kezsbom and Edward, believes that project management is a process that gives contemporary organizations the unique vehicle that will drive them to change. When it comes to defining project management, the same authors start from the idea that project management is a combination of people, processes, techniques and technologies needed to successfully complete projects / programs (Kezsbom and Edward, 2001).

Project management is a tool for planning, coordinating, realizing and controlling complex activities in modern industrial, commercial, social, cultural and political structures. It can be said that today project management has become an orientation for all organizations, both for the public sector and for the private sector. Project management tends to become the main form of existence in the economic environment (Dobrescu and Pavel, 2014).

As it is known, Hunedoara County was a county of superlatives. Unfortunately, its development was unbalanced. The entire county depended on the welfare of only two industries: the metallurgy industry and the mining industry. When these two industries collapsed, the entire county lost its economic base. That is why a method of economic re-balancing of the county must be considered so that it does not depend on such a small number of branches of the economy. For a balanced, harmonious development, it is necessary to design coherent programs to encourage the development of alternative branches of the economy (http://winklerygula.ro/pdf/pdf_rmdsz.pdf).

2. Analysis of the evolution of the main economic and social indicators in Hunedoara County

Hunedoara was, during 1950-1989, one of the most industrialized counties of Romania. Restructuring of the mining sector has led to the economic blockage of the entire area, as well as to the increase in the unemployment rate, because the area is a mono-industrial one. Now, the county through various actions, projects are trying to escape under the county label of the unemployed.

Workforce. The actual number of employees at the end of June 2018 was 114946 persons, 206 persons higher than in May and 3282 persons higher than in June 2017. The Table 1 represents „The actual number of employees“ at the end of June, 2018, according to statistical data provided by the National Statistics Institute of Hunedoara.

Table 1. The actual number of employees

The actual number of employees	June 2018	% in total
TOTAL COUNTY		
from which:	114946	100
agriculture and related services, forestry	3147	2.7
industry and construction	52175	45.4
Services	59624	51.9

Source: (http://www.hunedoara.insse.ro/wp-content/uploads/2018/08/COMUNICAT_iunie2018.pdf)

In Table 2, according to the data of the County Agency for Employment (AJOFM) Hunedoara, the total number of unemployed in the county reached 6755 at the end of June of this year, of which 3234 are paid and 3521 are not paid. Thus, in the records of AJOFM Hunedoara the unemployment rate is almost 3.73%.

Table 2. Total number of unemployed registered in 2017 and 2018

Years	Total No. unemployed	Total No. unemployed paid	Total No. unpaid unemployed	Unemployment rate %	Female unemployment rate %	Male unemployment rate %
2018	6755	3234	3521	3,73	4,13	3,38
2017	7898	3248	4650	4,36	4,54	4,2

Source: (<https://www.anofm.ro/statistica>)

Lower unemployment, more companies, these are the results of the latest report of Hunedoara County Bureau of Statistics. In the figure below, we can see that the unemployment rate registered in 2017 compared to 2018 is lower by 0.63%.

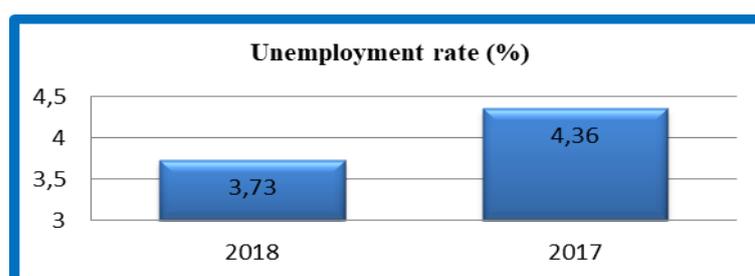

Fig.1. Unemployment rate 2017-2018

In Figure 2 is the total number of unemployed registered in 2017 and 2018, and there is a decrease in them from one year to another and we hope that this decrease will occur in the future as a result of the development of the business environment in Hunedoara County, funding opportunities, implementing projects to attract new technologies and equipment, and research and development activities, or increasing access to broadband and related services.

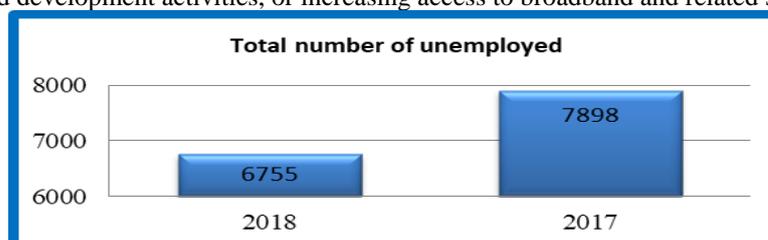

Fig. 2. Total number of unemployed 2017-2018

Industry. In Romania, in the years after the Revolution, about 1260 enterprises were closed, including several dozen enterprises in Hunedoara County. As the company is a basic link of the economy where the production of goods, the execution of some works or the performance of services according to the market requirements, their closure has led to an economic decline still felt to this day. Currently, 44298 companies are registered in Hunedoara County (<http://www.firme.info/hunedoara>). According to INS statistical data, industrial production in June was 8.6% lower than in May and 11.4% lower than in June 2017. In June 2018, the following developments were registered in June 2018, which we have represented in Table 3 and Table 4.

Table 3. Growth in industrial production, June 2018

Increases were recorded in the following branches:	-%-
Manufacture of textiles	+86.7
Manufacture of beverages	+86.1
Manufacture of other means of transport	+39.0
Manufacture of paper and paper products	+24.0
Manufacture of furniture	+18.4
Metal and metal products industry	+17.5
Manufacture of other non-metallic mineral products	+16.5
Other extractive activities	+16.0
Repair, maintenance and installation of machinery and equipment	+10.1

Source: (http://www.hunedoara.insse.ro/wp-content/uploads/2018/08/COMUNICAT_iunie2018.pdf)

Table 4. Decline in industrial production, June 2018

Decreases were found in the branches:	-%-
Manufacture of motor vehicles	-40,6
Extraction of coal	-26,6
Manufacture of wearing apparel	23,8
Production and supply of electric and thermal energy	-22,3
Food industry	-16,8
Manufacture of footwear, travel goods and leather goods	-14,4
Manufacture of electrical equipment	-11,5

Source: (http://www.hunedoara.insse.ro/wp-content/uploads/2018/08/COMUNICAT_iunie2018.pdf)

International commerce. In April 2018, goods were exported in the amount of 68339 thousand Euro, 15.7% less than in March 2018 and goods imported in the amount of 52136 thousand Euro, 17.7% less than in March 2018. The balance is 16,203 thousand Euro. During the first 4 months goods were exported amounting to 285826 thousand euro and goods imported in the amount of 221438 thousand euro were imported. The balance for the first 4 months is +64388 thousand euros.

Tourism. According to statistical data provided by the National Statistics Institute of Hunedoara, the number of tourists arrived in June 2018 was 16,726 (Table 5), with 1385 more than in May. The number of overnight stays in June was 32,624, 2637 higher than in May. The average number of nights per tourist was 2.0, the same as in May. For 6 months 2018 79503 tourists arrived, 12.4% more than in the first 6 months of 2017. The number of overnight stays in 6 months 2018 was 142,153, 0.3% lower than in the corresponding period of 2017.

Table 5. Arrivals in the tourism reception structures

Types of tourist accommodation structures	June 2018	% compared to the previous month	% compared to the corresponding month of 2017
TOTAL location, of which:	16726	109	102,1
Hotels	10242	107,9	95,2
Motels	438	99,8	151
Tourist villas	1865	109,1	117,6
Tourist cottages	440	99,1	143,3
Urban tourist boarding houses	1892	111,4	91
Rural tourist boarding houses	995	109	131,3

Source: (http://www.hunedoara.insse.ro/wp-content/uploads/2018/08/COMUNICAT_iunie2018.pdf)

The net use index of accommodation places was 22.4% in June, 2.2% higher than in May. For the economic recovery at county level, it is necessary to elaborate a general medium-term development plan, 2018-2023, to ensure a starting point and to set out the principles of development of Hunedoara County.

The strengths of Hunedoara County, which would help to change the economic course, would be to attract attention to tourism development as a new sector of economic activity, to focus investments on business incubators and business parks, to encourage the private sector - to develop SMEs.

3. Analysis of the economic restructuring strategies of Hunedoara County

The development of Hunedoara County, supporting the economic environment, ensuring decent living conditions for the inhabitants and at the same time respecting the unique natural environment are complex objectives, and their realization depends on a whole range of factors and the assumption of responsibility by both the public sector institutions, private agencies or non-governmental actors. Hunedoara County has developed a Regional Development Plan, which aims to guide the economic, social, territorial, balanced development of the county during the period 2014-2020, establishing access to European funds, sources of public and private domestic financing, as well as those coming from from other categories of donors, in the current context of Romania's membership of the European Union. The Regional Development Plan responds to the socio-economic development needs of Hunedoara County being at the same time correlated with the European, national and regional guidelines. Thus, it provides all local actors with a common framework and direction for action - a coherent set of priorities and objectives that can channel individual efforts and act synergistically in the community's interest.

The strategic directions defined in the Hunedoara County Development Plan 2014-2020 include the continuation of the strategies for the period 2007-2013, which indicate eight axes covering a wide range of measures in various fields, namely:

- Transport and Energy Infrastructure,
- Economic Competitiveness,
- Tourism,
- Territorial Cooperation,
- Rural Development,
- Development of Human Resources and Social Services,
- The environment and
- Urban development.

In addition to the Hunedoara County Development Plan, in 2009 was developed the Strategy for accessing the community funds at the level of Hunedoara County 2007-2013, which proposes an action plan for obtaining European financing by prioritizing the portfolio of projects of the local public authorities and developing the capacity necessary for the management of relevant projects.

Given the importance of the availability of non-reimbursable EU funds during the analyzed period, the financing contracts signed at the Hunedoara County level in 2007-2013 amount to over 680 million Euros. They have made an important contribution to achieving the strategic objectives identified in the county development plan. The fundings accessed during the 2007-2013 financial year were mainly obtained through the Regional Operational Program (30.64% of the total), respectively in Figure 3 we have presented the rate of use of the European programs in Hunedoara County during the period 2007-2013 and we have the Sectoral Operational Program Environment (29.61%), the National Rural Development Program (16.86%), the Sectoral Operational Program Increase of Competitiveness (12.97%), the Sectoral Operational Program Human Resources Development (9, 88%) and the Administrative Capacity Development Operational Program (0.04%).

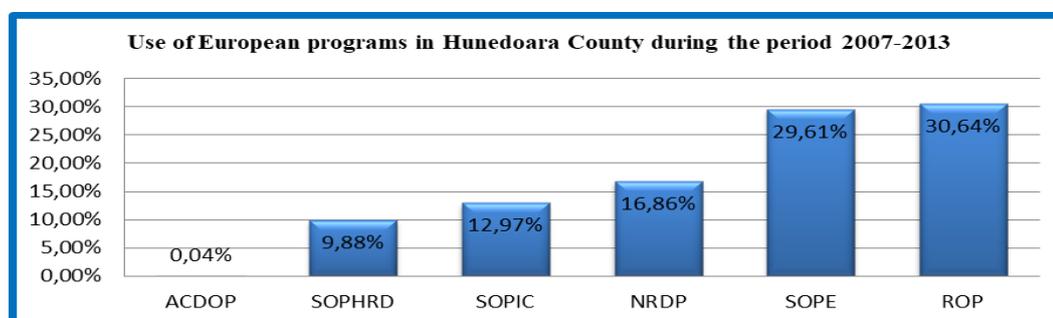

Fig.3. Use of European programs in Hunedoara County during the period 2007-2013

In the elaboration of the Hunedoara County Development Plan 2014 - 2020 were analyzed:

- Multiannual Financial Framework 2014-2020 of the European Union, Associated Financial Mechanisms or Partner of the European Union;
- Cohesion Policy 2014-2020 of the European Union;
- Financing programs of the Romanian Government;
- National Strategy for Sustainable Development of Romania;

- National Territorial Planning Plan;
- Master Plan of Transport of Romania;
- Western Regional Development Strategy 2014-2020;
- West Region Regional Development Plan 2014-2020;
- Waste Management Plan - Hunedoara County, approved by Decision no. 15/2015;
- The Territorial Interurban Territory Arrangement Plan - Deva - Hunedoara - Simeria, approved by Decision no. 142/2010;
- The tourism development strategy of Hunedoara County, approved by Decision no. 155/2010;
- County Strategy for Child Rights Protection - Hunedoara County, approved by Decision no. 65/2014;
- Master Plan on Extension and Modernization of Water Supply and Sewerage Systems in Hunedoara County by Decision no. 238/2014;
- The strategy for accessing the community funds at the level of Hunedoara County in the period 2007 - 2013, approved by the Decision no. 38/2009;
- Hunedoara County Development Plan 2007 - 2013;
- National Program for Rural Development and Rural Development
(http://www.cjhunedoara.ro/documente/hotarari/2017/anexa%20hot%20131%20plan%20de%20dezv/SDJ_HD_rev_09.06_N.pdf)

In addition to the Hunedoara County Regional Development Plan, on July 12, 2018, Minister of European Funds, Rovana Plumb, presented the projects for the development of the Jiu Valley in Brussels.

The projects submitted to the European Commission for the development of the Jiu Valley are:

Transport infrastructure - opening of Jiu Valley:

- The road from Câmpu lui Neag to Herculanu;
- Vâlcea-Voineasa-Petrila-Petroșani Road;
- DN66A - the connection of the cities of the Jiu Valley.

Jiu Valley Tourism Infrastructure:

- Jiu Valley ski area from East to West: Petrila, Petrosani, Vulcan, Lupeni;
- Museum, recreation, sports and adventure touristic complex "Retezat National Park" -Uricani.

Industrial development of the Jiu Valley:

- Industrial parks / business incubators - for all the localities in the Jiu Valley;
- Investments in the area's resources (coal and minerals - quartz).

The energy efficiency of Jiu Valley:

- Investments in the Jiu Valley district heating system by maintaining the production of coal, refurbishment;
- Thermal rehabilitation of blocks of flats;
- Rehabilitation of social housing in the Jiu Valley.

Support for the private environment Valea Jiului:

- Financing axis for the private sector - maximum 10% co-financing for job creation;
- Financing will target the areas of the Jiu Valley: rehabilitation / building of pensions / accommodation, agro-tourism; financing lines for processing wool, milk, meat, berries, mushrooms, wood, extraction of water;
- Start-up funding;
- Minimis aid for big investors.

Local development of Jiu Valley:

- Rehabilitation of small infrastructure for each locality (streets / sidewalks in former mining districts, parks, schools, etc.);
- Rehabilitation of public buildings, including those left in the mining and abandoned mining industry;

The social component of Jiu Valley (people and family in the spotlight):

- Social monitoring programs - social monitor employed at each town hall;

Ensuring the financing from the Romanian Government for co-financing projects from European and governmental funds accessed by the Jiu Valley.

Romania will also develop a strategy for implementing an appropriate integrated territorial investment instrument for the Jiu Valley region. In the same sense, the Ministry of Energy elaborated a draft Memorandum "The Hunedoara Energy Complex Company - Current Situation and Perspectives", to be promoted in the Government.

(<http://www.replicahd.ro/proiectele-pentru-valea-jiului-au-fost-prezentate-la-bruxelles/>)

4. Conclusion

If so far a number of development programs have been implemented in Romania, they have been selected in isolation, without an organic link between them and without an overall view. Hunedoara County faced some strange ideas, such as turning the Jiu Valley into a "tourism paradise" in just a few years. For this purpose, a number of tourist facilities have been created, but without a global vision.

For the harmonious development of the county, a holistic thinking is required, covering at the same time all the domains that are connected in the everyday life and which influence each other. Thus, we can not talk about infrastructure and environmental protection without talking about education, we can not talk about education without talking about transport infrastructure, we can not talk about tourism without environmental protection and a general landscape view of the area, etc. In life, all these elements are interconnected and mutually interrelated.

Corporate Social Responsibility in Polish Enterprises

Aleksandra Ptak *

Faculty of Management, Czestochowa University of Technology, ul. Armii Krajowej 19b, Czestochowa 42-200, Poland

Abstract

The concept of corporate social responsibility is nowadays treated as a business strategy. In the framework of all undertaken activities, the company takes into consideration the social interest and environmental protection issues, strengthening reputation, increasing the company's value, developing new products and services, as well as improving relations with stakeholders. The article presents the essence of corporate social responsibility and presents challenges and barriers to implementing CSR in Polish enterprises. It contains selected activities of Polish companies in the field of corporate social responsibility, and results of the research conducted among a group of Polish consumers, regarding their awareness and opinions in the field of CSR. The author tries to answer the question whether clients perceive social aspects of enterprises' operations.

Keywords: Corporate Social Responsibility, CSR, enterprise, consumers

1. Introduction

The term "responsibility" is clearly defined in the literature and defines the need to be responsible for ones behavior and its consequences (Drabik, Kubiak-Sokół, Sobol, 2017). The responsible person is characterized by the awareness of the inevitability of the obligation to bear the consequences of the actions taken.

Nowadays, companies have to be socially responsible to face growing competition on the market (Crane, Glozer 2016). Due to the easier access to information and growing social awareness, all unethical activities are often publicized by media, which results in negative consequences for the company's image. Enterprises, wanting to neutralize the negative impact of their activities on the environment and responding to the changing public awareness of recipients, began to consciously act for the benefit of the environment, seeing this as an opportunity to improve their image and increase competitiveness on the market (Bajdor, Lis, Nowodziński, 2016). Many of them pay attention not only to achieving the highest possible profit, but also take part in solving complex social and economic problems. Increasing expectations of the society in the field of corporate responsibility are caused by, among others, the increase in democratization of societies, aggressive marketing manipulating clients, increasing consumer awareness and development of consumer organizations, rapid processes of globalization of the economy and marginalization of local communities, the power of trade unions, economic scandals known through the media or degradation of the natural environment (Pawłowicz, Skriebkova, Wallis, 2009).

The concept of social marketing was created as a result of marketing transformations, as well as the ongoing process of environmental degradation and challenges faced by enterprises operating in the conditions of a growing global economy (Rabiański, 2011). The term "social marketing" was the first term of the modern concept of CSR and was used for the first time by Ph. D. Kotler and G. Zaltman in the early 1970s with reference to solving general social problems using commercial marketing tools.

2. The concept of corporate social responsibility

The concept of corporate social responsibility is a very broad and multidisciplinary concept (Garriga, Melé 2004). The complexity of the term was presented and published in 2010 in the Norm ISO 26000 *Guidance on Social Responsibility*. The standard defined by numerous experts cooperating with the International Organization for Standardization ISO, defines CSR as "the organization's responsibility for the impact of its decisions and actions (products, service, processes) on society and the environment" (ISO 26000, 2010) through transparent and ethical behavior that: contributes to the sustainable development and health and well-being of society, takes into account the

* Corresponding author. Tel.: +48 343 250 489
E-mail address: aleksandra.ptak@wz.pcz.pl

expectations of stakeholders, is compliant with applicable law and consistent with international standards of behavior, is consistent with the organization and practiced in its relations (Rojek-Nowosielska 2017; Bakanauskiene, Staniuliene, Zirgutis 2016).

As the author of the first CSR doctrine one considers A. Carnegie. According to him, it consists of two principles: the charity and trust. By charity one understands that the basic Christian principles were fulfilled, and from trust it resulted that the wealthy people became managers of the common good on behalf of other people. Carnegie spent a record amount of money on social goals and encouraged other wealthy people to fulfill their moral duty (Mazur-Wierzbička, 2012). Modern understanding of corporate social responsibility was born in the United States and Great Britain in the 1950s (Łukasiewicz-Kamińska 2011). The necessity for conducting business considering the needs of the environment, for the first time was mentioned by H. Bowen in his publication *Social Responsibilities of the Businessman* (Krajewska 2008; McWilliams, Siegel, Wright 2006).

The definition of the World Business Council for Sustainable Development, which is an agreement developing cooperation between the business community, governments and non-governmental organizations for sustainable development, specifies that CSR is a continuous commitment of business to ethical behavior and to actions for economic development, while at the same time improving the quality of life of employees and their families, the local community and the whole society (Shpak, Stanasiuk, Hlushko, Sroka 2018; Pushkala 2016).

The definition disseminated by B. Roka, captures CSR as a social business, ie the process of learning about and incorporating changing social expectations into management strategies, as well as monitoring the impact of this strategy on the competitiveness of companies (Bernatt, Bogdaniecko, Skoczny 2011).

The corporate social responsibility strategy is a basket of activities in many areas. The material scope of corporate social responsibility includes, among others: compliance with legal norms, philanthropy and development of the local community, environmental protection, sustainable development, human rights, employee rights, market relations, corruption, corporate governance and animal rights (Blowfeld, Murray 2008; Nehru 2016). An important opportunity for the development of corporate social responsibility may be the development of modern communication technologies, and mainly the resulting change in the way the information is disseminated.

3. Implementation of CSR principles in Polish enterprises - challenges and barriers

In Poland, the CSR concept is increasingly used in enterprise strategies. The increase in the involvement of Polish units in this area is evidenced by, among others, the increasing number of companies that present their achievements in the annual Responsible Business in Poland report prepared by the Responsible Business Forum, which is a summary of all CSR activities. The scope of this year's topics is very wide: business and human rights, business involved in humanitarian aid, effectiveness of measuring CSR, diversity, responsible universities or closed circuit business. Referring to the results of the report from 2017, it was recorded:

- 1190 good business practices in Poland implemented in 2017, including 639 new practices and 551 long-term practices (published in previous editions of the Report)
- an increase in the number of apprenticeships by as much as 330
- 13 articles on trends in corporate social responsibility
- 177 companies have reported practices, including 50 SMES.

Invariably from the beginning of the issuance of the report, the most practices, both new and long-term ones, concern the area of social involvement, along with the development of the local community and the second area of work experience in this respect. The area in which many practices are published every year is the area of the natural environment - in this area the number of long-term practices, that is activities that are more than a one-off action, has increased.

According to the Ranking of Responsible Companies 2018, containing the listings of the largest companies in Poland assessed in terms of the quality of corporate social responsibility management, the highest places were taken by: Polpharma Schenker Sp. z o.o., Polska Grupa Energetyczna, Bank BGŻ BNP Paribas and Coca-Cola HBC Polska. In the banking, financial and insurance sector the most distinguished are: Bank BGŻ BNP Paribas, ING Bank Śląski and Bank Zachodni WBK. In the category of consumer goods and pharmacy, the first three places were taken by: Polpharma, Coca-Cola HBC Polska and CCC SA. In the Fuel, energy and mining category, the first positions were taken by: Polska grupa Energetyczna, Grupa LOTOS SA and Polskie Sieci Elektroenergetyczne SA. In the Industrial production category, the following were distinguished: Grupa Azoty, Lafarge Polska and Grupa Velux and SITECH Sp. z o.o. ex aequo. In the Services, trade and transport category, the first three places were taken by: Schenker Sp. z o.o., Carrefour Polska Sp. z o.o. and Tesco Polska.

In 2014, as an auxiliary body of the Minister of Economy in Poland, the Team for Corporate Social Responsibility was established. As the part of the team's work, the challenges for CSR for the years 2014-2020 were defined:

- for environmental protection: reducing gas emissions, responsible waste management, responsible wastewater management, reducing energy consumption and water consumption
- on the issue of social policy: recognizing the importance of diversity in the workplace, caring for employees' health, programs facilitating the reconciliation of work and family life, respect for human rights

- in terms of social economy: activities of Social Economy Support Centers, supporting social entrepreneurship
- on the issue of senior policy: activities for the elderly in local communities, care for retired employees, mentoring programs in companies.

Among the barriers that hinder or prevent Polish enterprises from implementing the corporate social responsibility strategy, it should be mentioned above all (Bachnik 2017): insufficient knowledge of Polish managers regarding ethics in business and the possibility of applying the principles of social responsibility as a compact business strategy, economic conditions resulting from the lack of capital and poorly developed consumer movement.

4. The research methodology and the research results

The purpose of the conducted research was to determine awareness and opinions of consumers on corporate social responsibility in Polish enterprises.

The research was conducted in April and May 2018 among students of Czestochowa University of Technology. The questionnaire consisted of 9 questions, of which the first three concerned gender, age of the respondent and type of studies.

It was the one-off survey, the questionnaire had a form of paper, and it was handed over to fill by the respondents. All the survey questions were closed questions. All of them were of single choice. All of received questionnaires were filled out correctly.

The tested group consisted of $n = 209$ students (113 women and 96 men) of two fields of study at the age of 18 to 46. They were students of 1st degree studies and 2nd degree studies, studying in full-time and part-time. The highest percentage of respondents were students of full-time studies (62%) and students of first-degree studies (89%). 38% of them were part-time students, and 11% were students of the second degree studies.

Fig. 1 refers to the knowledge of the concept of corporate social responsibility

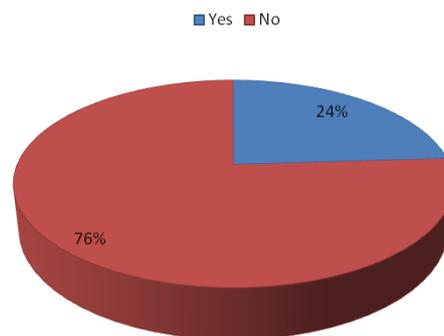

Figure 1. Have you ever heard about Corporate Social Responsibility (CSR)?
Source: Own work

As it is shown in Figure 1, 76% of surveyed stated, that they do not know the concept of corporate social responsibility, 24 % of respondents have heard of CSR.

Fig. 2 concerns the purpose for which (in the consumers' opinion) companies engage in social activities

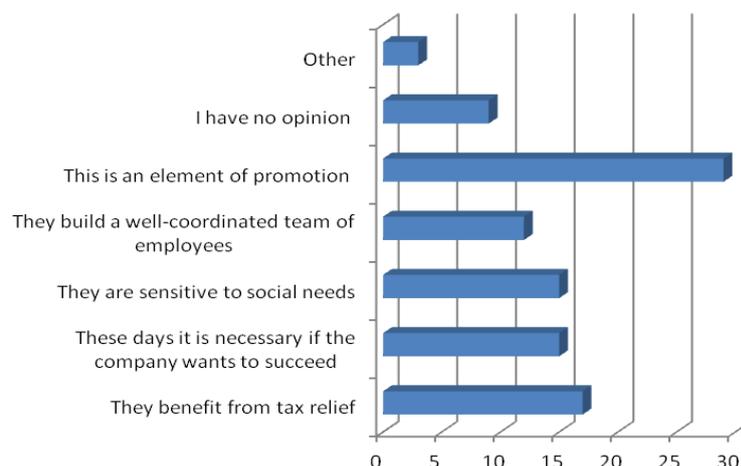

Figure 2. Why do you think companies are involved in social activities?
Source: Own work

The next question was on the knowledge of any socially responsible company. The vast majority, because as many as 93% of students, does not know any socially responsible company. The remaining 7% of respondents declared they know the socially responsible company. Among the responses received, Coca-Cola Hellenic Poland, BGŻ BNP Paribas, were listed.

As it is shown in Figure 2, 29% of respondents claim that the main reason for engaging companies in social activities is their promotion. 17% of surveyed are convinced that the companies are involved in social activities, because they benefit from tax relief. As many as 15 % of respondents believe that such activities are necessary if the company wants to succeed or the company is simply sensitive to social needs. 3% of surveyed chose the answer "Other", one person from his group of respondents is of the opinion that this kind of activities aims to divert public attention from breaking the law in companies.

The next question concerns whether or not, the companies should consider issues related to the environment in their daily activities

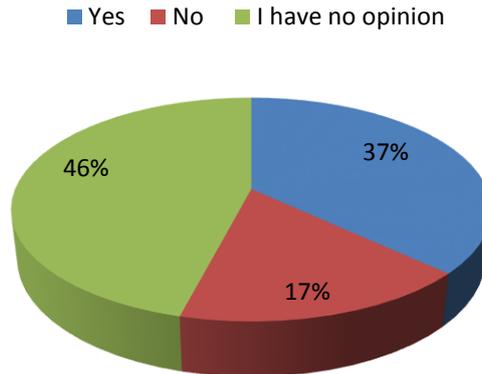

Figure 3. Do you think that companies should consider environmental issues in their daily activities?
Source: Own work

As it is apparent from Figure 3, vast majority of respondents (45%) does not have opinion on the subject of whether companies should introduce environmental activities to their everyday activities. In turn, 37% of surveyed students believe that such actions should be taken.

Figure 4 refers to the question whether the fact, that company is socially responsible would affect the choice of its products

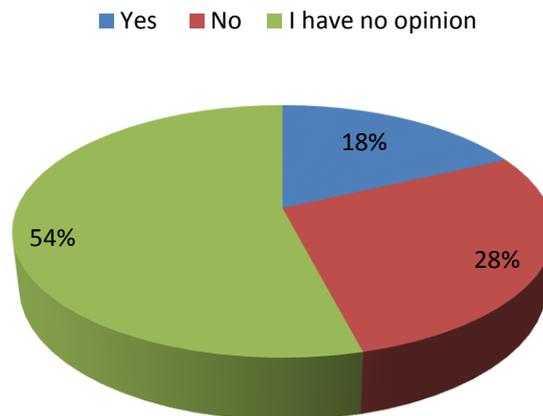

Figure 4. Does the information on the company's social and environmental activities have an impact on your choice of its products?
Source: Own work

The data presented in Figure 4 show that slightly more than half of the respondents have no opinion on whether the fact that the company has environmental and social activities could affect the selection of this company's product. Only 18% of surveyed declare that such actions of the company would affect their purchasing decisions.

The next survey question is whether the person would be willing to pay more for the product if the company from which he would buy it, would take care of employees and be environmentally friendly.

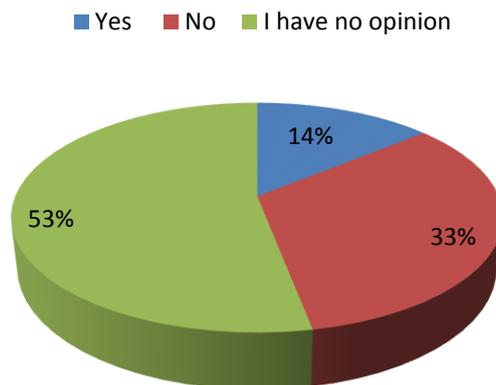

Figure 5. Would you pay a higher price for the product knowing that the company cares about the rights of employees and is environmentally friendly?

Source: Own work

As shown in Figure 5, most of respondents have no opinion on whether they would be willing to pay more for a product if they knew that the company from which they buy cares about the rights of employees and shows activities that are environmentally friendly. As much as 33% of students are of the opinion that this would not have any impact on their purchase decision.

Conclusion

Some enterprises introduce into their activity the full strategy of corporate social responsibility and are taking into account all its areas. Also, stakeholders are increasingly expecting an active attitude and full involvement of the organization in social issues. Polish organizations are increasingly willing to implement the corporate social responsibility strategy. Surely, entrepreneurs have noticed, that thanks to the adoption of the strategy that takes into account the needs of stakeholders, it is easy to build the positive image and the competitive advantage.

The analysis of the results of the survey, conducted among students of the Management Faculty of Czestochowa University of Technology, shows that corporate social responsibility is for the overwhelming majority of them not-quite-known concept. Most of the respondents omit the area of corporate social responsibility in daily choices. Small part of respondents admits that they heard about corporate social responsibility, but again a small percentage of these people could point out socially responsible companies. This situation indicates that activities of companies within the framework of the CSR strategy are very poorly identified with the companies themselves and are perceived by consumers as an excuse to create a promotional campaign or the use of tax reliefs.

Innovation of the Product as a Significant Factor in the Concept of the Development of a Toy Industry Enterprise

Agnieszka Noga *

Faculty of Management, Czestochowa University of Technology, ul. Armii Krajowej 19b, Czestochowa 42-200, Poland

Abstract

The paper presents the results in the field of evaluating the importance of product innovation in the concept of development of the toy manufacturing company. In the survey, opinions of production employees on the importance of seven factors of the company's development concept, among which the examined factor was found, were obtained. The company under study was presented. The author has made a presentation of the audited company. The research methodology (BOST survey) and the structure of the group of production employees of the examined company was presented to determine a typical respondent participating in the research. For the purposes of this paper, the analysis of the numerical and percentage structure of subjective assessments of factors as well as the analysis of the statistical significance of the variation of average scores was made. Combinations of various interpretations of graphical results are presented. In the surveyed company, the most important factors determining the concept of its development were: customer welfare and product innovation, what is confirmed by the structured summary of important factors.

Keywords: Innovation, manufacturing company, development

1. Introduction

Enterprises have to intensively create and develop their own productive potential to act quickly, flexibly and effectively in a market economy where competition is the primary economic phenomenon. These requirements for development and adaptation to the requirements of the environment make it necessary to innovate in various spheres of the company's functioning. The word innovation is derived from the Latin *innovatio*, meaning the creation of something new. This is not only about technical and technological, but also about socio-organizational innovations, and thus the sphere of management, which will allow for quick response and adaptation of own possibilities to the challenges posed by the competition (Mikołajczyk, 2002).

The aim of the research was to show how important in the concept of enterprise development, in the opinion of the company's employees, is product innovation.

2. Literature review

Every change undertaken in the enterprise has its main goal - the development of this enterprise, and therefore the profit and multiplication of capital. Thanks to the introduced changes, the companies improve product quality and competitiveness, because they increase the range, "rejuvenate" products and processes, and as a result increase their production capacity, reduce labor costs, etc. Companies can introduce changes by introducing innovations (Ali Taha, Sirkova, Ferencova 2016). Innovations can take different forms, but they always remain a decisive factor in the development of the company (Mirski 2014). There are many definitions of innovations in the literature in which the determinants of this category are mentioned (Krawczyk-Sokolowska 2012, Mirski 2014). One of the types of innovation are product innovations. These are changes consisting in a significant improvement of technical parameters, components and materials as well as functionality of the product already produced by the company (Kalinowski 2010,

* Corresponding author. Tel.: +48 343 250 489
E-mail address: agnieszka.noga@wz.pcz.pl

Kościelniak 2014). Product innovation, we can also call the introduction of completely new products to the market, the expansion of the product mix. This type of innovation affects the customer the most, because it meets his requirements and satisfies the needs. The potential consumer receives this type of innovation best, because the company provides the new or improved product or service, which increases customer satisfaction (Kalinowski 2010).

3. Research method

3.1. Characteristics of the examined enterprise

The surveyed company exists on the Polish market for twenty-eight years and produces doll strollers, mainly for the domestic market (since 2010 it has opened to the Eastern European market, especially Russia). In the assortment, there are 15 types of strollers for dolls, which differ from each other with: the number of functions, own weight, colors and sizes. The company manufactures strollers based on materials from renowned domestic and foreign companies (textiles: Polish and Italian, powder paints: German and Spanish).

3.2. The method for obtaining the results

The research was carried out using the BOST survey - Toyota management rules in questions (Borkowski S. 2012a). The name "BOST" comes from the first two letters of the name and surname of the author and is legally protected (Borkowski S. 2012b). The core of the BOST method are the Toyota management rules (Olejnik 2015), which are divided into sections, which is directly related to the structure of the Toyota road model described in the guiding works (Liker J.K. 2005, Liker J.K., Meier D. 2006). The BOST survey provides two groups of variables: an independent variable - the personal characteristics of the respondents and a dependent variable - an assessment of the validity of factors that describe Toyota's management principles. The structure of the survey consists of areas, each of them deals with a characteristic issue related to one of the 14 Toyota management rules (Noga, Ptak 2018). The study concerns two areas of the survey: the area, which set of factors describes Toyota's management principle 1 and the area describing the personal characteristics of respondents. The BOST survey (Borkowski S. 2016) is the measuring tool that has an ordinal scale, according to which respondents rank the importance of the described factors. Obtained results are subject to verification, statistical analysis and rating of assessments in a numerical or percentage system.

The study was conducted at a time. The survey questionnaires were in paper form and were provided to employees (respondents) to be completed. All questionnaires were completed correctly. By completing the questionnaire, the employee provides important information about the company under study. It helps managers to respond to the current state of processes taking place in it. By conducting surveys, one can determine the condition of the company.

3.3. Characteristics of the surveyed group of employees

First, the characteristics of respondents were made due to their personal characteristics such as gender, education, work experience, mobility and mode of employment. This is an important element in the analysis of subjective assessments of factors defined in the questionnaires. Each of the six distinguished features in the survey has several variants: gender MK (2), education WE (4), age WI (8), seniority SC (8), mobility MR (6), mode of admission to work TR (3). Three characteristics: gender, education and the work admission mode have descriptive characteristics and the remaining, numerical ones (Borkowski S. 2016). Table 1 presents results regarding the characteristics of respondents collected in the survey.

Symbol	Marking of features and their percentage characteristics					
	MK	WE	WI	SC	MR	TR
1	53	38	22	34	38	63
2	47	41	28	19	22	13
3		9	28	16	22	25
4		13	6	6	6	
5			3	9	3	
6			0	3	9	
7			3	6		
8	32			6		

Table 1. Features of respondents. Percentage characteristics

Source: Own work based on (Borkowski S. 2013)

The results presented in Table 1 indicate that 53% of the respondents are men and 47% women. People who work in the enterprise in most cases have a minimum secondary education. The largest group of employees (28%) are people aged 31-40 and 41-50. In the enterprise, the most of employees - 34%, are people with five years of work experience,

while 6% of employees have a job seniority of over 36 years of work. It is also the longest job seniority recorded during the study.

3.4. Presentation of results

In the surveys, opinions of production employees on the importance of seven factors of the company's development concept, among which the examined factor was found, were obtained (IP). Respondents had to decide **which factors determine the company's development concept**:

DK	Customer's good
IP	Product innovation
WK	Partnership with collaborators
ZP	Trust in relationships with employees
SP	Self-reliance and responsibility of employees
RT	Technology development
PR	Care of the company's culture

The question was rated on a scale from 1 to 7, where 7 was the most important factor, while 1 was the least important factor. Regarding Toyota's management principle 1, the question was chosen to check which factors have a decisive impact on the development of the company. This was dictated by their compatibility with Toyota's principles section one (Liker J.K. 2005) entitled: „Far-reaching concept”.

Figure 1 presents obtained results, in the form of a numerical statement of the validity of factors defined in the analyzed part of the survey.

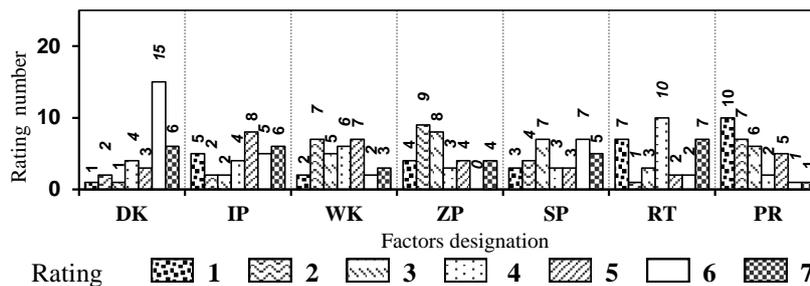

Fig. 1. Analysis of the distribution of grades for the factors of the selected survey area.

Source: Own study

When analyzing Figure 1, it is worth paying attention to the distinctive, highest bar, indicating the highest number of ratings (15) with the value of "6" for the customer's good factor (DK). However, the highest number (10) of the lowest "1" ratings was given to the factor: corporate culture care (PR).

This type of survey data set is the basis for determining the percentage structure of assessments, which is presented in Figure 2.

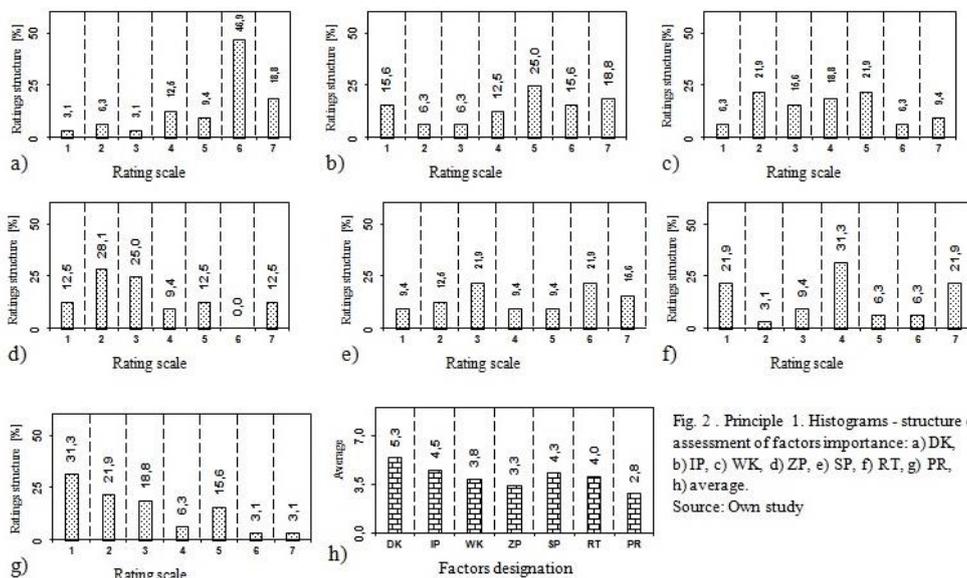

Fig. 2. Principle 1. Histograms - structure of assessment of factors importance: a) DK, b) IP, c) WK, d) ZP, e) SP, f) RT, g) PR, h) average.

Source: Own study

Analysis of the percentage data on histograms (Figure 2) allows the creation of further drawings and statistical analysis.

4. Results description

4.1. Assessment of significance of medium differences

The statistical average variation survey concerns seven factors describing Toyota's management principle 1. The comparative analysis of the average variation was calculated based on the student's test (Ostasiewicz S., Rusnak Z., Siedlecka U. 2001). Table 3 presents the results of the comparative analysis. The value of the correlation coefficient calculated from the survey results was adopted as the measure of significance of differentiation. The obtained value was compared with the critical value for a given probability level for a given number of measurements. Table 2 contains characteristic elements, i.e. seven factors describing Toyota management principle 1, test, and critical values for individual materiality levels α (α are respectively 0,05; 0,1; 0,2). Analyzing the content of such a tabular system consists of comparing the size of the test, for the relevant factors, with the critical values of the α coefficient. If the critical value is lower than the test value, it means that there is a significant variation in the averages (in the table "yes")

Table 2 . The results of significance analysis varied in average of the validity ratings of selected factors

Marks	IP	WK	ZP	SP	RT	PR	Marks	IP	WK	ZP	SP	RT	PR
DK	test	1,91	3,63	4,74	2,43	2,79	6,28	ZP	test	1,96	1,95	1,44	1,26
	$\alpha = 0,05$	no	yes	yes	yes	yes	yes		$\alpha = 0,05$		no	no	no
	$\alpha = 0,1$	no	yes	yes	yes	yes	yes		$\alpha = 0,1$		yes	no	no
	$\alpha = 0,2$	no	yes	yes	yes	yes	yes		$\alpha = 0,2$		yes	yes	no
IP	test	E6	1,32	2,38	0,43	0,83	3,63	SP	test	yes - significant differentiation		0,42	3,21
	$\alpha = 0,05$		yes	yes	no	no	yes		$\alpha = 0,05$			no	yes
	$\alpha = 0,1$		yes	yes	no	no	yes		$\alpha = 0,1$			no	yes
	$\alpha = 0,2$		yes	yes	no	no	yes		$\alpha = 0,2$			no	yes
WK	test		1,19	0,87	0,39	2,54	RT	test	no - irrelevant differentiation			2,63	
	$\alpha = 0,05$		no	no	no	yes		$\alpha = 0,05$				yes	
	$\alpha = 0,1$		no	no	no	yes		$\alpha = 0,1$				yes	
	$\alpha = 0,2$		no	no	no	yes		$\alpha = 0,2$				yes	

Source: Own work based on (Borkowski, Sygut 2014)

Table 2 shows, that for the factor - the good of the customer (DK) the average difference in seventeen cases was recorded at all α levels, in the following order: five times at $\alpha = 0.05$ and six times for $\alpha = 0,1$ i $\alpha = 0,2$.

4.2. Building the importance series of the considered factors

Based on Figure 1 and 2, series of validity of the analyzed factors describing Toyota management principle 1 were created.

They are presented as follows:

- for assessment "1" $PR > RT > IP > ZP > SP > WK > DK$ (1)
- for assessment "2" $ZP > PR > WK > SP > DK > IP > RT$ (2)
- for assessment "3" $ZP > SP > PR > WK > RT > IP > DK$ (3)
- for assessment "4" $RT > WK > DK > IP > SP > ZP > PR$ (4)
- for assessment "5" $IP > WK > PR > ZP > DK > SP > RT$ (5)
- for assessment "6" $DK > SP > IP > RT > WK > PR > ZP$ (6)
- for assessment "7" $RT > DK > IP > SP > ZP > WK > PR$ (7)

From figure 1 and 2, regarding the assessment of "1", it appears that the factor - corporate culture care (KW) has the least importance for the respondents (first place in the row - formula (1)). The factors: customer's good (DK), product innovation (IP) and technology development (RT) are recognized by employees of the surveyed company as the most important in the implementation of the production process of toys.

The client's good factor (DK) received the highest score of "6" (46.9%), the innovation of the product factor received the highest score of "5" (25%), and the technology development factor (RT) received the highest number of ratings "7" (21.9%). These factors take the first place in the appropriate series of importance: (5), (6), (7). The average values of the assessment for individual factors additionally emphasize that in the opinion of the respondents, for the development of the company, the most important are: customer's good (DK) and product innovation (IP). The least important is corporate culture care (PR). The above is shown in Figure 2h and in the series of validity of factors' assessments due to their average values (formula 8).

$$DK > IP > SP > RT > WK > ZP > PR \tag{8}$$

5. Conclusion

BOST research was used to determine the significance and place in a series of validity factors of the concept of development of a company producing toys according to the product innovation factor. Information was obtained from the employees of the examined company. In the opinion of the respondents, for the development of the company, the most important are: customer's good (DK) and product innovation (IP), the least important is care of the company's culture (PR). The simultaneous orientation of the company to the client's good and product innovation has a positive impact on the company's perception and bodes well for achieving success in the market over a longer period of time.

The introduction of innovative technologies and production processes, and ultimately ensuring innovation (Cruz, Paulino 2013, Bajdor, Lis, Ptak 2016) of products is a strategic goal of the company's operation (Wojnicka-Sycz, Sycz 2016). On the other hand, the involvement of all employees (Johansen et al., 2015) participating in the company's activities and orientation on bottom-up activities (eg by training employees physically implementing processes) (Mom, Van Den Bosch, Volberda, 2007) will ensure faster introduction of product innovation (Glor 2014). Teamwork and customer welfare are deeply embedded in philosophy (Garcia, Maldonado, Alvarado & Rivera 2014, Schwarz, Nielsen, Stenfors-Hayes; et al 2017), from which the BOST method used in the research derives. The Japanese, who have succeeded based on this philosophy, are still an example to follow for success for companies around the world (Schonberger, 2007).

Information and Customer Purchase Decisions on Dynamic Markets

Tomasz Lis *

Faculty of Management, Czestochowa University of Technology, ul. Armii Krajowej 19b, Czestochowa 42-200, Poland

Abstract

The functioning of a man has always been connected with information. This is the basic factor determining its activity. It applies to man's personal and professional life. Of course, it also applies to structures co-created by man, that is companies. Before making a decision, the client analyzes the information already available and acquires new ones from any source to which he has access. In this respect, today man has great, practically unlimited possibilities. In such a reality, according to the author, it is particularly important for companies to conduct active activities in the information world - in the paper called the information space. Conscious delivering, controlling, supervising the spread, correcting, identifying - information, but also identifying and establishing cooperation with entities having the power of influence in the information space is, according to the author, a key factor of success in the dynamic market. In the paper, results of research carried out on a group of over 300 students of the Faculty of Management at the Czestochowa University of Technology: employed and unemployed, are presented. Due to the active participation in the information space, the use of information to make purchases, and at the same time sales, as well as acquisition of knowledge in order to manage enterprises, it is a good research group. The aim of the paper is to identify the meaning of information in human life, especially in the context of purchasing decisions. The aim is also to identify the features, advantages and requirements of active functioning in the information space.

Keywords: Information, information systems, decisions, dynamic markets

1. Introduction

As states W. Krztoń information has always played a very important role in human life, however, in relation to enterprises functioning, it gained a special meaning when it was credited as resources in the 1970s. At the same time, as the author emphasizes, information has become a commodity that, like those with a material form, can be bought and sold. (Krztoń, 2015)

Information is the basis of the decision. The concept of decision itself is defined as "a conscious, non-random choice of one of many (at least two) possible ways of acting" (Bolesta-Kukułka, 2000). Decisions are related to a situation in which there are many, more than one possible events. Which event will happen depends directly on the actions taken, which are always the result of the decision.

Decisions affect everything that is associated with the functioning of all market participants. Their basis is awareness and knowledge of: the situation, circumstances, realities, future, the object related to the choice of event that will be realized. Awareness and knowledge are, in a way, an image of reality composed of information that reaches the individual and, most importantly, it is understandable and legible to it. (Lis et al., 2016)

The most important activities undertaken by the company one should include those intended to affect the operation of those market participants who may become their customers (Shankar and Smith, 2003).

Understanding of customer behavior allows to adjust the company's operations to their needs and expectations. It thereby contributes to competitive advantage (Liczmańska, 2015). Customers making purchasing decisions base on information already possessed, as well as those to which they can access.

* Corresponding author. Tel.: +48 343 250 378
E-mail address: Tomasz.lis@wz.pcz.pl

The activities of enterprises aspiring to gain the competitive advantage should be associated on the one hand with identifying, acquiring and using information, and on the other hand providing them. The key is to understand customers, their needs and expectations, to match the offer and to realize their own existence and competitive advantages.

2. Information in the decision-making process

As A. Holska states, "the decision-making process includes a logically connected group of thinking operations, in the right order, allowing assessment of the decision situation and selection of the most favorable option" (Holska, 2016). In this definition, there is no reference to information. However, in reality, each stage of the process is closely related to information, operations performed on them and using them.

Thinking operations are nothing but actions carried out in human mind on the information available to the individual at a given moment, using his knowledge and experience. The ordering of operations is also related to the available information, knowledge and experience. It should also be mentioned here, that knowledge and experience affecting the course and effects of the decision-making process are the result and also depend on information obtained during everyday normal functioning. (Lipczyński, 2014)

The key element of the cited definition of the decision-making process is the assessment of the situation and selection of the most favorable variant. Any limitation in the access to information, lack of possibilities and the ability to connect them negatively affect the analysis of the situation. This in turn influences the choice of event to be realized. Decisions are, therefore, the result of information that is visible to the individual, understandable and which are acquired and "absorbed" by it.

The described principle is used by enterprises (in order to try to influence customer behavior). Through promotions, price reductions, advertisements and suppliers one tries to convince them to take advantage of their offer. However, these activities are the source of only a small group of information used in purchasing decisions. Their participation in the author's opinion decreases with the development of IT and with increasing the general amount of information that becomes available (Tomaszewska, 2013) to contemporary recipient. This is despite the possibility of activating these activities, and thus increasing the amount of information consciously transmitted by enterprises.

According to the author, the information obtained by entities with direct experience in cooperation with the supplier or the use of certain goods gains in importance. The importance of information about the company and its offer is also given by entities, which, as a result of specific events and situations, acquired them, and which do not belong to the group previously indicated: employees, observers, people who obtained information as a result of hearing it.

Every action taken by and inside an enterprise is the source of information. It is not only a conscious action aimed at providing information to the environment. Increasingly, the client, as the person aware of the desirability of business operations (Pomffyova et al, 2017), which at the same time does not always translate into their honesty, is looking for independent information. By using information technology, especially from the Internet (Bucko et al, 2017), it has the ability to identify and obtain information about the company and its offer from a very large number of sources. At the same time, these sources are independent and often unrelated to each other, which increases their reliability and the value of generated information (Szpunar, 2011).

Every action (conscious and unconscious) is a source of information sent to the environment and thus to potential clients. Information is the basic factor in the decision-making process, including purchasing decisions. Thus, any negative information generated in and by the company has a negative impact on customers' purchasing decisions. Similarly, with any negative information generated by any market participant, which is beyond the awareness, control and operation of the company. (Lis et al., 2017)

According to the author of this publication, achieving success now requires the full awareness of the information generated. It is necessary to eliminate the possibility of negative information. Additionally, it is necessary to identify information about the company and its offer, in order to strengthen them, activate spreading, correct, explain and deny (untrue information).

This necessity results from the dynamism of contemporary reality, in which speed, volatility and uncertainty are the most important features of the market. Any information that is beyond the control and influence of the company has an unpredictable effect on the purchasing decisions of customers. It can thus limit the effectiveness of deliberate actions, hinder achievement of goals and negatively affect the competitive position.

3. Consumer behavior in a dynamic market

Characterizing the behavior of contemporary clients, one can use the features describing the dynamic environment of the functioning of enterprises. M. Matejun, M. Nowicki to these characteristics include: structure, complexity, variability, uncertainty, potential occurrence of opportunities and threats, multifaceted, space, time, conditional context. (Matejun and Nowicki, 2013)

Understanding current and future customer behavior is one of the most important goals of enterprises. Customer behavior can be defined as "all activities and perception of the consumer, comprising the preparation of decisions on product selection, making and consuming of that choice. (...) activities related to search, purchase, use and assessment of goods and services that have the ability to meet the needs" (Dąbrowska and Janoś-Kresło, 2014). On the basis of the

definitions provided, it can be concluded that customer behavior is based on decisions in which information plays a key role. In this respect, one can identify decision about: need (willingness, necessity), choosing the object of the need (eg choosing a product from the group of products with the same or similar features), choosing the supplier.

The decision about the existence of a need may be caused by information generated in the immediate vicinity of the unit, but also by those obtained from its external environment. The first group is information, which sources are, for example, objects (damage, destruction, expiration, limitation of the level of functionality resulting from technological development - it can be described as "dead"), but also people from close relatives (family, friends). The second group includes information from people around, the media and, in general, all sources from which an individual can obtain information. The choice of the subject of the need and the supplier are information from every possible source that, in the opinion of the entity, has and/or can dispose.

The presented model of customer behavior is current, regardless of the conditions in which the unit operates. It can, however, proceed in a static or dynamic way. What determines the increase or decrease of the degree of dynamism is the amount of information provided to the unit. Technological development, especially development in the field of ICT, gives the possibility of access to virtually unlimited amount of information, it also allows the flow of information in real time without time or place restrictions. (Łodziana-Grabowska, 2016) All this makes customer behavior in a dynamic reality more and more dynamic. They are variable and difficult to predict.

4. Information and customer behavior – research results

The article uses the results of a survey conducted on a group of 357 full-time and part-time students, 1st and 2nd degree of the Faculty of Management at the Częstochowa University of Technology. The questionnaires were completed by working people - 40.34% of respondents and unemployed. The aim of the study was to identify the meaning of information in the human life, both in professional and private life - the client.

One of the most important activities of enterprises focused on encouraging to start and continue cooperation, and thus on influencing customer behavior, is shaping an appropriate policy in the field of customer service. Because customers are the beneficiaries of these activities, it seems necessary to adjust the service process to their expectations and requirements. From of the persons participating in the survey who declared the fact of employment, 86.11% declared taking into account the requirements and expectations of customers in their enterprise. According to 5.56% of surveyed, this is not done, and 8.33% does not know anything about it (Fig. 1).

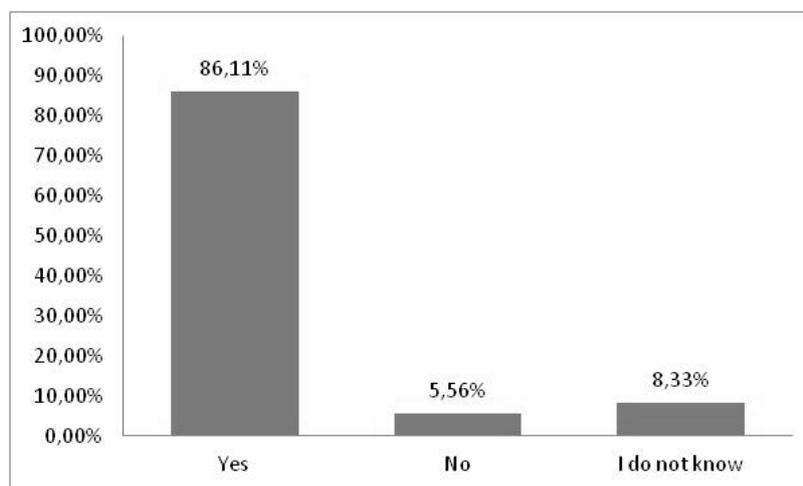

Fig. 1. Taking into account the needs, expectations and requirements of clients when developing the offer and / or customer service standards

Source: Own study

Adapting to the dynamically changing market conditions related to the use of opportunities and avoiding threats, requires not only listening and taking into account customer feedback. It is also necessary to monitor the actions taken by competitors and other entities whose activities may have an impact on the functioning of the company and its competitive position. Market monitoring and taking account information obtained this way in management was confirmed by 64.58% of the surveyed employees. According to 14.58% of them, such activities are not undertaken in enterprises that employ them. In turn, 20.83% does not know whether these activities take place or not (Fig. 2).

On the basis of the presented distribution of answers to 2 questions, it should be stated that as far as enterprises are aware of the need to monitor and take into account the needs and expectations of clients, they seem to downplay the issue of obtaining information related to competition activities and other entities affecting them. It is so strange that this information allows to gain knowledge about upcoming events, as well as consolidate knowledge about clients. While monitoring the behavior of customers, one cannot ignore the behavior of other market participants.

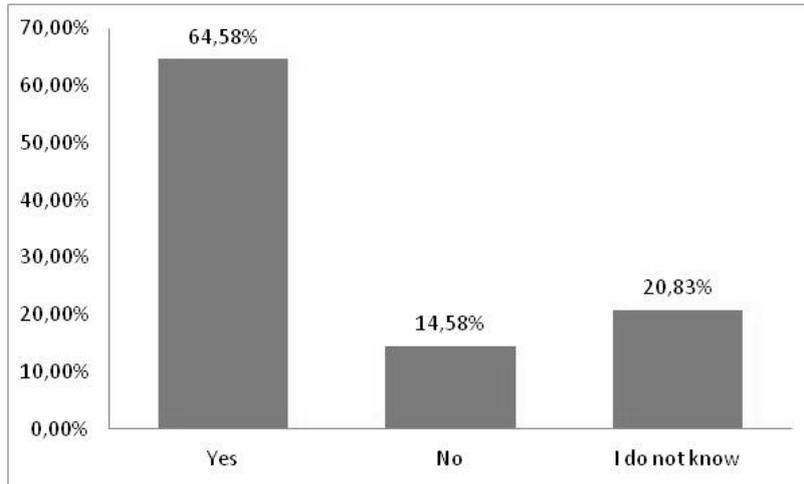

Fig. 2. Acquiring and taking into account in the management information about competition activities and market events in the environment

Source: Own study

Virtually all market participants, whose activities may have an impact on the functioning of the company and their competitive position, have information and knowledge that can be used to improve the company. Therefore, taking into account the dynamism on the market, it seems necessary to constantly monitor the market in order to identify and establish cooperation with entities that are or might be interested in establishing cooperation. This cooperation is to be connected with the acquisition/exchange of information and knowledge aimed at improving management (Goliński et al, 2016) and offer. The fact of conducting such cooperation in relation to the improvement of the offer is confirmed by 63.89% of respondents, and the improvement of management is confirmed only by 38.19% of the surveyed employees. There is no such cooperation in relation to the improvement of the offer according to 21.53% of surveyed, and the improvement of management 33.33% of respondents (Fig. 3). The obtained results are puzzling, because companies seem to listen to opinions about the course of the customer service process, while still a low percentage (and 63.89% should be considered as such should take into account the dynamism of the market) takes into account information and knowledge of clients and other market participants while shaping the offer. It is even worse in the case of improving management. It should be clearly emphasized that in the author's opinion attempts to influence customers behavior, including decisions (Gawas et al, 2018) made by them, have to be connected with providing positive information about the company and its offer to customers. And there seems to be no better way than to make every action aware that the client is really important and his needs are taken into account. At that time, he is more willing to provide strategically important information to make purchases (Mazursky, 2000), but also to provide positive information about the company to other (potential customers) entities, encouraging them to cooperate - on every level (Shamim et al., 2014).

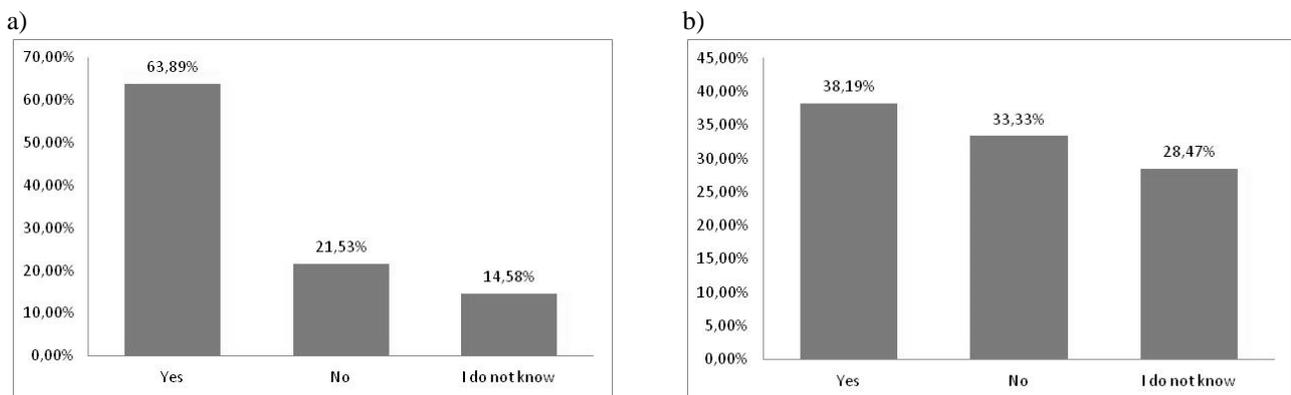

Fig. 3. Cooperation with the environment in the scope of a) improvement of offers b) business management

Source: Own study

Respondents asked about whether information gathered in the company, regarding the clients' needs, expectations and requirements affect its ability to take actions aimed at customer satisfaction with cooperation, thus influencing its decisions and behavior, stated that: it does not matter - 2.80%, it has a small meaning - 10.36%, significant - 81.51%, no opinion - 5.32% (Fig. 4). This confirms the awareness of the importance of information from the customer in shaping his contentment, and thus his behavior.

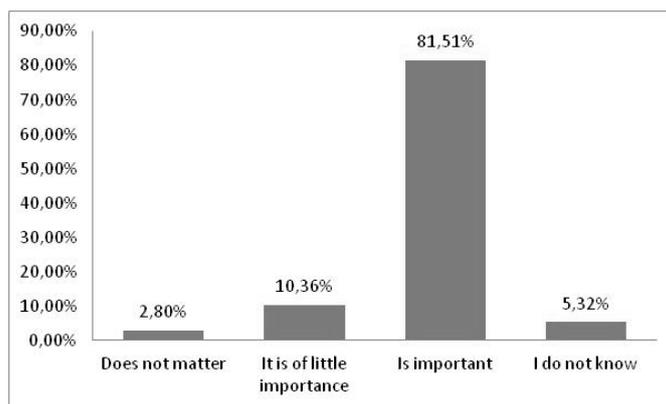

Fig. 4. Gathering information about the needs, expectations and requirements of customers, and the ability of enterprises to take actions related to customer satisfaction

Source: Own study

The importance of information in purchasing decisions of clients can also be illustrated by analyzing the impact of negative information obtained from various available sources. Only 4.20% of the responders said they did not affect their purchasing decisions. 20.17% of respondents said that they have an impact, but they pay more attention to the price or close location of the supplier. The majority of respondents believe that negative information has the big impact on decisions. 16.53% said their impact was decisive. No opinion was voiced by 4.20% of respondents. The distribution of responses confirms very important role of information reaching the customer - in the context of purchasing decisions.

Conclusion

Customer behavior is of interest to every company. The competitive position depends on them. Analyzes and research are carried out. However, the problem in this respect is the large volatility, uncertainty and dynamism of contemporary markets, including customers. It is highly probable, that the results of analyzes while recognizing in decisions taken to meet customer expectations and requirements, are no longer valid. Enterprises try to study behavior, including customer requirements, in a predictive way. Considering the significant pace of changes, these forecasts are always subject of high risk.

As the results of the research presented in the article showed, the clients take into account information about the object of their interest and suppliers having their offer in making their purchase decisions (Bajdor et al, 2016). In connection with the above, every effort should be made to provide the existing positive and potential positive information to customers. One should also try to eliminate, correct and explain misunderstandings, doubts and negative and untrue information. At the same time, one should try to cooperate on the base of information with all possible market participants who have or can have important information for the company. All of them allow to understand current, but more importantly, future customer behavior.

The Online Consumers' Recommendations

Elżbieta Karaś^{a*}

^a*Opole University of Technology, Faculty of Economics and Management, Luboszycka 7, 45-036 Opole, Poland*

Abstract

The development of the Internet and social media influenced the change of the business and communication environment on the market. Enterprises are more frequently doing online marketing activities. They use new ways and communication tools, acquiring knowledge and experience, and even the skills of their consumers. Currently, consumers on the Internet actively spread their opinions about enterprises and products. They exert an increasing and real influence on the functioning of enterprises, they are co-creators of the new business space in the virtual world - prosumers. The Internet provides them with free communication and dissemination of a huge amount of information about companies, brands, as well as opinions and recommendations about purchased products or services. In this way, consumers generate knowledge and increasingly transform the business market, the way of transactional relations and the implementation of social expectations. The specificity of this phenomenon influenced operations of many companies, which currently use recommendation marketing to implement specific strategic goals. Under these conditions, the business environment for enterprises becomes a completely new, difficult to predict and control area of operation. The development of a new strategy based on consumer recommendations may be an opportunity for them to build a positive image, reputation and further development of the company.

The aim of the article is to present the specifics of recommendation marketing and to identify changes in consumer behavior in the context of creating and perceiving marketing content in the Internet environment. General premises of the use of internet recommendations, threats and instruments of recommendation marketing used by Polish enterprises have also been indicated.

Keywords: consumer; marketing; recommendation marketing

1. The definition of recommendation marketing

In the modern world, traditional forms of marketing communication no longer show adequate effectiveness in the face of new technological and social phenomena. Enterprises are searching for alternative forms of communication with the market. The development of the Internet and changes in information technology have revolutionized mutual relations and communication. The Internet allows companies to freely communicate informally and quickly exchange the information they need on the web. An important element in this process is the presence and activity of consumers. As Internet users they communicate with each other, share their content and opinions about products. It is a new form of informal communication that can be effectively used in word-of-mouth marketing (WoMM). WoMM marketing is an activity aimed at triggering the recommendation of a product, brand or service to potential clients. The recommendation can spread in any environment, and the Internet seems to be the perfect place. This is mainly favored by the nature and specificity of communication on the web and the evolution that the modern consumer has undergone, transforming into an active and conscious prosumer. He has a huge resource of useful knowledge and information. His knowledge is available and very useful for the implementation of enterprises in a demanding and rapidly changing market. Prosumerism is generally defined as "the concept of customer participation (usually the consumer) in creating an enterprise offer by actively promoting it, mainly through modern forms of communication" [Niedzielska 2016, p. 350].

Contemporary prosumers co-create content, products and services, shape consumer opinions and images of companies, brands and products, actively seek information, share their consumer knowledge. Advertising information from the manufacturer or service provider in the traditional way is insufficient. The unilateral message has been replaced by interactive communication, and consumer choices are influenced by opinions and recommendations of others available online on the web. For modern prosumers, these are much more valuable and more reliable sources of

* Elżbieta Karaś. Tel.: +48 512 260 615
E-mail address: e.karas@po.opole.pl

knowledge than information coming directly from producers or from advertising. The recommendation is defined as a direct and verbal way of communication between two or more people, which contains positive, negative or neutral information about the company or its offer. Its non-commercial nature is emphasized. This means that the person providing the recommendation does not receive material benefits from their transfer [Tewes 2003, p. 100]. A distinction should also be made between active and passive recommendations. Active recommendations rely on intentional and conscious transfer of information, while passive on unconscious impact on other buyers [Wille 2005, p. 153].

As the results of consumer surveys show, the most important factor affecting the customer's recommendation potential is his commitment to purchase. Very often, consumer engagement is considered as a basic category describing consumer behavior after purchase. Product and situational engagement can be distinguished. The first one is based on long-term, internal, not related to a specific purchase situation, the consumer's interest in a given product category. It results in an intensive search for information by the customer, thus acquiring knowledge about the product. As a consequence, it strongly determines its future recommendations in the long-term. On the other hand, situational engagement is short-lived and occurs just before and immediately after the purchase. His influence on the recommendations may be very strong, but short-lived [Wagenheim 2003, pp. 90-92].

2. Reasons for applying recommendation marketing

The basic factor conducive to the use of recommendation marketing is primarily the development of social media and relationships in the Internet network along with the resources of knowledge that have become the main source for obtaining marketing information. Other factors are: less effective impact on consumers of traditional marketing instruments and a change in consumer behavior on the Internet. These factors will be briefly presented.

New business environment conditions set different approaches to marketing issues. Changes in marketing result from the fact that in recent years the roles and expectations of consumers have changed, they have become co-creators of the electronic space, they often form huge network groups that communicate through social media. At present, it is believed that efficient communication of enterprises with their clients using social media is the basis for shaping the right relations between the company and the environment. A. Kaplan and M. Haenlein define social media as a "group based on web-based application solutions that rely on the ideological and technological basis of Web 2.0 and which enable the creation and exchange of user-generated content" [Kaplan, Haenlein 2010, p. 59]. The essence of these media is the creation of such content that is readily reproduced on other websites, blogs and is generally easily spread on the Internet. They are completely independent of the company and have the greatest impact on the reputation and image of the company. Social media are today the strongest and most influential medium of communication, because they have all the features necessary for effective online information exchange: simplicity, honesty, trust in the sender, openness, impartiality, etc. Positive opinions and comments in the media are the most valuable for smaller ones companies that can promote their products and compete with well-known brands.

The development of the Internet and social media has also contributed to the creation of new marketing promotion techniques. They provide interesting opportunities from the point of view of the company to reach the larger group of customers, employees or representatives of public opinion. These include: viral advertising, WoMM marketing, web marketing (SEO), Web 2.0 marketing, e-mail marketing, e-branding and e-CRM [Budzyński 2008, pp. 184-189]. All mentioned promotion techniques can be used on the Internet and widely used in creating and monitoring the image of a company, brand or specific product. In this way, enterprises gain opportunities to build new business models, strategic and marketing activities in the virtual and real space.

Other elements favoring the use of recommendation marketing are related to changes in consumer behavior and expectations on the Internet. The process of making purchase decisions differs radically from traditional behaviors and consumer decisions. In general, there were two types of changes. The first change concerns the process of purchase decisions. The second change concerns the problem of trust in people grouped in social networks and the credibility of content passed between them.

Consumer's decision making process has been transformed. The traditional decision-making process is based on the consumer's gradual selection of potential offers, and after making the purchase, the relationship with the brand or company has not always been established. Such an approach to the decision-making process does not take into account the conditions that accompany modern consumers, that is, their active involvement in virtual social relations. The contemporary consumer behaves completely differently, makes purchase decisions very quickly and often follows the opinion of other users. Research on new media indicates a change in the consumer's decision-making process, followed by the stages of: consideration, purchase, evaluation and recommendation. The phases of consideration and purchase are much shorter, while the evaluation and recommendation phases are extended and strengthened. The consumer is suggested by the opinions and rankings of other members of social networks and is increasingly looking for information after making a purchase in order to confirm his decision. For example, the latest research from 2017 indicate that online opinions and recommendations affect purchase decisions among 90% of buyers [Hawlk 2017]. What's more, the indications from the respondents indicate that:

- 84% of people consider the opinion on the Internet to be reliable (it considers it as a personal recommendation).
- 54% of people visit company websites after reading positive reviews.
- 74% of people trust companies after reading positive reviews.

- 58% of people think that consumer ratings posted online are the most important source of information for them [Hawlk 2017].

Reports from research carried out in 2012 by Jupiter Research confirm the growing importance of recommendations on the Internet. According to the Jupiter Research report from this period: "77% of buyers read product reviews on various internet forums, and about 60% of respondents appreciate the opinions of other buyers from expert opinions and in their opinion the opinions of Internet users are the most valuable source of information" [Nielsen.com 2012]. In the last five years, therefore, the importance of consumer recommendations placed online has increased. The highest percentage of indications occurred in the group of consumers aged 22-29 [68%], in other age groups it gradually decreased to 42% of indications for buyers over 75 years of age [Rudawska 2012, p. 286]. These results show that the majority of Internet users increasingly base their purchase decisions on the product rating of the network. If the user does not find reviews about the brand and product on the web, he usually treats this as a lack of confidence and does not make a purchase. The lack of other people's assessments is a sufficient reason to look for another product, recommended by network users, with whom it combines a sense of belonging and trust resulting from it [Czarnecka 2012, pp. 170-178].

These facts suggest the necessity for the enterprise to change its marketing strategy, which should be focused on content creation and management in social media [Edelman 2011, pp. 99-102]. Effectively conducted communication in social networks brings a favorable assessment of the brand chosen by the consumer and positive opinions published on the web, which are extremely important for building consumer awareness and encouraging other users to buy. The new consumer decision-making method is also important due to the separation of the new phase - recommending, and thus building strong virtual relations on the Internet [Czarnecka 2012, pp. 170-178]. Social networks have strengthened the way network users interact. The mechanism of exerting influence, known from the real world, is intensified by almost instant access to opinions and rankings of others, because the network for many consumers is a favorite place for seeking recommendations [Nielsen.com 2012]. Due to high awareness of the needs, consumers more frequently provide feedback to enterprises, but above all to each other [Rudawska 2012, pp. 282-289]. Therefore, it becomes important to involve enterprises and consumers themselves in the virtual social relations.

The second aspect of considerations regarding consumer decision making concerns the problem of online trust. A novelty brought about by social networks is increased trust in people from the network, in contrary to people recognized socially as authorities. This is an important signal for companies that have so far promoted their products using the services of sports or pop culture stars. However, according to the rules of exerting influence, the people who we trust and recognize as familiar are more convincing. Network users feel safe in the group of people who have invited them to their circle of friends or whom their relatives know. Using the recommendations of people from a known and trusted social group is much more frequent among Internet users than referring to authorities or imitating celebrities [Czarnecka 2012, pp. 170-178]. These trends are also confirmed by the Global Web Index report, which reveals data on Internet users' activity in the network. It turns out that they primarily look for opportunities and promotional prices, make purchases, communicate with other Internet users and establish relationships. Consumers are also aware of their needs, know how to satisfy them and look for products that in the rankings of other users were the best [Global Web Index 2016].

3. Application of recommendation marketing in Poland

The Americans are the world's precursors to recommendation marketing. In 2001, the world's first agency specialized in the activities of Word of Mouth - Tremor/VocalPoint was created by Procter & Gamble. In Poland and simultaneously in Europe, the first WoMM agency - Streetcom Polska was established in 2004 [Juszczak 2014, p. 74]. Since that period in Poland, there has been an increase in interest in modern marketing instruments adapted to the conditions of Internet space. Not without significance for the popularity of recommendation marketing is the fact that traditional forms of advertising and promotion are insufficient and inadequate to the needs of today's consumers.

As it was indicated in the article, recommendation marketing has a significant impact on consumer decisions, especially in the Internet, resulting in the activation of activities in this field, both from customers and enterprises on the Polish market. According to a survey carried out by the research firm Nielsen, in 2009, among over 25,000 people in 50 countries around the world, including Poland, 90% trust their friends' recommendations before making purchases [in section 2, similar data was presented; see also: Dwornik 2010, p. 6]. Generally, it can be stated that the published content about a brand or product, including reviews, play a very important role in the decision-making process, regardless of whether the purchase is made online or offline. Analyzes show that depending on the type of product, up to 85% of internet users follow the initial stage of purchasing decisions, and 69% of customers are convinced of their credibility. The assessment of the credibility of the review increases with the age of the respondents, 67% of people aged 15-24, 70% of people aged 25-34 and 72% of people aged 35 and over consider them a reliable source of information [Andreasiak 2015, p. 69]. On the basis of the research, it was also shown that consumer recommendations placed in real and virtual space generate about 13% of sales [Zajac 2015, p. 78]. Recommendation marketing always reinforces the effect achieved through promotional activities undertaken by enterprises in commercial media by 15%. According to other data, the marketing of recommendations in real space increases sales five times than other paid advertisements in various types of media [Juszczak 2014, p. 74].

Recommendation marketing can take many different forms to be used in parallel, complementarily or in an integrated manner. In Poland, most enterprises combine traditional and new marketing tools. The most commonly used marketing instruments of recommendation are: shill marketing, internet amplifying (reinforcing), blogging and social media, product seeding campaigns with online participation of experts and opinion leaders, and e-commerce platform.

One of the classic forms of recommendation marketing is shill marketing. In his case, the information carrier should primarily be customers (brand ambassadors) who have good experience with the company and want to share them with others, usually in accordance with the rule of reciprocity, according to which a person would like to reciprocate with good advice to others, because beforehand someone did it's for him. An excellent indication of this type of activities are customer reviews posted on comparison websites and online stores, e.g. ceneo.pl; bonprix.pl. Before purchasing a specific product, you can read the opinions of people who have previously purchased it and its averaged rating on a scale from 1 to 5. This is extremely helpful, because it allows you to obtain objective (both positive and negative) information, including on the quality of clothing, size, fabric condition after washing, etc.

An example of activities in the field of recommendation marketing using the opinions of brand ambassadors was the Morning Fresh dishwashing fluid produced by PZ Cussons Polska SA campaign organized at the end of 2014 by the company Streetcom. The aim of the campaign was to increase brand awareness, inform about the qualities of the product, and gathering brand recommendations. The action was attended by 300 ambassadors who received a package with two of the four liquid variants available on the market and information materials about them. The ambassadors' task was first test the products and then recommend them friends and posting opinions on social media. The main emphasis, however, was on online activity. During the five weeks of the campaign its overall reach in virtual and real space amounted to over 1.5 million people, with an initial assumption of 400,000, and the recommended product gained a significant advantage over other brands - both among ambassadors and their friends [Zajac 2015, p. 79].

Another form of recommendation marketing is internet amplifying, which mainly involves communication with consumers on forums websites, but also placing reviews on sharing sites (e.g. YouTube, Slideshare) or social networks. The Internet amplifying most often takes the form of e-Spokesman for the brand and online Expert. e-Spokesman of the brand is its official representative who speaks in a discussion expressing the official position of the organization and answering questions. The e-Spokesman's function is completely public, which ensures credibility of the message and distinguishes suspicion about dishonest practices in the field of marketing carried out by alleged clients, and in fact employees of the enterprise [Ratuszniak 2010, p. 22]. Online Expert is a form of the e-Spokesman of the brand, supported by constant network monitoring. The main task of the online Expert is to manage the brand's reputation on the web, which is an important element of SERM (Search Engine Reputation Management), through impact on the positioning of positive and neutral threads in the search engine, as well as locating threats and preventing the development of crisis situations [Niedzielska 2016, p. 348].

An ideal environment for the development of recommendation marketing is the blogosphere. Blogs are understood as a systematic, chronological publication of own opinions and beliefs for non-commercial purposes by Internet users [Bednarska 2015, p. 14]. A modern blog is a website characterized by frequent entries, with a personal, informal style that can be commented on by Internet users. Not all blogs are, however, suitable for a recommendation platform, and not every blogger can be an effective amplifier. Blog must be very popular and credible, its author - honest and trustworthy. Recommendations on blogs, in addition to many positive elements, such as the use of the opinion of a recognized person for the authority in specific circles or the opportunity to reach a broad but targeted group, they also have a negative aspect. Very unethical action in this area may be running so-called flogs, or false blogs presenting products specified brands in the most favorable light. Such activities led, among others Sony or Wal-Mart. These blogs, after the discovery of fraud by Internet users, have been ceased.

Other recommendation marketing tools are product seeding campaigns, as well as the activity of trendsetters and opinion leaders. Product seeding consists in providing campaign participants, usually opinion leaders, with a full-fledged product for testing, and in the next stage on stimulating testers for recommendations. In many seeding campaigns, opinion leaders receive not only products, but also their samples, which facilitates their recommendation when distributing the tested product among friends and increases the reach of the seeding campaign. In Poland, many enterprises use this method of running a campaign, locating their productive various forums, and above all in social media. In Poland, there is a clear trend of growth in the number of social media users and communicators through phones, in the last year it was a 20% increase in population. The most popular social media are YouTube and Facebook, Poles use it much more willingly than the average users in the world. Almost 60-64% of network users in Poland use at least once a day YouTube or Facebook, while on average in the world declared it to 45.7% respondents. According to the Gemius study, these websites are at the forefront of their category in Poland - over 22 million real users of Facebook on a monthly basis, and almost 20 million of YouTube. The ranking of the most common social media that is used, at least once daily, is following [Global Web Index 2016]:

- YouTube 64%
- Facebook 62%
- Google+ 33%
- Fb Messenger 32%
- Skype 25%
- Twitter 24%

In Poland, however, there is a low interest in using the WhatsApp communicator. According to the study, it is used by 38% of people globally, while in Poland only by 11%. The communication application taken over by Facebook has never gained much popularity in Poland, and Poles prefer to chat with FB Messenger [Global Web Index 2016].

There are other solutions on the Polish market based on recommendation marketing. Such an interesting solution that has big development perspectives are social commerce sites, which are a combination of e-commerce platforms with an active user community system. It is a solution based not only on consumer recommendations but, above all, using social relations and a communication system between Internet users built on them. Users of this type of services can optimize their purchasing decisions and reduce the associated risk using information provided by other users. The basic idea behind the creation of this type of services is the assumption that most purchase decisions are made under the recommendation of other people, and social commerce platforms are an ideal place where Internet users can exchange information about specific products, evaluate them, recommend and verify information provided by producers, and also follow the opinions of people who personally checked the product or used a specific service. However, social commerce services are fundamentally different from comparison websites or websites that publish consumer opinions. The idea of their creation is not impersonal and anonymous generation of reviews and opinions. Their functioning is based on social relations and mutual trust of users. The value and quality of the opinions posted there results mainly from the fact that users receive them from well-known and trusted people with whom they connect their real relationships. The most popular social commerce site in Poland is Allegro.pl auction platform, where consumers can post their recommendations and reviews online and make purchases. They also have the opportunity to meet in the real world, because Allegro.pl has been organizing meetings for its users since 2000 in order to increase loyalty, trust and willingness to cooperate between them [Karas 2016, p. 106].

4. Conclusion

Recommendation marketing in Poland is developing intensively, there are more and more network users who are very active in the Internet space. There are indications that the growth tendency will continue. According to data from the Central Statistical Office, “about 82% of Poles use the Internet in 2016, and 3/4 of them declare to have an account on a social network” [Rajchel 2017, p. 128]. In this context, the prospects for the development of recommendation marketing, especially in social media, may prove to be a source of success for many enterprises. The use of appropriate marketing tools - activating consumers as carriers of recommendations - can be successfully used in social media. Their recipients are primarily young people, because in the case of people aged 15-24, the percentage of people using the network and portals reach almost 100%. In the future, they will be potential users of various products or services and will strongly influence the way of market transactions in the virtual world [Bednarska 2015, p. 27]. Recommendation marketing in social media currently adopts the most common form:

- running profiles and funpages,
- running applications, competitions and games, including on Facebook or Google+,
- launching video channels on YouTube and other platforms,
- monitoring and testing the condition of brands in the Internet,
- conducting campaigns on online forums [Niedzielska 2016, p. 350].

The analysis of the subject literature presented in the article and selected research results available in secondary sources confirm the significant impact of recommendation marketing on consumer purchasing decisions. Contemporary consumers are active people, they search the Internet space in order to gain knowledge and help in meeting their needs. They connect to various social groups, using modern technological and communication solutions. The prospects for the development of recommendation marketing are huge, especially in the Internet, which results in the continuous activation of activities in this field, both from customers and enterprises. Recommendation marketing can turn out to be a very effective form of action on the real or virtual market provided that they are ethical and reliable.

Abstract

The manufacturing industry is becoming one of the industries that are included in the agenda of the President of Republic Indonesia to have readiness to face industry 4.0. This research uses purposively selected samples of managers at 3 largest cement companies in Indonesia. The growing number of foreign cement industry in Indonesia make the domestic cement companies should have a strategic orientation (resource, market, entrepreneurship, and learning) in order to be able to increase the organizational innovation and organizational performance in the middle of a very high environmental uncertainty. Respondents were taken with proportional area random sampling techniques based on managers' perception. The statistical technique is using Partial Least Square to test the hypothesis. The result concludes that environmental uncertainty has a great impact on the increase of strategic orientation (resource, market, entrepreneurship, and learning). Strategic orientation is required for companies to improve organizational innovation in facing the industry 4.0 that require a very high level of difficulty

Keywords: Environmental Uncertainty; Strategic Orientation (resource, market, entrepreneurship, learning); Organizational Innovation

1. Introduction

Currently, the Indonesian government is committed to improve the industry's competitiveness and independence through the industry 4.0, including cement industry as manufacturing industry in Indonesia. It is known that the strategic orientation of a company depends on what the company wants to achieve. Cement industry is faced with the condition of a very turbulent environmental uncertainty. The level of cement industry competition in Indonesia is increasingly competitive. Several foreign cement companies have been permitted to operate in Indonesia, such as Lafarge–Holcim, Conch, China National Building Material, and Heidelberg-Indocement. They are competing to reap a huge market share in Indonesia. This makes some domestic cement companies overwhelmed to compete. The growth of production capacity above the increase of national cement consumption is the main cause of the high competition of the national cement industry for a long term. It is estimated that the national cement industry will experience an oversupply of 43 million tons in 2018 compared to 2017. The continuation of cement industry competition will make the producers difficult to raise the selling price. Some research has proved that environmental uncertainty can have an influence toward strategic orientation directly or indirectly (Muafi, 2009a; Zahra et al., 1997; Covin and Slevin, 1989). Orientation strategy can also enhance organizational innovation (Obeidat, 2016; Szczepańska-Woszczyzna, 2014). This research focuses on the three largest cement companies in Indonesia, because these companies have been known to have an increasing performance.

2. Literature Review

Some theoretical studies and findings of previous researches concluded that environmental uncertainty is the greatest challenge in managing business. Corporate executives are often confronted with the difficulty to control external environment due to limited costs, time, and information (Jones, 2007; Muafi, 2009a; Elbanna and Alhwarai, 2012; Sachpazidu-Wójcicka, 2017). Elbanna and Alhwarai (2012) have stated that sometimes managers are faced with decisions that are very irrational, unreasonable, and difficult to predict. This is because of the things as follows; (a) the gap due to causation of a relationship, (b) future events that are difficult to predict, (c) the resulting outcomes have uncertainties due to uncontrollable causes. The manager is faced with the inability to predict something accurately (Jonek-Kowalska, 2017). The capacity of information processing management becomes overloaded, so that it will have implications for the decision making that will be implemented (Robbins, 1994). The researcher identifies and summarizes from various literature sources that can be seen on Table 1.

(1998), (8) Luo (1999), (9) Lukas et al. (2001), (10) Li (2001), (11) Choe (2002), (12) Hodge et al. (2003), (13) Muafi (2009a), (14) Elbanna (2009), (15) Elbanna and Alhwarai (2012), (16) Carvalho et al. (2016).

Elbanna and Alhwarai (2012) have stated that company will have difficulty in achieving company outcomes when faced with hostile environment conditions. Muafi (2009a; Covin and Slevin, 1989) adds that environmental uncertainty is characterized by the setting of precarious industry, intense competition intensity, rigorous and competitive business climate, lack of exploitable opportunity, full of risks, pressure, and domination. On the other hand, if the company is faced with benign environment, then it is faced with a safe setting for business operation, has many investment and marketing opportunities, munificent, and easy to be manipulated. In relation with strategic orientation, hostile environment is more appropriate for entrepreneur strategic orientation, and benign environment is more appropriate for conservative strategic orientation. The research result from Luo (1999; Simerly and Li, 2000) concludes that there is no significant influence of munificent environment toward strategic orientation (innovation strategy, proactive, and high risk). In the contrary, complex and dynamic (hostile) environment have a significant effect on the innovative, proactive, and high risk strategic orientation.

Competitive strategy is identical to the term strategic orientation, which has been defined as “how an organization uses strategy to adapt and/or change aspects of its environment for a more favourable alignment” (Manu and Sriram, 1996). Hakala (2011) also defines strategic orientation as organization principles that drive and influence organization activity. Strategic orientation manifests the company culture and functions as the antecedent for organization practice and decision related to resource allocation and pursuit opportunities (Deshpande et al., 1993; Piłat, 2016). Different types of strategic orientations are not mutually exclusive (Gatignon and Xuerab, 1997). Resource orientation means that companies have to be able to mobilize its resources in a valuable and useful way. A unique, rare, and non-imitative resource will be a competitive advantage if the company can manage them strategically (Grant, 2002; David, 2001; Muafi, 2017). Several research findings have proven that when companies successfully implement market orientation, then they can produce superior innovation and a bigger success of new products (Deshpande and Webster., 1989; Kohli and Jaworski, 1990; Mahmud et al., 2017; Dabija et al., 2017). According Ključnikov and Popesko (2017) the export orientation of enterprises represents an important attribute of the enterprises’ competitive ability. In this context, the area of export financing becomes a very important field of company management (Kozubíková et al., 2017; Ključnikov and Belas, 2016).

In relation with entrepreneurial orientation, it means that the company is oriented to be the first in the market in innovation, has the courage to take risks, always be proactive (Lumpkin and Dess, 1996; Kozubíková et al., 2017), and have the principal to identify and exploit opportunities (Lee and Chu, 2011). Nevertheless, the company’s chairman must keep pushing its organization so that all members in the organization have the orientation to continue to learn. This is important because without having the right learning orientation, the company will not be able to implement the organization strategy that has been formulated. If the leader of the company can utilize the existing resources to support

the creation of effective organizational learning and can embrace and understand individuals within the company to organize organizational learning, then organizational learning in the company can work better (Imran et al., 2016) so that it will be useful for a better future (Schein, 1996; Ali Taha et al., 2016). Rose et al. (2010) in her research proves that resource orientation of the company will be able to improve the efficiency and effectiveness of the organization. Some empirical studies have proven that strategic orientation will affect organizational innovation and organizational performance (Obeidat, 2016; Reulink, 2012).

3. Research Methodology

This research was conducted on the three largest cement companies with the largest market share in Indonesia. These three companies are required to continue to increase their sales revenue although the current level of competition is very tight. The emergence of several foreign cement companies to Indonesia (Lafarge–Holcim, Conch, China National Building Material and Heidelberg-Inocement) keeps these three companies constantly tidying up from all aspects, especially the aspect of product and service quality given to customers. The population of this research is all 705 managers in 3 large cement companies in Indonesia (top, middle, and lower manager). The sample of this research is mostly managers who work in three different regions in Indonesia, with the sample target of 165 respondents. The sampling technique is using proportional area random sampling. The result of the questionnaire that is proper to be processed and analyzed is 121 questionnaires. The scale technique is using 7 scale of Likert scale, start from score 7 (very strongly appropriate/agree) up to score 1 (very strongly inappropriate/disagree). The statistical technique is using Partial Least Square (PLS). The result of validity and reliability test of the questionnaire shows that it is valid and reliable.

4. Research Result

From the results of the data, it can be seen that the majority of respondents are men (67%), age 42-47 years old (41%), working period of 8-14 years (51%), and have bachelor education (62). Table 2 shows that all of the 8 hypotheses path are significant with $\alpha = 0.05$ and all proposed hypotheses are accepted (sign < 0.05).

5. Discussion

The cement industry in Indonesia is mostly faced with a very high environmental uncertainty. The three main concerns for managers in the cement companies in Indonesia are; intensity of competition, construction growth, and government regulations. The emergence of foreign cement companies to Indonesia make the domestic cement companies have to struggle and have the agility in capturing the existing opportunities. However, the characteristic of local communities and local culture are become the entry point for the domestic cement companies to be agile and fight smartly in searching new markets and maintaining existing markets (Kustyadi, 2014). The market outside Java becomes a market that can be used as an alternative to be targeted besides the market in Java that is still very large. It cannot be denied that the previous research result found a unique result, which is the people around the company’s location still love to buy cement products with brands that they already know since childhood (Hidayat, 2003;

Kustyadji, 2014). An area where the cement company is located and the area around the company that has no other cement company (referred to as 'main market') has a very loyal market share with the brand of cement company where the people live (Hidayat, 2003). However, the company must remain focused in improving a good service quality both in the main market and outside the main market. In order to maintain loyal customers, there are various efforts that can be done, for example: fostering, binding, and maintaining loyal customers so that they will continue to conduct repeated transaction and it can affect toward the company performance, both short and long term (Parasuraman, et al., 1985; Zeithaml, 1981). D'Aveni (1994) also adds that the aspect of fixed price war is recommended if the company is faced with a very tight competition dynamics. Therefore, serious efforts are required to overcome the competition intensity by seeking new alternatives outside the main market that has been handled, for example, by strengthening the brand equity outside the main market, competing with competitive price with the competitor companies in the main market, and maintaining market prices in the main market (Hidayat, 2003), and also provide excellent services. These efforts should be supported by strong ownership of resources, capital, technology, and raw material that are still depend on local government regulations and policies.

Resources are still become very valuable asset for companies, especially cement companies. Companies should have unique resources and capability, be different and dynamic because it will be able to improve business performance and organizational innovation (Muafi, 2017; Barney, 1991; Rathinam, 2017). Processed resource must synergize each other to make organization have a high bargaining power if it can process and manage it to be more valuable (Reulink, 2012). Environmental damage that is volatile and hostile requires organization to have a strong organizational agility especially in mobilizing and synergizing their resources to increase business growth. Resource orientation is important for the company manager to empower their resources to be more strategic, highly valuable, and innovative (Reulink, 2012). This is required to meet the market demands that is more dynamic and grow quickly. The industry 4.0 requires the cement industry to have an effective and efficient business model (Ślusarczyk, 2018).

Narver and Slater (1990) emphasize that market orientation must be implemented in a balance way so that the customer can be satisfied and the company performance can increase. Besides customer orientation and competitor orientation, company also have to coordinate between functions in a way; resource and information distribution to all existing business functions and units, all resources must be integrated with company strategy, and must contribute to create customer value. In relation with entrepreneurship orientation, Covin and Slevin (1989) suggest that companies continue to implement an effective management practice. Managers must have proactive behavior, autonomy, risk-taking, innovativeness, and competitive aggressiveness. This is because managers' behavior will be able to increase the growth of company business and organizational innovation (Covin and Slevin, 1989; Muafi, 2009b). All members of organizations and managers must also have shared vision, commitment to learn, and open mindedness orientation to achieve the goal of the organization. Hurley and Hult (1998) emphasizes learning orientation as a precursor in explaining the company culture into innovation. Organizational learning is considered as a process where the organization change or modify their mental models, process, rules, behavior, or knowledge (Chiva and Habib, 2015). The culture of organizational learning needs to be created because it is a factor that can improve organizational innovation, company performance, and individual performance in the company. This needs a strong and consistent commitment from all stakeholders to maximize the capability in the digital transformation of industry 4.0. Cement companies must have a high entrepreneurship and continue to do a learning process continuously, especially from technological aspect. This is because in the future, all products and services offered by competitors are based on technology. The technology that is offered should be effective in the use of time or cost allocation, so that the company can produce and offer their products and services efficiently and effectively. The impact is that the products and services that are offered can be cheaper but still have a good quality and can compete in domestic and foreign market.

The limitation of this research is the research object that is too narrow, because it is only test three biggest objects of the cement companies, so it is feared to be not really able to generalize cement companies in Indonesia. The managers of the cement companies that are researched should be taken by considering work experience and age because those are related to the strategic decision making of the company. For future research, researcher should use a thorough in-depth interview, so that they can use mix method approach (quantitative and qualitative). Besides, it is better to use longitudinal method instead of cross section, so that the result can be more accountable, because it includes the aspect of strategic decision making in a big company

Aspects of Organisational Culture and Change Management

Elena-Izabela Popa^{a*}, Eduard Edelhauser^a, Eugenia Jornea^a

^a University of Petrosani, Universitatii street, No. 20, Petrosani, 332006, Romania

Abstract

Effective adaptation of organisations regarding the competitive environment involves undergoing a process of important changes which must take into account the organisational culture, which is an essential component of an organisation's transformation process. In order to meet the demands which must be made and to become efficient, organisations need to pay more attention to the organisational culture. Organisational culture can become a factor that either facilitates or prevents the adaptation process. Therefore, regular evaluation and changing the organisational culture become real and important. Changing the organisational culture represents a far-reaching activity due to each organisation's culture containing a set of objectives, roles, processes, values, communication practices, attitudes and hypotheses. These are the implementation tools for achieving the desired results. In this context, this paper addresses a topic that has been little explored in the Romanian specialty literature: to establish a possible link between the organisational culture, the resistance to change and the performance of an organisation.

To make a first pragmatic approach to the research topic, we have conducted a case study on organisational culture assessment at an organisational level within a power generation company.

Keywords: organisational culture; improvement; management; performance; change.

1. Introduction

Discovering the importance of two essential elements in the functioning and the development of an organisation – the importance of employees and the socio-human climate – represented the debut of organisational and managerial theories.

Any organisation has two “universes” among which we need to make a clear distinction. One of them is represented by employees, the relations between them, the level of training they have, manifest and apply, the values they adhere to and they expose as a reference in their relations with the surrounding world, and the other universe is made up of cars and technology, the production processes, the productivity and competitiveness of the products and services offered, and the market.

It is already well known that society reflects the “states” that organisations face. In this sense there are expressions at a national level - society is largely the expression of what exists, happens, develops or changes in the organisational space (Vlăsceanu, 1999) – and also at an international level – the organisation is an important marker of the contemporary age, and society represents the mirror of the organisations that make it up (Drucker, 1999).

Organisations are perceived as “*social inventions designed to achieve common goals through group effort*” (Johns, 1998), as social structures formed of groups of individuals acting in a coordinated and unitary way to achieve their goals. Regardless of their type (private, state, profit/non-profit, economic etc.), organisations function under the impact of certain values; in other words, each of them possesses a certain organisational culture. To know an organisation's culture is to understand how it works, the cultural factor having an important influence on management policies.

Hence, besides the structure, economic processes and people, an important element of an organisation is **culture**. We must distinguish between the culture seen as a very broad concept (mentality being one of its components) and **organisational culture**.

2. Organisational culture: evolution, concept, and approach over the years

Organisational culture represents a relatively new concept; it has become a discussion and analysis topic in the recent years. Just 40 years ago organisational culture has been introduced in the managerial field. After only 10 years of existence it came to the attention of schools and universities.

Although concepts such as “group norm” and “climate” have been used since 1939 (Lewin, apud. Schein, 1990), organisational culture has been explicitly used over the past decades.

Since the 1970s, organisational research has started to use cultural concepts in organisational behaviour analysis.

The phrase “*organisational culture*” was introduced in specialty literature in 1979 by Pettigrew in his paper “*On studying organisational culture*”. Pettigrew conducted a study on the evolution of an English school under the influence of events that were perceived by the organisation’s members as critical events, from its establishment in 1934, until 1975, when the author collected the latest data.

There has been a significant increase in the popularity of organisational culture starting in the 1980s; relevant to this were the pieces of work of Terrence Deal and Allan Kennedy (1982) “*Corporate culture: The Rites and Rituals of Corporate Life*”, “*In Search of Excellence: Lessons from America’s Best Run Companies*” of Thomas Peters and Richard Waterman (1982), and also “*Culture’s Consequences*” of Geert Hofstede (1980); the coming out of these works triggering an explosion of research on the concept of organisational culture.

After 1990s, the emerge of investments from multinational companies in Eastern Europe countries made the concept of organisational culture known in this part of the world.

Organisational culture arises out of the need for concepts that differentiate organisations of the same society, especially in relation to efficiency levels. This concept semantically integrates the values, symbols, believes, myths, rituals, ceremonies, and aspirations that define the spiritual space of an organisation (Burlacu and Cojocaru, 1999).

Currently, taking these aspects into account, the understanding and using of the concept of organisational culture, it has become necessary as a tool within a company, in the case when a company targets a top position in the ranking of the field which it operates in.

3. Case study within Oltenia Energetic Complex

Oltenia Energetic Complex (CE OLTENIA) is a mostly state-owned company, a major player on the Romanian energy market, being the largest electrical energy producer using fossil fuel.

The Romanian energy market is constantly changing and the energy consumption has fluctuations of more than 40% even in the spare of a week. Under these circumstances, the organisation’s status recommends that changes be implemented immediately and consistently across the organisation’s structure.

The quality of being the leader of vocational training activity within CE OLTENIA and that of being the first author of the paper has determined me to initiate a research project regarding organisational culture and, together with the co-author of this paper, to establish a possible link between the organisation of culture, resistance to change and the performance of an organisation.

We believe that the change of organisational culture plays a crucial role in the rapid adaptation of the organisation to the external changes it faces. First, the managers’ resistance to change must be defeated, as organisational culture represents “the result of the effort of managers to guide staff in the spirit of excellence” (Edelhauser, 2011).

If the paradigm of change can also be a change of paradigm, we can conclude that “in order for the world to be different, we must also change the paradigm” (Abrudan, 2012).

The aim of this paper is to make an assessment of the organisational culture in CE OLTENIA, to show that the main element leading to the valorisation and development of the organisation is the continuous improvement through *change*.

A case study will be carried out throughout this paper; it is not representative of Romania, but it is only a trend reflected by electric energy company, within which the issue of the evaluation of the organisational culture and its impact on long term performance was raised.

The data used comes from CE OLTENIA, a company which has undergone restructuring and *change* programs.

The sample this research was conducted upon is representative of technic economic socio-administrative and managerial staff.

The research conducted aims at assessing the organisational culture, highlighting the specificity of the culture within CE OLTENIA, observing whether organisational culture is viewed within the organisation as a powerful strategic tool used to guide the company and all its employees towards common goals, to mobilise the employees’ initiative, to ensure loyalty and ease the communication between them. It has been analysed whether the organisational culture is understood by employees and whether they fully adhere to it, but also the connection between this concept and the human resource of this society.

3.1. Research methodology

The *research method* used was the *survey based on a questionnaire*. The *questionnaire* helps determine organisational culture and assess it in terms of employee behaviours and the way they perceive whether they match the organisation they belong to and whether their expectations are met.

Performing a research program, regarding the conduction of the survey, is essential for estimating the cost and the time needed to take steps to ensure the effectiveness of the study.

In the realisation of the survey as a methodological tool, *the questionnaire* used was the one applied in CE OLTENIA between the 14th of May and 15th of June 2018.

In order to avoid the *halo effect* (employee's tendency to respond similarly to multiple questions), a lean presentation of the study was chosen without delimiting by title the category or dimensions the question was looking for.

The questionnaire consists of 30 open, close, and multiple answers questions.

The questionnaire contains in the beginning a brief overview of its subject, and then it is structured in two parts.

Part I of the questionnaire is generically titled *Identification Data* and it consists of a set of nine general questions in order to ease the entry into the subject.

Part II of the questionnaire is generically titled *Enterprise values evaluation data* and it consists of a set of 21 questions introduced in order to determine what are the values, norms, ethical principles of the organisation and the extent to which employees adhere to the society's values, objectives, policies.

The choice of *scales* for this type of questions (with scale) was made according to the studied variable, hence avoiding the generation of appreciation errors (the tendency to give neutral or contradictory answers).

The types of scales frequently used in *the questionnaire* are *nominal scales*, namely *dichotomous* with answers such as *yes, no, neutral*, and with *a possible answer from a given list*.

In *the questionnaire* there were also used questions with an *ordered scale* with *the hierarchy of preferences* (from most important to least important), Likert (from total agreement to total disagreement), *questions with differentiated scales by importance* (from a lot to not at all).

The following criteria have been applied to the applied *research method*: accuracy of results, cost, timing, nature of reference population, sample size, available information.

The advantages that support the efficiency of the chosen method are: the facilitation of the extraction of the employees subject to the study, the possibility of a rigorous control of the data collection process, a low cost and a limited time for sample determination.

In the interest of ensuring the confidentiality of the information regarding the respondents in order to increase the accuracy of the data obtained, their names were not specified, but only their position within the company, their gender, and their age, to which it is added the seniority in the company.

3.2. The population and sample observed

The population under investigation is made up of 50 employees from the personal management and execution categories of CE OLTENIA. The age of the respondents varies between 35 and 55 years and regarding their gender, they are both women and men. The questionnaire was distributed through direct contact to employees in different positions and functions.

3.3. Analysis and interpretation

Questionnaire survey data were collected, processed, analysed, and interpreted between May 14th and June 15th 2018.

All 50 *questionnaires* were correctly completed, these being the subject of statistical analysis.

For data processing, the program used was *Statistical Package for the Social Sciences – SPSS*, one of the most used programs in statistical analysis of data. This program has been favoured not only by availabilities, but also by the fact that it offers a larger flexibility in the case when the desired information is predominantly of quantitative nature, which has made it data recording and analysing easier.

It is not excluded that the results of this research may contain possible errors due to lack of field experience.

3.4. Results

The centralised data shows that CE OLTENIA is an organisation oriented towards respecting ethical principles, values, promoting a customer-oriented attitude.

The society's mission is *to produce efficient, clean and safe electricity, based on exploiting the lignite potential with maximum efficiency in Oltenia, to ensure Romania's energy security.*

The company's motto is *Excellence through quality.*

The company's slogan is *OLTENIA ENERGY COMPLEX – ROMANIAN LAND'S ENERGY.*

Behavioural rules: *immediate execution of the orders of bosses, respect of discipline and order, ethical behaviour and integrity, assuming responsibility and consequences for the committed deeds, teamwork* are respected by the employees.

The sources of information regarding the values of the company are represented through the following: official website, internal communication network, intranet, publication edited by CE OLTENIA, regular meetings and training with the employees, company regulations. The organisation has a preference for oral communication, although it is present within the society the written communication highlighted through procedures, instructions, and company regulations.

There is also a *desire* within the society *to avoid conflicts by reaching a compromise.*

Staff adheres to the organisation's goals and policies, showing loyalty to it. Sources of information regarding company values are represented by: internal regulation; code of ethics; organisation and operations regulations; system, administrative, and operational procedures; regular meetings and training with employees.

On the other hand, it can be said that, *after contributing to performances*, CE OLTENIA falls into the category of *forte culture* or *positive culture* characterised by the homogeneity of values and perspectives that provide positive motivation.

According to the accepted risk level and the speed of obtaining feedback, CE OLTENIA falls into the Process culture category, being a rigid culture, based on rules and procedures. Employees are disciplined, orderly, punctual and thorough.

Furthermore, *according to the type of transaction by which the individual is linked to the organisation*, it can be concluded that CE OLTENIA belongs to the *hierarchical culture* type because it is based on employees respecting procedures and regulations in an environment of stability and control. In CE OLTENIA the authority lays in the rules and the power is executed by specialists. Decisions are based on detailed analyses, and leaders tend to be conservative and cautious.

According to the organisation's configuration, CE OLTENIA falls into the *Role culture (temple type)* due to it being a large society, with bureaucratic mechanisms which determine the appearance of subcultures in specialised departments, which form the column on which the temple rests; the values and perspectives, given by the roof of the temple, are clear, expressed in writing, with an obvious tendency towards stiffening, discipline, respect of codes, instructions, procedures, regulations of society, individuals are offered the possibility of professional specialisation.

Depending on organisations' characteristics and the differences between the national cultures, CE OLTENIA falls within the *Eiffel Tower culture type*, because the relations between the employees are regulated in advance by imposed interactions; authority is attributed to the most important roles, people being distant but very powerful.

CE OLTENIA is a *collectivist society*, due to it favouring interdependence, loyalty to a family or clan with a feminine culture because it accepts different roles regarding genders, emphasizing gender equality.

Within CE OLTENIA the following are emphasised: rules, regulations, hard work, compliance, safety, which, in terms of *avoiding incertitude* (the degree of assuming risks, the degree to which the employees feel uncomfortable in uncertain and ambiguous situations), make it fit in strong avoidance.

Taking into account the orientation, CE OLTENIA fits into *long-term oriented cultures*, as it emphasises perseverance, prudence, attention to position differences.

CE OLTENIA falls into the type of organisations characterised by a *small distance from power*, within which: inequality is minimized, superiors are accessible, and power differences are not given great importance.

In a proportion of 90%, employees are identified with the organisation's values and they adhere to the company's objectives and policies.

4. Conclusions

The result of the research shows that CE OLTENIA represents an organisation that *promotes a customer-oriented attitude and values*.

The most important *values* promoted by CE OLTENIA are: professional excellence, team spirit, solidarity, valorisation of synergies, ethics, integrity and loyalty, fairness and respect, standard of business ethics (internal and external) towards colleagues, customers, providers, the respect and responsibility towards the community and environment.

Therefore, it can be concluded that the *hypotheses of this research on the organisational culture of CE OLTENIA are valid* because the moral values have an impact on the performance of the organisation and its employees. There are no differences between the values promoted within the company and those in which employees find themselves. Ethical behavioural values and norms are promoted within the organisation.

Organisational culture promoted within society is known and understood by the organisation's employees. Employees' values match the requirements of organisational culture promoted within the company.

Organisational culture represents a combination of conscious and unconscious, rational and irrational, group and individual elements, which influence each other and have a major impact on the functionality and performance of the society.

Society culture is a support in orientation, essential for both managers and employees, it is a source of identification and it creates a sense of security and refuge.

Any organisation can be seen as a social structure, consisting of a group of people who act together to achieve the organisation's goals. The success of an organisation is conditioned by the extent to which the personnel act as a whole in order to achieve its goals.

Quality-oriented *organisational culture* is a guarantee of continuous survival and development for any organisation, regardless of whether it operates in a highly competitive market or in an unfavourable economic, social, or politic environment.

This is because the organisational culture, through its components, dictates certain rules of employee behaviour, guides how the employees perceive and represent reality, how they should react to environmental changes.

The existence of an organisational culture involves the transmission and learning of a behavioural type that must become a habit for the employees. By the way they behave on a daily basis; managers encourage employees to adopt an identical behaviour in their relations with others.

If the society imposes through its own culture behaviours that lack ethics, not only will the leadership behave this way, but also the employees, taking the managers as an example.

Within an organisation with an authoritarian management, an organisational culture lacking values and moral principles, employees will also adopt an immoral behaviour.

Organisational culture has become fashionable topic in the recent years, a topic that has been frequently approached both in the academic world and in the economic environment. Its importance is mainly reflected by the impact it has on the results of an organisation.

Thus, regardless of whether we are talking about a public institution, a state owned company, or a foundation, we can definitely affirm that a healthy organisational culture is a safe chance for success; it is one of the main factors that can determine the performance of that organisation.

Integration of Human Resources Strategy in the General Strategy of an Enterprise

Ioan Rus

University of Petrosani, University Str. no. 20, Petrosani, Romania

Abstract

Starting from the definition of human resources management, the activities carried out within the human resources management, the difference between the personnel management and the human resources management are explained, and the connection between the human resources management and the strategic management of an organization is presented. Similarly, the paper establishes the role played by the human resources manager in the organization, the new tendencies in human resources management are presented, and the means of assessment of human resources management are explained.

Keywords: human resources management; personnel function; human resources manager; human resources strategy.

1. What is human resources management?

Human resources management is the process as a result of which the employees obtain the desired level of satisfaction, and the organizations to which they belong reach their proposed goals, by harmonizing four elements: environment, organization, job, and employee.

1) The organization exists within the environment and only survives if it efficiently interacts with it. The *environment* has four components:

- ✓ *Economic component* (number and competitive force of organizations, unemployment rates, interest rates, inflation etc.)
- ✓ *Social component* (values and attitudes of customers and employees as far as work, products, businesses, aptitudes, educational level, their expectations are concerned)
- ✓ *Political component* (laws and regulations)
- ✓ *Technological component* (raw material, technology).

2) The *organization* should provide, by its characteristics, employees' satisfaction and performance. These characteristics are: dimension, structure, technology, culture.

3) *Jobs* are the entirety of tasks and activities of an employee. Job characteristics influence the employees' performances and satisfaction. These characteristics are: degree of difficulty, variety, autonomy offered to employees.

4) The *employee* brings to the organization a set of his own characteristics. The good performances of an employee in a certain job depend on: aptitudes, knowledge, personality, values, and expectations.

All these four elements have experienced important modifications in the last years.

2. From personnel management to human resources management

Personnel function came up in an organization as a result of:

- Increase of its dimension;
- Increase of number and complexity of legal regulations regarding personnel;
- Modifications occurred in the social component of the environment.

In several organizations the titles of chief or director of personnel are maintained. These manage the following activities: creating jobs; recruitment and selection; orientation; training and specialization; assessment of performances; work compensation; career management; labor protection; motivation of employees; management of labor conflicts.

The responsibilities of the human resources managers include a wider range, implying their direct involvement in the process of development, implementation, control and modification of strategies, as well as counseling in problems connected to a good management of the human resources.

Considering the tight connection that should be between human resources management and strategic management of an organization, we consider that it is necessary:

- On the one hand, for the human resources managers to know the elements of the strategic management;
- On the other hand, for the general directors and other managers of an organization to know the activities that should be covered related to the organization's personnel.

In organizations of over 100 employees, managers and specialists in the compartments of human resources coordinate and /or cover the specific activities, mentioned above. These activities imply the involvement of all the managers of organizational links, which during the activities should work in team with the first ones. Together, the managers from the human resources compartments and the other managers of the enterprise should:

- Establish the goals and objectives of the organization;
- Develop and implement strategies;
- Monitor their efficiency and modify them, so that they should be adapted to the environment.

3. Connection between human resources manager and strategic management of an organization

The pressure exerted by the environment on the organization made the increase of the involvement of the human resources specialists in the strategic management process, necessary.

The long-term strategy of an organization establishes future directions such as increase of incomes, of market quotas, cost reduction or diversification in another field of activity. Therefore, long-term, large-scale plans, regarding recruitment and selection of new employees, training of the existing ones, or dismissal of employees that are no longer adequate to the necessities of an organization, are necessary. Consequently, the human resources director develops the human resources strategy, which is then forwarded to the Administration Board to be approved, the personnel categories to be employed being established, as well as the funds to be allocated for recruitment – selection and training – specialization, so that the enterprise should have sufficient competent personnel at the right moment.

When the strategy has been established, the specialists from the human resources compartment develop concrete action programs, such as develop documents required for recruitment, and organize visits in university campuses, interview candidates, employ and train. In all these activities, they closely cooperate with the managers of the operational links. Strategic management of human resources is the process by which the human resources management connects to the general strategy of the enterprise, in view of accomplishing the organization's goals and objectives.

The human resources strategy is that part of the general strategy of the enterprise which strictly refers to human resources function; therefore, it is a functional strategy.

As in the case of general strategy of the organization, in the strategy of human resources *decisions are made on three levels*:

- *At strategic level*, the general director and the human resources manager establish long-term directions, such as career management, rewards policies;
- *At managerial level*, long-term plans are concretized by developing concrete programs, for example recruitment program of training program;
- *At operational level*, the concrete programs developed are implemented. Salaries are paid, as well as other reward forms, courses and other forms of training and perfecting are organized, recruitment and selection of personnel is done. The strategy should be developed in time, and not as a reaction to the upcoming crises. Thus it has to be *pro-active*, not *reactive*. The more the human resources managers are involved in the strategy development stage, the less will the crises be, for the solving of which they would have to provide assistance.

Human resources strategy is adopted in such a way as to achieve harmonization between the individual, job, organization and environment, by *five principal policies*:

- Assurance policy for the necessary staff by employment;
- Performance management policy;
- Employees' development policy;
- Reward – motivation policy;
- Organizational change policy.

Four human resources strategy types can be adopted, function of the job situation, on the one hand, and on the employees' situation on the other.

- *Stable employee – stable job*. This combination involves choosing the employee corresponding to the job. The most important policy is the employment policy, by recruitment, selection, orientation activities.

- *Flexible employee – stable job*. In this situation, the activity and performances of the employee should be altered so that he /she would acquire knowledge, aptitudes attitudes required for the accomplishment in the best conditions of the job requirements. Performance management and employees development policies become fundamental by assessment, training, coaching, mentoring activities

- *Stable employee – flexible job.* In this case, the situation of the job should be modified regarding the requirements, work or reward conditions to correspond to the employees' demands. The activities involved are job planning, negotiations with the Unions, altering work reward and motivation programs, health and labour protection programs.

- *Flexible employee – flexible job.* This time both components are modified. In this situation, all policies and all human resources activities, which are continually changing and mutually influence each other, are applied.

In order to see what is the relationship between the employee and the job, a thorough analysis of the two components: job and employee should be made.

- *Job analysis* studies the activities, attributions and work conditions involved, the knowledge, aptitudes and attitudes required for the employees' adequate performances and the relationships with other jobs.

- *Employees' analysis* involves studying their previous performances, their potential as well as their necessities, desires and values.

In view of accomplishing the established objectives, it is necessary for the human resources strategy of the organization to be developed and monitored by the entire staff of the organization, and the top management of the corporation and the human resources managers should closely cooperate. A special attention is needed for domains that demand special talents and for events that significantly affect human resources, such as: geographic extension, introducing products and services, increase of automation level, mergers and acquisitions, to see if there are or can be trained specialists in the respective labour markets. Factors affecting human resources management should be considered, such as: economic, demographic, social, political ones, as well as modification of branch configurations. The organization's units should be regarded in their interdependency, so that together they might contribute to the accomplishment of the organization's objectives. It is absolutely necessary to review periodically the developed strategy, making the necessary modifications, in view of adapting them to the environment.

Human resources strategy represents a combination of the approaches described above, depending on the stage in the life cycle through which the organization moves.

In the stage of creation of the organization, preponderant is the policy of the personnel assurance, by hiring staff having entrepreneurial aptitudes, enthusiastic, adaptable to the founder's vision and ready to perform a relatively low complexity, but intense activity. In this stage, the entrepreneur has many current tasks to solve and neglects planning. It is dangerous not to be preoccupied with the future of the employees, which will become necessary in the future. Cash is scarce in this period, therefore the employees accept either to be paid less, the difference being paid at a future date, or to receive social parts or shares to the enterprise.

In the stage of organization development, recruitment and selection of the personnel are equally important, but should become more rigorous, looking for specialists in certain field of activity, which would develop alongside with the organization. The training activity becomes very important, because it allows the personnel to respond to higher exigencies and to implicitly advance in better jobs. Rewards should stimulate the personnel into acting in view of development, bonuses being very important in this stage. Since rewards should be well correlated with the employees' performances, personnel assessment systems become especially important. Rewarding loyalty can result in retaining in the organization inadequate persons, which will lead to disastrous effects in the maturity stage.

In the maturity stage, activities become better and better structured. Specialized compartment come into being, and work procedures are standardized. Recruitment and selection are no longer vital, as in the previous stages, but rewarding work and personnel development become a priority, as means of motivating and obtaining performances. Rewards can be in the form of fixed salaries. Personnel development is especially important, since creativity has to be stimulated, without which the enterprise is in decline. The more new products and services would be discovered and the existing ones would be improved, the longer the maturity period would be, both in the benefit of the employees, and of the founders.

In the decline stage, the choice of the reward type becomes particularly important. The employees are rather frustrated because of the sombre future; therefore the work itself does no longer bring them satisfaction. When the objective of the organization becomes gradual liquidation, it would be unfair for the pay to be correlated with the performances of the organization. Moreover, if rewards are function of the profit, the unwanted situation would arise, when the employees would act to increase it. Therefore, monetary compensations should be correlated with how the employee fulfils his/her tasks, incentives being given function of the deadlines met and quantities set out.

In the situation in which the corporation wishes to stay in the market, even though a strategic unit is in decline, replacement of a part of the personnel becomes important. In order to dismiss some of the older employees and replace them with others better suited for the circumstances, assessment becomes especially important. It is recommended for the competent employees to be stimulated to stay. Selection should be done in such a way as to bring in 'fresh blood', which might contribute to recovery. If the survival strategy has in view entering new markets, personnel training becomes vital, because the staff should become familiar with the new products and services.

4. Structuring human resources functions

If making organizational structure definitive is one the ways in which the organization strategy should be implemented, restructuring human resources function is the prerequisite of the success of human resources strategy, by correctly connecting the related activities to the environment of the organization.

The structure of the human resources function depends, as it has been shown, on the organizations dimensions. If in small organizations the activity is limited to recruitment – selection, dismissal, training and compensation, being able to be covered by the director or one single specialist, the range of services increases with the size of the enterprise.

The concept of ‘human resources management’ differ from the concept of ‘personnel management’, by the number and complexity of activities. The first includes planning, career management, social dialogue, benefits given to employees (medical services, meals). These activities are under the guidance of human resources specialists, coordinated by a head of service or a director, who reports either to the general director or to a deputy director, usually the administrative one. In large corporations, with complex activities, the service is divided in offices, their personnel being well specialized in a certain activity. Moreover, departments of human resources can be organized in the strategic units of the corporation.

The activity of human resources managers has a serious interactive character; therefore they should have, besides a high level of competency, certain additional qualities, namely:

- Negotiation aptitudes;
- Influencing power;
- Talent to be made respected, sympathized, and to earn the trust of the general director and the management team;
- Strategic thinking, with the help of which to develop human resources strategies at corporate, managerial and operational level;
- Capacity of counseling the general director, of influencing him/her and the top managers and of entailing them in solving problems related to human resources;
- Talent of noticing and indicating when the modification of the organization’s culture becomes necessary and of creating new practices to ensure personnel and socialize;
- Capacity of continually perfecting the informational system, by using the process of personnel assessment, publications, internet, organizational communication;
- Capacity of developing public relations activity;
- Capacity of using strategically the activities of human resources created, emphasizing the benefits they bring to the organization, thus obtaining a greater influence of the human resources department in the decisional process.

5. The role of the human resources manager in the organization

In the last years, it is considered that the activities of the specialists in human resources can fall into four large categories:

1) *Initiation and formulation of policies*. These are meant to solve the problems existing in the organization or to anticipate the occurrence of others.

2) *Consultancy*. The human resources specialists are required to have knowledge on and give advice regarding: labour legislation, practices in the branch and in the economy, experience in the respective domain, practices in the field of branch and economy, experience in the respective field, requirements of the organization and employees, possibilities of their harmonization.

3) *Service*. They will have to coordinate the activities of recruitment, selection, assessment, career management, employees’ training.

4) *Control*. They also have to monitor the performances carried out in the operational and functional compartments to ensure that their activities would be aligned to the established policies, procedures, and practices.

Although all the four attributions of the specialist in human resources listed above are extremely important, the most important is that of counsellor in the organization. He has the task of identifying the best ways to harmonize people, jobs, organization and environment, counselling the managers and the directors in this sense.

Exerting the role of consultant involves earning the trust of the managers by competencies and experience accumulated in years. Counselling given to managers by the specialist of human resources consists of identification and solving problems they have relating the personnel with which they work.

Among the managers and specialists in human resources there is a relationship of cooperation involving several stages to be covered:

1) Identification of negative symptoms related to an employee or a group of employees. Usually, this is noticed by the operational manager, who has in is in charge of the employees and who has the closest relations with them.

2) Diagnosis. The human resources specialist identifies the problems and their causes, collecting information on the employees, jobs, organization and environment, using methods like: observation, documentation and interview.

3) Planning. The human resources specialist establishes measures by which the problem will be solved, including revision of policies and practices.

4) Implementation. This stage implies conjugated efforts from the part of the human resources specialist and the directly involved manager.

5) Follow-up. The domains where initially the negative symptoms have been noticed are examined, assessing the improvements obtained.

Consequently, the human resources manager advises the managers in various structural links of the organization what measures should be taken, to solve certain personnel related problems, how to implement those and how to follow them up.

One shouldn't forget his/her major responsibilities regarding: recruitment; selection; orientation; training; performances assessment and recommendations on salary increase, promotions or transfers; draw up career management programs and labour protection.

6. Human resources' function assessment

Many of the specialists in the field of human resources consider that the results of his/her activity cannot be quantified (for example, increase of work satisfaction, or greater opportunities for career development) and the financial contribution of the human resources function to the improvement of the enterprise activity cannot be established. Therefore, general directors are not always aware of the importance of this position, and cut down the budgets of human resources whenever the slightest financial problem comes up, although they declare that personnel is the most important resources of the organisation. In many organizations there are no available financial resources for important activities, such as job analysis, assessment of training activity or the use of more complex methods of employees' selection.

Generally, human resources are seen as cost generating activity, without directly contributing to the incomes of the enterprise. Therefore, it is often in the focus of expenses reduction. Considering the costs and benefits, human resources activities are classified by the directors and managers in; essential activities, optional activities, optional studies.

Essential human resources activities are those, in their view, without which the organization cannot develop. The need for these activities is decisive and real, although they involve high costs, and the benefits of these activities are direct and measurable. Such activities are: recruitment, selection, training at the workplace, salaries, benefit programs, labour protection, and relations with the Unions.

Recruitment-selection programs provide the necessary employees for the organization, with adequate qualities for the respective jobs. Training programs at the workplace provides accomplishment of the necessary performances standards. Programs ensuring compliance with the government regulations, contribute to avoid legal expenses. Good relations with the Unions, and the success of salaries and benefits negotiations with the Unions contribute to avoiding strikes and related expenses. Optional human resources activities are considered: job analysis, performances assessment, career development, training programs, organizational communication, human resources planning.

Managers believe that those are useful management instruments, but costly, and without a clear and immediate usefulness for an organization. Since the benefits of these activities are considered indirect and unquantifiable, in certain organizations they are treated as being unimportant, in others they are treated as a luxury possible to be satisfied only in favourable economic conditions.

Optional studies of human resources such as:

- survey for analysis of employees' attitude;
- assessment of personnel training programs are the least admitted as being necessary by the managers, who rarely understand their usefulness, which is difficult to be quantified.

It has been previously shown that the human resources managers' power of influence depends on their competency and qualities, especially that they have no direct decisional power. In order to obtain the required funds for the human resources activities, they have to find economic justifications to demonstrate their effectiveness.

To this end, they can use the cost-benefits model of assessment of human resources program. This has four components: 1) efficiency model, 2) economic model, 3) cost benefits comparison and 4) decision to continue, repeat, or change the training program.

1) *Efficiency model* is quite often used (for example, when training programs or employees' attitudes are assessed). It has five stages:

1.1) *Analysis of the program's necessity* emphasizes the problems it has to solve, and allows comparison between the situation of the enterprise before and after the program. In the case in which the identified problems in this stage are not gone by the end of the program, it means that it did not have the expected success. In the analysis of the necessity of the program, one starts from the identification of symptoms; this puts in the limelight the lack of correlation between employees, jobs, organization and environment. In order to be able to better evaluate the changes occurring as a result of the program, it is useful to measure as many symptoms as possible, such as personnel fluctuations, absenteeism, work productivity, overtime etc.

1.2) *Planning the program* means choosing the most adequate alternatives, meant to improve the relations between employees, jobs and organization. Irrespective of the variant selected, the program efficiency assessment methods should also be set out, as well as the ways the human resources manager and the interested managers can be involved.

1.3) *Quality assessment* of the way in which the program is implemented involves:

- follow-up of the activities in their succession;

- data collecting and processing, according to the established program;
- identification of the deviations from the program or the imperfections of the designed program;
- information on how the program is covered.

1.4) *Quantification of the program effects on the perceptions and attitudes of the employees*, if the perceptions and attitudes of the employees are not changed, it means that the program was not well designed and covered.

1.5) *Measuring the program effects on the changing of the employees' behaviour*, for example work productivity, quality of the activity covered, absenteeism, fluctuation, occupational accidents, complains, medical leaves.

Each of the five stages offers important information regarding the causes of the success or failure of the program.

2) *Economic model* transposes the respective human resources program in the language of the decision-makers of the organization, namely the economic ones. They want to know the investments the program involves, on the one hand, and the value of its effects, on the other. When in the human resources department, the economic effects of the expenses with the respective program cannot be calculated, which happens quite often, the top managers naturally cut down the human resources activities related budget. Therefore, a competent human resources manager should be capable to calculate the economic costs of the program, and also the economic effects, namely the additional incomes and/or reduction of expenses obtained as a result of the improvement of indicators, such as: absenteeism, delays, fluctuation, strikes, plans accomplished in due time, quality of activities, occupational accidents, accidental repairs, use of materials and stock reduction.

3) *Costs-benefits comparison* should lead to the conclusion that the latter are superior. Otherwise the program is not justified.

4) *The decision to continue, repeat or even change* the program involves four stages to be covered:

4.1) Description of all the programs alternatives (in operation or proposed), depending on the objectives, program costs and benefits.

4.2) Separate the human resources programs imposed by the legislation from the optional ones.

4.3) Feasibility assessment of each program according to criteria such as: complexity, qualified personnel in the human resources department or consultants' department, easy implementation, net economic benefits, risks.

4.4) Programs hierarchy in order of their necessity, the first being those required by legislation, which are allied irrespective of their efficiency. Optional programs are put in the hierarchy, according to the easy or difficult implementation, and their expected economic effects.

7. Conclusions

In conclusion, we can say that in conditions of increased competitiveness, the organizations will spend large amounts of money only for human resources programs, with clear costs and value benefits as a result of which the benefits are higher than the costs.

Discrepancies identified at an organizational level between managers and employees

Maria Magdalena Criveanu^a

^aUniversity of Craiova, Alexandru Ioan Cuza 13 Street, Craiova, 200585, Romania

Abstract

One of the major concerns of today's management is the harmonization of employee-management relationships. It is a known fact that one of the main sources of conflict at the organizational level is the discrepancy between the employees' expectations and those of the managerial staff. Thus, managers are increasingly involved in the relationship with the staff, wanting to identify possible inconsistencies, in order to prevent conflicts. As a consequence, the present paper aims at providing managers with an organizational analysis model in order to identify possible discrepancies between higher and lower hierarchical levels, in terms of organizational culture. In order to come up with the diagnosis in what the organization is concerned, we have used in our research a tool for assessing the organizational culture, which records the choices that the members of the organization have made. The data is then processed by bearing in mind the two categories, which are employees / managers, then interpreted according to the scale of points assigned to each organizational dimension. This will give us a dual representation of the organizational culture for the two categories, namely, employees and managers. The end of the paper provides with an assessment of these data, giving solutions to improve or even suppress these discrepancies.

Keywords: organizational culture, leadership, organizational conflict, managers.

1. Introduction

In the context of a labour force crisis, triggered mainly by the employee migration from the private sector to the state sector as a consequence of some favourable actual regulations of this sector, the managers are striving to develop a series of tools meant to offer an explanation regarding the employees' lack of satisfaction with the private sector. Of course, one of these complaints are related to the organizational conflicts, which are usually generated by the cultural discrepancies between the employees and the leaders. In this respect, we have analyzed the dimension *Organizational leadership* within a private company from Craiova whose main area of activity is the distribution. Thus, the people who were involved in this study have answered a series of questionnaires that evaluate the organizational culture by mentioning both the actual state within the company, but also the state they aim at. The questionnaires have been divided into two categories of wage earners, managers and employees, and the results have also been interpreted in a different way by bearing in mind this division. In this way, we were able to analyze both the discrepancies between what the employees regard as being valid in what the leaders are concerned, but also the situation they strive for, which means the path that the members of the management could follow, but also the board's opinion regarding the actual leadership and the one they want to achieve. In this respect, we have used a tool in order to evaluate the organizational culture (Organizational Culture Assessment Instrument - OCAI), which belongs to the two specialists, Kim Cameron and Robert E. Quinn, who have identified the 6 dimensions one should approach when shaping a full cultural profile. The 6 dimensions refer to: Dominant Characteristics, Organizational Leadership, Management of Employees, Organization Glue, Strategic Emphases, Criteria of Success.

The first part of the study aims at identifying a cultural type in what the dimension *Organizational leadership* is concerned. This dimension is analyzed both from the employees' perspective, as well as reflecting the status of the individuals who have a leading position. The role of this division into two wage earner categories, managers/employees, is that of pointing out some potential inconsistencies between what the employees regard as being something dominant within the organization and what the managers think the specific culture is. The leading style is a specific element, because the leadership is increasingly significant when it comes to organizing the activity of the private companies. This study has counted with the answers of 50 subjects, out of which 12 have signaled that they have a leading position within the enterprise, whereas the rest has rendered itself as normal employees.

2. The hypotheses of the scientific research

Throughout this study we have borne in mind also the validation/ invalidation of the following scientific hypotheses:

Hypothesis no. 1: When it comes to the dimension *organizational leadership*, there is a conflict between the employees and the managers, because the two categories of subjects tend to identify two different types of culture for this dimension.

Hypothesis no. 2: The culture identified by the employees will be the market type one, whereas the culture pointed out by the managers will be the clan oriented one.

Hypothesis no. 3: The employees strive for a clan oriented culture, a human resources oriented culture, thus claiming that they need the managers' attention.

Hypothesis no. 4: The managers aim at a hierarchy oriented culture because they assume that the more strict, formal and organized environment from the public sector is important for the personnel's stability and therefore that the harsher rules forestall the migration from the public sector towards the private one.

3. The Dimension of the Organizational Leadership viewed from the managers' perspective:

Before starting to analyze the results that we have come up with, we will briefly describe the 4 types of culture, i.e. the clan oriented culture, the hierarchy oriented culture, the market culture and the adhocracy oriented culture.

The clan oriented culture: The leaders are seen as mentors or even as fatherlike figures.

The market culture: The leaders are regarded as being strong, productive and competitive managers. The managers are firm and strict.

The hierarchy oriented culture: The leaders are perceived as being good coordinators and organizers, efficiency oriented. Their purpose is that of maintaining the organization at a constant level.

The adhocracy oriented culture: the leaders are innovative, willing to take risks.

The dimension *Organizational Leadership* stresses out how the organization's leaders are perceived, the way they behave towards their employees and which their perception regarding success is. By analyzing the results that we have come up with after having interpreted the questionnaires, there can be noticed that, the opinion of the subjects who are at a high hierarchical level, which means, they have leading positions, is that leaders are innovative and willing to take risks (the adhocracy oriented culture has registered 35.00 points). They are, at the same time, competitive, productive and good managers (the market culture has 30 points).

At a lower level, they are regarded as good coordinators and organizers (the hierarchy oriented culture has 20 points). At a lower scale, the leaders are regarded as being mentors or fatherlike figures (the clan oriented culture has 15 points). This points out that, for this dimension, the discrepancies between the wanted culture and the actual one don't register higher differences than 10 points or even this value, thus this does not require an increased attention in any of the 4 situations. The clan oriented culture has registered a positive increase of 5 points, whereas the market culture has a decrease of 5 points. The adhocracy oriented culture and the hierarchy oriented culture have registered no changes. (as you see in figure no.1).

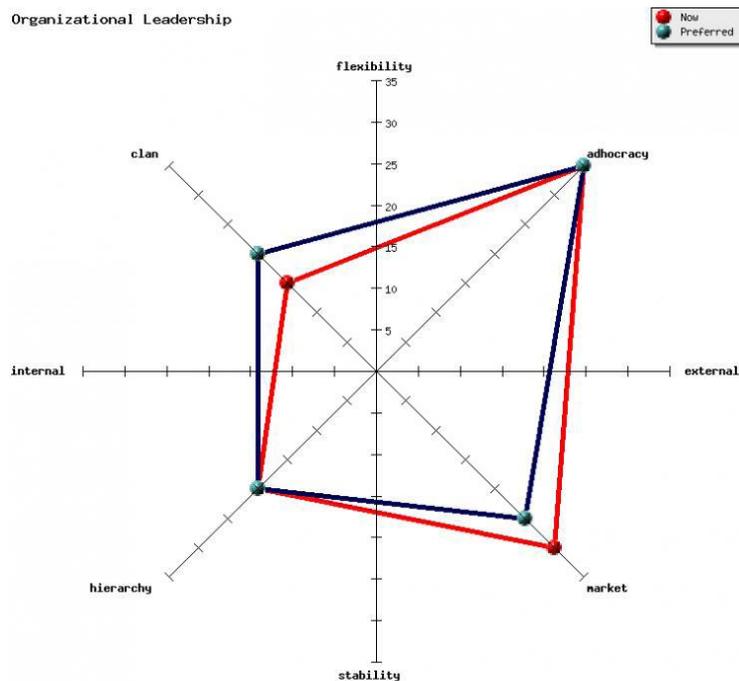

Fig.1. Organizational Leadership Dimension viewed from the managers' perspective

4. The Dimension of the Organizational Leadership viewed from the employees' perspective:

By analyzing the same dimension, but from the employees' perspective, there is a different situation in what the identified type of culture is concerned. The employees regard the leaders as being strong, productive and competitive, but, at the same time, also as being firm and strict (the market culture has the highest score - 50 points). When referring to the wanted situation, there is a significant difference regarding this type of culture, which means a decrease of 30 points, a wish to improve, even to supersede these features. Such a difference points to a way too high disparity between what the employees experience as being the actual organizational climate and what they really want. The adhocracy oriented culture has 30 points, and not 35 points as in the managers' perception, the latter ones have also mentioned features such as creativity and willing to take risks. Also in this case there is a tendency of improving this predisposition, sometimes the risk is considered to be a threat against the employee and the job reliability. The hierarchy oriented culture has only 15 points and thus the concepts of stability, reliability, of being something permanent do not shape the leader's profile, whereas the clan oriented culture is almost invisible. At this level also there is a difference of 45 points between the actual and the wanted state, a difference that urgently requires the managers' interference because it is an obvious source of conflict.

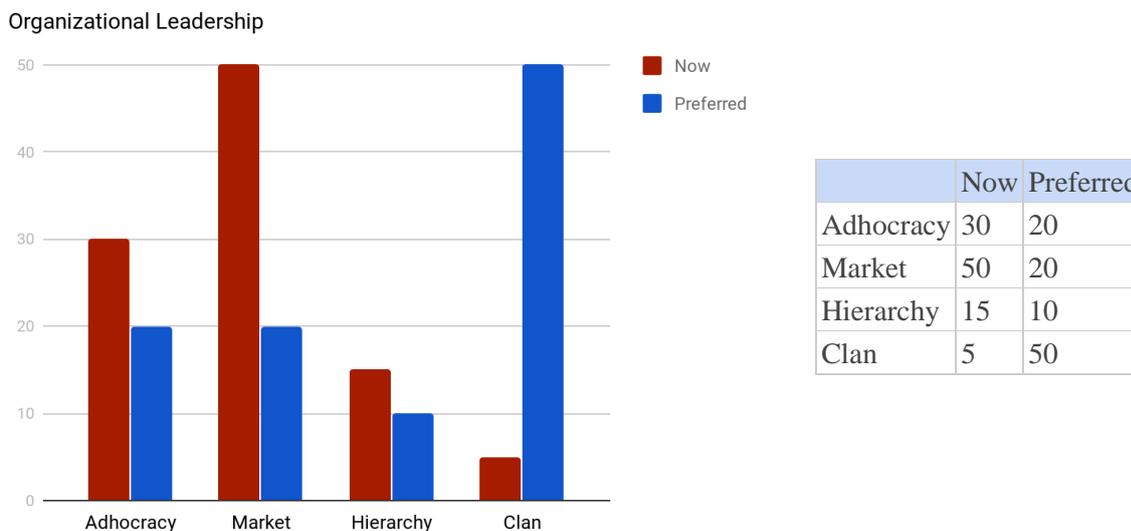

Fig.2. The Organizational Leadership Dimension viewed from the employees' perspective

5. The validation of the hypotheses of the scientific research

Hypothesis no. 1 is totally valid, the two categories of wage earners have different visions regarding the leaders' behaviour. Hence, if, in the employees' opinion, the leaders appear as being firm and strict, (the market culture is the dominant one) they will consider themselves rather as being innovative and willing to take risks (the adhocracy oriented culture mainly shapes the leader's profile).

Hypothesis no. 2 is partially valid, the employees render the market culture as the dominant one, but the managers accept the low interest towards the human resources or towards the creation of a familiar environment, by rather stressing out a competitive climate.

Hypothesis no. 3 is totally valid, the employees claiming that they need an increased attention from their managers, who, being dominated by a high trade sense, ignore the significance of the human resource and become the prey of the desire to make profit.

Hypothesis no. 4 is not valid, therefore there are no significant discrepancies between the actual situation and the one the managers strive for. The adhocracy oriented culture has not registered any changes and it is still considered to be the best attitude the managers could have.

6. Conclusions and recommendations

As a conclusion, with the help of this analysis we have identified the existence of a conflict within the organization, a significant unease pointed out by the employees, but also some disparities between the perspectives of the two categories (employees and managers). Hence what can be noticed is that the actual situation within the enterprise is perceived differently by the higher hierarchical levels, where the managers render themselves as innovative, autocrat, ambitious, whereas the lower hierarchical levels regard them as firm and strict. But the most important source of conflict is not the actual situation, but the situation the enterprise is striving for. If, from the leader's perspective, the situation is accepted, tolerated and even still wanted, the differences between the two states being insignificant, things are different from the employees' perspective. Not only they identify a different type of culture, but the major source of conflict is the dissatisfaction degree with the actual situation. The employees reprobate the authoritarian leading style,

whose main purpose is the profit, the clients and requires an increased attention in what the employees' needs are concerned. Taking this into consideration, it is recommended that the managers notice these disparities and take into account the employees' perspectives, especially when confronted with such a labour force crisis. Because the public sector offers its employees a series of indisputable advantages, such as the job reliability, continuity, a stable schedule, stability and even motivating incomes, the statistics showing that the incomes from the public sector are higher than the ones in the private sector, a change of attitude and perspective is required in order to annihilate or, at least, to improve these negative aspects. Probably one of the aspects that the public sector does not take into consideration refers precisely to the close attitude between the employees or to the familiar environment which is not specific to state institutions. This aspect must be speculated on by the private environment that can compensate these disadvantages by showing an increased interest and attention in what the employee is concerned.

Taking this into account, the manager who is supposed to make the change must have as the center of his preoccupations the human resource and therefore to identify its needs and potential ways of complying as efficient as possible with the employees' requests. A lot of private companies gamble on the relationships between the co-workers established within the enterprise, but also on the relationships between the employee and the manager, because they act as a bond, as a connection between the employee and the enterprise, thus ensuring a sustainable and stable relationship. In this respect, the manager stands for communication, for solving conflicts through negotiation, for the cancellation of the borders between the higher and the lower hierarchical levels, for the team work, for the organization of social events which act as an integrating myth.

Hence, the first step takes place when the managers admit that there is a need for change, then try to implement the way the company is going to follow in order to achieve this change. A pertinent example refers to setting up team buildings, where the employees will acquire new skills or knowledge, where they have the possibility of knowing each other better, of creating social connections and of cooperating in order to solve some tasks, because team buildings are usually organized based on common activities. Another significant aspect is connected to identifying a leader for these activities who manages to make the teamwork and encourage it, thus contributing to the annihilation of the borders between leaders and employees because when it comes to such activities the leader status is gained through the presence of a series of indisputable capacities and not through the stiff higher position within the organizational chart.

What counts as another important aspect can be the increased attention shown to the signs and symbols, the rituals and the myths, that contributes to the shaping of an inner and outer organizational identity. The employees end up accepting these elements as their own and will form a powerful culture, which will prevent the surfacing of certain negative phenomena such as the migration and will cause the group to fall apart. The participatory management contributes to the annihilation of the differences between the two categories of wage earners, therefore making decisions together is a good way to involve the personnel in the company's activity, to offer them attention trust and even to provide them with a series of responsibilities.

At the same time, managers refuse to invest in the human capital any longer, because they regard the investment as useless when the employees leave the company and the possibility to recover the lost investment is basically non-existent because of the increasingly higher personnel mobility. On the contrary, such investments increase the degree of involvement the employee has, because he achieves new knowledge and it becomes more productive, and the investment is regarded as a way of agreeing with his skills, but also as a proof of the increased attention whose beneficiary the employee is, which is exactly what they claim as being necessary in order to improve the cooperation.

Changing the organizational culture will also imply benefic effects in what the whole activity is concerned, thus annihilating a series of negative effects such as absenteeism, not being willing to work overtime when necessary, but also the improvement of the efficiency and efficaciousness through involvement.

Advances in Occupational Ergonomics and Risk Management

Sabina Irimie^{a*}, Adrian Lucian Pal^a

^aUniversity of Petrosani, Universitatii street, No. 20, Petrosani, 332006, Hunedoara

Abstract

Quality of life in the workplace implies the well-being of employees. Lately, the expression "happy employees" has become more and more common and it is a concern of the inseparable relationship between employers and employees. This paper aims to present a new model of ergonomic risk assessment in the field of automotive industry, field with a significant weight in Romania. The challenges of such an industrial branch in terms of designing the workspace or setting it up are significant, because in many companies at national level there are no specialists to assess the worker and the place where he performs the work task, based on the concept of security process and rules, and the ergonomic aspects of the workplace.

The goal of this paper is to sensitize specialists who, in the future, using the results of an assessment of the ergonomic risks on which is subjected the worker from the assembly line/rubber processing machine operator in the automotive industry, can be identified the level of risk associated with aspects of this industrial area and measures to improve the workplace can be proposed to increase productivity and eliminate or minimize present risks.

Keywords: occupational ergonomics, ergonomics risk, risk management

1. Introduction

Wellbeing at work, which is one of the world's main concern in terms of both occupational safety and health and ergonomics, and has consequences both at the organizational, individual and ultimate levels of society. This aspect was also highlighted by the 7th International Ergonomics Conference ERGONOMICS 2018 from Zadar, Croatia, which took place in June 13-16, 2018 under the title "Emphasis on Wellbeing".

Many specialists (Felce and Perry, 1995; Danna and Griffin, 1999; Diener, 2000; Waddell and Burton, 2006) defined well-being as the subjective state of being healthy, happy, contented, comfortable and satisfied with one's quality of life. It includes physical, material, social, emotional ('happiness'), and development & activity dimensions.

Recent global approaches reflect these concerns by focusing on integrating occupational safety and health and ergonomics into applications and models for improving the quality of work, designing or creating a healthy workplace and eliminating or minimizing the risks associated with exposures to the poor working environment, the non-economic working conditions and the psychosocial, psychosomatic, cognitive environment, etc., concerns that once neglected inevitably lead not only to deficiencies in the production rhythm but also to the occurrence of musculoskeletal disturbances or disorders. All this results in economic and social losses.

In Romania there is no national legislative basis for the development of workplace wellbeing activities or a model established among communities in the field of public health, safety and health at work. The concept is known only by occupational health and safety and human resources specialists. There are different work patterns applied differently in some companies (health education - collective sessions, health education - individual counseling, fitness center, etc.). Also, the profession of ergonomist appeared only in 2017. (Irimie et al., 2017; Boatca et al., 2018)

Experts Anttonen and Räsänen (2008), Hämmäläinen (2007) knowing that one of the common goals ergonomics and safety and health is well-being, have analyzed at European level if the legislation mentions this concept and if it is implemented. The results of the study are presented in Table 1.

The main ergonomically specific risks, the working situations from the assembly lines characteristic of the automotive industry and a new assessment method are presented below.

2. Ergonomic risk assessment

“In line with the EU Strategic Framework on Safety and Health at Work 2014-2020, one of EU-OSHA’s priorities is to support the prevention of work-related diseases. The aim is not only to improve the lives of individual workers, but also to minimize the costs of work-related illnesses and deaths.

The number of workplace accidents has decreased by 25% over the last 10 years. However, work-related diseases still account for an estimated 2.4 million deaths worldwide each year, 200,000 of which are in Europe.” (EU-OSHA, 2018) According to the observational epidemiological study program worldwide Global Burden of Disease Study (GBD) 2010, work-related musculoskeletal disorders are the second major cause of global disability and have risen by 45% worldwide, being considered the main cause of pain and long-term disability in the world, (Byl et al., 2016). Since then, in all reports of the EU-OSH, musculoskeletal disorders are still the first and the automotive industry has many jobs with such risks. (EU-OSHA, 2010)

In Middlesworth's view, risk factors are grouped into two categories, ergonomic risk factors and workplace specific risk factors. Extensive exposure to ergonomic and individual risk factors leads to musculoskeletal disturbances or disorders. (Figure 1) We can also mention ergonomic risk factors lack of education in this field, which also determines the manifestation of individual risk factors.

Fig. 1. Risk factors that lead over time to musculoskeletal disorders
Source: Middlesworth, M. (<http://ergo-plus.com/musculoskeletal-disorders-msd/>)

In the specialty literature it is recommended that the risk management process be integrated and adapted to the culture, practice and organizational activity. (Figure 2)

Figure 2 exposes from the perspective of risk management, the logic schema of the risk management process, and figure 3 presents the logical schema of the risk management process from an ergonomic perspective.

In terms of risk assessment, this is defined as "activity identifying risk factors for injury and/or occupational disease and quantifying the level of risk of a workplace/workstation." (Mohanu, 2015)

In order to identify the ergonomic risks on which rubber processing machine operator in the automotive industry is subjected, an ergonomic risk assessment model was used, proposed by the University of Washington Ergonomics Laboratory, Department of Environmental and Occupational Health Sciences of the School of Public Health.

There are two approaches to initiating an ergonomic risk assessment: proactive and reactive. In order to implement an ergonomic risk assessment, there is a need for coordination and teamwork, aspects that ensure that the evaluation process is carried out in a systematic manner. (Department of occupational safety and health ministry of human resources Malaysia, 2017)

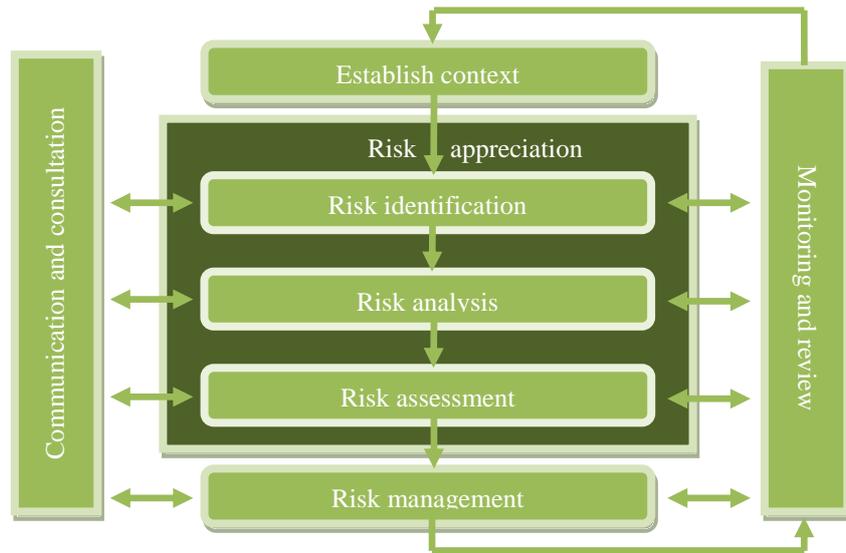

Fig. 2. Risk management process
Source: Moraru, 2017, p. 10

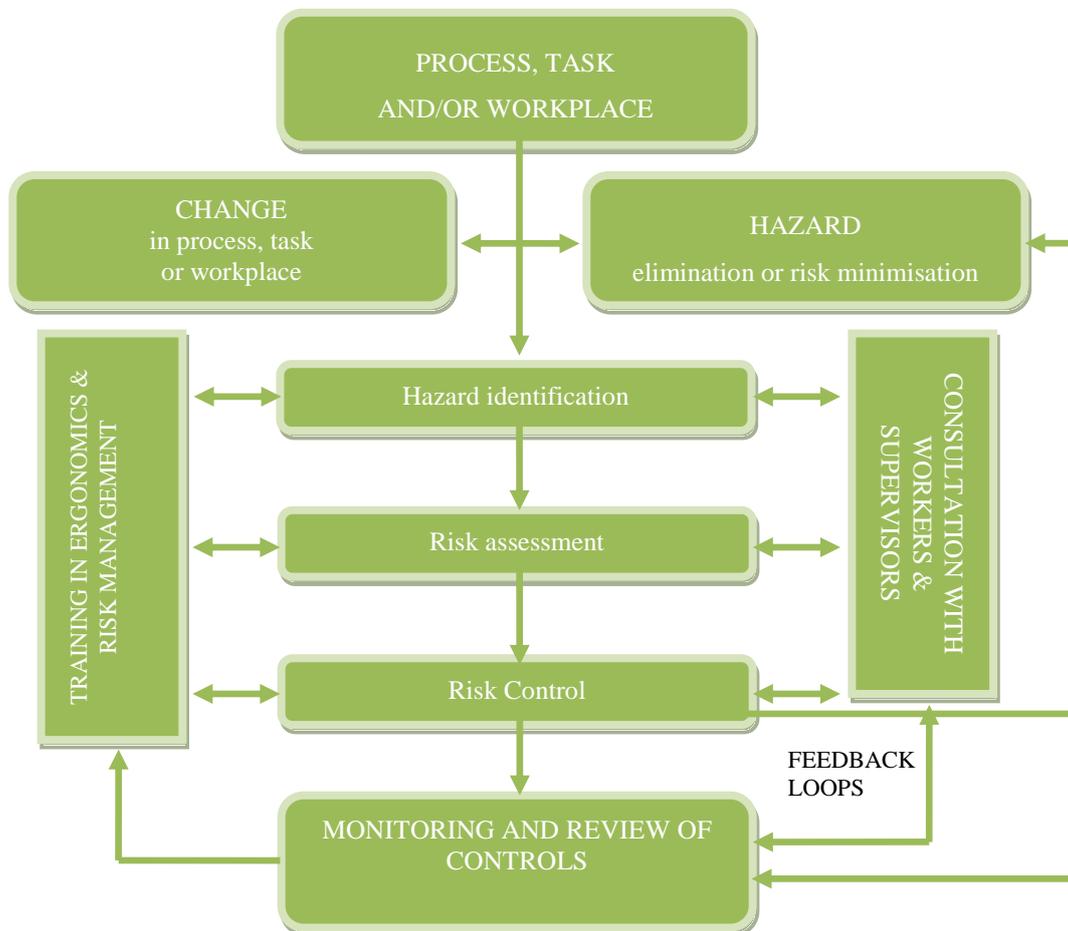

Fig. 3. Ergonomic risk management process
Source: Scott, P., Kogi, K., McPhee, B., 2010, p. 37

Person responsible for leading the evaluation team must be a trained person, a person in charge of the overall evaluation management. In order to prepare an ergonomic risk assessment, consideration should be given to team training, tools, materials and facilities, communication and coordination.

Initial ergonomic risk assessment sheet (table 2) is a dated and assumed document developed at the ergonomic risk assessment initiation stage addressing the aforementioned issues as well as risk factors reported through the proactive approach inspection.

Table 2. Initial ergonomic risk assessment sheet

Task: Tire manufacture		Task description: The rubber once manufactured reaches the “Building / Confections” location, where it is processed using machines in different sizes, depending on the manufacturing process stage. The tire maker, in the first stage of the manufacturing process, uses a three-layer folding machine (tire strap) on the inner skeleton of the tire. The worker must always ensure that the machine is operating at normal operating conditions, take measurements to ensure that there are no deviations from dimensions or gaps, ensure that the machine is continuously fed with rollers containing thin rubber strips, textile strips and metal strips. The task is completed when the tire, at this stage, is sent on the line to the next worker. The worker performs the work load alternating between the orthostatic position and the sitting position. In order to carry out the work load the worker uses his hands in most cases.

As can be seen in the initial ergonomic risk assessment sheet, the first instruments of action used are the evaluation and the exposure scores sheets. Two of them are used for the evaluation, one for the observer's assessment, and the second for the worker’s assessment.

The observer's assessment sheet is structured into five sections for each section, selecting only one of the associated situations, situations that concern aspects related to the following body areas of the worker: back, shoulder/arm, wrist/hand and neck.

The worker’s assessment sheet is structured on eight sections, just like the observer's assessment sheet, selecting only one of the associated situations. In this case, it should be noted that the “environment” that is spoken in Section Q, in fact, means the stressors specific to the organizational environment (temperature, lighting, noise, etc.).

The scores obtained through the assessment made using the evaluation sheets and the exposure score sheets should be used for:

- Determination of the comparative exposure levels for each body area;
- Identification of the areas where the exposures are highest and concentration of interventions on such areas.

Assessment of the observer and worker, respectively the calculation of the exposure scores, for the situation of the operator in the rubber processing is presented below.

After the exposure scores have been calculated, the next step in the ergonomic risk assessment is the identification of the ergonomic risk level for each section using the risk assessment matrix (Table 3).

Following the interpretation of the scores obtained in table 3, for the first four sections, a low risk level was obtained for the “back” and “wrist/hand”, and for the “shoulder/arm” and “neck” the risk level is moderate. In order to better observe the classification of the scores obtained in the risk levels, the following four graphs were made for the first four sections (Figure 4).

Table 3. Risk assessment matrix

Risk assessment	Low	Moderate	High	Very high
	Evaluation scores			
Back	10-20	21-30	31-40	41-56
Shoulder/Arm	10-20	21-30	31-40	41-56
Wrist/Hand	10-20	21-30	31-40	41-56
Neck	2-6	7-10	11-14	15-18
Stable base/Driving	1	4	9	-
Vibration	1	4	9	-
Work pace	1	4	9	-
Environment	1	4	9	16

Source: adapted from <http://depts.washington.edu/wineryhs/Resources.html>

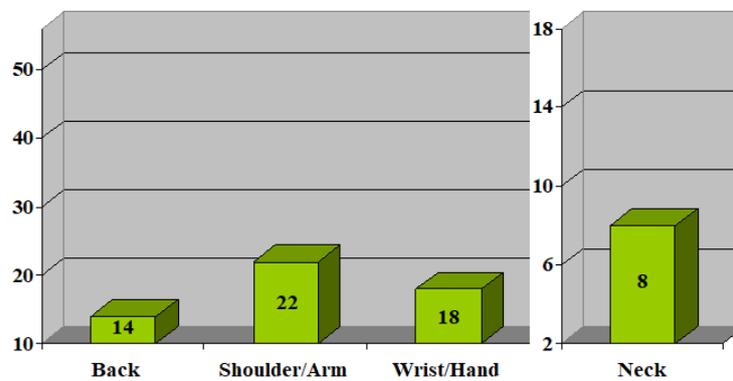

Fig. 4. Level of exposure scores for back, shoulder/arm, wrist/hand and neck

In the case of the last four sections, the level of risk obtained is low for “driving” and “vibrations”, and for “work pace” and “environment” the risk level is moderate. As for the first four sections, a graph was created for the last four (Figure 5) to observe the scores obtained in the risk range.

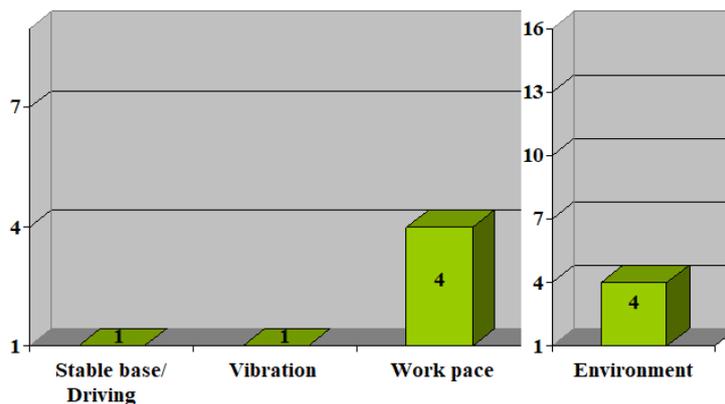

Fig. 5. Level of exposure scores for driving, vibration, working pace and environment

It can be seen from the interpretation of the scores obtained for each section, that the maximum ergonomic level at which the rubber processing machine operator is subjected on which this assessment was made is a moderate one.

It should be kept in mind that the moderate risk level with respect to the body parts of the worker is present at the shoulder/arm and neck, which confirms what was noted in the initial assessment sheet as a risk factor observed in the inspection carried out in order to initiate the assessment.

The “wrist/hand” section should not be neglected, even if the risk level is low in this case, the value of the scores obtained for this section is at the upper limit of the value range for this ergonomic risk level.

Compared to the “shoulder/arm”, “neck” and “wrist/hand” body parts, which could have been identified as ergonomic risk factors following the inspection to initiate the assessment, there are also issues that could not be identified as a result of this inspection. The “work pace” and “medium” sections with moderate risk levels can not be assessed in the initial phase by inspection, but only identified and interpreted by evaluating and calculating the scores obtained

Conclusions

The conclusion is obvious, the need to increase the quality of wellbeing at work. Therefore, there are at least two major national challenges in this area. One of the challenges, since in most enterprises there are no ergonomic, health and safety professionals to carry out an assessment of the ergonomic risks associated with the workplace with a view to proposing and subsequently implementing the improvements for a job reduce or eliminate the risks associated with the industrial fields in which they operate, or instruct workers on exposure to such risks.

The second challenge is to improve legislation with ergonomics and well-being stipulations in organizing workplaces and companies, in general, to achieve the goal of "happy employees".

Minority in the Middle East: The Monotheists "Druze" in the Middle East, changes and competes

Mansour Radwan^{a,*}

^a West Timisoara University- Romania

Abstract

This article is intended to reflect on a comparative descriptive study the changes that have taken place in the community of the monotheists "Druze" throughout their history. Although this community was a relatively small minority living inside or outside a stronger majority and sometimes-hostile society to them, they continue to survive in contrast to the forces that acted against them, and did not assimilate into another population. The study examines phenomena in the monotheist "Druze" community. Some of their specialties and uniqueness, and includes the following fields : social changes over their history, the transition from a traditional society that lives in a closed circle to modern and semi-modern society, what remains and what has changed in its traditional society. Changes in the scope of marriage, the interaction between this community and the State of Israel over the years, social and historical aspects. Changes in education, in employment, in social and historical expressions of solidarity and social coherence among the monotheists "Druze" community. Religious customs, the monotheists "Druze" woman and her status in comparison with other communities. The monotheists "Druze" migration over history and its social implications in secularism. Religion, concept of the individual versus the collective, hatching in solidarity, grinding in status of clergymen, parents, and their crisis of identity. The purpose of this study is to point out and identify unique phenomena of this little community survival, to examine them over time and to compare them to other communities, to reflect on its status, to predict and point out its future directions.

Keywords: monotheists "Druze"; modernization; women status in Druze society; religion; isolation.

1. Introduction

The monotheists "Druze" lived in isolation on top of the mountains and kept the solidarity among themselves in various areas and among others in the Middle East. In this manner, the community existed as a special category, which has its own cultural, historic and ethnic basis distinguishing it from the Arabic and Jewish population. Although the monotheists "Druze" do not have a national state, they did manage to survive and keep an ethnic, religious, cultural and geographic uniqueness (Sofer, 1998 from Dana, 188-192). After the establishment of the state of Israel, the monotheists "Druze" chose to be part of the geopolitical-national entity. Although they are not part of the majority's nationality. On the other hand, they did not abandon their cultural legacy, did not assimilated and continue keeping religious isolationism and independence. The law of compulsory recruitment to the IDF was applied on them in 1956, and they were integrated in the Israeli security system. This recruitment deepens their differentiation and brought changes to the society of the monotheists "Druze. Even they have the Arabic as mother language like other minorities. (Halabi, 2009: 50). This change, push the modern world to find its way to the village's residents with new ideas that are strange to the monotheists "Druze", reduced to a higher education among this community's members (Hassan, 1992). Their localities began go through changes and urbanization and modernization processes, economic, occupational, physical and other changes in addition to geographic, political, social and religious changes. All those deepen the differentiation of the monotheists "Druze" and shaped specific category of their localities. But, simultaneously, kept the "selective modernization" model, in which they adopted new structures and values besides keeping the existing "traditional" systems in sort of instrumental functioning pattern. Their life in a social closed circle does not accept the other into society, marriage is internal endogamous, in the localities of the monotheists "Druze" and between localities in different areas. First, marriages were in the clan and between relatives. All land and assets were kept inside the relative's circles and strengthened the sense of belonging and solidarity between relatives and against external forces. The husband

* Mansour Radwan. Tel.: +972506810631;
E-mail address: radwanmans1@gmail.com

monotheist "Druze" calls his wife "My cousin" and it is not accidental. However, the phenomenon of relatives' marriage is common in many places in the world and is not necessarily unique to the monotheists "Druze" (Ladislav, 1989: 1).

Later, due to the clan's size and the localities' expansion, a distribution process started of concentrated building of the clans that brought a process of households' dismantling, economic independence and an individualization processes that is a part of global modernization. The marriage between clans strengthened blood ties, primordialism between clans and among the community members in localities. In addition, it created and strengthened large branched social networks of relatives on various levels of proximity. These connections strengthened the mutual guarantee and assistance, the solidarity, identification and sense of belonging within the community members in different areas. This is also not a unique phenomenon of the monotheists "Druze" and there are additional examples in the world (Osterreich, 1965:144). These blood ties who reside in a community in a close social circle, created an endogamous system of marriage, which strengthened members' solidarity. Furthermore, the sense of social bond, development of significant relationships and some even interpret it as blood brotherhood, (Brain, 1976). An additional process that took place in these localities was integrating immigrants, whole clans, immediate families and singles. In the 12th, 15th and 16th centuries, for example, lots of Druze immigrated from the Lebanon mountain, "Wadi a-teem" in southern Lebanon and Jabel Al-Aa'la in the Hallab area in Syria (Firro,1992:31-34).

This occurred as a result of an economic need and security reasons. Therefore, many Druze settled in Israel, specifically in the Upper and the Lower Galilee and in Carmel Mountain. The civil war in Lebanon in the 19th century encouraged an additional immigration, including the Maronites and the monotheists "Druze" that made entire clans follow even whole villages from the Lebanon Mountain to the Druze Mountain and to the land of Israel (Falah, 2000: 29-33). In the second half of the 20th century, many of the monotheists "Druze" from Syria and Lebanon searched for employment in Saudi Arabia and in the Persian Gulf countries. Others chose to immigrate to Europe, North and South America and to Australia (Saleh, 1989: 13). There were also immigrations to Canada, Brazil, Argentina, Venezuela, African countries, Western Europe, England, France and Germany (Halabi, 2009: 51-52). In Israel, by a multi-annual view, the number of students among the monotheist "Druze" increased within a decade and a half, between 2000 to 2015, to 2.98 times and almost tripled. Those that studied for a BA degree were 90% and 7.2% studied for a MA degree. Another change in 2010-2015 was an increase in the number of Master's degree graduates by 2.79 times (the CBS 2017/106). The generation that lived in the time of the establishment of the state of Israel showed loyalty to the state unconditionally and without reservation. However, the next generation was different as this was. This generation stopped being like the Jewish population and returned to reestablish and rebuild ethnic identity. This was like the transition stages described in the Helms model who researched the ethnic identity of black people in the United States (Helms, 1990). Unlike modern society, that leaves space in behavior norms and values related to life events including loss, it has no clear expectations; no clear and defined behavior rules and, it is in a state of lack of clarity (Granot, 1985: 90). The mourning customs fulfill the needs of the mourners and emphasize the intensity of solidarity from the community members' side. The relation of the monotheists "Druze" to death and mourning is special and different from other divine religious customs. For example, the body and life is treated as a transition phase. Life is described as a cloth which the soul wears and changes until its death (Talea', 2001:100). "Druze" believe in reincarnation, and the belief influences mourning customs and strengthens the internal solidarity and coherence among the community members.

2. Discussion of changes in the monotheists "Druze" minority society

The belonging of the monotheists "Druze" as a persecuted religious minority strengthens the mutual guarantee and solidarity among its members. The structure and religion institutes of the monotheists "Druze" shows a firm grip of legacy, identity, culture, religious leaders and the social structure. This also includes harmony, consolidation and solidarity among members. The religious structure is first expressed in the pray house "AL-KHLWA", this is intended to be a place of being alone with the soul and far from daily affairs. It is also to review and read religious books and pray to God. The praying houses are quite modest, without any distinguishing marks or prominence. The religious books must be guarded zealously. Each locality of village has a praying house and sometimes there is more than one praying house. Sometimes, in a hostile environment and beside the praying houses of the monotheists "Druze" community, members built Mosques in order to survive and integrate in the Islamic environment and there was an unforgiving attitude towards being different (Al-Halabi, 2008: 47-48). In addition to the praying houses, the monotheists "Druze" have sanctity places, which are religious public buildings in places where a prophet passed, lived or an eminent religious person was buried. Almost in every locality of the monotheists, "Druze" there is a sanctity place (Al-Halabi, 2008: 45-48). In a social aspect, with mutual support and guarantee, alongside with the solidarity of the monotheists "Druze", independent public institutions were established and managed. These included associations, and maintained contact between the community members around the world. In Lebanon, the council of research and development (1977) was established as well as the religious council to repel slander and offensive publication of images. This council operated to conduct statistics, publish books and researches related to history, faith, customs and traditions of the monotheists "Druze".

The women from the monotheists "Druze" community had many roles in the agrarian society. Some of these included sewing and harvesting, and covered about 60% of a family's food source for many years. This was until the sixties of the 19th century. (Taki-A-Din, 2007: 30-33). A woman has a lofty status that entitles respect, appreciation and a special status in family and society. The woman is a central figure in the household and even has been defined as the beating heart of the house. The woman is responsible for raising and educating the children in the family and manages the house and the farm (Al-Halabi, 2008: 87). Note that the prohibition of polygamy in the monotheists "Druze" community is one of the woman's empowering expressions. Since the mid-20th century, there was a change in the monotheists "Druze" society and the process of immigrating from the intimate villages to larger cities began in order to find a suitable livelihood for families. The father moved temporarily and started working in the city. Later, these families settled after emigration, integrated in the new society. This caused a distance from the tradition, customs and values in which the families had been raised in the monotheists "Druze" community. Another change was the reduction and abandonment of the extended family and a focus on the immediate family. This means, that the individual had become a priority and thus began the process of individualization as practiced in contemporary liberalization in modern society (Taki A-din, 2007: 44-45). Overall, the social status of women in the monotheists "Druze" community is far superior to in comparison to other religions. This is due to the attitude of the monotheists "Druze" towards women. There are quite a few cases of women who have been at the center of social-religious activity (Taki A-Din, 2007: 39-42, 134 and on, Abu A'zz al-Din, 1990: 312-322).

3. Summary

A visitor in the monotheists "Druze" villages sees a view of "white scarves like a group of pigeons arranged on the branches of a thick tree. Carrying scarves that hang from the head and wrap the shoulders and fall below the waist. There is refined clothing which are a pale color, these are clothes worn by an ascetic. It is a picture in which sincerity and spiritual beauty are deeply embedded, stemming from the pain of a soul that complements fate, surrenders to God's will and expresses both well-being and distress. It is a picture worthy of commemoration before it disappears from our memory" (Sa'eb from Dana, 1998: 199). Nowadays, when there is a semi ideological valuable vacuum and erosion of religious leadership, the white veil has slipped to the shoulders and sometimes even forgotten at home. The Symbolic White subtle colors have turned into a colorful, stylish and not modest look. Although there is spiritual beauty, there is physiological beauty and extravagant grace. The society of the monotheists "Druze" is in a transitional period from a being traditional which, used to be a patriarchal society, to a modern or semi-modern society without ideological anchors and without religious leadership. Thus, the secular moves towards secularism and nurtures one's intellectual and personal achievements. In addition, expands knowledge and education, wealth and assets, opens up to the world and constantly interacts with it. Moreover, asks questions of existential existence and identity, which do not necessarily have conclusive answers in intellectual sources. The life of the sons and daughters of the monotheists "Druze" in modern times is characterized by mental development, broad education, technological knowledge, improved quality of life, economic independence, and professional development of both men and women. On the other hand, it is possible to identify some distance from the original norms, customs, tradition and religion. These changes undermine social cohesion and identity formation among the younger generation in particular. The exclusivity of parents' education to the children has been severely impaired and the status as exclusive educators has been eroded in the face of environmental competitors.

4. Conclusions

The status of the monotheists "Druze" community is in significant changes from traditional to modern class. This transition has challenged the community with complex questions and identity problems. To a largely extent, distances of the young from religion and thus social solidarity cohesion are greatly enlarged. This has resulted in the young generation getting distant from the authentic norms. The values and customs have become a blind imitation of modern phenomena, submission to external influences and temptations. This includes, adopting strange behaviors to the community and in the absence of a communal dialect with the religious people, parents or qualified leadership and without guidance and educated choice. This causes the transition from traditional society to modern society to become more complicated. When the distribution of the population by age group and statistical data in Israel is examined on a regular basis each year. It is found that the vast majority of the monotheists "Druze" population is aged 30 and under (CBS 106/2017). Those aged 70 and over, have become a marginal minority in numbers and influence the social processes. The middle generation at the ages of 31-69 years is the parents' generation, whose status as educating figures and designers is significantly damaged. From all of the above, it can be concluded that the immediate and religious spiritual sources may be strong enough, but they do not approach all the individuals living in the monotheist "Druze" society. In the absence of access to sources and in the absence of deliberate and directing spiritual leadership, a situation arises in which there are many external influences. This sometimes it is not even understood how or why they were adopted. The result on the collective level is that the monotheists "Druze" do not know where to go. From the religious aspect, the woman is supposed to receive full protection, understanding, blessing and respect. However, the son and the husband because of distance from legitimate sources and religious laws often undermined this status (Za'eb from Dana,

1998: 121). From now on, it seems that more necessary than ever it is necessary to combine the monotheists "Druze" clergymen and scientists, with a concentrated effort to build integrated institutions that will bring together the segments of the "Druze" community to some uniformity. The role of these integrated institutions is to establish an intelligent discussion of the beliefs, principles and religion and adaptation to the modern age. In addition, this includes discussions regarding adults, youth and to working in the community according to an integrative built-in program. Moreover, directing the path of the monotheists "Druze" community to the design of its solidarity and communal coherence. Also, increasing awareness of the religious nature of the community and highlighting the foundations of ethnic identity that characterize the broadest common denominator of the monotheists "Druze".

Digital game – game or danger?

Mhana Khatib*

West Timisoara University

Abstract

Due to the centrality of digital games in the leisure culture of children and teenagers, it is especially important to understand the impact of violent digital games on this age group. A large part of the digital games, including multiplayer games that have become part of almost all types of users in recent years, include a main component of violence. This paper purpose is to examine the risks and dangers to children and teenagers from modern computer games. The complexity of the issue of risk perception in modern society and aggression are concepts that have been researched in the past. However, there are few researches of the changes in these perceptions due to the technological development of the internet, computer games, and the increasing use of it at home, especially by teenagers. It is very important to understand how children and adolescents perceive the dangers of computer games, how this affects their socialization process, since many theories dealing with health risk behaviors claim that the risk perceptions are a main and important component in shaping risk behaviors.

Keywords: Risk; Internet; Digital games; Compulsiveness; Aggression, Cyberbullying.

1. Introduction

Digital games are an integral part of the daily routine of children and teenagers. More than 95% of them spend a large part of their free time to it (Greenberg, Sherry, Lachlan, Lucas & Holmstrom 2010). Since many of the games contain blatant elements of violence, by the last few years there is an argument regarding the influence these games have on violent aspects of the personalities and behavior of the players. Due to the centrality of digital games in the leisure culture of children and teenagers, it is especially important to understand the impact of violent digital games on this age group. A large part of the digital games, including multiplayer games that have become part of almost all types of users in recent years, include a main component of violence.

Most teenagers in modern western societies use the internet and computer games in various places (home, school, friends) and on various devices (computer, tablet, cell phone). According to a survey performed in the United States in 2010, 84% of ages 8-18 have access to the internet from their homes, an increase of about 14% of the estimated home-based approach five years earlier, and it was also found that young people spend about two and a half hours a day using computers (Ridecut et al., 2010). In Europe, 60% of ages 9-16 use the internet almost every day, for an hour and a half on average, and the average age of joining is 9 years old (Livingstone et al., 2011). In Israel, 86% of ages 12-18 use the internet every day (Dror & Saar, 2012).

2. Risk behaviours on the Internet

The involvement of adolescents in dangerous behaviors is considered a natural and normal developmental phenomenon. According to the article of Greene et al (Greene, Krcmar, Walters, Rubin & Hale, 2000), there are two ways to look at this phenomenon: the first, as a normal developmental stage in which adolescents seek the appropriate behavior, and the second, as a negative by-product of cognitive development, i.e. egocentrism. According to the

* Corresponding author. Tel.:972528703828
E-mail address: mhana_ch73@walla.co.il.

normal / adaptive approach, involvement in risk behaviors is associated with a poor assessment of the risk in a given situation resulting from lack of maturity or lack of experience. According to the egocentricism approach, which characterizes adolescence so much, there are situations in which adolescents find it difficult to recognize the need for judgment since they are overwhelmed by feelings of lack of vulnerability and uniqueness. One of the arenas where the adolescent's misjudgement may lead them to behave dangerously is the internet environment. For example, their flawed consideration may cause them to reveal sensitive information about themselves, to bully others or to make contact with strangers. The unique characteristics of the internet - anonymity, asynchrony, lack of social clues, wide distribution, the distance created by the network, which reduces inhibitions and emotions of empathy, ease of operation and use, availability, absence of time and space limitations, infringement of home privacy and lack of supervision and control mechanisms (Valkenburg & Peter, 2011), all these may contribute to an increase in risk behaviors on the internet, to the expansion of the circle of children and adolescents participating in them, and to the exacerbation of behavioral outcomes. . Anonymity can stimulate impulsive behavior that can lead to the removal of inhibitions, aggressiveness, sending abusive messages, harassment and cyber bullying towards members of the peer group (Valkenburg & Peter, 2011). The asynchrony of online communication enables users to read, think, and change the messages they write before they are sent (Walther, 2007). This feature of communication technology can be used improperly by formulating messages so carefully that they become particularly painful to the recipient (Valkenburg & Peter, 2011). The high availability of the internet allows young people to communicate easily with others with malicious intentions and become a target for online sexual solicitation.

Valcke, Wever, and Van Keer & Schellens (2011) proposed a synopsis of the internet dangers to adolescents according to which the internet dangers are divided into three domains: content hazards, communication hazards, and commercial hazards. Content hazards refer to children's exposure to potentially harmful content (pornography, violence, racism, false information). Commercial hazards refer to the involvement of children in consumer activity, sometimes unconsciously, through games that include hidden offers for the sale of "brand communities" products aimed to young people in the internet and advertising of food and drink products.

3. Digital games

A digital game is an interactive program for one or more players, meant to provide entertainment at the least, and quite possibly more. An adaptation of 'traditional' game systems, with rules, player representation, and environment managed through electronic means. There are some definitions for it:

- Any game played using electronic device, either online or stand-alone.
- The result of the interaction of the player with an electronic system or computer is to be displayed via a display or similar display system.
- Is an interactive program enabling one or multiple players to engage with the content primarily for entertainment purposes.
- Popular form of entertainment and media use, which also offer possibilities for learning. Digital games are designed for play with e.g. a computer, videogame console, mobile device or interactive televisio.
- An electronic game in which players control images on a television or computer screen.
- Any game that is controlled by and displayed on an electronic device or computer.
- A computer game is a software program in which one or more players make decisions by controlling game objects and resources, in the pursuit of its goal.
- A set of challenging and/or novel experiences, scenarios, or decisions, structured by rules and/or goals, and mediated by a digital electronic device.
- A game whose system is (partly or wholly) implemented in a digital device such as a game console, a personal computer, a smart-phone or tablet.
- An electronic creation, recreation, or adaptation of a game; a type of play activity where the participants agree upon a set of rules that they follow and is decided by luck, skill, or strength.
- Digital games are play in single or multi-player games over the internet.

Violent contents have become common in digital games and the popularity of violent digital games increases when it contains many violent effects. Digital games can be played in a competitive or collaborative manner. In a competitive game strategy, players try to keep others from winning or getting a game resource. In contrast, in a cooperative game strategy, players help each other achieve a common goal, and the success of one player is the success of all. The influence game strategy on current player aggression after the game, findings show (Schmierbach, 2010) low level of aggression among players who have cooperated with others against the computer as a rival (cooperative mode) compared to those who played alone against the computer as a rival (solomode) and those who played alone against a

human rival (competitive mode), suggesting the possibility of reducing the level of aggression by adopting a cooperative strategy during a violent digital game

As for the effect of interaction between basic aggression and game strategy (competitive / cooperative), among low aggressors, the current level of aggression remains unchanged before and after the game, both cooperative and competitive, while among those with high level of aggression there was a decrease in the level of aggression in a cooperative violent game, compared to an increase in non-violent competitive game (Dubi, 2012)

Compulsive use of the internet is the pattern of internet use in general or in specific applications that cause disturbances in person's life, but does not imply illness or addictive behavior (Morahan-Martin, 2008). Examples of the characteristics of compulsive use of the internet are use which harms sleep, relationships with significant people, proper functioning in work or learning, and unceasing thinking about the next opportunity to connect to the network (Young, 1998).

Unlike compulsiveness of using digital applications that have an off-line version, like gambling, compulsiveness the using games is unique to the digital medium (Charlton & Danforth, 2007).

4. Aggression of players in violent digital games

The research literature relates to aggression of two different types: aggression baseline that is the trait of participants, while current aggression is violent behavior of the participant in a given moment. Aggression baseline is a multi-dimensional trait that includes four factors (Buss & Perry, 1992): physical aggressiveness, verbal aggression, anger and hostility.

Concerning the consequences of violent games on aggressive behavior outside the game, in the study of digital games, different theoretical approaches with contradictory predictions can be found (Bösche, 2009). General Aggression Model (GAM) (Anderson & Bushman, 2002) claims that exposure to violence in a digital media will necessarily lead to increase of the current level of aggression. According to the model, consumption of violent digital games increases violent behavior outside the game and reduces empathy, both in the short and long term (Anderson & Dill, 2000). Players who persist in violent games are characterized by high basic aggression (Bartholow, Bushman, & Sestir, 2006) and more forgiving attitudes towards violent behavior (Weber, Ritterfeld, & Mathiak, 2006) compared to non-persistent players.

Other researchers point also the positive side of violent digital games (Bösche, 2010). Some claim that violence in a digital game allows catharsis to release aggression harmlessly in the game environment and thus reduce violent behavior outside the game (Ferguson et al., 2010).

Cyber Bullying

Cyberbullying is defined as "behavior carried out through electronic or digital media by individuals or groups that repeatedly transmit hostile or aggressive messages with the intent to cause harm or inconvenience to others" (Tokunaga, 2010, p.278) it can be done in various ways, including sending an offensive text or images, prevention or exclusion from activities, threats, use of derogatory names and insults (Jovonen & Gross, 2008), and more. It is customary to divide the children involved in cyberbullying into three groups - network victims, cyberbullies, and witnesses (Treblus et al, 2011). There is a growing number of researches that speak of another group - victims / cyberbullies that grows rapidly. Moshna et al. (2012) report that 26% of the participants in the research belonged to the group of victims / cyberbullies. Li (2007) claims that the chance of being a victim of cyberbullying on one hand and cyberbully on the other is big and stems from belonging to an active social group whose members tend to harass each other in the group. This implies that cyberbullying behavior becomes part of the accepted behavior in the peer group.

The literature shows correlation between traditional bullying and cyberbullying, i.e. bullies in physical life tend to be cyberbullies, victims in physical life are also tend to suffer of cyberbullying (Talmud, 2013). Yabarra et al. (2007) performed a research among 10-15-year-old who reported that 36% of children experienced traditional bullying and cyberbullying, 13% of them of the same attacker. Another research found that 54% of the students were victims of traditional bullying, and a quarter of them were also harassed via the internet (Li, 2007). These findings indicate a continuum between bullying behavior in the real world and in the virtual world. The internet has become an additional arena of activity, but due to its unique characteristics (anonymity, distance that reduces inhibitions and empathy, independence of time and space, ease operation and widespread distribution), the number of participants - both attackers and witnesses - has increased since the digital environment allows children who have refrained from traditional bullying to engage in cyberbullying (Tokunaga, 2010).

Digital space allows attackers to more easily evade the consequences of their actions because children and adolescents avoid involving adults in their experiences for a variety of reasons. Adults are perceived as strangers in virtual culture and therefore the children fear that they will not understand them. The children also believe that bullying cannot be proven or that the attacker cannot be found, or they fear that adults, in order to protect them, will deny them access to the network and this is perceived by them as punishment (Mishna et al., 2012). Therefore, action to reduce the phenomenon should be carried out in the educational preventative level, which requires an understanding of the risk factors of cyberbullying.

5. Cases that took place in Israel during 2015-2017

1. Two teenagers from Jerusalem area got out to have fun, drank some alcohol, and on their way home bumped into a homeless man who slept on the bench in a public park. They asked a cigarette from the homeless, he didn't have any, so the teenagers decided to beat him with a tree plank they found in the park. They attacked the homeless man who is about 60 years old, seriously hurt him and left in the part till he died. The two teenagers were arrested later and claimed that from their point of view it was a game. The homeless man cursed them and they thought that, like in the computer games, they can hit him and "nothing will happen". The closer examination revealed that the two of them really liked violent computer games, and their behavior in front of the helpless person was a replication of their games' behavior. They did not pay attention to the fact the man was bleeding and needed medical help.

2. A boy 15 years old from one of the north villages decided to revenge on other pupil from the same class who did not help him on exam. He wrote a post telling the other boy loves "caressing". The excellent pupil got disturbed and bothered by other pupils from the class, who laughed at him and humiliated him. From the moment the post was published, he started deteriorating in his school achievements and sometimes preferred not to go to school at all. The parents were informed by the school authorities, the boy was treated by psychologist, changed the school and never got back to it.

3. A 15-years old girl who dated a guy who was 17 years old was taken picture when making sex, without her knowledge. The guy blackmailed her and threatened to publish the movie. The parents and authorities did not know anything about it till the girl decided to commit a suicide. She was rescued and then the story became known. A police investigation found the guy. He didn't feel any regrets. In his vision, there are lots of similar movies made all the time, so nothing wrong can be found in his actions. His lawyer argued that his client is innocent since he learnt from the internet- a place open to everybody.

6. The research method

In my research I used various tools. After an exploratory research, I performed a semi-structured interview. The interviewee was asked to tell about his experience of participating violent digital games and the personal process he goes in these games. A semi-structured interview is a phenomenological interview aimed at obtaining a detailed image of the person's world perception and belief in the examined subject (Fontana & Frey, 1994). The advantage of this interview is in its flexible and dynamic structure that enables freedom and dialogue between the interviewer and the interviewee (Bogdan & Taylor, 1984). The questions related to the following subjects: sense of belonging to the game group, the number of friends in the game context and the nature of the relationship with them, the compulsiveness of using the game (according to Young's criteria, 1996), and the expression of aggression in the game if exist. The goal of the interview was to ensure dealing with the subject and all its aspects, however, this flexible structure enabled freedom and dialogue between the interviewee and the interviewer when the interviewee was able to "speak out", to describe his personal experience as a player, lead the interview and raise points significant to him within the subject.

7. Research hypotheses

In this research, the author examined the research hypotheses that the interaction effect between the social (cooperative / competitive) context of the game and the basic level of aggression (low / high) of the participant on the sense of belonging to the game community, the number of members in the social network, and the level of compulsiveness of using the game will be found. Participants with high level of basic aggression will be more affected from violent competitive games than people with low baseline aggression.

The interaction effect between the basic level of the participant's aggression (high / low) and the type of game (interpersonal / group) on the sense of belonging to the game community, the number of members in the social network, and the level of compulsiveness of using the game will be found. Participants with high level of basic aggression will be more affected from violent multiplayer games than people with low baseline aggression.

8. The research findings

The findings of the qualitative research indicated that compulsiveness of using the game mainly depends on the player's personal factors rather than on the game design. Comparing the criteria of the questionnaire of compulsive use of internet (Young, 1996) with the interviewees' claims, shows there is a great similarity between the two cases in the symptoms of compulsive use of the game, as anticipation of the next login, discomfort when login is not possible, harming social connections or symptoms of compulsive use of games according to family members' report. Some of the interviewees showed the understand that this was compulsive behavior and tried to reduce the impact of the game on interpersonal interaction outside the network, while others preferred to associate the compulsive symptoms of other players. However, most of the interviewees described a similar process they have experienced when they started to play, they spent a lot of time playing, felt a difficulty in disconnecting from the game, and described situations in which the game took control of their lives. But as liabilities increased, their ability to regulate the time spent in the game improved. The game is a kind of substitute for interesting engagement and the escape to the game environment is growing and tends to be less controlled as the player has no other interesting alternative for leisure.

The findings showed that the compulsiveness of the participants is not a dichotomous but spreads on a scale in which on one end there are the players that explicitly referred the shift to limited use in violent game as a legitimate way to release pressure in the harmless game environment, while at the other end are players who describe their compulsive behavior and totally ignoring the negative consequences these games have on daily life.

Summary and conclusion

Therefore, it can be concluded that the collective - group game has an advantage over the competitive - interpersonal game in terms of increasing the sense of belonging to the game community. It is therefore possible to recommend players with a low level of aggression who cannot sense a strong sense of belonging to the game group in competitive strategy and in interpersonal games to play group games in a cooperative strategy so they could feel more belonging to the game group and to win more friends. In addition, the findings show that there is no fear that low-aggressive individuals will become compulsive players. On the other hand, players with high baseline aggressiveness should avoid or limit the use of violent digital games that may lead to compulsive use, although this can sometimes increase the circle of their friends, even if it is collective games or group games.

As for the implications of violent digital games on the behavior of the players in the game environment, we have seen that these games enable the release of negative emotions in the game environment according to the catharsis theory that claim that alleged violence in a digital game enables violence release in the game environment and thus reduces violent behavior outside it (Ferguson et al., 2010). According to the quantitative and the qualitative analysis it seems that the player's character has a decisive influence on the negative projection of violent digital games - players with a predisposition to aggression will play the game more obsessively than less aggressive players, mostly regardless to the type and strategy of the game.

Comparing the criteria of the questionnaire of compulsive use of internet (Young, 1996) with the interviewees' claims, shows there is a great similarity between the two cases in the symptoms of compulsive use of the game, especially according to a new meta-analysis, the level of compulsive use of internet in the Middle East is the highest in the world, when Israel is one of the four Middle Eastern countries that entered the analysis (Cheng & Li, 2014).

Change management process and its characteristics in schools

Sarsour Raed^a *, Sarsour Alaa^a

^a West Timisoara University- Romania

Abstract

Teachers know education does not stand still, and welcome thoughtful and coherent change that is in the best interests of students. Change will inevitably impact on teachers because the learning conditions of students are also the working conditions of teachers.

Educational institutions have more and more power to decide both on financial and operational matters. Who exercises this power in reality is therefore not insignificant. The opinions of leaders and principals are reflected in the decisions being made – some more than others. New opportunities have also brought about more and more responsibility for the effects of decisions and the relative weight assigned to different functions.

One of the most obvious changes currently occurring is the change in the relative global population distribution between countries. In the recent decades, developing countries became a larger proportion of world population, increasing from 68% in 1950 to 82% in 2010, while population of the developed countries has declined from 32% of total world population in 1950 to 18% in 2010. China and India continue to be the largest countries, followed by the US as a distant third. However, population growth throughout the world is slowing. Population growth among developed countries has been slowing since the 1950s, and is now at 0.3% annual growth. Population growth among the less developed countries excluding the least developed has also been slowing, since 1960, and is now at 1.3% annual growth. Population growth among the least developed countries has slowed relatively little, and is the highest at 2.7% annual growth.

With the global world changes, also the schools change, which makes it inevitable to change schools' management. School management has become an increasingly important factor in the education policy debate. As resources become scarcer while demands are growing, issues relating to management, leadership and principalship emerge in a new light. At the same time, the extensive nature of management becomes more prominent. School management is not only about administrative management but also about pedagogical and knowledge based leadership. Leadership and leaders still play a crucial role in terms of school development as well

The research was conducted in Arab-speaking schools in Israel. 200 head teachers participated and gave their opinion about the need and the possibilities of management change in school. The most of them are ready for changes and also claim the community is also ready. However, there are lots of administrative and organizational obstacles on the way of a true change. The field study came to the following conclusions and recommendations: There should be a policy in the Education Ministry that encourages the implementation of a new management in schools; Individual differences among school needs should be taken into considerations; The teacher should diversify from the methods of explaining the subject using the technology; Enough time should be given to head teachers to use management in education; The school administration should encourage teachers to use computers, telegrams and all means in education.

Key words: Change; Management; Process; Education; Teachers; Schools.

1. Introduction

One of the most obvious changes currently occurring is the change in the relative global population distribution between countries. In the recent decades, developing countries became a larger proportion of world population, increasing from 68% in 1950 to 82% in 2010, while population of the developed countries has declined from 32% of total world population in 1950 to 18% in 2010. China and India continue to be the largest countries, followed by the US as a distant third. However, population growth throughout the world is slowing. Population growth among developed countries has been slowing since the 1950s, and is now at 0.3% annual growth. Population growth among the less developed countries excluding the least developed has also been slowing, since 1960, and is now at 1.3% annual

growth. Population growth among the least developed countries has slowed relatively little, and is the highest at 2.7% annual growth (Bjørnholt, 2014).

With the global world changes, also the schools change, which makes it inevitable to change schools' management. School management has become an increasingly important factor in the education policy debate. As resources become scarcer while demands are growing, issues relating to management, leadership and principalship emerge in a new light. At the same time, the extensive nature of management becomes more prominent. School management is not only about administrative management but also about pedagogical and knowledge based leadership. Leadership and leaders still play a crucial role in terms of school development as well (Boikhutso, 2013).

Many researches study mainly concentrates on the last two decades, years of 1990–2010, changes that have influenced school management have definitely been made earlier. Changes in different decades can be viewed as forming a chain of changes, which has resulted in current school management. Based on doctoral research examining principals' operating environments, work, role and identity development over the last ten years, the chain of changes seems to have culminated during the last two decades (Burnes, 2004).

The operating environments and duties of principals of the 1980's and the 2000's are significantly different from each other (Risku et al., 2014). It can also be presumed that the chain of changes will continue and become even more intense. Based on these assumptions, many researcher looks for improving the enthusiastic characteristics of change management process in schools.

2. Discussion of the need for change in school management

This study presents some basics regarding change management and it does so from several perspectives, including those of change management as:

- (1) the task of managing change,
- (2) an area of professional practice,
- (3) a body of knowledge and
- (4) a control mechanism.

It also examines change management as a matter of problem finding and problem solving and it reviews some basic change management strategies and required skills.

Change management is one of the biggest tasks in which a business may be involved. It is a deliberate approach in the bringing major changes for meeting people's expectations to move the business forward smoothly (Cameron and Green, 2004, p. 65).

When the need for change arises, organizations and businesses have no option, but to respond— or else they will lose their competitiveness in the market. Burnes (2004): states that change management can support a range of change projects, including the implementation of a new process, new systems, updated structures, or technology – in the establishment of a new working culture or set of values in any particular area. Changes in society are changes in education, and changes in education change the place that the educational institutions have in the country, and that inevitably leads to changes in running and managing with the educational institutions. Changes in order to increase the quality of management towards improving the quality of educational services to the demands of the modern times. Only a modern management is appropriate to modern times. The director, as a lead character in the implementation of management in schools, has the responsibility of coping with the needs of modern times, setting goals and scoring in a high level, because living means solving problems, and growing means greater ability to solve bigger problems (Burnes, 2004).

3. Resistance to change

Often, there is unwillingness to change, both from the employers and management and the employees' side.

A long established assumption in the literature on organizational change is that resistance constitutes a problem. For example, in Coch and French's (1948) seminal study in a US pyjama sewing factory, employees reacted to being moved to different jobs by quitting, being absent, restricting output and showing hostility towards management.

It was concluded that this behaviour constituted resistance to the change and, accordingly, the study was designed explicitly to examine why people resisted change so strongly and what could be done to overcome such resistance.

This problematizing of resistance was then taken up by Lawrence (1954: 49), who argued that employee resistance to change was one of "the most baffling and recalcitrant of the problems which business executives face." Other studies followed, which also focused on overcoming resistance (e.g., Zander, 1950), especially in the Organization Development (OD) approach to change (Cummings & Worley, 1997).

Even processual and political approaches (Maurer, 1996), which criticized OD for failing to capture the "messiness" of change, explicitly acknowledged the strong possibility of resistance and treated it as something that needed to be overcome – an assumption which continues to be popular today.

Not surprisingly, studies went on to investigate the causes of, and solutions to, resistance. Causes were typically conceptualized in terms of shortcomings in an individual's attitudes, emotions and/or behaviors (Piderit, 2000).

For example, parochial self-interest led employees to resist because they focused on "their own best interests and not on those of the total organization" (Kotter & Schlesinger, 1979: 107).

Change is a firmly established priority for organizations. The 1980s and 1990s saw organizations experiment with TQM, customer service initiatives, reengineering, right-sizing, downsizing, culture change, and countless other managerial fads and fashions (Reichers, Wanous & Austin, 1997).

More recently, global environmental, technological and financial shocks have forced organizations to adapt and transform their activities (Bennebroek Gravenhorst & in't Veld, 2004; Bercovitz & Feldman, 2008). To realize such changes, it is commonly held that successful change requires the cooperation of employees, since any resistance on their part can hamper the change initiative (Piderit, 2000).

4. Experimental study in Israel

The sample of the study included 200 male and female head teachers who teach at school of Israel in 2018. The researcher selected them randomly from Arab- speaking schools. 55% of the sample were males, the rest- females, most with BA academic degree. Questionnaire for collecting information about "change in management" was developed based on previous studies dealing with the same subject. Surprisingly enough, most of the respondents (about 81%) agree there is a need for change in managing an Arab school in Israel. Most of them (60%) agree that head teachers are ready to accept changes and implement them in classes. Change management is a positive phenomenon in Arab schools- this is the opinion of most of the respondents (88%). However, less of them are enthusiastic about the school system ability to make changes- due to organizational, administrative reasons, but not social ones. No significant differences were found between males and females in their attitudes towards changes, neither were differences in answers of respondents with different education levels.

5. Conclusions and recommendations

The world is changing rapidly, and so do the society, economics, population and education. The methods and the means of bringing up the young generation have to change, since the old ways are not working any more. Unexpectedly, most of the head teachers' in Arab-speaking school of Israel are ready for changes and understand their crucial role in the future of a teacher profession in particular and the education system in general.

The field study came to the following conclusions and recommendations:

- There should be a policy in the Education Ministry that encourages the implementation of a new management in schools.
- Individual differences among school needs should be taken into considerations
- The teacher should diversify from the methods of explaining the subject using the technology.
- Enough time should be given to head teachers to use management in education.
- The school administration should encourage teachers to use computers, telegrams and all means in education.

Managing the implementation of Information Technology (IT) and its influence in school

Sarsour Alaa^{a*}, Sarsour Raed^a

^a West Timisoara University- Romania

Abstract

In this article it was attempted to research managing the implementation of information technology in schools.

New technologies have changed teaching and learning in a number of ways from graphing calculators to online lesson plans to virtual field trips and simulated dissections, educational technologies can help students access content in new and often exciting ways. In fact, one would be hard pressed to find a single school that doesn't have access to some kind of educational technology.

To conclude, the researcher believes that information technology (IT) is a versatile and valuable tool for teaching and learning and becoming a way of life. The most important thing is that teachers need to be prepared to use these technologies effectively. Schools can use technology effectively and for the welfare of students, teachers and society, it must be done.

The sample of the study included 200 male and female technology teachers who taught at the elementary school in Israel within 2018, The researcher was selected them randomly, half were males and half females. 70% of them have a BA degree, 30%- more than BA. Questionnaire for collecting information has been developed after surveying some previous studies dealing with the same subject. The questionnaire consisting of 20 questions which are distributed into four parts (teachers, pupils, methods and surroundings).

The results demonstrate that the teachers and pupils are ready to use more actively the IT in school lessons, but the current curricula makes it difficult and does not consider individual pupils' differences.

Key words: Managing; Implementation; Information; Technology; Teachers; Schools.

1. Introduction

Information technology (IT) is the use of computers to store, retrieve, transmit, and manipulate data, or information, often in the context of a business or other enterprise. IT is considered to be a subset of information and communications technology (ICT). Humans have been storing, retrieving, manipulating, and communicating information since the Sumerians in Mesopotamia developed writing in about 3000 BC, (Butler, 2012), but the term information technology in its modern sense first appeared in a 1958 article published in the Harvard Business Review; authors Harold J. Leavitt and Thomas L. Whisler commented that "the new technology does not yet have a single established name. We shall call it information technology (IT)." Their definition consists of three categories: techniques for processing, the application of statistical and mathematical methods to decision-making, and the simulation of higher-order thinking through computer programs (Leavitt and Whisler, 1958).

According to surveys, as many as 95% of schools are connected to the Internet; even at the level of the individual classroom, connection is nearly as universal close to 75% of classrooms in the United States have Internet access (CEO Forum, 2000).

Despite this nearly ubiquitous access to computer technology, however, there is a significant gap between the presence of technology and its usage in the classroom. While some type of technology is present in nearly every classroom in the country, it is rarely used to its fullest potential (Royer, 2002).

* Sarsour Alaa. Tel.: +972507535212;
E-mail address: ala.kris1@gmail.com

Some of this discrepancy is due to a lack of comfort with using technology for teaching and learning. Even teachers who are using technology and report a high degree of comfort with technology tend to use it in fairly rigid ways, such as searching for activities to use with students, communicating with other teachers, and word processing (Price, Cates & Bodzin, 2002).

And while students frequently do use computers in the classroom, use is often limited to information gathering and word processing rather than using multimedia tools or digital content to design and create products (Price et al., 2002). Often, learning with technology is teacher-centered rather than student-centered.

While many teachers still feel uncomfortable using technology in their teaching practice, it is also likely that teachers feel new technologies are unproven in the classroom (Royer, 2002). Though there has been a great deal of research on the efficacy of technology tools for teaching and learning, many of these studies may not translate well to the reality of the classroom.

2. The Statement of the problem

Teaching and learning information technology (IT) is crucial for both teachers and learners. Students, teachers, schools and other stakeholders will use IT effectively as a tool for enhancing the effectiveness of learning and teaching, with a view to preparing our students for the information age, turning schools into dynamic and interactive learning institutions, and fostering collaboration among schools, parents and the community.

If schools want teachers to use technology to enhance student learning, then it is important to address these issues. Teachers are inundated with new initiatives every year; new ideas come and go and are rarely sustainable (Zorfass, 2001). To avoid "initiative fatigue," schools must focus not only on introducing new technology, but also on implementing and scaling up new technologies.

Based on these assumptions, the researcher looks for improving the enthusiastic influence of information technology (IT) in schools.

3. Change in Student and Teacher Roles

When students are using technology as a tool or a support for communicating with others, they are in an active role rather than the passive role of recipient of information transmitted by a teacher, textbook, or broadcast. According to Khloff. (2010), the student is actively making choices about how to generate, obtain, manipulate, or display information. Technology use allows many more students to be actively thinking about information, making choices, and executing skills than is typical in teacher-led lessons.

Moreover, when technology is used as a tool to support students in performing authentic tasks, the students are in the position of defining their goals, making design decisions, and evaluating their progress.

The teacher's role changes as well. The teacher is no longer the center of attention as the dispenser of information, but rather plays the role of facilitator, setting project goals and providing guidelines and resources, moving from student to student or group to group, providing suggestions and support for student activity.

Khloof (2010) claims: as students work on their technology-supported products, the teacher rotates through the room, looking over shoulders, asking about the reasons for various design choices, and suggesting resources that might be used. (See example of teacher as coach.)

Project-based work (such as the City Building Project and the Student-Run Manufacturing Company) and cooperative learning approaches prompt this change in roles, whether technology is used or not. However, tool uses of technology are highly compatible with this new teacher role, since they stimulate so much active mental work on the part of students. Moreover, when the venue for work is technology, the teacher often finds him or herself joined by many peer coaches--students who are technology savvy and eager to share their knowledge with others.

4. Experimental study in Israel

4.1. Study Sample

The sample of the study included 200 male and female technology teachers who taught at the elementary school in Israel within 2018, The researcher was selected them randomly, half were males and half females. 70% of them have a BA degree, 30%- more than BA. Questionnaire for collecting information has been developed after surveying some previous studies dealing with the same subject. The questionnaire consisting of 20 questions which are distributed into four parts (teachers, pupils, methods and surroundings).

4.2. Results

Most of the respondents (70%) about agree that the teacher plays the main role through learning the students using the computer; and also that the teachers has the qualification for learning the students technology skills; about 80% agree that the teacher takes into account individual differences among students while teaching computer skills; and about 90% says that teacher uses multiple technological means in classrooms. In questions regarding the pupils: almost all the respondents agree that the student's desire for technological learning has a major role through learning process; but there are individual differences among students in learning computer skills. Most of the teachers (80%) claim that a students' awareness for the importance of computer skills plays a major role in their learning of technology. 90% say that a student who understands the importance of learning technological skills is faster than others. And to conclude, about 90% think that there is a need to conduct additional practical activities that help students master the skill of electronic devices. The school curriculum, however, is not enough suited for implementing the IT technologies in school (about half of the respondents think so), and most agree that the current curricula does not take into consideration the cognitive and emotional personal differences between the pupils. When talking about the surroundings of teaching in Israeli school, most of the teachers say that modern school uses IT greatly, but there is not enough diversity and flexibility, especially when dealing with individual differences of the pupils.

5. Conclusions and recommendations

The researcher believes that the teacher has an important and direct role in the implementation of technology through the answers to paragraphs of the questionnaire, which showed that high to very high and the teacher can encourage students to implement and use technology through classroom classes. The researcher pointed out that motivation in the student has a direct and important role in the implementation of technology at schools, in addition to the students' interaction with technology activates students in school and diversifies the methods of education. The researcher believes that there are parts in the curriculum that need some improvements: it should encourage more the use of technology, take into account many individual differences between students, be simpler to implement and use.

No differences were found between male and female subjects. The researcher attributed the absence of gender differences in the sample of the study to the fact that both male and female teachers in schools are subject to one law from the Ministry of Education and what applies to males applies to females.

Recommendations

Since the world is changing and the technologies become part of our everyday lives, there is a need to change the school curricula as well and use more technological methods of teaching.

Compared to conventional classrooms with their accent on verbal knowledge and multiple-choice test performance, technology provides a very different set of challenges and different ways in which students can demonstrate what they understand (e.g., by programming a simulation to demonstrate a concept rather than trying to explain it verbally).

A related technology effect stressed by many teachers was enhancement of student self esteem. Both the increased competence they feel after mastering technology-based tasks and their awareness of the value placed upon technology within our culture, led to increases in students' (and often teachers') sense of self worth.

Students clearly take pride in being able to use the same computer-based tools employed by professionals. As one teacher expressed it, "Students gain a sense of empowerment from learning to control the computer and to use it in ways they associate with the real world.

" Technology is valued within our culture. It is something that costs money and that bestows the power to add value. By giving students technology tools, we are implicitly giving weight to their school activities. Students are very sensitive to this message that they, and their work, are important.

- There should be a policy in the ministry that encourages the implementation of technology at schools.
- Take into consideration individual differences among students.
- Provide an environment conducive to the use of technology.
- The teacher should diversify from the methods of explaining the subject using the technology.
- Enough time for teachers to use technology in education.
- The school administration should encourage teachers to use computers, telegrams and all means in education.

The Contribution of Druze women to the development of Druze society

Faraj Faraj^a

^a *Sociology faculty, West Timisoara Universty*

Abstract

A society that recognizes the value and role of a woman should nurture the woman through education in order to expand and strengthen her personality and to prepare her for public and private life (marriage, parenting and house duties). The house is the place to begin with the profound change in values that guide our lives everywhere. Thus, the woman will be able to enter the field of work to help develop the community. The role of legal Feminism is to make a change and contributes to the discrimination of women in society. The categories "women" and "men" are currently in the process of change and goes towards a justice society and creation of a new man. The honor of women is of supreme value to the Druze, who are certain that "the woman is a pearl" that must be preserved and without male preference. The status and dignity of the Druze woman has significant cultural content in maintaining the social order and the Druze identity. After the establishment of the State of Israel in 1948, changes and successes began in the manner of relations between women and men that led to a breakthrough in Druze society in Israel. The percentage of female Druze students is higher than male Druze students, a trend that over the years could lead to a change in the social structure of the Druze community. The successes were mainly in the education system and especially during the last decade. Today at the top of the pyramid in the Ministry of Education on the department of Druze sector, a Druze woman is in charge of the Druze education in Israel, a woman that was formerly to her current role a school principal and supervisor.

Keywords: Druze women in Israel; Druze society; development; higher education; employment.

1. Introduction

Development has become an urgent and persistent demand for all current companies. The development is extensive on significant topics such as: social, economic, political and important cultural issues. This also effect current and future societies. Today, the main goal of development is to answer the needs and happiness of humans. In order to develop a proper and successful society, the society must pay attention and focus on all human energies without discrimination between women and men (Yoram Harpaz, April 2008).

Women constitute half of human society and half of its outputs forces, so any society that would like to reach the benefits of women involvement by participation of women in social and economic development should eliminate all forms of discrimination. (Jone Johnson Lewis, 2017). A society that recognizes women's value and there significant role must invest in education in order to expand women's abilities and strengthen personality characteristics in order to enable women to fulfill adequate role in the family and be able to enter workforce that will assist in production and community development (Abbas, 2010). Training women properly gives them the ability to live comfortably and reliably and have the ability to innovate and create. The more Druze women receive a greater share of education, the more they are able to understand and influence negative influences and to resist them (Wiener-Levi, 2004).

The Druze society in Israel was designed for many years by religion, when the social-traditional framework and the living conditions determined the individual's connection to his community (Yitzhak, 1998). The Druze religion calls for equality according to the laws of legitimacy written by the Druze prince Al- mir al-Assayid from Lebanon, who gave an integrated picture of the role and status of women in society. He compared men and women with religious duties, responsibility, reward and punishment. Among other things, he arranged all personal status issues and anchored them in laws that serve as the basis for Druze personal law (Fuad Abu Zaki, April 1997). The Druze religion gave Druze women the freedom to choose and decide, and the right to choose who to marry. It also gave women the right to divorce their husbands, and gave them a strong status for dignity and equality between men and their right to participate actively in life. In other words, the Druze religion espouses equality between men and women, and the woman can serve as spiritual leader of the Druze community, and moreover, equality in inheritance (Marcel Nasser, 1997). Therefore, the

status of Druze women in society and in law provides a solution to basic human rights, rights of life, equality, dignity, liberty, family and personal security. This approach places the issues of the "status of women" as issue of "human rights." (Orit Kamir, 2000). In author's opinion, if the members of the community implement the Druze religious laws, the Druze society will be the most advanced society in the world. And today the world is developing an interest in feminism, and feminism is a set of beliefs and ideas belonging to a social and political movement whose goal is to achieve greater equality and freedom for women (Bell Hawkes, 2002). The role of the legal feminism as embrace change function, is itself part of the mechanism that contributes to the discrimination of women in society (Noya Rimalt, 2010).

The categories "women" and "men" are subject that can be change and are currently in process of changing. The distinction between them is becoming increasingly blurred, not least because of feminism (Yoram Harpaz, echo of education, April 2008). Today we see difficulties in dealing with the gaps between the old and the new, and emphasize the conflict between the preservation of culture and the unique identity and the environmental pressure that emerges from modern culture (Saleh, 1999). The author supports the women's struggle for liberation and the establishment of a right society, and observe that change that defined as "a new man". As a Druze person, the author believes that if we implement the basics of the religious laws and values that we espouse in our society, we will succeed in educating our children and achieve gender equality.

The roots of Druze education, both religious and non-religious, are characterized as:

- Prohibition of drinking alcohol, gambling and smoking.
- Protect women honour.
- Ignore and throw away superstitions and not to believe in them, and to rely on reason and common sense (Fuad al-Atrash, 2003).

On the other hand, the foundations of Druze social education are emphasized and recommended to stay away from ostentatiousness and pornography. The Druze man must preserve the honour of the woman as he keeps his own life, in order to achieve sobriety and serenity. The Druze raised the issue of protecting women's honor as a supreme value according to the Druze religion. And anyone who does not respect the honor of woman (mother, sister, aunt, or any Druze girl...) finds himself in distances from religion and society. Preserving the honor of women is a supreme value among the Druze because women are pearls that must be preserved without male preference (Abbas, 2010). It is necessary to invest in the education of Druze woman, raise her awareness and give her full rights. And finally to have part of fathers' inheritance in order to preserve its existence and dignity (Marcel Nasser, 1997). This "pearl", meaning a Druze woman, consider as the best women in the world, and the most respected ones. On the same time, regarding the Druze society, the man must preserve his dignity and respect for the woman. Thus it is possible to build a healthy and correct society with a proper social order. The good manners among the Druze are part of the religion, and the Druze characterized by high morality, integrity and people of grace (Dana, 1974). Today, the big challenge we face beside all the nations of the world, after the imposition of the almost universal spiritual and ideological approaches, both economic and politics, has become programmed. Yes, here is the main challenge: Will the Druze maintain its values and principles? Will he preserve his identity as a bridge between the social connection and the personality of the individual, his personal values framework and the living conditions determined the individual's connection to his community (Yitzhak, 1998). The Druze religion calls for equality according to the laws of legitimacy written by the Druze prince Al-Amir al-Assayid from Lebanon, who gave an integrated picture of the role and status of women in society. He compared men and women with religious duties, responsibility, reward and punishment. Among other things, he arranged all personal status issues and anchored them in laws that serve as the basis for Druze personal law (Fuad Abu Zaki, April 1997). The Druze religion gave Druze women the freedom to choose and decide, and the right to choose who to marry. It also gave women the right to divorce their husbands, and gave them a strong status for dignity and equality between men and their right to participate actively in life. In other words, the Druze religion espouses equality between men and women, and the woman can serve as spiritual leader of the Druze community, and moreover, equality in inheritance (Marcel Nasser, 1997). Therefore, the status of Druze women in society and in law provides a solution to basic human rights, rights of life, equality, dignity, liberty, family and personal security. This approach places the issues of the "status of women" as issue of "human rights." (Orit Kamir, 2000). In my opinion, if the members of the community implement the Druze religious laws, the Druze society will be the most advanced society in the world. And today the world is developing an interest in feminism, and feminism is a set of beliefs and ideas belonging to a social and political movement whose goal is to achieve greater equality and freedom for women (Bell Hawkes, 2002).

2. The contribution of Druze women to social and cultural development

Development and education in the Druze community are based on equality between men and women. Amongst the Druze child care and education continues until adolescence. Society plays an important role in providing services that assist women in their role and in the implementation of their duties. The society must prepare these mothers by providing information and developing their abilities in using information, and supporting them in defining their rights and obligations. All these can be done by increasing cultural awareness and education of women. The Government of Israel has made great efforts to expand the access of all children to basic educational services, while providing access to free education for all children (the Compulsory Education Law) (Salman Falah, 2000). Some of the stated goals of the education system are equality, as defined in Article 8 (2) of the State Education Law in 1953, which aims to provide

equality opportunity for every boy and a girl (Weissblai, 2006, p. 3). Al-Amir Al-Sayyid, one of the Druze Clerics of the 15th century, wrote in his commentary that the absolute equality in raising the children is that the father is responsible to educate the son and the mother will educate her daughter until the age of 15. The parents have the responsibility to tell them "words of wisdom", stories of prophets and righteous people that have high moral standards. In addition, Israel state encouraged girls' education in the Druze sector, where Druze girls' classes were opened in the early 1980s (in order to raise their level), which helped to improve the level of education in the Druze sector, and confirmed the provision of free educational services. This has led to a decrease in the rate of illiteracy and has also caused a change in the Druze society. All these factors led to a change in the Druze society regarding the daughter's leaving to school and even today, the Druze ban against women regarding leaving the village for educational purposes such as schools, high schools, colleges and universities was stopped (Yusuf Hassan, 1992). Until the 90s, the girls' departure from the village was perceived as contrary to the concepts of modesty in Druze society, but in the last two decades there has been a trend that accepts and even encourages the departure of Druze women to higher education and to work outside the village (Abbas, 2010). Since the 1980s onwards, the pressures of the Druze women's movements in Israel increased and the level of cultural awareness, developments and changes of scientific and technological development, especially the media of all kinds, has influenced cultural awareness, human rights, local and international vast aspects. These changes influenced all dimensions of the modern society and particularly the Druze community. Increasing awareness beside cultural and scientific influences affects high income levels, and the creation of new variety of professions. The social and cultural awareness increased the activity of Druze women and led to the establishment of associations of women who are working hard to make changes in the conditions of Druze women and to achieve full equality of rights between men and women (such as Eshet Hayil, a pioneer woman of a soldier etc.). All these developments, as we mentioned earlier, led to the awareness of Druze women, which in sequence led to their understanding and awareness of their rights. However, alongside those developments, some of the family's roles continue to be carried according to tradition and certain roles disappear. Thus, new dynamic roles are created, and since these roles contradict the roles that have been before, the struggle between those two attitudes is significant. But the struggle is more sensitive when it comes to the role of Druze mother in the family. Prior to the establishment of the State of Israel, she had daily housework, often with the task of raising children and helping her husband in agriculture (Yosef Hassan, 1992). The perception of role is one of the most important behavioral aspects of social situations. In the Druze society, for example, the father is expected to fund and provide all the needs of his family. A father that is not providing that, or if unemployed, will lose his status as a "head" of the family, especially after the economic and social developments and changes in the Druze community. As a result, a father that can't support his family's demands, enter into a conflict between his roles. Thus, the conflict between new couples leads to the creation of a problem that describes the issue of "social pressure regulation." Despite the transition to non-agricultural employment, and the fact that Druze men were forced to work outside the village or even work far from the village, most of the Druze remained in their villages (Brudnitz and Czernansky, 1986). The changes that took place in the Druze society led to a confrontation between men and women, and as part of the responsibility to solve this conflict the Druze man began to change some of the dominant standards. The role of Druze women today is changing. She is using more educational services and institutions such as kindergartens to raise her children and is available to new roles and new definition of motherhood. A large part of the youth community also experiencing significant changes towards total separation between the two roles and the distinction between them. When Druze women and men choose their profession in life, they will take in consideration the fact that they will have to share domestic home tasks between them. They are dealing with gaps between old and new, and mainly on the conflict between conservation of culture and unique identity and dealing with the environmental pressure resulting from modern culture (Saleh, 1999). These influences often lead to controversy among generations regarding major social issues, particularly in education, identity, values, religion and the status of women. Young Druze today has new perceptions about their status deriving from religious and economic point of view, while the affinity to the Druze community and the elders of the community is weakened. The weakening of this framework in our times can jeopardize the continued existence and future of the community (Abbas, 2010). Today, religious leaders, elders and community leaders are unable to provide answers to all the questions asked by the young people (Wiener-Levi, 2004).

3. Druze social norms

Social norms in Druze society are not precise and coordinated, so it is difficult to establish clear and recognized criteria for the complexity of the social situation. For example, the manner in which certain laws, customs and traditions are compatible with scientific and technological developments in the world. There are also inherent differences between couples, for example in the area of science, culture and economy perceptions. These differences in levels leads to the difference in the way children are raised and leads to differences in the layers of Druze society (Halabi Rabah, 2003). Each society set certain standards, so it will be clear to its members what is right and what to avoid. These standards control behavior in some way, but we need to understand the unknown variables around the rules that consists social systems. Social norms are the norms and social standards that the individual follows in his life and is measured on the basis of his behavior. It is determined an acceptable and unacceptable behavior in the group and the reasons for accepting them or rejecting them and it is mainly focused on habits, customs, values and tradition. The ideas and beliefs of the Druze community represent their religiosity and their holy places, which cannot be touched and are above all else. Beside those beliefs, customs and traditions built by acts or active behavior that arose through an agreement

between the religious leaders of the community and are passed on from generation to generation (Dana, 1974). In the Druze community, values and habits are agreed upon by a group of elderly people of high religious and social status. They can also change these laws, behaviors and traditions after their have declared that publically. Their changes and amendments will be acceptable by the Druze society. But today there is a mismatch in these decisions and patterns of behavior that reflect values, customs and tradition, and therefore a group in the community began to show that they are unwilling to accept the decisions made by the religious leaders in some aspects of life. The Druze youngsters today have new perceptions about their status based on religious and economic point of view. Thus the affinity to the Druze community and elders of the community is getting weakened. The weakening of this framework in our times could endanger the continuation and the future of this community (Abbas, 2010). Religious leaders, elders and community leaders are unable to provide answers to all the questions asked by the young people (Wiener-Levi, 2004). We can conclude that the set of actions and behaviors that a person adopt are according to the rules of tradition, common values in his society, and in social interaction, so every individual in a society whether it is a man or a woman will improve their behavior according to their perceptions of each other. We can conclude that each person has different role that could create difficulties with others. If each person performs his or her duties according to what is expected of him, there will be compatibility between the roles, which leads to understanding, prosperity and success in the family and society in generally. And if not, the opposite will occur, that will cause conflict and struggle between the two sexes and thus will create Section name e.g. Druze life is conducted in a democratic spirit. That was also the case in the past. In the Druze society, the issue of the status and honor of the Druze woman constitutes a significant cultural content in maintaining the Druze social order and identity, and the respectable status accorded to her by religion, especially in the aspect of family life (Falah, 2000). In these elements the Druze woman can integrate socially, develop and influence the advancement of society in general.

Abstract

Society is becoming increasingly concerned, at a global level, with research and innovation, considering also the permanent technological evolution, and the capacity of research and innovation of improving the living and working conditions of people. There are various elements that contribute to the innovation level of a country, one of these being the human factor, which is considered to be one of the most crucial elements that can generate success. Scientific and practical progress has also become a necessity for any developed or developing country, with innovating enterprises playing a very important role in determining the level of progress. The present paper aims to illustrate a comparative analysis regarding the innovation activity of various entities in several countries around the world. For this objective to be achieved, there were studies various reports and datasheets, developing conclusion based on the statistical data.

Keywords: innovation, enterprises, entities, research, innovative capacity

1. Theoretical framework

When analyzing literature, we note that innovation is a concept that receives an increased attention during recent years, considering not only the importance of technological evolution, but also the wellbeing of the population and its linkage to other aspects, like research and development. Some sources even consider that innovation is vital nowadays to sustainable development worldwide, emerging “as a persuasive means to enhance sustainability” (Behnam et al, 2018).

Innovation becomes an aspect which can be considered “critical to business” (Luqmania et al, 2017), especially if we refer to a long-term success, Schumpeter (Schumpeter, 1942) stating a creative destruction in the case of innovation failure.

The term “innovation” has been explained in several ways in literature, but the main ideas that could be summarized as a definition indicate innovation as “the development - based on new ideas or inventions - of new products, services, processes and methods believed to create added value for society” (Cantwell, 2017), innovation being associated mostly with technology.

Literature approaches it in terms of a “successful implementation of creative ideas”, as well as a “non-linear, complex, ambidextrous process which includes components of exploration and exploitation” (Amabile, 1996 and Rosing, 2011 in Cox, Khan, 2017).

Despite these ideas, referring to the fact that innovation is strongly connected to the development of new products or processes, and also to technological advances (Edquist, 1997, Nelson, Rosenberg, 1993), we can also identify non-technological innovation, which targets a more “soft” side of a business, taking into consideration the social aspects, development of new strategies, the focus on the human nature of an organization, summarizing all these under the concept of social innovation.

Speaking both of technological and non-technological innovation, the concept is considered as “one of the most important factors of economic growth” (Strychalska-Rudzewicz, 2015), technological change being considered to be “one of the most important single factor standing behind” this phenomenon (Czerniak, Smygur, 2017). On the other

hand, the Global Innovation Index points out the concept of innovation as a factor that is both critical and supportive for the policies implemented nationwide (GII, 2016), but also of changing nature (Schwaag-Serger et al, 2015).

The basis of innovation remains the novelty of ideas, these being brought “to fruition by finding certain applications that result into new products, processes or services” (Rodriguez, Hechanova, 2014), the consequence residing in a positive evolution of the business, whether we refer to a growth in the number of customers, higher sales or better financial results.

The concept of “innovative enterprise” is also mentioned in various studies, being referred to as an „entity that in a certain period of time, adopted either products or new technologies that are "specific to the knowledge-based economy", highlighting new ideas (Băloiu, Frăsineanu, 2004, in Demyen, Ciurea, 2017).

2. The relationship between culture and innovation

Countries started to become more and more concerned with research and innovation, not only in present, but starting with the year 1986, through the Single European Act. It then transformed into a policy goal in order to support the technological evolution, industry and science. Other important actions followed through the years, the two concept gaining increasing attention in the European Union especially in the year 2000, when the Lisbon strategy was established, aiming the increase of competitiveness and targeting economic growth.

According to the Global Innovation Index, 2018 edition, in 2015 the states member of the United Nations “adopted the 2030 Agenda for Sustainable Development (the 2030 Agenda) and the Paris Agreement”, documents that “recognize that effective national innovation systems are key to promoting scientific and technological solutions that lead to improvement in energy efficiency systems”.

Researchers thus often link innovation to culture, stating that there can be identified “a significant relationship between a nation’s culture and its level of innovativeness” (Andrijauskienė, Dumčiuvienė, 2017), considering that “countries may not be able to increase their rates of innovation simply by increasing the amount of money spent on research and development or industrial infrastructure” (Shane, 1993), being necessary a strong concentration of attention upon the true values of the nation.

As stated in literature, the term “culture” is not simple, although it seems to become crucial in “various respects” (Kaasa, Vadi, 2008). It defines a specific set of fundamental values of a community, but the bearers of these values are individual members of the respective community. For an economist, culture is a description, performed by other scholars of social reality, of the most comprehensive and representative utility function of a collectivity (Fudulu, 2007).

The economic definition of culture is thus limited to the core values of a community. The sociological definition, on the other hand, includes, in addition to values recognized as a central element, and a number of other elements. Geert Hofstede (Hofstede, 2010) identifies five dimensions of the concept of culture to which there was added the aspect of indulgence:

1. power distance index
2. uncertainty avoidance
3. Individualism vs. Collectivism
4. masculinity versus femininity
5. Long term orientation vs short term orientation
6. Indulgence.

The innovation performance of countries is linked to all these cultural dimensions, but the way one or the other influences the level of innovation it differs from a case to another. Often, researchers state that low power distance cultures tend to encourage innovation, by financing inventions and emphasizing the importance of autonomy for the work of subordinates. In these cases, also creativity and novelty are considered essential.

Other authors indicate a relationship between individualism and innovation, by analyzing certain sets of parameters (Kalaycı, 2015).

According to www.hofstede-insights.com, there can be determined the values for each of the 6 dimensions of the concept of culture, mentioned above. The results will be presented in table 1.

In order to achieve relevant conclusions regarding the six dimensions, we must analyze each of these individually. Thus, starting with the first dimension, the power distance, we can conclude that countries that have a score over 50 are countries that accept a certain hierarchical order, considering that this first dimension refers to the extent to which societies are equal. In the countries that score over 50 points (Belgium, Bulgaria, Greece, France, Malta, Poland, Portugal, Slovenia), we notice a high dimension, there are inherent inequalities, while in organizations, usually employees are told what to do.

Individualism states the degree of independence at both country and society level. In case that the score is stated under 50 points, as in the case of Bulgaria, Croatia, Greece, Portugal, Romania, Slovenia, we identify a collectivistic society, which promotes extended relationships and long-term commitments, focusing on family and groups.

The third dimension can be interpreted a little differently, as a high score indicates masculine societies, which promote competition, while a low score indicates a feminine society, focusing on the quality of life. We identify Italy, Poland, Ireland, Hungary as masculine societies, while Denmark, Finland, Latvia, Netherlands, have low scores from this point of view, which determines us to classify them as feminine societies.

Table 1 Scores achieved by UE 28 countries in 2018

Country	Power distance index	Individualism vs. Collectivism	Masculinity versus femininity	Uncertainty avoidance	Long term orientation vs short term orientation	Indulgence
Austria	11	55	79	70	60	63
Belgium	65	75	54	94	82	57
Bulgaria	70	30	40	85	69	16
Cyprus	*	*	*	*	*	*
Croatia	73	33	40	80	58	33
Denmark	18	74	16	23	35	70
Estonia	40	60	30	60	82	16
Finland	33	63	26	59	38	57
France	68	71	43	86	63	48
Germany	35	67	66	65	83	40
Greece	60	35	57	100	45	50
Ireland	28	70	68	35	24	65
Italy	50	76	70	75	61	30
Latvia	44	70	9	63	69	13
Lithuania	42	60	19	65	82	16
Luxembourg	40	60	50	70	64	56
Malta	56	59	47	96	47	66
Poland	68	60	64	93	38	29
Portugal	63	27	31	99	28	33
United Kingdom	35	89	66	35	51	69
Czech Republic	57	58	57	74	70	29
Romania	90	30	42	90	52	20
Slovakia	100	52	100	51	77	28
Slovenja	71	27	19	88	49	48
Spain	57	51	42	86	48	44
Sweden	31	71	5	29	53	78
Netherlands	38	80	14	53	67	68
Hungary	46	80	88	82	58	31

Source: realized by authors, according to information achieved from www.hofstede-insights.com

Uncertainty avoidance indicated the extent to which society is opened to face uncertain situations, a high level showing a pronounced preference for avoiding uncertainty. Countries like Belgium, Greece, Malta, Hungary, Spain, Romania promote rules, precision, low level of innovation.

A score above 50 in case of the fourth dimension speaks about pragmatic societies, a strong adaptability and perseverance.

As researchers state, a growing number of countries decided to develop national councils for innovation, promoting a high level of interest in implementing efficient innovation policies (Schwaag-Serger et al, 2015). As Michael Porter wrote: "National culture can substantially determine business innovation" (Porter, 2000, in Strychalska-Rudzewicz, 2015), thus we can conclude that "what differentiates one culture from another are its institutions and its ways of dealing with the variety of universal problems (Williams et al, in Cox, Khan, 2017)".

When analyzing the results, measured through a series of indicators, we observe that there are several countries that can be considered "innovation leaders". Often, still, a very important factor that determines the classification is represented by the income group in which the countries are included.

The Global Innovation Index, 2018 edition indicate the following situation:

Fig. 1. Innovation leaders by income group

source: Global Innovation Index Report, 2018

When deciding, however, which country belongs in which group, there are numerous other aspects taken into consideration, the GII realizing a statistical coherence and correlations between pillars and sub-pillars. The main pillars can be mentioned as follows:

- Institutions
- Human capital and research
- Infrastructure
- Market sophistication
- Business sophistication
- Knowledge and technology outputs
- Creative outputs

While the sub-pillars target the following: political environment, regulatory environment, business environment, education, tertiary education, research and development, information and communication technologies, general infrastructure, ecological sustainability, credit, investment, trade, competition and market scale, knowledge workers, innovation linkages, knowledge absorption (GII, 2018).

3. The main actors in innovation projects

Innovation projects implemented worldwide assume the implication of various entities, “actors” in innovation projects (Behnam et al, 2018), each of these having different innovation capabilities, different capacities to absorb knowledge and to transfer information. Usually, entities that manage to successfully implement innovation project are rewarded with positive results, in terms of growth, customer share and profitability.

However, the results mainly differ according to the level of resources invested in the process.

According to the Global Innovation Barometer, 2018, the main actors driving innovation are:

- small and medium sized companies
- entrepreneurs and startups
- multinational companies investing in countries
- universities and research labs
- government and public authorities at national level.

But their innovation drive is different from a country to another and even from a year to another. The Global Innovation Barometer compares the results from two different years, 2014 and 2018 respectfully, the interpretation being made considering the results of a complex survey applied on representatives of the above mentioned entities, worldwide. Considering these results, it seems that currently, in the year 2018, the innovation activity is carried out at a larger scale by multinational companies and entrepreneurs or startups, and on a smaller scale by SMEs, universities, research labs or governments. We notice a great difference by comparison to the year 2014, when the innovation activity was mainly carried out by small and medium sized companies and entrepreneurs.

The results differ from a country to another, but it can be globally observed that there is a shift from small businesses to multinationals, as presented in the chart below.

Multinationals’ growing reputation as the driver of innovation is seen across the majority of countries, a decrease can be observed in case of India, South Korea and the UAE. Meanwhile, the small and medium sized enterprise face a decrease of reputation as innovation drivers, especially in European countries. According to the Global Innovation Barometer, “in parallel, in some economies where government traditionally dominated innovation, such as Turkey and South Africa, business executives now see increasing value driven by the private sector”.

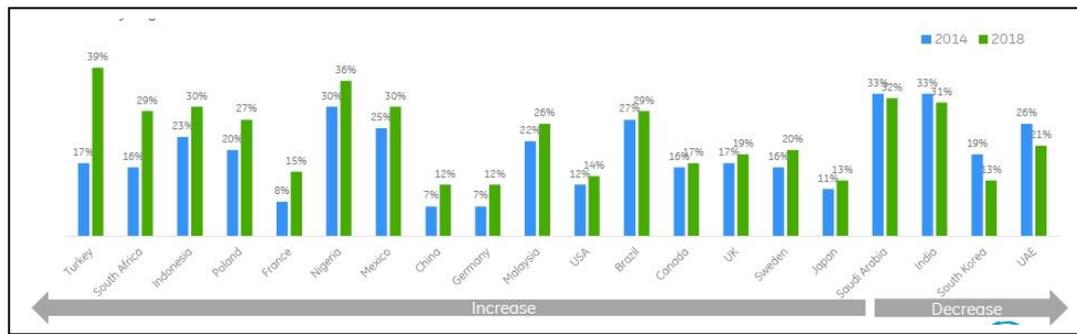

Fig. 2 Evolution of multinationals reputation in various countries

source: Global Innovation Barometer Report, 2018

In most situations, the government doesn't support innovation at a desired level, thus multinationals come as a salvation from this point of view. In some cases, traditional economies, where innovation was achieved by government until recently, we notice an increase in the private sector importance.

On the other hand, while until recently, the United States and Germany were the main innovators, the scores indicate that Asian countries like Japan and China are positively evolving and even exceed the first two, previously mentioned.

Still, despite the results acquired through studies, small and medium sized enterprises play a very important role in promoting innovation, because they are involved not only in the process of development, but also in selling the products.

They become an element of linkage between multinationals, universities and other institutes, although an additional support is necessary in order for them to carry out complex innovation projects.

Innovation can be considered as "the motor for economic change", of "importance to knowledge and learning as processes necessary for economic growth" (Cantwell, 2017).

We cannot ignore that innovation is a very important tool for technological and non-technological evolution (Ismail et al, 2014).

National culture can certainly determine the level of business innovation, while culture determines in a great measure the thinking and also the behavior of people.

Technological progress is in a great measure in a strong relationship with innovations influencing the productivity and the level of well-being of the people.

Synergies between lean and sustainability: a literature review of concepts and tools

Ilie Mihai Taucean^{a*}, Larisa Ivascu^a, Serban Miclea^a, Mircea Negrut^a

^aPolitehnica University Timisoara, Piata Victoriei nr. 2, Timisoara 300006, Romania

Abstract

The concepts of lean and sustainability are increasingly used practical in companies, at all levels vertically and horizontally. Also they are used together, unitary and complementary, more and more as a single tool for reducing waste, being also an actual interdisciplinary theme of research.

Lean is one of the concepts which lead to efficiency increase of the organizations through productivity increase and in the same time with resource consumption decrease. Lean philosophy suppose that any activity without value added to be considered waste and should be eliminated. Sustainability became important with negative impact of environment changes starting with the industrial revolution (XVIII century). Research regarding sustainability highlighted the importance of responsible interaction with the environment.

The concepts of lean and sustainability started to be considered together in research literature. Studies show that there is compatibility and synergies between them, first of all, because of the waste elimination will benefit both the companies and the environment.

A literary review was carried out to search for lean and sustainability tools and their use in various domains. Relevant keywords were selected and use to find the relevant research papers. A database for paper sampling was used (Web of Science). The sample's analysis give us an overview about the distribution of the topics, ratio of journals and conferences articles, distribution over time and countries from where research came from. Also a deep evaluation was done regarding the interrelations between the two concepts and tools, and the challenges of integrated implementation of the two in companies for improving of their activity.

Keywords: Lean; sustainability; literature review; synergy

1. Introduction

Lean and sustainability are increasingly used concepts in companies, at all levels. They are used together, unitary and complementary, more and more as a single tool for reducing waste, being also an actual interdisciplinary theme of research.

Lean is one of the concepts which lead to efficiency increase of the organizations through productivity increase and in the same time with resource consumption decrease. Lean philosophy suppose that any activity without value added to be considered waste and should be eliminated. In research literature we can find references to a many lean tools, stating with the research of Jim Womack and Dan Jones in 1996, at Toyota Company. Lean tools appeared as a result of practical solutions found by the companies in concrete and specific situations when they have to resolve this kind of problems.

Sustainability became important with negative impact of environment changes starting with the industrial revolution in the XVIII century. Research regarding sustainability highlighted the importance of responsible interaction with the environment. In 1976 appeared the first paper with the word sustainability in the title (Stivers, R. L.: Sustainable Society: Ethics and Economic Growth, Westminster Press, Philadelphia). Studies show that those companies that take under consideration the sustainability will be the more competitive ones.

The concepts of lean and sustainability started to be considered together more and more in research literature. Studies show that there is compatibility and synergies between them, first of all, because of the waste elimination will benefit both the companies and the environment.

A literary review was carried out to search for lean and sustainability tools and their use in various domains. Relevant keywords were selected and used to find the relevant research papers. A database for paper sampling was used (Web of Science). The sample's analysis gives us an overview about the distribution of the topics, ratio of journals and conferences articles, distribution over time and countries from where research came from. Also a deep evaluation was done regarding the interrelations between the two concepts and tools, and the challenges of integrated implementation of the two in companies for improving of their activity.

2. Concepts of lean and sustainability

2.1. Lean concept

Lean philosophy supposes that any activity without value added to be considered waste and should be eliminated. In research literature we can find references for many lean tools. In the research of Jim Womack and Dan Jones in 1996, at Toyota Motor Company, lean tools appeared as a result of practical solutions found by the companies in concrete and specific situations when they have to resolve this kind of problems.

Toyota Motor Company applied a new production approach called Toyota Production System (TPS) (Ohno, 1988), in order to be competitive against the American companies, in a period when Japan has resources constrained (after the Second World War). The new approach "make more with less" was later called "lean production" by Womack et al. (1990). Toyota engineers designed the TPS so that fewer and fewer resources would be required for delivering the right products at the right time at the shortest timeframes possible, by eliminating all type of waste.

Wastes were classified by Ohno (1988) in seven categories (overproduction, over processing, transports, defects, motion, inventory and waiting), and Womack and Jones (1996) defined the five Lean Principles (value, value stream, flow, pull production and pursuit of perfection). The principles aim to reduce or eliminate the 7 wastes by specifying value through the customer's perspective, identify the value flow, make the value flow continuous, with no interruptions, allow the customers to pull the value along the value stream (Hallam and Contreras, 2016). The principles are cyclical and lead to continuous improvement (known as Kaizen).

Tools and techniques of LM (like JIT, TPM, VSM, pull production, 5S, Kaizen) can facilitate achieving sustainability (Vinodh et al., 2011). Organizations are competitive and achieved better results through implementation of lean concept. Companies that have adopted lean to improve their results also want to be seen as socially responsible. Sustainability is considered the new lean manufacturing frontier; this necessitates investigation of lean impact on the three sustainability dimensions: environmental, economic, and social (Martínez-Jurado and Moyano-Fuentes, 2014).

2.2. Sustainability concept

Sustainability became important with negative impact of environment changes starting with the industrial revolution in the XVIII century. Research regarding sustainability highlighted the importance of responsible interaction with the environment. In 1976 appeared the first paper with the word sustainability in the title (Stivers, R. L.: Sustainable Society: Ethics and Economic Growth). Studies show that those companies that take under consideration the sustainability will be the more competitive ones.

The approach to sustainability involves economic, social, and environmental responsibilities. The balanced use of these resources without affecting the development capacity of future generations contributes to sustainable development (Izvercian et al., 2014). From an economic perspective, businesses need to improve their results. This can be achieved by increasing the level of efficiency and reducing defects. Reducing defects helps reduce costs. Reducing the waiting time is another indicator that contributes to the economic efficiency of the enterprise. Social responsibility for sustainable development takes into account society, human resources and the ability of the enterprise to engage in the development of local communities. Increasing the level of innovation has to take into account its effect on employees (reducing the number of employees, training employees to use new equipment and technologies). The company's involvement in corporate social responsibility activities is another activity of this responsibility. These activities have a number of benefits for the company: increasing the level of innovation, improving the public image, increasing the attractiveness of candidates, increasing the level of training and performance in the workplace and reducing professional risks (Izvercian et al., 2014; Băbuț and Moraru, 2018).

From the environmental perspective, industry has an important impact on the environment. This impact is mainly generated by energy consumption. Globally, energy consumption in the industrial sector accounts for over 50% of total consumption. As a result, the industrial sector has to improve its processes so that consumption is reduced and its own generation of energies is a new direction of development. After assessing current consumption levels, it can be argued that the projected growth rates follow the principles of the Paris Accord - an agreement under the United Nations Framework Convention on Climate Change (UNFCCC). From the environmental perspective, waste generated by the company must be taken into account. Reducing the amount of waste and applying the concept of circular economy

contributes to the improvement of the generation rate. The recycling capacity of the company is an important part of sustainability. Applying these principles at the enterprise level also generates a number of benefits for the company: expanding process durability by improving quality, developing new and innovative technologies, improved processes, increasing the impact of the company's image in the economic environment (Yadav et al., 2017).

Sustainability consist thus in a series of behaviors, strategies and practices aim to prevent, reduce and eliminate negative impact on the environment (Salvador et al., 2017).

3. The methodology of the study

A literature review was conducted with the aim to give an overview of the research in the fields of “lean” and “sustainability”, searching for the tools of these concepts which are used/propose for use in various domains. In the end we try to find if there are synergies of the two concepts as they are presented in specialized literature. A digital database for search was used: Web of Science. Although there are many digital libraries, we consider that this one give us the most valuable results for our research purpose. Relevant keywords were selected and use to find the relevant research papers: lean, sustainability, sustainable, concept and concepts, tool and tools. Publications were selected by used of the keywords in: title, keywords and abstract.

The sample’s analysis give us an overview about the distribution of the topics, ratio of journals and conferences articles, distribution over time and countries from where research came from. Also a deep evaluation was done regarding the interrelations between the two concepts and tools, and the challenges of integrated implementation of the two in companies for improving of their activity.

4. Results

Initial publications that met our search criterion using keywords: lean and sustainab* (used for word “sustainable” and “sustainability”) were 887. We consider that these publications were too many and the study will not fully meet our aims. Out of these publications we select 184 for our study by adding in the search the keyword “tool” (or tools). We use here also an exclusion criterion: we decide to analyze only articles, proceedings and book chapter, so we exclude reviews (5) and editorial material (1). The final number of publications is now 178 and the distribution per publication type is shown in figure 1. Most publication in our analysis are articles in journals (107, around 60%) and in conferences proceedings (76, around 42.7%). As we can see from the figure 2, the time range of the publications is from 1998 to today. In 2012, Azevedo, says there is no study to show the relationship between sustainability and lean. Prior to 2012, most studies presented how sustainability benefits lean operations, and were particularly limited to environmental responsibility (Kainuma and Taware, 2006, Farish, 2009, Mollenkopf et al., 2010, Oglethorpe and Heron, 2010). For our research, we decided to include the publications prior to 2012 (27 publications, 15% of the total), as they present and analyze the concepts and propose possible tools to use in the industry applications.

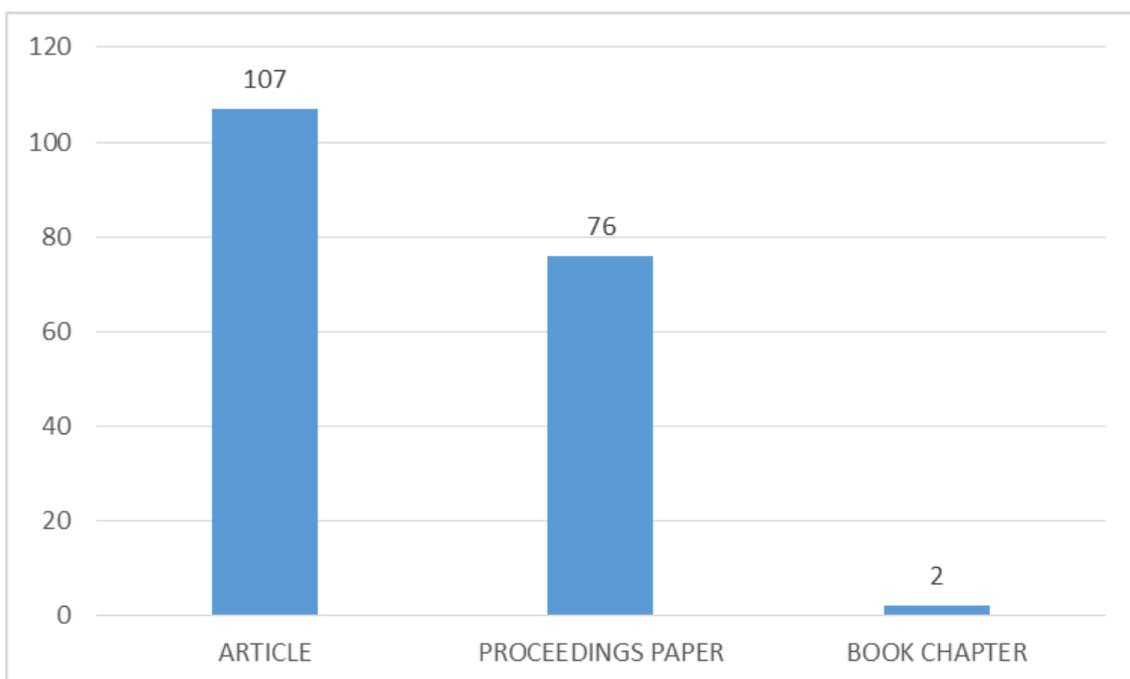

Fig. 1. Number of publications by type

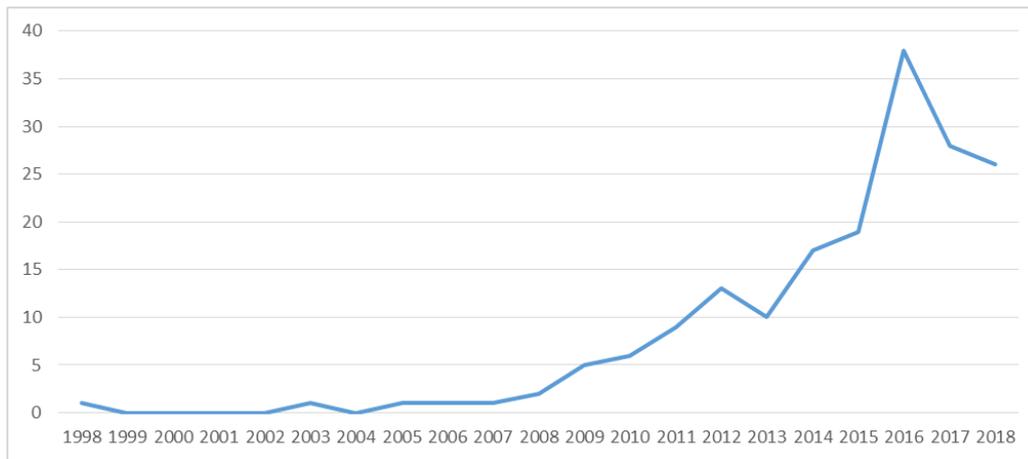

Fig. 2. Number of publications by year

As almost 85% of the papers are published since 2012, we can focus a next deep analysis on these 151 publications, which falls into Pareto rule (20/80): from 20% of the years (in our case 7 out of 21, which means 33%) we'll find 80% of the publications (151 out of 178, which means 85%). Another results here is the fact that publications peaked in 2016 (38, doubled from the previous year) and remain after 2016 higher than 2015.

Regarding the research area, there are 43 areas as seen in the figure 3 as a Pareto analysis. There are 9 areas, 21%, with 80% of the publications, starting with engineering (99) and related areas (68), environmental (23), business economics (31), and educational research (9). Here we can't exclude from our study the areas with less publications, as they are relevant to the two concepts proposed for analysis (lean and sustainability). Such areas include: energy fuels (2), food science (1), transportation (1) and urban studies (1), water resources (1) and so on.

In order to see if there are synergies between lean and sustainability, we evaluate the publications using keywords as a first analysis, and an in-depth evaluation using the concepts and tools of lean and sustainability in those publications.

First, there are a number of 144 publications which use the word "lean", respectively 129 which use the word "sustainability/sustainable", and 109 for the both words, as shown in figure 5 using a scaled Venn diagram. This is a good indication that between the two there are synergies, when more than 60% of publications use both words. But our analysis want to go beyond just the words, we looked after the tools to implement the two concepts (see table 1).

In table 1 we add (in column "Tools in publication") the number of publications with tools appearing (out of 178 publications) and number of tools appearances (in column "Tools appearances", out of 415 tools appearances).

This reveal fist that there is equilibrium of publications that mentions the two words and both words. Regarding tools appearances, there is a lean/sustainability ratio approximately of two thirds over one third. Also we find many approaches/concepts/frameworks for the two, from classical tools, to new derived tools and new tools, with works trying to integrate lean with sustainability.

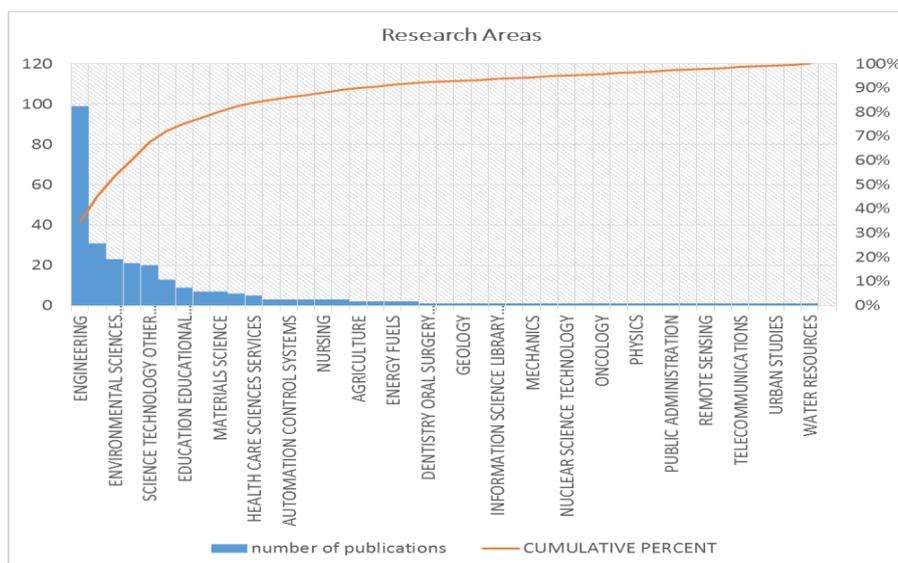

Fig. 3. Research area of publications

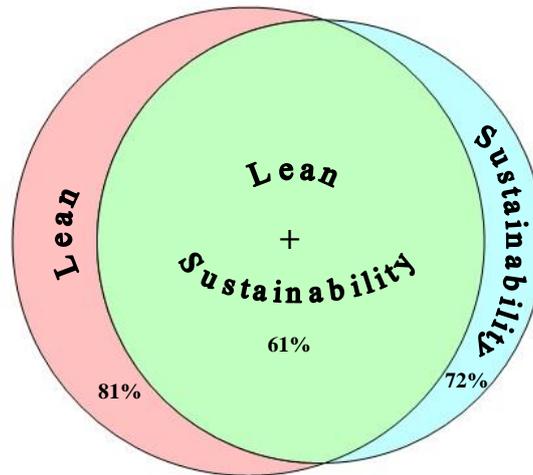

Fig. 4. Synergies of lean and sustainability

Table 1. Synergies analysis of lean and sustainability

Concepts	Keywords in publications (no. of publications)	%	Tools in publications (no. of publications)	%	Tools appearances (no. of appearances)	%
Lean	144	81	107	60	260	63
Sustainability	129	72	74	42	124	30
Lean + Sustainability	109	61	26	15	31	7

Regarding lean, the VSM tool (Value Stream Mapping) appear the most (34), followed by LSS (Lean Six Sigma and Six Sigma with 21 appearances) and 5S. Regarding sustainability, there is a larger number of different concepts, variation of concepts, with a most frequent tool LCA (Life Cycle Assessment 8 times), followed by eco-design/sustainable design (5).

There is a generous number of common/integrative tool for lean and sustainability (31) and many other studies try to put together a framework/methodology to use the two concepts in order to be successful. We can mention latest studies proposals (in the last 3 years, 2018-2016): LIMSSI (Lean-Integrated Management System for Sustainable Improvement, Souza and Alves, 2018), Lean-Sustainable Indicators Model (Isa et al., 2018), GELPM (Green Embedded Lean Production Model, Fu et al., 2017), LSS-EnMS (Lean Six Sigma Energy Management System, Mkhaimer et al., 2017), Agility-Sustainability Criteria model (Singh and Vinodh, 2017), Lean and Green SCM and LGrSCM (Colicchia et al., 2017 si Li and Found, 2016), Lean and Green House (Verrier at all, 2016), LARG Index (Lean, Agile, Resilient, Green Index, Azevedo et al., 2016), LCA-VSM (Life Cycle Assesment VSM, Vinodh et al., 2016).

5. Conclusions

The concepts of lean and sustainability are increasingly used in companies, more and more together, unitary and complementary, as a single tool for reducing waste. Studies showed that there is compatibility and synergies between them, first of all, because of the waste elimination will benefit both the companies and the environment.

A literary review was carried out to search for lean and sustainability tools and their use in various domains. Relevant keywords were selected and use to find the relevant research papers. A database for paper sampling was used (Web of Science). The sample’s analysis gives us an overview about the distribution of the topics, ratio of journals and conferences articles, distribution over time and countries from where research came from. Also a deep evaluation was done regarding the interrelations between the two concepts and tools, and the challenges of integrated implementation of the two in companies for improving of their activity to be successful in a dynamic and competitive economy.

Study regarding optimum functionality of analyzers (motor and optic) increasing the precision and efficiency in ball transmission

Ioan Stelescu *

University of Petroșani, University street no. 20, Petroșani, 332006, România

Abstract

The improvement of the functionality of the analysers – especially the kinaesthetic one and respectively the optic one – shall ensure the activity of the sensors and of the perceptions by refining the sensitivity thresholds and lead to the increase of efficiency and precision in passing the ball and nevertheless the capacity to solve the changing tasks of the game nowadays.

Sensory perception specific to each player (in our case) the visual analyser gives the player fast information regarding the situation on the pitch

Keywords: sensory receptivity, increase of efficiency, increase of precision, technical procedures, ball passing

1. Motivation of choice

We have started from the idea that if the improvement of the functionality of the analyser, namely the kinaesthetic and the optic analysers, ensures the activity of the sensors and the perceptions by tuning the sensitivity thresholds it will certainly lead to the increase of the efficiency and the precision of passing and consequently of the ability to solve forever changing tasks the actual game keeps bringing forward.

The improvement/teaching of neuromuscular control shall be reflected in superior efficiency indexes of the technical procedures of ball passing at the level of the inferior and respectively the superior limbs and the head.

2. Purpose of the research

It can thus be said that sensory perception specific to each player (in our case) the visual analyser gives the player fast information regarding the situation on the pitch. The receipt of the visual information by the Central Nervous System (CNS) creates a basis for the decision to be taken and sends the command to the muscle of the inferior limbs in order to carry out the hit toward the goal or pass the ball. This sensory receptiveness is manifested as well in relation to the information from other analysers of the human body (muscular sensation, hearing and vestibular sensations).

3. Research methods

In order to create the present paper, the following methods were used:

- The bibliographic study;
- Direct observation;
- The graphical method – used to express a large number of data;
- The case study;
- The “transversal” experimental method where the change of different variables for an athlete was followed during a specific moment.

* Corresponding author. Tel.: +4.025.454.2581 int.170

E-mail address: i_stelescu@yahoo.com

- The statistical – mathematical method was used to determine and calculate the following indicators while analysing the data obtained through precise measurements:

M_0	- module
M	- median
\bar{X}	- arithmetic mean
W	- amplitude
A_m	- average deviation
S	- standard deviation
CV	- the coefficient of variability

The significance between the lines of data for correlated samples

Content of research

The present research was carried out experimentally and proposes to study the precision of ball passing and its role during technical and tactical training for 14-16 year olds junior football players considering a cycle of 284 football training sessions, respectively between 06.07.2017 - 17.06.2017.

The materials used for the experiment were:

- records
- timer
- flags
- pickets
- medicine balls
- footballs

The venue for the experiment was and the football pitch and the gymnasium of the Satu Mare Sports High School.

4. Researched human subjects

In order to perform the experiment, researches were carried out on a number of 18 students (16 field players and 2 goalkeepers) who are part of the junior group of players born in 2003 of the Satu Mare Sports High School. They all have 4 years of experience in playing football.

During the research, students have shown a really responsible behaviour and deep understanding of the objectives considered for their training, creating therefore an optimum and correct motivation regarding the role of the technical procedures used during the football game. Data and appreciations regarding the effort capacity of each subject were recorded in different training period. The health of the students who took part in the experiment was quite good.

Control tests

The research makes use of 7 control tests which assess the level of specific skills required for the game of football.

Technical tests for junior players:

❖ *Precision ball passing*

- ball in one place: a corridor of 3m wide and 25m long is drawn; each player will be allowed 5 runs; the length is measured from the kicking spot to the spot where the ball touches the ground for the first time; he number of successful trials is recorded; the number of trials where the ball is out of the bounds of the corridor do not count.

❖ *Shooting 8 balls toward the goal from a distance of 16 m / time unit*

- the maximum number of shots at the goal / time unit (the goal divided vertically in 3); 8 shots are carried out – 3 consecutive shots in the sides and 2 in the centre.

❖ *Technical set - taking over – dribble – shoot from 16m / time unit*

- the starting point is at 9 m in front of the 16 m line; the player receives a ball at 1 m from the first picket after which he starts while leading the ball between 3 pickets placed every 3 meters and will finish by shooting toward the goal from the 16 m line; each player shall have 2 trials; the time passing from the start to when the ball crosses the goal line shall be recorded, shoots in which the balls touches the ground before crossing the goal line shall not be taken into account; the best trial is recorded.

❖ *8 ball shooting toward the goal, hitting the ball with the head while jumping from 11 m*

- the goal is vertically divided in 3; the player has the ball thrown having to score as follows: 3 consecutive goals in the sides and 2 in the centre; only the successful trials are marked; the trials in which the ball hits the ground before crossing the goal line are not taken into account

❖ *Technical tactical set*

- the following actions are performed by the player successively and with speed: jits the ball from the corner, with the right foot toward the penalty spot (11 m) (4 m radius), runs to the corner of the surface on the length of which there are 4 balls placed at a 2 m distance; running he shoots all 4 balls with his left leg; he then runs toward the other side of the pitch where he shoots the ball from the corner toward the penalty spot (11 m) (4 meters radius circle) runs again toward corner of the penalty surface on the length of which there are 4 balls and shoots them with his right leg;

- the time required for the execution of the set and the successful trials (namely the kicks which manage to send the ball into the net and the ball does not touch the ground before it crosses the goal line) are marked down.

❖ **Precision ball passing**

Considering the carrying out procedure – number of successful executions in the established space – the coordination skill was tested for the able foot, as well as the strength at the level of the inferior limbs muscles.

Figure 1, brings forward the average value is 2.06 successful trials for initial testing and 3.22 for final testing the progress being therefore of 1.16 executions.

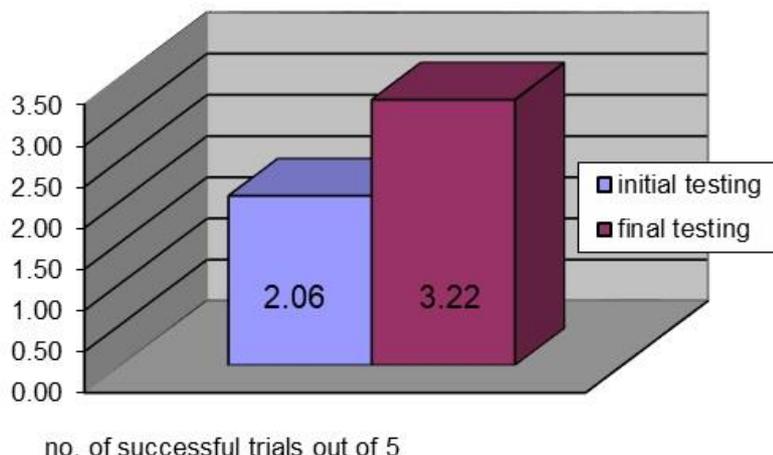

Fig. 1. Precision ball passing

The vertical analysis of tables 1 and 2 shows individual values comprised between 1 and 5 executions, while the horizontal analysis highlights the continuous increase for almost every member of the group.

The statistical mathematical indicators show an average of 3.22 executions for the final testing the standard deviation being ± 1.17 , while the coefficient of variability highlights a lack of homogeneity (36.21%).

The determination of *t* confirms that the differences are 95 – 99% significant.

❖ **Shooting toward the goal from 16 using 8 balls / time unit**

Considering the procedure of the trial – number of executions during a time unit / number of successful executions in the goal – the strength development level of the muscles of inferior limbs as well as the coordination skills of the able foot and the sense or responsibility for the shoots were tested.

The vertical analysis of tables 1 and 2 represents the number of executions / time unit, individual values comprised between 15s and 13.5s, while the horizontal analysis highlights a continuous increase of the performances together with the increase in the number of successful trials. The diagram presented in Figure 2 highlights the increase of the average of the group for trials with 2.79 executions, respectively 3.50 to 6.31 executions and a drop in the time of the execution of the 8 shots with 5s respectively 15.0s to 14.5s.

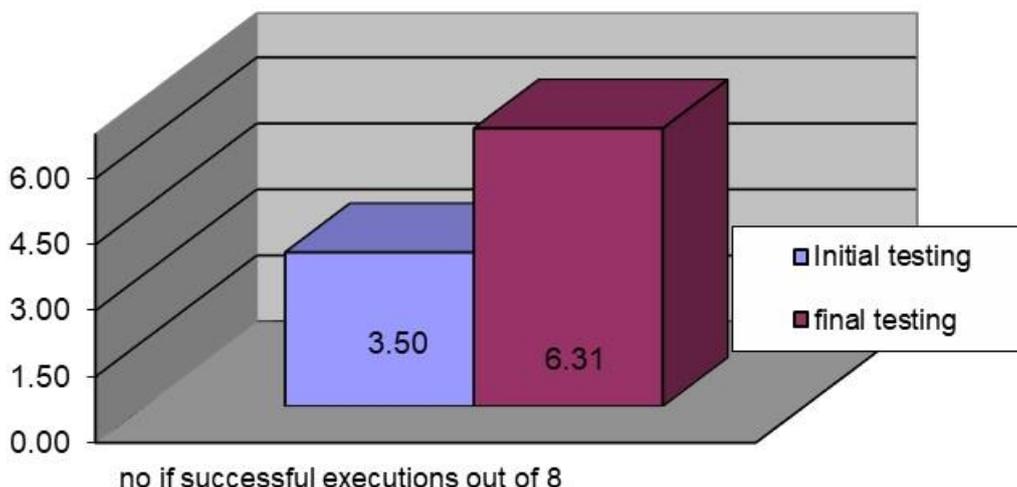

Fig. 2. Shots toward the goal with 8 balls from 16 m / no. of successful executions

The statistical indicators of the number of successful executions / time unit represents an average of 14.54s, while the standard deviations represents a normal distribution of over 68%, the coefficient of variability indicating a higher homogeneity during executions, namely with 6.59%, while the average of successful trials is 6.31, and the standard deviation is (+/-1.45) being normal and comprising 68% of the cases, the coefficient of variability indicating a lack of homogeneity, namely 22.98%.

t is calculated and determined and confirms that the differences are significant and 95-99% sure.

❖ **Technical Set**

The execution of the trial tested the coordination skills of the able foot and the sense of responsibility of the shoot toward the goal under time pressure.

Vertically analysing table 1 it results that out of 16 players 4 did not manage to send the ball in the goal from 16 m in order for the ball to fall behind the goal line.

The vertical analysis of table 2 brings forward individual values comprised between 4.7s and 6.1s, while the horizontal analysis highlights a continuous increase of performances

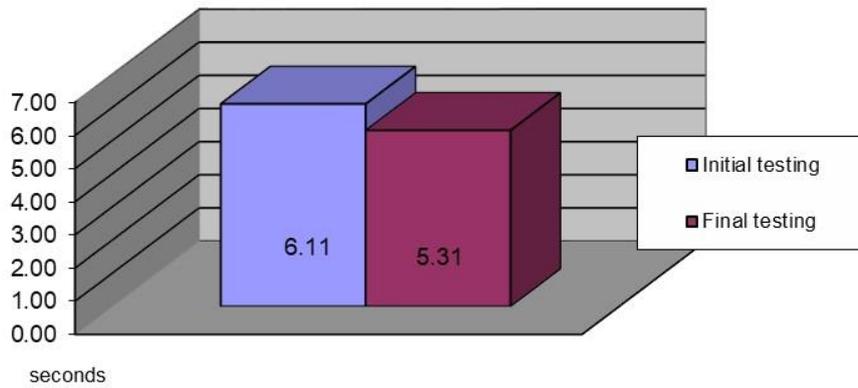

Fig. 3. Technical Set

The diagram presented in Figure 3 highlights a drop in the execution time from 6.11s to 5.31s. the statistical indicators highlight an average of 5.3s, while the standard deviation ($\pm 0,51$ s) presents a normal distribution, the coefficient of variability bringing forward a high homogeneity namely of 9.57%. *t* being determined and calculated confirms that the differences are significant being 95-99% sure, the risk of failure being comprised between 1-5%.

❖ **Shots toward the goal using 8 balls, hitting the ball with the head while jumping from the penalty spot (11 m)**

The execution of the trial puts to a test the coordination skills at the level of the head as well as the development of the strength at the level of the muscles of the inferior limbs. The analysis of the diagram presented in figure 4 highlights average values of 3,81 for successful executions for the initial testing and respectively 6.19 for the final testing, the progress being of 2.38 successful executions

The vertical analysis of table 2 brings forward individual values comprised between 4 and 8 executions, while the horizontal analysis highlights a continuous increase for 15 players.

The statistical indicators bring forward a standard deviation with normal values which comprises 68% of the cases, the calculated and determined coefficient of variability highlighting an average of 17.91%.

The calculated *t* confirms that the differences are significant being 95-99% sure

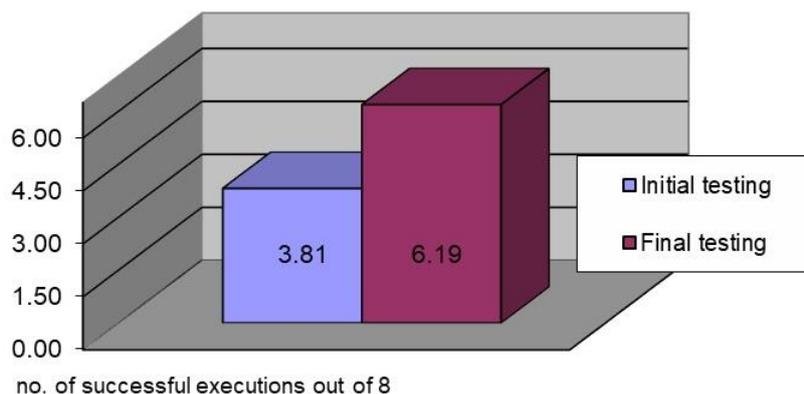

Figure 4. Shots toward the goal using 8 balls, hitting the ball with the head while jumping from the penalty spot (11m)

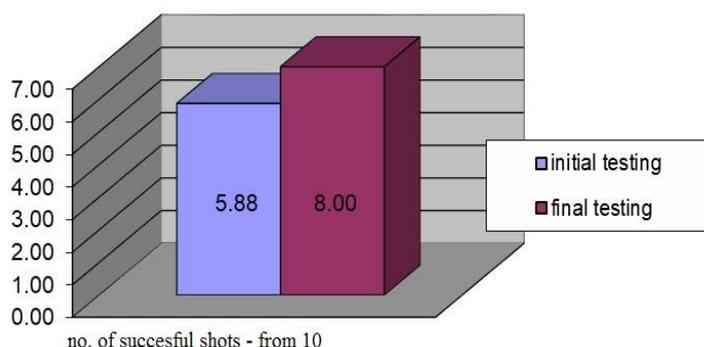

Fig. 5. Technical tactical set / no. of successful executions

❖ The technical tactical set

The model of the execution – number of executions in a time unit / number of successful executions puts to a test the level of the strength as stamina at the level of the muscles of the inferior limbs, of ambidexterity at the level of the inferior limbs and the sense of responsibility of the goal kick.

The vertical analysis of table 2 brings forward the number of executions / time unit, individual values comprised between 33.6s and 43.2s, while the horizontal analysis highlights a continuous increase of performances together with the increase of successful executions.

The diagram presented in **Figure 5** highlights an increase of the average of the group for trials with 2.12 executions respectively from 5.88 to 8.00, and a drop of the time of execution from 39.07s to 38.13s. The statistical indicators for the number of successful executions / time unit presents an average of 38.1, the standard deviation presents a normal distribution of over 68% while the coefficient of variability indicates a homogeneity of 7.91% and for the successful executions the average is 8.00 the standard deviation being normal comprising 68% of the cases and the coefficient of variability indicating an average homogeneity of 16.46%.

The calculate and determined value of t confirms that the differences are significant for 95-99% of the cases the risk of failure being comprised between 1 and 5%.

5. Conclusions

- The present study is part of a series of searches carried out by specialists in the field in order to increase the efficiency of the training session, the accuracy in passing the ball, its contribution to the training of future football player taking into consideration the requirements imposed by the modern football game.

- The values obtained following the researching procedures for precision ball passing, hitting the ball with the head (for players) as well as sending the ball with precision at a distance and throwing the ball with precision at a distance (for goalkeepers), have recorded a continuous increase of performances compared to the initial testing.

- the values obtained for the technical set, the technical tactical set, as well as for the goal shooting from 16 m, are continuously increasing with the consequent reduction of the time necessary for successful executions.

- The statistical – mathematical indicators reflect a standard deviation with a normal distribution, comprising over 68% of the cases, the coefficient of variability highlighting the high and medium homogeneity for most of the trials, while the value of t highlights that the differences between the two executions are certain in 95-99% of the cases with only 1-5 % risk of failure.

6. Recommendations

- In order to train the visual-kinaesthetic interaction we propose the use of means for sending the ball with precision, in order to improve target hitting, as well as the use of special methods to improve the clarity of the visual field in the game (both between the games as well as during the said game).

- The existence of a series of external stimuli for guiding the movement in order to create the optimum conditions for the specific target practice exercises, through visual appreciation of the distance and the adaptation of the visual receptivity to the specific actions of the game.

Strenght and distance in relation with intensity of throwing, running and jumping in youth football

Stelescu Ioan*

University of Petroșani, University street no. 20, Petroșani, 332006, România

Abstract

The physical performance of a football player mainly consists in speed / moving speed and the execution of technical elements as well as in the availability of the subject to repeat as many times as possible during a game the actions and high intensity movements.

The strength of the protractor muscles stagnates or regresses during this period which implies the large and varied use of strength training exercises destined for this group of muscles as well as those groups used while moving and performing technical movements (inferior limbs).

Keywords: development, quality of movement, precision of movement, strength, muscles

1. Motivation of choice

Having carried out multilateral researches on different samples in terms of age and level we have come up to valuable conclusions which allow the practitioners to reconsider some of their methodological procedures, their objectives and even the way they are realised.

We have always considered the development of fine motor skills as very important as they ensure harmonious physical development on one hand and the development of strength necessary for the training on the other.

Any football player holds a so called sensorial perception, if the interaction between the visual analyser and the fine motor effector in football players is flawed and especially if the visual analyser of the athlete is not trained and it is not prepared to perform competition specific activities (i.e. the estimation of the distance, visual acuity, estimation of the speed) then, naturally, there is no chance for a high quality game to occur.

2. Purpose of the research

Conditional skills are in direct dependence on the stamina and are based on metabolic efficiency of muscles and other systems such as the cardiovascular, respiratory or nervous systems. The conditional aspects depend on the fine motor skills: force, speed, stamina, being nevertheless tested in the present paper. Coordinative skills imply the appearance with the individual of alertness, cleverness, ingenuity, reaction speed, focus capacity and attention transfer, movement precision (spatial, temporal, dynamic) and their rationalisation from a biomechanically point of view.

The study tries to highlight the fact that in the present phase football playing organised scientifically contributes largely to the development of morality, willingness and character. The methodological analysis verifies that the principles are respected and especially tries to establish the optimum articulation of methods, techniques and researching instruments into one efficient strategy.

2.1. Researching hypotheses

1. Continuously assessing the fine motor skills of football players corroborated with the creation and the implementation of training tests which we prepared a continuous adjustment of the fine motor skills shall be performed.

2. The permanent monitoring of the development level of the fine motor skills specific to football combined with the creation of training tests for each step and phase of the specific training leads to getting superior results during competitions.

* Corresponding author. Tel.: +4.025.454.2581 int.170

E-mail address: i_stelescu@yahoo.com

3. Research methods

In order to create the present paper, the following methods were used: the bibliographic study; direct observation; the graphical method – used to express a large number of data; the case study; the “transversal” experimental method where the change of different variables for an athlete was followed during a specific moment. The statistical – mathematical method was used to determine and calculate the following indicators while analysing the data obtained through precise measurements: M_0 - module, M - median, \bar{X} - arithmetic mean, W - amplitude, A_m - average deviation, S - standard deviation, CV - the coefficient of variability. The significance between the lines of data for correlated samples.

3.1. Content of research

Either considering the competitions between young players or adult players independent on their level, the physical performance of a player consists in fastness / speed and the execution of technical elements such as the availability to repeat as many times as necessary during a game the high intensity actions and movements.

Therefore, a process for training – development of training sessions directed toward the stimulation of organic functions, the neuromuscular quality and the growing processes need to contain exercises which will allow the junior player to train his strength, stamina and speed.

The materials used for the experiment were: records, timer, flags, cone markers, medicine balls, footballs.

4. Researched human subjects

In order to perform the experiment, researches were carried out on a number of 18 students (16 field players and 2 goalkeepers) who are part of the junior group of players born in 2003 of the Satu Mare Sports High School. They all have 4 years of experience in playing football.

During the research, students have shown a really responsible behaviour and deep understanding of the objectives considered for their training, creating therefore an optimum and correct motivation regarding the role of the technical procedures used during the football game. Data and appreciations regarding the effort capacity of each subject were recorded in different training period. The health of the students who took part in the experiment was quite good.

❖ 30 m dash test

This type of test highlight the speed of young players expressed in m/s, being in close accordance to the explosive strength at the level of the inferior limbs. The horizontal analysis of tables 1 and 2 the results obtained by the subject highlight a continuous evolution, but speed being mainly a motor skill determined by genetics, the improvement and variation of speed is not spectacular.

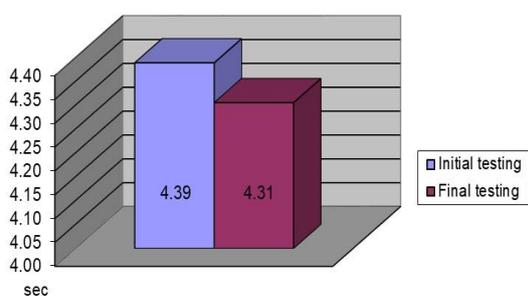

Fig. 1. 30 m dash run

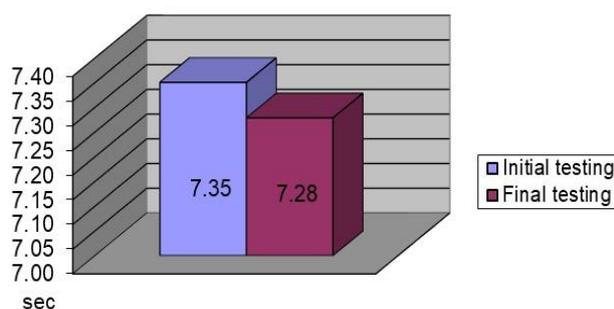

Fig. 2. 2000 m endurance run

The standard deviation (± 0.19 or rounded ± 0.2) is normal, comprising more than 68% of the cases, in our case the average is 4.3 ± 0.2 s, namely the values situate between 4.1 s and 4.5 s deviate from the average with the standard determined and calculated for the group; coefficient of variability highlights a large homogeneity of 4.33%.

The vertical analysis of the table highlights individual values observed during the final testing comprised between 4.0 s and 4.6 s.

The determination and calculation of t confirms that the differences are significant being 95-99% certain.

❖ 2000 m endurance run test

The execution of the test highlights the aerobic endurance ability of the body.

The horizontal analysis of tables 1 and 2 highlight that the results obtained by the subjects are under constant evolution.

The dynamic of the average of the group (see figure 2) increases from 7.35 to 7.28 with a progress of 7 s. the statistical – mathematical indicators highlight a standard normal deviation (± 12 s), comprising over 68% of the assessed cases, the coefficient of variability recording a high homogeneity of 1.71%.

The vertical analysis of tables 1 and 2 highlight individual values during the final testing comprised between 7.05 and 7.50.

The determination and calculation of *t* confirms that the differences are significant being 95-99% certain.

❖ **Penta jump**

This test highlights the explosive strength (expansion strength) of the inferior limbs. The dynamic of the group average (see figure 3) increases from 11.96 during the initial testing to 12.20 m during final testing, namely a progress of 24 cm. the statistical indicators highlight a standard normal deviation (± 40 cm), comprising 68% of the cases tested, the coefficient of variability recording a homogeneity larger than 3.29%.

The vertical analysis of tables 1 and 2 from annex 1 respectively 2, highlight individual values during the final testing comprised between 11.45 and 12.94 m.

The determination and calculation of *t* confirms that the differences are significant being 95-99% certain.

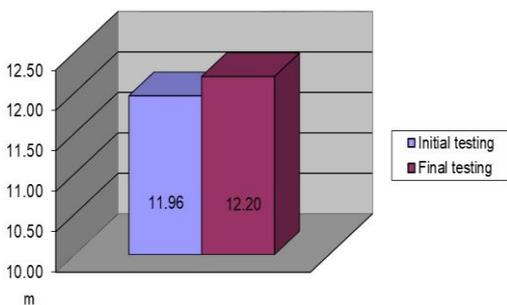

Fig. 3. Penta jump

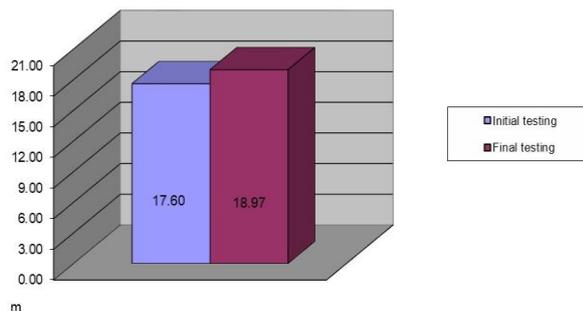

Fig. 4. Throwing the 2 kg medicine ball

❖ **Throwing the medicine ball from a static position to a distance using both hands above the head**

The test highlights the expansion strength of the superior limbs, testing the level of the strength and speed of the muscles of the superior limbs.

The vertical analysis of tables 1 and 2 from annex 1 respectively 2, highlight individual values during the final testing comprised between 16.80 – 23.40 m, while the horizontal analysis highlights a continuous individual evolution of each member of the team.

The distribution of individual values presents an asymmetric distributions compared to the group average, highlighting both the weak results as well as the results better than the group average.

The statistical mathematical indicators highlight an average of 18.97 m, the standard deviation presents a normal distribution of over 68%, while the coefficient of variability brings forward a homogeneity of 9.63%.

The determination and calculation of *t* confirms that the differences are significant being 95-99% certain.

❖ **Hitting the football while jumping from a stative position**

The model of the test – maximum number of executions / time unit – follows to assess the development level of the strength as speed of the muscles of inferior limbs.

The analysis of the diagram presented in Figure 5 highlights average values of 24.83 executions for initial testing and respectively 27.78 during the final executions, the realised progress being of 2.95 executions.

The vertical analysis of tables 1 and 2 brings forward individual values comprised between 24 – 30 executions, while the horizontal analysis highlights a continuous increase for each member of the group.

The statistical mathematical indicators bring forward an average of $\bar{x}=27.22$ executions during the final testing, the standard deviations presenting normal values which comprise more than 68% of the cases, the coefficient of variability presenting an homogeneity higher than 6.97%.

The determination and calculation of *t* confirms that the differences are significant being 95-99% certain, the risk of failure being comprised between 1 – 5%.

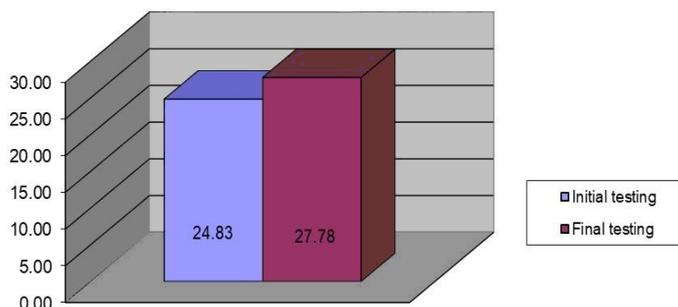

Fig. 5. Hitting the ball with the head from a static jumping position

5. Conclusions

The present study is part of a series of searches carried out by specialists in the field in order to increase the efficiency of the training session, the accuracy in passing the ball, its contribution to the training of future football player taking into consideration the requirements imposed by the modern football game.

Dash running being mainly determined by genetics a speed increase rate has been highlighted which needs to be researched further considering the biomechanical considerations, respectively the improvement of the running technique.

For the 2000 m endurance running, the obtained values present an increase by the reduction of the average time for the distance with approximately 7 s.

The speed strength (compression strength) of the inferior limbs highlight an optimum functional status of the muscular groups at this level.

The strength of the protractor muscles stagnates or regresses during this period which implies the large and varied use of strength training exercises destined for this group of muscles as well as those groups used while moving and performing technical movements (inferior limbs).

6. Recommendations

As it is all about a complex adaptation process of the body to permanent effort, passing to a new quality state of the capacity to withstand effort more importance needs to be given to effort dynamics during a lesson and respectively the recovery break.

Physics Labs for Engineering Students: a Case Study Based on “Learning by Doing” Principles

Constantin Dan Buioca *

University of Petrosani, 20, University Street, 332006, Romania

Abstract

The work presents the main stages in preparing and performing a physics lab for engineering students (dependence on temperature of electrical resistance of a resistor), based on “learning by doing” principles: putting into evidence the theoretical and practical aspects of the studied phenomena; modeling and simulation using MathCAD software; conceiving experimental setup and measuring physical parameters; evaluation of theoretical and practical (real) experimental errors; estimation of practical applications. Steps to be followed and MathCAD programs presented allow an increase of measurements precision and fast acquiring of important practical skills.

Keywords: physics, lab, electric rezistance, temperature, measuring errors, MathCAD, learning by doing

1. Introduction

The work presents a typical physics lab, based on modern “learning by doing” principles, because it allows to:

- Put into evidence the physical phenomenon and basic theoretical aspects, allowing the modeling and simulation of the studied phenomenon (dependence on temperature of the electrical resistance of a metal conductor);
- Conceive experimental set-up and measuring methods;
- Evaluate measuring errors (related to measuring apparatus);
- Process experimental data, using adequate software (MathCAD, in this case);
- Determinate of governing theoretical law of studied phenomenon;
- Evaluate real measuring errors (including also random and caused by experimenter errors);
- Estimate possible applications of the studied phenomenon (using the conductor as temperature sensor, in this case).

2. Theoretical aspects

Metallic conductors have an electric resistance depending on temperature as:

$$R=R_0[1+\alpha(t-t_0)] \quad (1)$$

where R_0 is the electrical resistance at initial temperature t_0 , and α is a thermal coefficient characterizing the resistor material.

Relation (1) describes a linear dependence of resistance with temperature:

$$R(t)=a+bt \quad (2)$$

which gives:

$$a=R_0(1-\alpha t_0) \quad (3)$$

* Corresponding author. Tel.: +40-075-610-864.
E-mail address: constantinbuioca@upet.ro.

$$b=R_0\alpha \tag{4}$$

Relation (1) allows experimental determination of the coefficient α_e using measured values of resistance and temperature:

$$\alpha_e=(R-R_0)/R_0(t-t_0) \tag{5}$$

while relations (2)-(4) allow calculation using the found theoretical dependence $R(t)$:

$$\alpha_c=[R(t)-R(t_0)]/R(t_0)(t-t_0) \tag{6}$$

The quality of measurements is given by relative errors in determination of resistance and temperature:

$$\delta R=\Delta R/R \tag{7}$$

$$\delta t=\Delta t/t \tag{8}$$

where ΔR and Δt are absolute errors in determination of resistance and temperature.

Finally, once the relation (2) determined, we can experimentally determine temperature if we measure resistance, as:

$$t=(R-a)/b \tag{9}$$

3. Experimental technique and data processing

Resistance and temperature were measured using high quality digital instruments, allowing absolute errors of $\Delta R=0,1 \text{ } \Omega$ and $\Delta t=0,1 \text{ } ^\circ\text{C}$. Temperature sensor and resistor were introduced in an oven ensuring heating between 24 and 40 $^\circ\text{C}$.

Measurements results were inserted in table 1.

Table 1.

Det. No.	t ($^\circ\text{C}$)	R (Ω)	α ($^\circ\text{C}^{-1}$)	α_{average} ($^\circ\text{C}^{-1}$)	a (Ω)	b ($^\circ\text{C}^{-1}$)	Obs.
1							
2							
...							

Measurements results were used in a MathCAD program presented below.

Results for temperature and resistance were inserted in vectors t and R, with element's index from 0 to 16 (figure 1):

The linear function Rteor (a,b,i) was defined, then a graphic was generated, for measured values (R_i, t_i) and Rteor, for different values of constants a and b. After a few attempts, the result from figure 2, corresponding to a=33,95 and b=0,19 were obtained.

Relative errors are defined:

$$\delta R_{\text{teor}}(\Delta R, i) := \frac{\Delta R \cdot 100}{R_i}$$

$$\delta R_{\text{pract}}(i) := \frac{|R_{\text{teor}}(33.95, 0.13, i) - R_i| \cdot 100}{R_i}$$

This will allow their evaluation, as in figure 3.

24	37.1	i :- 0, 1.. 16
25	37.2	
26	37.4	
27	37.5	
28	37.6	
29	37.7	
30	37.9	
31	38.0	
32	38.1	
33	38.2	
34	38.3	
35	38.4	
36	38.6	
37	38.8	
38	38.9	
39	39.0	
40	39.2	

Fig. 1.

$$R_{\text{teor}}(a, b, \bar{i}) :- a + b \cdot t_i$$

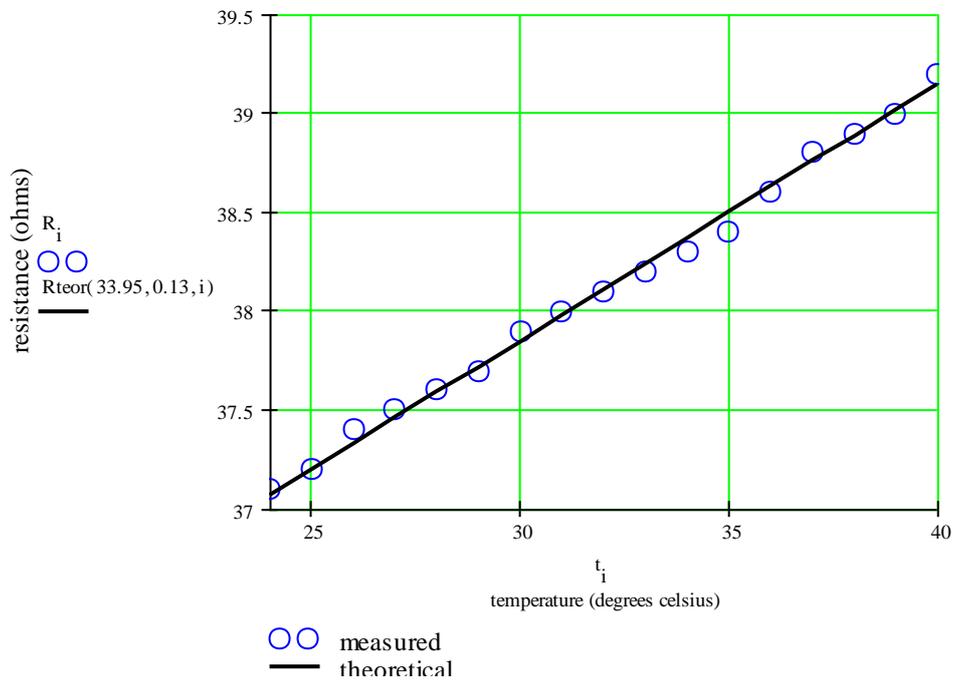

Fig. 2.

One can see very small errors, under 0.3%, determined by high quality instruments. But remarkable is that practical (final, after data processing) errors are even smaller, under 0.2%, because by data processing and establishing linear dependence, some measurement errors were removed. In other words, adequate processing of experimental data leads to an increasing of measurements accuracy.

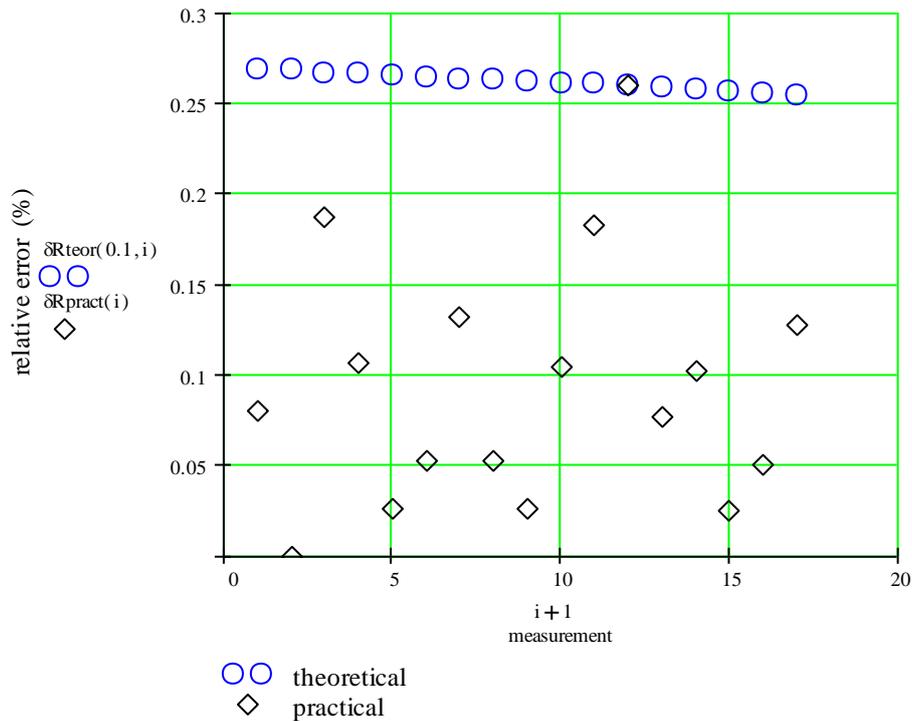

Fig. 3.

4. Conclusions

Preparing and performing a physics lab for engineering students based on “learning by doing” principles allow the increase of efficiency of learning process. Students can learn faster and better how to put into evidence the theoretical and practical aspects of the studied phenomena; how to model and simulate a physical phenomena using a specialized software; how to conceive experimental setup and measure physical parameters; how to evaluate theoretical and practical (real) experimental errors; how to estimate practical applications. Steps to be followed and MathCAD programs presented allow an increase of measurements precision and fast acquiring of important practical skills.

Optical study of Saharan dust transported in Jiu Valley in 2018

Constantin Dan Buioca *

University of Petrosani, 20, University Street, 332006, Romania

Abstract

Dust particles from Sahara, transported by wind and rain in Jib Valley, in April 2018, as well as typical dust found before and after, were studied using an optical Zeiss microscope. The obtained images were processed using Windows Paint and MathCAD software. Results were compared with theoretical ones, obtained by MathCAD simulation of dust transport by wind in Sahara Desert. The study put into evidence that Saharan dust particles are mainly reddish quartz ones, having dimensions between 50 and 100 microns, not really dangerous, but causing some discomfort.

Keywords: optical microscopy, MathCAD, simulation, wind transport, saharan dust, Jiu Valley,

1. Introduction

For the beginning, why this research subject?

A simple answer: the orange snow from fall March and reddish dust from beginning April 2018, all Saharan provenience, were media news intriguing – but without any scientific details. Searching that kind of details, one can see that there are none, that’s why I’ve took dust samples and studied them using optical microscopy.

City dust is an important atmospheric pollutant, created by human activities but also by natural phenomena – like storms or volcanic eruptions. Knowing dust’s physical and chemical characteristics allows the evaluation of its impact on environment and especially on humans, as well as establishing methods to reduce impact.

Clinical studies show that most frequently found dust particles, having dimensions between 1 and 100 microns, determines only discomfort during inhalation. Most dangerous particles are those with dimensions between 0.1 and 1 microns, which are breathable and are blocked in loans alveoli. Particles under 0.1 micron are breathable but, caused by Brownian motion, behave like gases and are eliminated from loans during exhalation.

2. Theoretical aspects

A first aspect is related to the size of the particles that we expect to find in Saharan dust transported on thousands kilometers after a desert storm.

In order to evaluate the particle’s (considered spherical) radius, we must compare their weight against the drag (by wind) force:

$$G=4\pi r^3\rho g/3 \tag{1}$$

$$F_d=6\pi\eta r v \tag{2}$$

where $g=9,8 \text{ m/s}^2$ is free fall acceleration, r is the particle’s radius, v is wind velocity, ρ is the particle’s density (for quartz/sand, $\rho=2500 \text{ kg/m}^3$), and η is the air’s dynamic viscosity coefficient ($\eta=1,81\cdot 10^{-5} \text{ kg/m}\cdot\text{s}$).

* Corresponding author. Tel.: +40-075-610-864.
E-mail address: constantinbuioca@upet.ro.

Equalizing the two forces, one get the minimum speed of wind lifting the particle:

$$v=2r^2\rho g/9\eta \tag{3}$$

Evaluation of this velocity with a MathCAD program gives the result seen in fig. 1.

$$r := 10^{-6}, 2 \cdot 10^{-6} .. 3 \cdot 10^{-4}$$

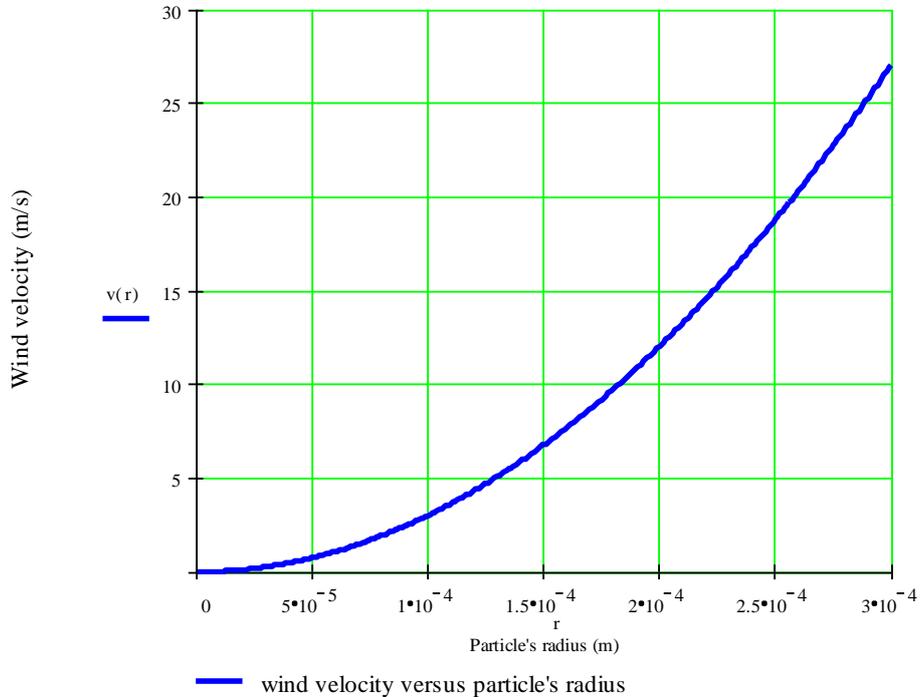

Fig. 1.

As one can see, a weak wind of a few m/s, lifts particles of a few microns, while strong wind (storm) of a few tens of m/s lifts particles having dimensions of tens of microns or bigger. We will expect then that Saharan dust particles transported by storms will have dimensions of tens of microns or bigger, depending on the intensity of the storm who lifted the particles.

The second aspect is related on the theoretical minimum dimension of the detected particles. It depends on the microscope's power and digital picture's quality. A correspondence pixel-length can be established using a scale, as shown in figure 2. Reading the image's characteristics reveals that it has 4608 pixels corresponding to 2.5 mm of scale, therefore 1 pixel=0.5 μm. Theoretically, we can put into evidence particles having 1 μm diameter.

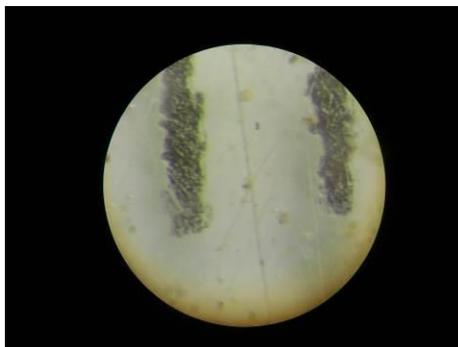

Fig. 2.

3. Experimental results

Samples of Saharan particles were obtained from rain drops, by water evaporation. For comparison, samples of usual city particles were obtained, one week after the studied phenomenon.

Pictures were obtained using a Zeiss optical microscope, with a magnification of 4×200, captured with a camera Nikon Koolpix L610 at quality 4608×3456 pixels. The obtained pictures were analyzed using Windows Paint – allowing the display in pixels of picture's or particle's dimensions.

Figure 3 shows typical pictures of observed particles, including Saharan ones. One can see 4 different types of particles.

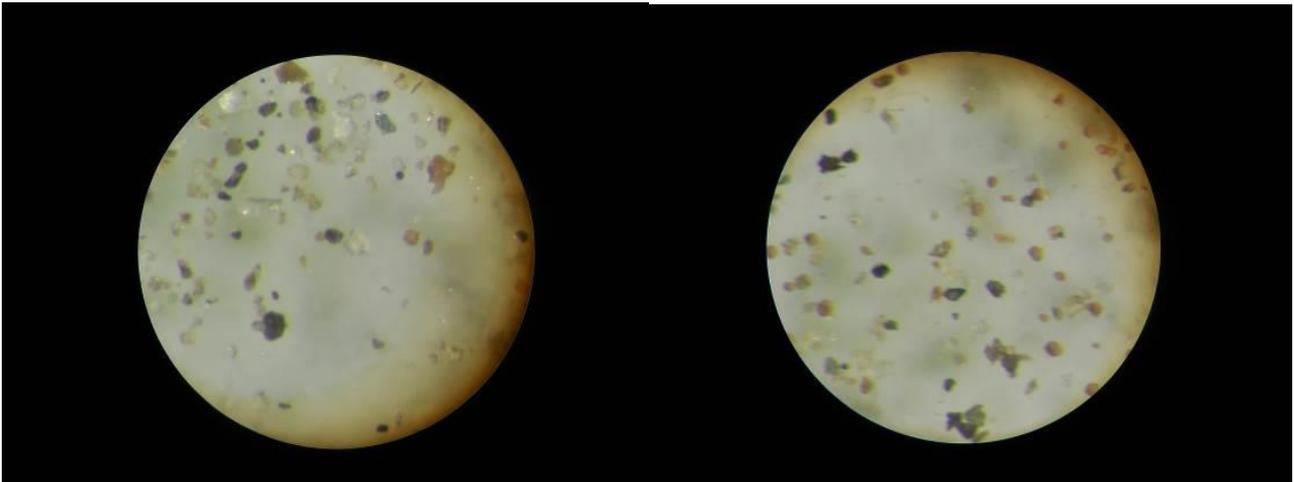

Fig. 3.

The first type is the reddish ones, characteristic to Sahara desert, having dimensions between 50 and 100 microns. These are particles of quartz with iron impurities, similar to those observed in Sahara desert.

The second type is the shining-white ones, having dimensions between 50 and 100 microns, less frequent than the first ones. These are particles of (almost pure) quartz, of local provenience, lifted by local wind or vehicles.

The third type is black particles, relatively frequent, having dimensions between 20 and 70 microns. These are polluting particles from Diesel engines.

The last type is the very small shining-white particles, having dimensions of a few microns. These appear in pictures with in-door dust, therefore are not Saharan ones.

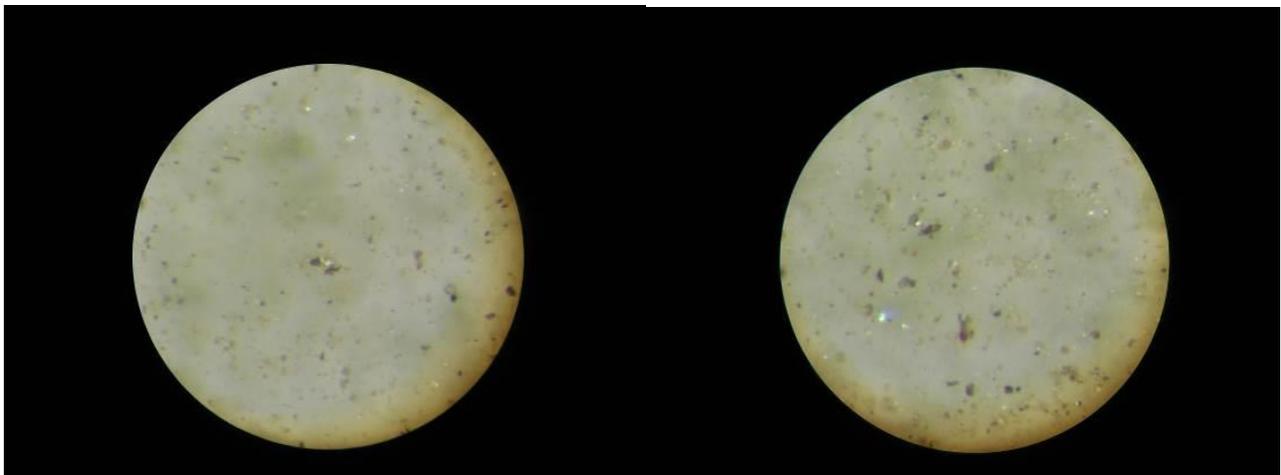

Fig. 4.

For comparison, figure 4 shows pictures obtained one week after the Saharan event. One can see that most particles are small, rarely reaching 50 microns, rarely reddish.

4. The MathCAD program

The MathCAD program for simulation of particles drag by wind is presented in figure 5.

The program logic is obvious. Values are given for involved parameters, and then the formula of wind velocity is defined. The graphic of wind velocity as a function of particles radius is generated. For details, see author's book, specially written for beginner MathCAD users.

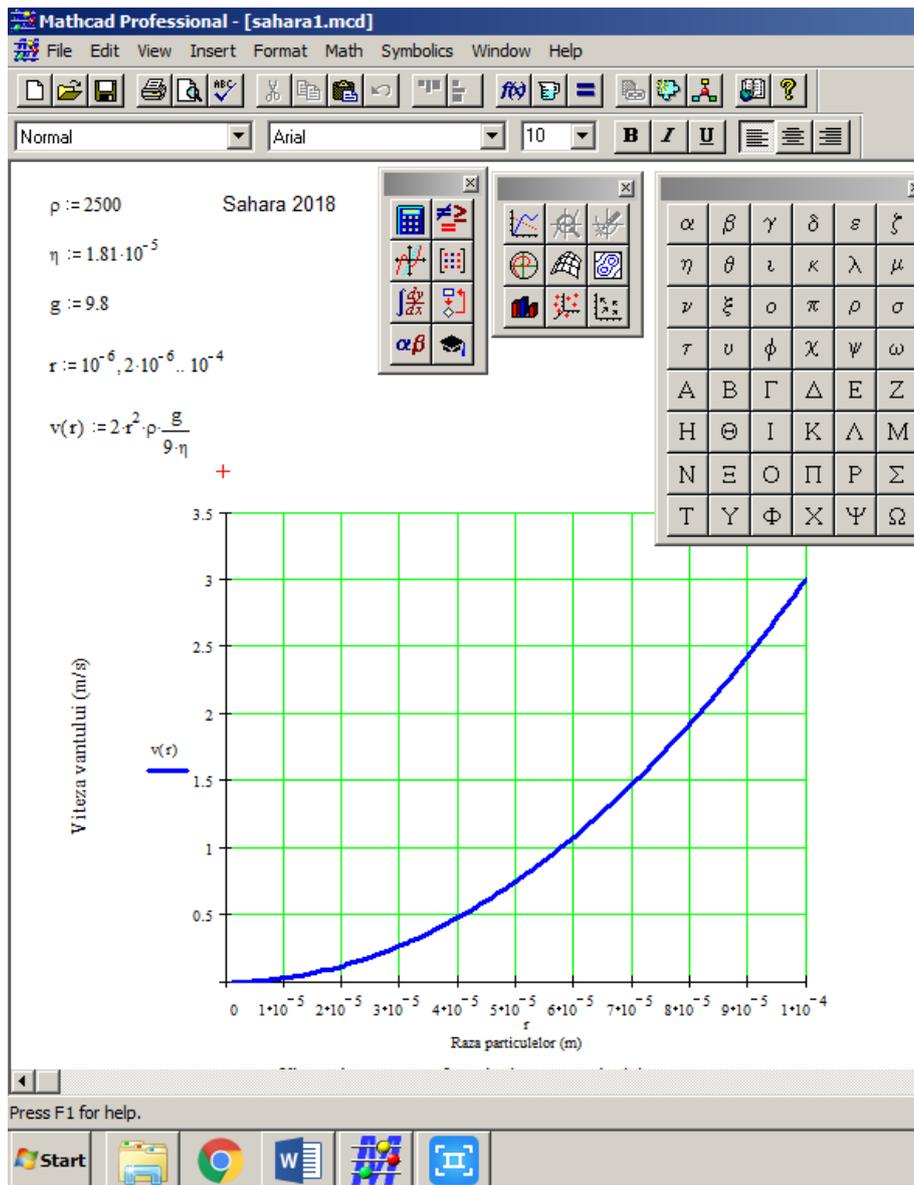

Fig. 5.

5. Conclusions

Microscopic analysis of dust transported in Jiu Valley from Sahara desert put into evidence the presence of typical reddish quartz Saharan particles, having dimensions between 50 and 100 microns. These are not significantly affecting the quality of air, on both atmospheric and ground level, because after water evaporation they are staying on ground level, in small amounts, and (being so big) are not lifted in air by usual wind. Even if lifted by strong wind, they are not a real danger for humans, causing eventually a small discomfort.

Sustainable Development - Never Fulfilled Dream

Janusz Grabara^a *

^aThe Management Faculty, Czestochowa University of Technology

Abstract:

The sustainable development can be introduced in different ways. It is necessary to consider whether for sustainable development, it is possibility to create universal model. The model has to fulfil certain requirements and at the same time as simple as possible to implement elements of sustainable development. It is necessary to remember, while creating this model, that some particular streams of elements, which allows to form sustainable development influence one another. The paper, it is the introduction concept of such a model, which takes into consideration streams of sustainable development management. It is necessary to present impossibility of full realization of sustainable development. Because, there are a few important factors. At first it is electricity over 65% is produced from coal, natural gas and oil. The new regulations and trends give us information about limitation of classic fuel engine cars sell since 2015 in Netherlands and Norway. It will prohibited selling of new cars excluding electrical cars. The same situation will obligate citizens of UK in 2025. Short analysis gives us information that it will be not enough energy for supply electric cars and the rest electricity consumers. Considering those situations, the Author discuss real possibility of sustainable development introduction as well as proposes new model of sustainable development evaluation.

Keywords sustainable development system, matrix, set

1. Introduction

The space that covers the whole of sustainability is enormous. In a short article it is difficult to list all aspects, factors and conditions, which is why the article signals some elements of sustainable development. Some big business acts contradict sustainable development policies through semi-illegal or illegal activities to reduce product use time only to increase the sales of newly produced goods. This paper presents the definitions of sustainable development as well as the groups of issues related to these definitions including the comments. The aim of this article is to show that under current conditions, the global introduction of sustainable development is impracticable and the prospects are very distant

2. Sustainable development critical literature review

Nowadays, environment and ecology preservation become more important. Better political, social and economic management involves respecting and protecting surrounding wildlife. Humankind became more aware of the environmental issues and now it values acts that have positive impact on nature and criticizes those who contribute to environmental depletion (Grabara 2017; Adamisin et al., 2018). This philosophy is not something new because almost 50 years ago the destructive effect of industrialization on environment was clearly emphasized. On June 16, 1972 the definition of sustainable development came into being and its political, economic and social aspects were discussed in the Declaration of the United Nations Conference on the Human Environment. After that, sustainable development was defined as follows: "the right to meet the development aspirations of the present generation, without limiting the rights of future generations". Hence, present economic expansion cannot reduce future generation's chance for the same economic development. Using natural resources should be done reasonably and responsibly in order to avoid situation where future generation will have not enough reserves to sustain themselves. There are two ways of looking at the

* Corresponding author. Tel.: +48 604 16 39 22; fax: +48 34 325 0244.
E-mail address: janusz@grabara.eu.

definition of sustainable development. The first is that this process refers to one country or city. The wider context indicates that it is a global phenomenon including the future of next generation. It is said that sustainable development is "a sequence of changes in which, the use of resources, the structure of investments, orientation of technological progress and institutional structures can be carried out in such a way, that there will be no contradiction between the future and present needs". J. Adamczyk and T. Nitkiewicz (2007) suggested that when it comes to sustainability, well-balanced development is a key and "...consists in establishing the connection between the economic and social development by assuring an access to the renewable and non-renewable resources together with improving quality of life in a natural and clean environment. Economic development ought to assure a more effective utilization of natural resources and other resources of nature, rationalization of the input of energy and work, as well as the development of pro-ecological technologies and the protection of environmental and cultural heritage. Thus, the continuous and sustainable development is a humanitarian concept of global development, whose basic feature is the improvement of the quality of life and welfare of mankind under the conditions of a limited availability of natural resources, taking into account the far-reaching consequences of industrial development. This concept assumes a common responsibility and solidarity of the present and future generations." Another definition of sustainable development was constructed by D. Loorbach (2010) who stated that "Sustainable development is a process of change (development), which implements the feature of balance assessed positively in terms of at least anthropocentric system of values or less, less precisely though – it is development with the sustainability attribute" . During the United Nations Conference "Environment and Development" (Rio de Janeiro, 3rd-14th of June 1992) twenty-seven principles of sustainable development were constituted in order to confirm the declaration of the United Nations Conference on the Human Environment. Until today, these principles are the most complex and most relevant definition of sustainable development. They contributed towards establishing new and equal partnerships between countries and between nations and fundamental social groups. Moreover, it facilitated the process of creating "international agreements, favorable for everybody and protect the integrity of the global environment and development system, recognizing the indivisible and interdependent nature of the Earth's affiliate, our home". Nowadays, there are two concepts of development. Firstly, we distinguish the development of conventional thinking which assumptions relate to the present generation and achieving material stability. In this model high rate of economic growth is essential for social and economic improvements. The effect of industrial development on ecosystem is not taken into account. On the other hand, there is a concept of sustainable development where future ecological and social situation are included in the process of managing economic expansion. The main purpose of sustainable development is to increase, not only the level, but also the quality of life. One of the most important aspects of sustainable development is that human needs must not breach the stability of ecosystems (Grabara et al., 2016; Dobrovolskienė, et al., 2017; Askadilla, et al., 2017). Furthermore, human development respects and protects natural environment at present and has positive impact on the future. Sustainability means using the resources of natural environment in a reasonable way – the level of utilization is high and the level of waste is minimal. Eco-development is sometimes used as a synonym for sustainable development. When discussing the idea of sustainable development, one of the definitions states that it is a balance between economy, environmental issues and culture. In this connection, humankind should not disrupt surrounding wildlife while enhancing economic growth. Sustainability is also achieved when future generation can still benefit from the same environment. There are several definitions of sustainable development and these are some of the most popular. First one states that "sustainability is conducting any business in harmony with nature, so not to cause irreversible changes in the nature or the management of environmentally acceptable, socially desirable and economically viable" . The next one defines sustainable development as "socio-economic development harmonized with the natural environment, both local and wider - including the various ecosystems and resources, and the structure of soil, water, geological and atmospheric and generally understood the beauty of the landscape in order to preserve their values in the longest possible time intervals" . According to another definition "sustainability is a comprehensive harmonization of economic activities with the possibilities of the natural environment". The concept of sustainability may be a result of increasing awareness of environmental damage done by rapid industrialization, human development and culture. It is a global issue referring to the knowledge that some of the resources are not renewable and may be depleted. This can be done by inappropriate use of these reserves at present which may cause unstable and uncertain situation for future generation.

3. Sustainable development today

From a practical point of view, the idea of sustainable development is the introduction of so-called. "integrated governance", which would integrate environmental governance, socio-economic, spatial and institutional and political order. It follows, that sustainable development can be achieved only in the case of conducting environmental, socio-economic and spatial policy (Kot, 2018; Mashokhida, et al., 2018; Rajnoha and Lesníková, 2016; Ilysheva, et al., 2017; Streimikiene, et al., 2016).

In pursuit of sustainable development, development of environmental awareness is extremely important. "The awareness term determined the relationship of man to nature, the team of the information and beliefs about it, and the system of values, which is directed against him on in his ways".

"Environmental issues are closely linked to social, economic, and cultural factors and cannot be solved only through technological means. The attitude of people to the natural environment, depends on their awareness, that is, their

knowledge and beliefs about the environment, and the values which guided them in conduct towards the environment. To make people aware of environmental degradation and the consequences flowing from the last few decades, has resulted in a change in environmental awareness and, consequently, of the Initiative practices ".

Difficult to carry out the task of sustainable development

The Sustainable Development Conference (Rio + 20), held in Rio de Janeiro in June 2012, outlined four key elements needed to realize global sustainability. These are: planet Earth, prosperity, world peace and partnership.

The composition of these elements seems impossible.

Our planet, we want to protect the Earth from deteriorating environment through sustainable consumption and production, sustainable management of natural resources and taking urgent action against climate change, supporting the needs of present and future generations.

Prosperity, we want to ensure that all people have a dignified and satisfying life and that economic, social and technological development is in harmony with nature.

Peace in the world, we build peaceful and inclusive societies, free of fear and violence. There is no sustainable development without peace, and there is no peace without sustainable development.

We will mobilize the resources needed to implement this agenda by revitalizing the Global Partnership for Sustainable Development in the spirit of enhanced global solidarity, focusing in particular on the needs of the poorest and most vulnerable groups, and in the cooperation of all states, parties and people around the world. Protect the planet from deteriorating environmental conditions through sustainable consumption and production, sustainable management of natural resources and urgent action against climate change, supporting the needs of present and future generations.

This is a wish for no chance for realization. There are many elements that have a significant impact on the realization of this postulate. The most known aspect of the negative impact humans have on our planet is climate warming, which is a fact and we all feel its effects in the form of more frequent and stronger hurricanes, typhoons and floods and tsunamis.

The next element is deforestation, where, despite the loss of habitat, especially in Africa and South America, there are about 4 million hectares a year. This progress contributes to the increase of desert areas. About 20 million hectares of land surface annually.

Fuel and energy are also a frighteningly important factor. We consider this as coal, natural gas and oil. There are two reasons for this concern. Firstly, the use of these fuels contributes to the greenhouse effect as well as to the formation of smog (Tvaronaviciene, 2018; Popp et al., 2018a, Grabara and Kot, 2017) and secondly, the reserves of these minerals, with only 34 billion barrels of oil extracted annually, are significantly reduced with coal and gas. Energy consumption is still increasing, with an approximate 570 EJ consumed at the primary energy level in 2014. Of this total 78.3% was provided by fossil fuels, 2.5% from nuclear, 8-9 by biomass mainly from wood combustion, 3.9% from hydro, and 6.4% from other renewable energy sources (Oláh et al., 2017; Tvaronaviciene, et al. 2018; Mikita et al., 2017). Transport biofuels are currently the fastest growing bioenergy sectors even they represent around 3-4% of total road transport fuel and only 6% of total bioenergy consumption today. Low oil prices and poor margins continue to challenge biofuel producers in Europe (Popp et al., 2018a).

Similarly, in the area of electricity production where only about 5 percent of energy is produced using new technologies in renewable sources, about 16% in hydroelectric plants, and 12% generate nuclear power plants. The distribution of these power plants is disproportionate, for example, nuclear power supplies more than 80 percent of electricity demand in France, and in Germany the share of this energy system is decreasing, which is linked to successive shutdowns of nuclear power plants. However, on a global scale, more than 40% of electricity produced is coal-based, leading in China and the United States.

The third element is extinction, a very tragic phenomenon, as it causes irreversible loss of many species of flora and fauna as the so-called "butterfly effect" causes irreversible changes in the ecosystem of the Earth.

Elements are definitely more than we could attribute to the concept of Earth from a sustainable development perspective.

The next major element outlined by the Sustainable Development Conference (Rio + 20) is Prosperity.

Prosperity is a difficult concept to define, prosperity is something that should give all people a dignified and satisfying life and make economic, social and technological development in harmony with nature. The concept of prosperity is probably the fastest evolving concept of our times, and one could even argue that it evolves faster than the ICT industry.

In terms of social (i.e. non-personal) this awareness of prosperity arises from the conditions of "being". Simplifying things strongly: As people bring down to the level of satisfying the basic needs (even according to the Maslow classification), "we will shape their "consciousness" very shallow and superficial, but very dangerous - they will have nothing (or almost nothing) to lose and formed a class of opponents All people living so long in the margins that it will be for them a field of their "normal" action". Therefore, achieving global prosperity seems very remote in time.

Peace in the world, we build peaceful and inclusive societies, free of fear and violence. There is no sustainable development without peace, and there is no peace without sustainable development.

According to a recently published work, by July 2011 nearly 500,000 people died in the Iraq war. Another work (Iraq Body Count), which is based on mass media reports, shows that by December 2012, 110,000 died.

Estimates include: The share of civilian war victims increased from 5 to 90 percent in the last hundred years. So it does not seem possible to extinguish all armed conflicts in the near, future or even very distant future.

The last of these is partnership (Popp et a., 2018b). Partnership as well as global peace are elements of utopian thinking. The brutal reality shows that they win particular interests, nationalisms, and similar macro-level, micro and nano factors on the good of the whole of humanity and the implementation of sustainable development. It should also be mentioned that the debt of the majority of states is so great, reaching up to about 90% of GDP, which makes it impossible to step up efforts to remove obstacles to sustainable development.

Threats in sustainable development currently affect not only our planet, but also its surroundings, which has been postponed by NASA.

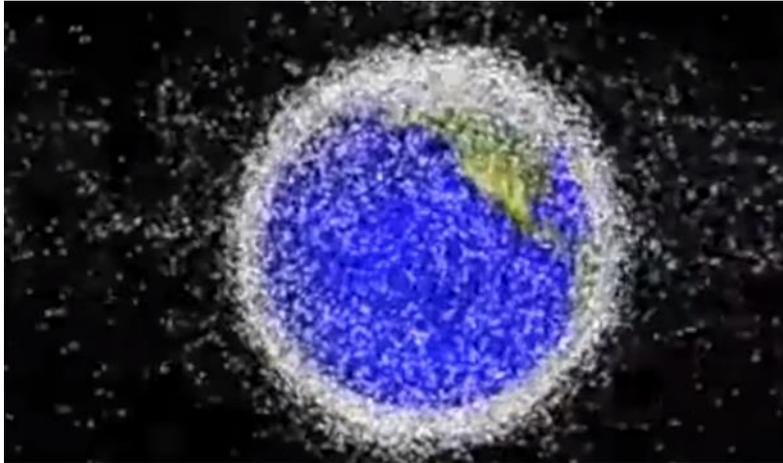

Fig. 1 White Dots mean garbage left after the implementation of space programs orbiting the Earth

4. Model of sustainable development progress

Sustainable development process can be introduced in different ways. One of such ways in the tables used is structural analysis, which take into consideration sustainability and economic policy divisions or determine directions of Sustainable development progress in the world with use of simulation methods. All methods that progressing sustainable development can be introduced as right structural models.

It is necessary to think whether for sustainable development progress there is possibility to create universal structure, which allows building sustainable development structure model. The model has to fulfil certain requirement at the same time as simple as possible to implement.

In this paper it is a trial of introducing of such model, which take into consideration sustainable elements and their interaction. This model consists of matrix mutual connections sustainable elements and economic policy decisions.

Let us include factors mentioned by Sustainable Development Conference (Rio + 20):

Prosperity and Peace also the Negative impact humans, Extinction and Debt of the majority of states. We can try to determine the weight of these four factors, but this seems insufficient, as according to the author, one more factor should be included. We can call it random factor, as it depends on the countries' and regions' ability to eliminate the outcomes of natural disasters, like earthquakes, floods, wildfires, volcanic eruptions and industrial disasters.

These factors are strictly related to each other.

Using the matrix projection of elements' configuration and streams, the relation $*ik$, created by particular factors D_i

Using here and aforementioned characteristics of matrix record allows read for each factor all links ingoing to its and outgoing from its.

And so:

relation ensuring from Peace and Prosperity P (D1)

$$*11 = f_1(d_{12}, d_{13}, d_{14}, d_{15}, d_{21}, d_{31}, d_{41}, d_{51}, z_{11}, z_{21}, z_{31}, z_{41}, z_{51}, z_{61})$$

relation ensuring from Negative Impact Humans N (D2)

$$*22 = f_2(d_{21}, d_{23}, d_{24}, d_{25}, d_{12}, d_{32}, d_{42}, d_{52}, z_{12}, z_{22}, z_{32}, z_{42}, z_{52}, z_{62})$$

relation ensuring from Extension E (D3)

$$*33 = f_3(d_{31}, d_{32}, d_{34}, d_{35}, d_{13}, d_{23}, d_{43}, d_{53}, z_{13}, z_{23}, z_{33}, z_{43}, z_{53}, z_{63})$$

relation ensuring from Debt of the majority of states D (D4)

$$*44 = f_4(d_{41}, d_{42}, d_{43}, d_{45}, d_{14}, d_{24}, d_{34}, d_{54}, z_{14}, z_{24}, z_{34}, z_{44}, z_{54}, z_{64})$$

relation ensuring from Random factor R (D5)

$$*55 = f_5(d_{51}, d_{52}, d_{53}, d_{54}, d_{15}, d_{25}, d_{35}, d_{45}, z_{15}, z_{25}, z_{35}, z_{45}, z_{55}, z_{65})$$

Matrix record of investigated structure will provide identification of those relation as a function of ingoing factors to framework of system. It will be relations effecting on Sustainable Development Progress particular factors flowing from blocks detailed determining relation.

Table 1. Matrix projection of elements' configuration as well as procedural and subjected streams of sustainable development progress.

	W ₁	W ₂	W ₃	W ₄	W ₅	W ₆	D ₁	D ₂	D ₃	D ₄	D ₅
D ₁	ϕ_{11}	ϕ_{12}	ϕ_{13}	ϕ_{14}	ϕ_{15}	ϕ_{16}	0	d ₁₂	d ₁₃	D ₁₄	d ₁₅
D ₂	ϕ_{21}	ϕ_{22}	ϕ_{23}	ϕ_{24}	ϕ_{25}	ϕ_{26}	d ₂₁	0	d ₂₃	D ₂₄	d ₂₅
D ₃	ϕ_{31}	ϕ_{32}	ϕ_{33}	ϕ_{34}	ϕ_{35}	ϕ_{36}	d ₃₁	d ₃₂	0	D ₃₄	d ₃₅
D ₄	ϕ_{41}	ϕ_{42}	ϕ_{43}	ϕ_{44}	ϕ_{45}	ϕ_{46}	d ₄₁	d ₄₂	d ₄₃	0	d ₄₅
D ₅	ϕ_{51}	ϕ_{52}	ϕ_{53}	ϕ_{54}	ϕ_{55}	ϕ_{56}	d ₅₁	d ₅₂	d ₅₃	D ₅₄	0
W ₁	s ₁₁	s ₁₂	s ₁₃	s ₁₄	s ₁₅	s ₁₆	z ₁₁	z ₁₂	z ₁₃	Z ₁₄	z ₁₅
W ₂	s ₂₁	s ₂₂	s ₂₃	s ₂₄	s ₂₅	s ₂₆	z ₂₁	z ₂₂	z ₂₃	Z ₂₄	z ₂₅
W ₃	s ₃₁	s ₃₂	s ₃₃	s ₃₄	s ₃₅	s ₃₆	z ₃₁	z ₃₂	z ₃₃	Z ₃₄	z ₃₅
W ₄	s ₄₁	s ₄₂	s ₄₃	s ₄₄	s ₄₅	s ₄₆	z ₄₁	z ₄₂	z ₄₃	Z ₄₄	z ₄₅
W ₅	s ₅₁	s ₅₂	s ₅₃	s ₅₄	s ₅₅	s ₅₆	z ₅₁	z ₅₂	z ₅₃	Z ₅₄	z ₅₅
W ₆	s ₆₁	s ₆₂	s ₆₃	s ₆₄	s ₆₅	s ₆₆	z ₆₁	z ₆₂	z ₆₃	Z ₆₄	z ₆₅

Assuming the result of these computations must fit in between 0 and 1, where zero means lack of any progress in sustainable development and 1 means proper progress, it could be possible to determine how advanced are actions in field of the sustainable development.

Conclusion

Based on the available data, it can be concluded there is no evidence for effective implementation of sustainable development rules at the moment. Furthermore, there is little chance they will occur in the future. Because of this article's space limits, detailed relations and computations are not included.

Considering study limitations, it should be stated that the model is in initial stage of elaboration and it was calculated based on pilot data collection. The model will be developed both in theoretical sphere as well as using large data sets. Those action would allow for more independent and reliable sustainable development evaluation.

Role of ergonomics in sustainable development

Maria Elena Boatca^{a*}, Anca Draghici^a

^aPolitehnica University of Timișoara, 14 Remus street, Timisoara 300191, Romania

Abstract

In the current sociopolitical context, sustainable development is a subject of major importance considering the concerned statistics and disastrous impact of the resource-intensive economic model. Considering more countries' concern for environmental protection and the urgent need of a more sustainable lifestyle and economic practice, ergonomics could be the solution for certain problems. As for the International Ergonomics Association, Human Factors and Sustainable Development (HFSD) the topic is a relatively new sub-sector related to ergonomics, it roots back to disciplines such as ecology, engineering, development studies and public health. HFSD does not limit to theoretical perspectives but approaches domains such as occupational risk prevention and workplace life quality. Further, integrating aspects such as innovative design, ergonomics and human factors enable ergonomic interventions that create value added not only for the organization but for the society, too. The paper aims to clarify the connections between ergonomics (human factors) and sustainable development.

Key words: Ergonomics, Sustainability, Reporting, Key Performance Indicators (KPIs).

1. Introduction

Integrating ergonomics in the sustainable development approach is a rare practice and the literature in the field do not make a clear presentation of any methodology. As for the International Ergonomics Association, Human Factors and Sustainable Development (HFSD) the topic is a relatively new sub-sector related to ergonomics, it roots back to disciplines such as ecology, engineering, development studies and public health. HFSD does not limit to theoretical perspectives but approaches domains such as occupational risk prevention and workplace life quality. Further, integrating aspects such as innovative design, ergonomics and human factors enable ergonomic interventions that create value added not only for the organization but for the society, too. In this context, the aim of the present paper is to clarify the connections between ergonomics (human factors) and sustainable development through the support of the knowledge (and approach) from the performance management domain. After some considerations on relationship between ergonomics and sustainability there will be analyzed the case of transparency of ergonomics in sustainability initiatives across companies. Thus, a proposed model for considering the Key Performance Indicators for reflecting the support of ergonomics in sustainable development will be proposed. Finally, some conclusions and remarks will be made.

2. Brief considerations on relationship between ergonomics and sustainability

It is not a novelty that ergonomics significantly contributes to employee wellbeing, generating major benefits for both the company and the society. Further, it became a common practice in the past years to adhere to sustainability targets and to report performance as per renowned models or principles. However, there is little evidence on how companies complement ergonomic activities with their sustainability and environmental initiatives. The reason behind this would be on the one hand, the design of the sustainability Key Performance Indicators (KPIs) and, on the other hand, lack of understanding on the interconnections between ergonomics and sustainability.

E-mail address: boatcaelena_2009@yahoo.com.

There has been little evidence of a clear connection between ergonomics and sustainability, despite their common aims of improving human well-being and generating benefits at individual, corporate and society levels. However, in the past decades there have been noticed steps taken towards highlighting the importance of ergonomics in achieving sustainability goals (Haslam and Waterson, 2013). International Ergonomics Association (IEA) established a Technical Committee dedicated to ‘Human Factors and Sustainable Development’, an innovative concept aiming to define and optimize the connections between ergonomics (human factors) and sustainability (Zink and Fischer, 2013). Considering the importance of IEA for the ergonomics global scientific and professionals’ community, this attempt indicates small steps towards coordinating sustainability with ergonomics.

To understand why this situation persists, Dekker (2013) research proved that “epistemological and ethical characteristics or ergonomics limit the validity of almost any ergonomic contribution to sustainability”. This research also brings to light a very interesting aspect: ergonomics, by itself, focuses on a problem-solving approach avoiding moral and social concerns that typically come up in sustainability debates. It is not that ergonomics wouldn’t be able to address more deep society concerns, but the way ergonomics is usually implemented is centered towards a specific problem, without necessarily addressing more “delicate” aspects related to ethics or whose interest is served (Dekker et al., 2013).

Leaving aside the prominent sustainability and ergonomics common interests, it is necessary a change of paradigm to define and approach ergonomics in its broader meaning. It is a feasible solution for development of ergonomics-specific KPIs that would be included in sustainability assessments of companies in the coming years, to obtain a more comprehensive understanding of the extent to which companies focus on their long-term impact on society.

3. Case study: transparency of ergonomics in sustainability initiatives across companies

3.1. Key Sustainability Rankings Globally

There have been developed several initiatives to measure how companies commit to sustainability and, implicitly, highlight those companies that meet and exceed targets and performance. Nevertheless, these rankings bring in the spotlight large companies, capable of heavy investments and with the necessary know-how to implement sustainability measures. After all, these companies are the ones with the highest social and environmental impact.

The most important and renowned ranking is the one developed by Corporate Knights and United Nations Global Compact initiative. Corporate Knights is a Canada-based private company engaged in publishing of corporate responsibility magazine and sustainability-related rankings and reports. One of the most interesting rankings issued by the company is ‘Global Most Sustainable Corporations’, an annual ranking that highlights world’s most sustainable public companies based on objective assessment using a series of key performance indicators (KPIs), including the following:

- Energy productivity;
- Carbon productivity;
- Water productivity;
- Waste productivity;
- R&D/revenue;
- Cash taxes paid ratio;
- CEO-average worker pay ratio;
- Pension fund status;
- Injury rate;
- Fatalities number;
- Employee turnover rate;
- Women on board;
- Women executives;
- Sustainability pay link;
- Clean air productivity score;
- Supplier score;
- Clean revenue.

Additionally, each KPI is weighted to indicate the relative performance of the sector where the company activates. For example, the energy KPI would weight more in the case of a company operating in an energy-intensive sector (such as steel manufacturing, or oil and gas) as compared to a company operating in a sector that accounts for a smaller energy use rate.

Further, United Nations (UN) came with a sustainability initiative companies can adhere to: UN Global Compact. UN compiled a sustainability reporting system that enables any company to track certain KPIs across sustainability-related categories. The KPIs are compiled into ten principles derived from the Universal Declaration of Human Rights, the International Labor Organization’s Declaration on Fundamental Principles and Rights at Work, the Rio Declaration on Environment and Development, and the United Nations Convention Against Corruption.

The principles are as follows:

1. Support and respect the protection of internationally proclaimed human rights;
2. Make sure not to be complicit in human rights abuses;
3. Uphold the freedom of association and the effective recognition of the right to collective bargaining;
4. Eliminate all forms of forced and compulsory labor;
5. The effective abolition of child labor;
6. Eliminate discrimination in respect of employment and occupation;
7. Support a precautionary approach to environmental challenges;
8. Undertake initiatives to promote greater environmental responsibility;
9. Encourage the development and diffusion of environmentally friendly technologies;
10. Work against corruption in all its forms, including extortion and bribery.

Despite that major rankings measuring sustainability commitments of companies across the globe include parameters such as gender equality and equal payment across levels/countries, or diversity (referring to diversity of gender, ethnicity etc.), it is very difficult to quantify the extent to which ergonomics is a real part of the sustainability programs and strategies of each company included in the respective rankings. Further, parameters used to evaluate companies differ from a ranking to the other, and, hence, the companies included in one ranking do not appear in another although all these companies are supposed to be leaders in sustainability. This complicates even further any attempt to evaluate the extent to which ergonomics is truly a part of the company's long-term vision for employee well-being and overall sustainability.

From the above-mentioned KPIs, ergonomic-related metrics would only be injury rate and fatalities number. These two provide little information on how the company implements ergonomic interventions or what importance the company gives to ergonomics. Further investigations based on companies' sustainability reports and related documents might reveal further insights.

3.2. Analysis of transparency on ergonomic-related performance for top five sustainability leaders

The analysis is based on the Table 1 content of top five companies and their KPIs focused on environmental and financial performance.

Table 1. Top five sustainability leaders and their performance

Company:	Dassault Systemes	Neste Oyj	Valeo SA	Ucb SA	Outotec Oyj
Sector	Software	Oil, Gas & Consumable Fuels	Auto Components	Pharmaceuticals	Construction & Engineering
Country	France	Finland	France	Belgium	Finland
Energy Productivity Score	69.2%	66.9%	80.0%	92.3%	84.6%
Carbon Productivity Score	79.2%	78.6%	71.4%	94.0%	70.8%
Water Productivity Score	93.8%	74.1%	100.0%	92.6%	85.1%
Waste Productivity Score	95.0%	46.0%	58.3%	91.1%	88.7%
R&D/revenue 2014 - 2016	18.4%	0.3%	8.2%	26.2%	4.7%
Cash taxes paid ratio	26.5%	7.8%	12.2%	36.8%	36.6%
CEO-Average Worker Pay ratio	30	36	61	26	10
Pension Fund Status	65.2%	73.7%	59.3%	75.0%	60.6%
Injury rate	0.06	0.56	0.46	0.41	0.36
Fatalities number	-	-	-	-	-
Employee turnover rate	8.3%	11.2%	11.9%	16.0%	21.6%
Women on board	45.5%	42.9%	35.7%	30.8%	25.0%
Women executives	20.0%	18.0%	13.0%	27.0%	13.0%
Sustainability Paylink	100.0%	100.0%	0.0%	0.0%	100.0%
Clean Revenue (%)	25.0%	21.7%	40.0%	8.3%	65.0%
Clean Air Productivity Score	0.0%	57.5%	22.3%	0.0%	25.0%
Supplier Score	8%	24%	18%	14%	1%
Overall Score	86.13%	85.19%	83.59%	79.52%	78.27%

Considering the rankings, we have decided to focus on ‘Global Most Sustainable Corporations’ 2018 ranking as source of analysis on how companies report ergonomic-related initiatives as part of their sustainability efforts. Irrespective of the major social impact companies make when adhering to UN Global Compact reporting system, the ten principles do not serve the scope of this study. Consequently, we decided to leave aside leading companies included in Global Compact 100, a stock index that highlights sustainability performance in correlation with financial performance of the analyzed company.

Table 1 presents performance of top five companies across a variety of KPIs that are primarily focused on environmental and financial performance. However, injury rate and fatalities number provide a picture of how these companies perform in terms of ergonomics. While injury rate is relatively low, a positive sign is the absence of fatalities.

Based on the collected data, it has been observed that majority of the KPIs focus on the companies’ performance on environmental, economic and social aspects, without properly highlighting at least more detailed occupational health and safety-related commitments. This does not implicitly denote that the company does not measure these aspects, but their absence from the assessment of sustainability performance leads to lack of clarity on any potential indicators of how each company approaches ergonomics.

Furthermore, analyzing the five companies’ reports and publications on sustainability leads too little to no evidence on how these address ergonomic challenges of if they consider ergonomics as part of their sustainability efforts.

Coming back to the purpose of the paper, it is very difficult and inaccurate to analyze the relationship between sustainability and ergonomics based only on injury rate and fatalities number. This confirms, again, the hypothesis that ergonomics is not regarded as an essential parameter of sustainability, despite its major importance for achieving good occupational health and safety performance and generating a positive social impact.

4. Proposed KPIs for characterizing the role of ergonomics in sustainable development

The new group of sustainability KPI was developed based on the concept and literature review as shown in Table 2.

Table 2. Proposed KPIs including the ergonomics support for sustainable development of the industrial system (extended from Helleno et al, 2017)

Dimension	Proposed KPIs	Description of the sub-indicators
Economic	Cost Management	Costs (equipment, materials and services); Acquisition; Return on Investment (ROI)
	Corporate Management	Competitiveness; Tools of Corporate Management; Strategic planning process; Market Share; Number of Recycled Material suppliers
	Operational efficiency	Cycle time; Lean manufacturing waste; Set-up time; Flexibility; Inventory and Stock; Quality of products and services; Total Quality Management (TQM)
	Products	New products; Innovation and insertion in international markets; DFMA (Design for Manufacturing and Assembly)
	Operating Results	Profits; Price; Operational Indicators.
	Suppliers	Standards for Supplier; Just-in-time; Delivery
	Customers	Number of complaints per customer/region; Deadline
Social	Infrastructure	Proximity to transportation hubs; Alternative transport availability; Availability of storage facilities; Efficient use of transport resources; Available manufacturing facilities
	Economic	Salary and benefits
	Satisfaction Level	Level of Employee satisfaction; Absenteeism; Turn Over
	Quality and Health	Health and Safety Programs; Ergonomics; Average distance travelled by employees to the company
	Human Resources	Availability of labor, skilled labor; Recruitment and selection; Hours of training; Performance evaluation (for employees)
Environment	Community	Corporative philanthropy; public health; community development
	Environmental Management	Policy/Environmental Standards; Indicators and Environmental Goals; Structure Responsible for the Environment; Monitoring Biodiversity; Voluntary disclosure of information on environmental performance
	Environmental Aspects	Environmental Aspects and Impacts; Supplier relationship with the environment; Company image in relation to the Environment
	Responsibility	Treatment/Disposal of Waste; Consumption of hazardous materials
	Consumption	Water, energy and paper
	Product life cycle	Product Lifecycle analysis
	Recycling	3 Rs (Reduce, Reuse, Recycle) Culture

The scope of the approach is to develop a conceptual method of assessment of sustainable development for industrial processes. This is separated into two distinct parts: (1) a literature review regarding sustainable indicators (considering the above mention aspects) and (2) the definition of sustainability indicator groups that compose the assessment method. The proposed approach aimed to define a new group of sustainability indicators (Economic, Environmental and Social KPIs), which must reflect also, the ergonomics efforts of the company. This will generate a conceptual method for assessing sustainability in the case of industrial processes. The integration of ergonomics with sustainability indicators was based on the research approach and results presented by Kuhlman et al. (2011) and Faulkner and Badurdeen (2014). The selection of sustainability indicator has followed the concept of Triple Bottom Line, considering the three dimensions of sustainability as suggested by (Helleno et al., 2017).

The focus was most on social KPIs dedicated to Quality and Health sub-indicators, where the ergonomics intervention and support are much helpful and visible. This development aims to contribute to the current sustainability assessment methods with a group of indicators that measure the parameters that can be improved by an ergonomics intervention and that influence the productivity and thereby promote the improvement of sustainability. In addition, ergonomics was considered a source for continuous improvement of the production system.

Previous researches in this field have been presented by (Lee et al., 2014; Brown et al., 2014) that have analyzed changes in production systems and services towards sustainable solutions, and they highlighted the need to develop methods to measure the levels of sustainability of manufacturing processes, but they do not detail ergonomic indicators. The proposed indicators related to the social dimension of sustainability were related to work safety, ergonomic aspects and level of noise, but only at the declarative manner.

In the context of our research, the proposed indicators in the Quality and Health sub-indicator are:
Health and Safety Programs (HSPr) [no. of existing/on-going programs in the assessment period];

$$HSPr = \text{No. of health programs} + \text{No. of safety programs} \tag{1}$$

This indicator is relevant for the prevention management related to OHS in the organization. It could be determined also, by reporting the number of OHS programs to the number of employees (NEO) to see if all them were involved in such programs.

$$HSPr = (\text{No. of health programs} + \text{No. of safety programs}) / NEO \tag{2}$$

Accident Rate (ARa) [accident in the assessment period]:

$$ARa = NA / NEO \tag{3}$$

In equation (3) there have been used the following notations: NA - number of accidents; NEO - number of employees. The relative ARa is inversely related to the ARa (1-ARa).

In the same way there have been defined the Occupational illness Rate (HRa) [new cases of occupational illness in the assessment period]:

$$HRa = NI / NEO \tag{4}$$

In equation (4) there have been used the following notations: NI - number of new illnesses cases in the assessment period; NEO - number of employees. The relative HRa is inversely related to the HRa (1-HRa). From the literature review point of view, indicators (3) and (4) reflects the quality of the professional life and the maturity level of the occupational health and safety system in the organization.

For the Ergonomics aggregate indicator (ERGO), average per NEO, there have been choose the definition inspired by the RNUR method (Draghici, 2004; Vasiliu and Bordei 2013; da Silva et al., 2016):

$$ERGO = \text{Postural} + \text{Physic ambience} + \text{Pshychological stress} \tag{5}$$

The notations used in equation (5) are: Postural represent the cumulative scores for the physic load factors score (posture, work effort, handling effort); Physic ambience – cumulative score for thermal ambience, sound ambience, artificial lightning, vibration, air quality, workplace design; Psychological stress - cumulative score for mental task, autonomy, work relationship, repetitivity of work tasks and work content. The aggregate indicator Ergonomics need a special attention from the ergonomic team in the organization because of the permanent evaluation of each factors considered in equation (5) and the regulations for each of them.

Average distance travelled by employees to the company (Dtr):

$$Dtr = \text{Total distance travelled by employees to the company} / NOE \tag{6}$$

This indicator could adjust the way employees travel from their home location to the company and back and avoid accident occurrence (providing a unique safety transport system by the company).

5. Conclusions

Building a bridge between ergonomics and sustainability is not impossible but requires efforts from both sustainability-related organisms and companies committed to becoming sustainable. A major aspect that needs to be taken care of is development of ergonomic-related KPIs that would accurately reflect companies' commitment to both ergonomics and sustainability. Currently, the only KPIs that might be considered as ergonomic-related are occupational health and safety indicators such as number of injuries (or injury rate) and number of fatalities. These do not offer any transparency or understanding of how a certain company performs in terms of ergonomics.

Hoping that global initiatives aimed at constantly improving measurement of sustainability commitments will understand the significance of ergonomics, the only thing that remains on the shoulders for ergonomists is changing the way we regard ergonomics and expand its applicability across innovative fields and more 'delicate' aspects (such as business ethics).

The presented set of KPIs proposed for the social dimension of sustainability can be considered in organizations' practice. There have been agreements that for better reflecting the ergonomics efforts, an aggregate indicator could be used to assess and continuously monitor the physical load factors, the physical ambient conditions and the level of psychological stress factors. The proposed aggregate ergonomic indicator should be determined using the RNUR method adapted and adjusted to the specific context of the organization.

Future researches will be focused on the practical demonstration of the proposed schema for integrating ergonomics and sustainability to prove the usefulness of this approach for the continuous improvement of organization's sustainable development.

“Pro-Integra” project's comparative survey of main stakeholders' opinions on the educational offer of "1 Decembrie 1918" University of Alba Iulia

Călina-Ana Buțiu*

"1 Decembrie 1918" University of Alba Iulia, 15-17 Unirii Street, Alba Iulia, 510009, Romania

Abstract

The creation of tertiary-level educational opportunities is a stated objective of both European and national policies. More and more policy makers see stakeholders' opinions becoming more and more valuable. "1 Decembrie 1918" University of Alba Iulia's "Pro-Integra" project analyzes both the convergence and the divergence of program choice opinions among educators, students and administrative personnel in an open market economy. The understanding of these motivations helps improve the relevance and quality of the educational offer and helps attract candidates with promising development potential.

Keywords: tertiary education, social inclusion, stakeholders, opinions, intervention

1. Introduction

In the knowledge economy of today education becomes key to the development of human capital and governments around the world are placing it at the centre of their economic and social policy concern. Furthermore, education is not just important to developing economic competitiveness, but is also crucial to fostering active citizenship, social cohesion and international cooperation. There are nevertheless educational inequities, which, as they become more and more aware of, governments are trying to address through a diversification of programs. They are confronted with a dilemma: should they accept the education inequities as an unavoidable 'fact of life' and forego the wasteful costs their handling comes with or should they pursue intervention, in the hope they will eventually go away? An adequate answer to this dilemma does not seem to exist yet (Power, 2012, p. viii).

Frاندji (2012) notes that a series of issues like questions about the welfare state, changes in the business world and their implications for the educational system, the emergence of a new market logic and of new forms of school policy regulation, the concern for social stability and the demands for group recognition, they all require a rethinking of priorities in educational policy-making.

While inclusive education is not exactly a new concern, it does nevertheless require periodic rethinking (Slee, 1998, Waitoller and Artiles, 2013). Several studies ask for changes in educational policy and practices for students with disabilities and learning difficulties (Norwich, 2002, Bond and Castagnera, 2006, Schmidt and Venet, 2012, McGhie-Richmond et al., 2013), for students coming from underprivileged backgrounds (Cremin and Thomas, 2005, Palardy, 2013), or for students with diverse cultural or linguistic backgrounds (Artiles et al., 2006). The fact that each student has particular needs requires a most individualised strategy to the didactic approach and a redesign of the general curriculum accordingly (Howery et al., 2013).

Another series of works examine the multitude of factors, aside from the personal ones, leading to academic dropout. To the traditional sets of factors like race/ethnicity, gender, socio-economic, etc as *social background*, skills, abilities, test scores, etc. as *academic background* and school engagement, school grades, course completions and failures as *academically related behaviours*, Lee and Burkam (2003) also add factors of organizational nature. Their conclusion is that small universities with more positive student-professor relationships are facing less academic dropout. Similarly, Heck and Mahoe (2006) found that aside from personal and social factors, the organizational qualities of

* Corresponding author. Tel.: +40-258-813-994; fax: +40-258-806-126, E-mail address: butiu.calina@uab.ro

schools have a decisive influence on the probability of graduation. Noticing that even the well-performing students sometimes abandon studies, Belloc et al, (2010) argue that it may be a "consumer-oriented" type of behaviour (p.137) reaching a point where they feel they are being sold a product they don't really need, i.e. a study program unsuitable to their interest.

2. Stakeholders in the *Pro-Integra* Project

The Pro-Integra project undertaken by "1 Decembrie 1918" University of Alba Iulia has as stated goals the increase in the student-at-risk inclusion capacity of the academic institution and the development of an equity-improvement educational strategy. Part of the project also included a Research and Territorial Development Centre-tested and validated methods-based *social intervention* application. The *results restitution* method used determines social behavioural change among social actors once more in-depth knowledge of problematic features becomes available (Pascaru and Butiu, 2007).

During the research stage, three successive surveys were taken, data being collected through standardised questionnaires from the three groups considered representative for the goal of the project: 1038 students, 61 faculty members (teachers) and 38 administrative subjects. The following phase included group interviews, one for each of the representative group. The research stage was followed by interventions based on the results interpretation, achieving thus in a relatively short period of time, a series of sustained and interconnected activities of great intensity and institutional scope, involving diverse stakeholders (Table 1).

Table 1. Stakeholders and specific activities in *Pro-Integra* project

Stakeholders	Activities
Students	Survey response Group interview participation Training Counselling session participation <i>INTEGRA platform interaction</i>
Faculty	Research on the issue of equity in education Survey response Group interview participation Curricula modification proposals <i>INTEGRA platform interaction</i>
Career counsellors	Training At-risk students' socio-occupational counselling and orientation Student training on <i>INTEGRA</i> platform use <i>INTEGRA platform interaction</i>
Administrative staff	Training <i>INTEGRA platform interaction</i>
Managers	Access and Social Equity Strategy for 2016-2020 of the "1 Decembrie 1918" University of Alba Iulia Access and Social Equity Strategy Implementation Plan for 2017

Source: Butiu, 2017, p. 9.

3. Comparative stakeholders' opinions on educational offer

Educational offer in the context of the current study refers to a wide set of facilities, including not only the choice of academic programs, but also those aspects that complete and support the educational act and which can become the object for improvement intervention.

The main stakeholders (students, faculty and administrative personnel) were asked questions both specific to their area of interest and to each competences, and questions common to all categories. This allowed for a comparative study of different perspectives. One question queried the specific advantages of the "1 Decembrie 1918" University of Alba Iulia (UAB). The answers showed that while students take the educational offer to be the most important reason for choosing the school, 93% of faculty and 60% of administrative personnel have more appreciation for the public nature of the institution (Table 2). Access and location are more important to faculty and administrative personnel than to students and also the lower living costs, which 82% of faculty see them as a critical edge over other cities; only 56.6% or students and 56.7% of administrative staff consider them important. The conditions for study and the quality of the facilities are also in higher regard by faculty than by students or by administrative personnel, and finally the prestige of the school, although chosen by less than half of the students, is nevertheless more appreciated by students (40.8%) than by faculty (34.4%) or administrative staff (35%).

Table 2. Opinions on „1 Decembrie 1918” University's advantages (%)

UAB Advantage	Students	Faculty	Admin. Personnel
Access	33.0	60.7	50.0
Tuition	35.2	62.3	58.3
Location	53.2	77.0	38.3
Costs compared to other cities	56.6	82.0	56.7
Educational offer	80.7	54.1	48.3
Being a public institution	65.2	93.4	60.0
Conditions and the quality of facilities	57.0	73.8	58.3
Prestige	40.8	34.4	35.0

In order to design the most suitable interventions one also queried students' (S) and faculty's (F) degree of satisfaction with the educational aspects, and administrative personnel's awareness of these aspects. The data in Table 3 shows differences of opinions on some aspects and less divergence on others. Aggregating the "Satisfied" and "Very Satisfied" answers shows students being overall more satisfied than faculty members with all but two of the aspects, the top being the theoretical knowledge acquired (90.1%) followed by the quality of the facilities (85.1%), whereas teachers are substantially more satisfied with the time schedule (91.8%), in spite that this ranks low on students' satisfaction list. The result reflects the reality that most scheduling is done primarily around teachers' effort to fit in lecturing and seminars with lab, consulting, student counselling and academic research work. Under the "very satisfied" rank alone, both students and faculty score most frequently teacher's availability to discuss their problems (40.2%) and 29.5% respectively. Also noticeable is that while ranking high on the theoretical knowledge, the university is ranked low by both groups on supplying practical knowledge. These findings were useful to the development of the Pro-Integra technology platform, which has been fitted with a modern, user-friendly, intuitive interface to its *Communication* and *Counselling* modules.

Table 3. Students and Faculty's degree of satisfaction with educational aspects at UAB (%)

Concerning "1 Decembrie 1918" University of Alba Iulia, to what extent are you satisfied with...?	Very Satisfied		Satisfied		Total of Satisfied and Very Satisfied		Little Satisfied		Unsatisfied		Total of Unsatisfied and Little Satisfied		N/A
	S	F	S	F	S	F	S	F	S	F	S	F	
	Theoretical knowledge acquired	33.7	27.9	56.4	59	90.1	86.9	6.3	9.8	0.8	0	7.1	
Practical knowledge acquired	25.5	11.5	47.3	52.5	72.8	64	17	32.8	5.1	1.6	22.1	34.4	5.1
Time schedule	28.4	26.2	48.8	65.6	77.2	91.8	15	6.6	2.9	0	17.9	6.6	4.8
Facilities (libraries. labs etc.)	34	26.2	51.1	54.1	85.1	80.3	8	16.4	1.1	1.6	9.1	18	5.9
Student's chances for employment after graduation	20.6	18	48.7	45.9	69.3	63.9	22.8	26.2	2.9	8.2	25.7	34.4	4.9
Teaching methods	36.2	16.4	46.7	57.4	82.9	73.8	11.1	14.8	1.6	8.2	12.7	23	4.3
Teachers' availability for students' problems	40.2	29.5	40.1	57.4	80.3	86.9	11.8	9.8	3.2	1.6	15	11.4	4.8

There are noticeable differences in the degree of administrative staff awareness of the same educational aspects (Table 4). As expected, they are better informed about facilities and time schedules - to which they have direct access - than about teaching methods. What is less expected is their claim to be fairly informed of the availability of teachers to discuss students' problems and of the theoretical knowledge acquired. Where they clearly lack awareness is on the student's chances for employment after graduation (60.5%).

Table 4. The level of administrative personnel's information on educational aspects at UAB (%)

When thinking of the specialisations offered by "1 Decembrie 1918" University of Alba Iulia, how much information you have on...?	Very much	Much	Little	None
Theoretical knowledge acquired	7.9	44.7	36.8	10.5
Practical knowledge acquired	5.3	34.2	50	10.5
Time schedule	26.3	18.4	42.1	13.2
Facilities (libraries. labs etc.)	39.5	52.6	7.9	0
Student's chances for employment after graduation	5.3	31.6	60.5	2.6
Teaching methods	10.5	23.7	55.3	10.5
Teachers' availability for students' problems	18.4	50	23.7	7.9

Conclusions

In stakeholders' opinions intervention is justified for both ethical and effectiveness reasons. In a vicious (or virtuous) circle, opinions are anchored in attitudes and lead in turn to attitudes. The objective of Pro-Integra's project, as that of many other tertiary educational inclusion projects, was to enhance the chances for participation to university education of young students. The identification of both convergences and divergences of opinions on the significant drivers for student access to and success in education was both the starting and the pivotal point of the project. Finding out main stakeholders' perspectives has helped initiating those actions needed to both form and inform. Faculty learned that student's perspective is different from theirs and students in turn got to better understand what their educators' consider to be the most important aspects of the educational act. The most valuable finding perhaps was the need for raising the awareness of the administrative staff of the needs of the students and in general, of a more effective communication with the administrative department; the Pro-Integra information technology platform was implemented to facilitate that. The project helped with the understanding that the different roles of teachers and administrators should not lead to divergent positions and that they are both contributing to the educational process with different instruments. Notwithstanding the different motivations they are driven by, the final purpose of the project should be improved student access to higher education.

Acknowledgements

The Pro-Integra project has been financed through a 2016 CNFIS-FDI grant. While management and implementation teams are hereby credited and appreciated for their effort, it should nevertheless be said that the project, with its wide range of research and intervention activities, was a collective effort of many academic, technical, financial and logistical contributors whose list is too long to be spelled-out here in detail.

Financing the development of the city of Opole based on its budget

Dariusz Rajchel^{a*}

^a*Opole University of Technology, Faculty Economics and Management, 45-758 Opole, Prószkowska 76, Poland*

Abstract

The city's budget is the most important financial document including income and expenses for statutory tasks (obligatory) and optional one. Cities dispose of a largest financial resources, therefore, local authorities decisions should contribute to their cultural and socio-economic development to improve the quality of life of citizens. The purpose of the paper is to show the funds spent for tasks that have a significant impact on the development of the examined unit in Opole city's budget.

Keywords: Opole, budget, finances, developments

The budget of the local government unit (LGU) in accordance with art. 211. The Public Finance Act (Act of 27 August 2009 on public finance) is an annual plan of income and expenditure, as well as revenues and outlays of this unit, adopted for the fiscal (calendar) year in the form of a budgetary resolution that is the basis for the financial management of a local government unit in a given budget year. The budgetary resolution consists of the budget of the local government unit and annexes.

Recognized local government units in Poland are the commune, county, and voivodship as a regional level. The city according to art. 2, point 3 of the Act on official names of towns and physiographic objects (Act of 29 August 2003 on the official names of towns and physiographic objects) is a settlement unit with a predominance of compact buildings and non-agricultural functions, having city rights or city status granted in the mode specified in separate legal regulations. However, in art. 4, item 1 point 2 of the Local Government Act (Act of 8 March 1990 on local government), there is a provision: The Cabinet Council, in the form of regulation, gives the commune or town the status of a city and sets its limits.

When discussing the budget of LGU including a town, it is important that potential sources of financial support for local government authorities include:

a) own income - most often understood as income which, according to the various Acts and regulations, is permanently given to the local government authorities, including shares in central taxes, income from local taxes, fees for various services, income from property rights, income from the sale of property,

b) compensatory income - it is primarily transfers from state authorities to local authorities in the form of subsidies, subsidies,

c) earnings (revenues) from loans (Owsiak, 2017).

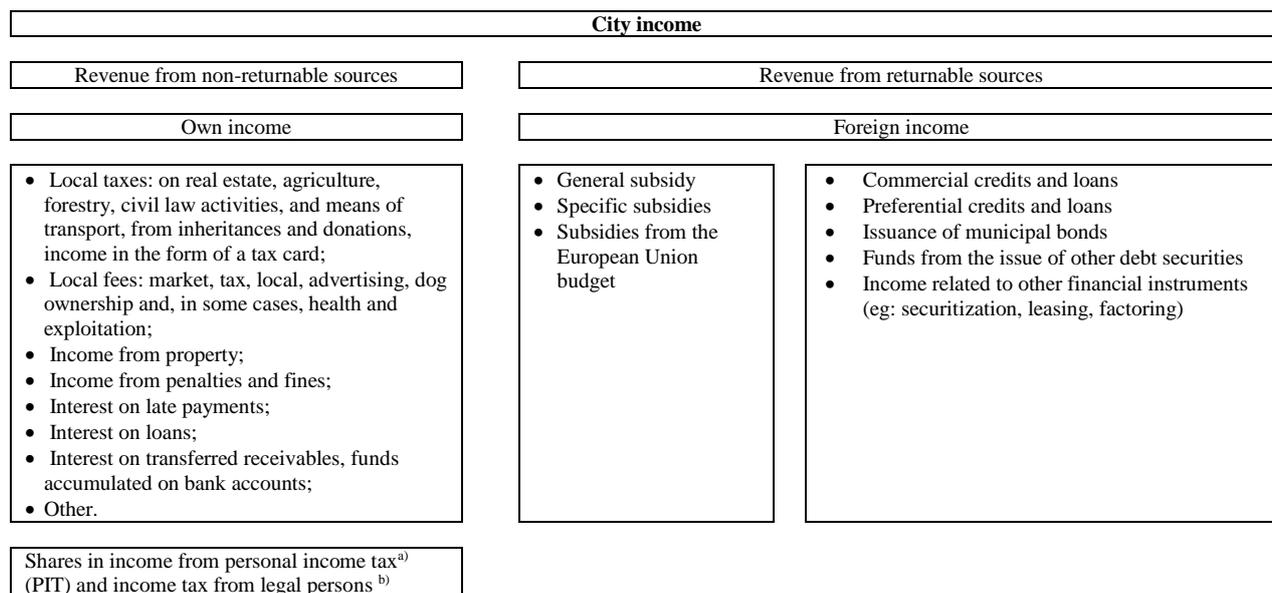

In addition to the LGU budget revenues listed above, there are also potential revenues such as: funds from non-refundable foreign sources, funds from the European Union budget and other funds specified in separate legal regulations (Owsiak, 2017).

The budget of the local government unit is a reflection of the general socio-economic situation and the expectations of local residents of spending funds on key undertakings for the city, commune, county or voivodship. Cities have the largest financial resources, therefore decisions made by local authorities should contribute to their socio-economic and cultural development, to improve the quality of life of residents.

The aim of the article is to show the financial resources spent within the city budget of Opole on tasks having a significant impact on the development of the examined unit.

* Dariusz Rajchel
E-mail address: d.rajchel@po.opole.pl

Income of the commune, including the city, are defined in art. 3 of the Act on revenues of local government units (Act of November 13, 2003 on revenues of territorial self-government units). The classification of city income is shown in Diagram 1.

a) The Ministry of Finance informs that the share of communes in income from personal income tax, determined in accordance with the principles set out in Art. 9 section 1 in connection with Article 89 of the Act of 13 November 2003 on the incomes of local government units (Journal of Laws of 2016, item 198, as amended), in 2018 will amount to 37.98%

b) The amount of share in income from corporate income tax, from taxpayers of this tax, with registered office in the area of the commune, is 6.71%.

Figure 1 Income of cities in Poland

Source: Act of November 13, 2003 on revenues of local government units (Journal of Laws 2003 No. 203, item 1966, as amended) and Z. Przygodzki, *Finansowanie rozwoju miasta*, [w:] *EkoMiasto# Gospodarka. Zrównoważony, inteligentny i partycypacyjny rozwój miasta*, pod red. A. Nowakowskiej, Wydawnictwo Uniwersytetu Łódzkiego, Łódź 2016, p. 129.

According to art. 54, point 2 of the Act on municipal government, the income of the commune may also be revenue from self-taxation of residents. Self-taxation can only take place through a municipal referendum referred to in article 2, paragraph 2 point 2 of the Act of 15 September 2000 on the local referendum (The Act of 8 March 1990 on local government).

Presenting the income side of the city budget, it is also important to present their spending on specific goals, tasks and investments. The city's expenditures have been specified in art. 236 of the Public Finance Act. Expenditure of the city budget is shown in Diagram 2.

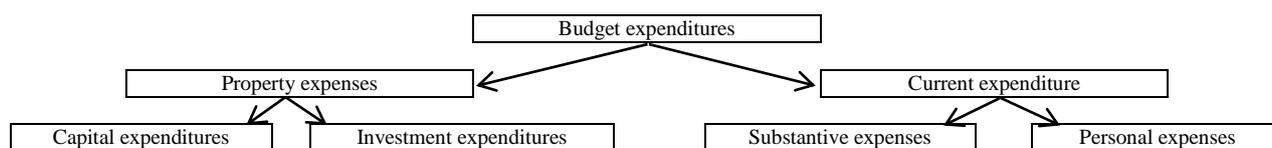

Figure 2. City budget expenditure

Source: Z. Przygodzki, *Finansowanie rozwoju miasta*, [w:] *EkoMiasto# Gospodarka. Zrównoważony, inteligentny i partycypacyjny rozwój miasta*, pod red. A. Nowakowskiej, Wydawnictwo Uniwersytetu Łódzkiego, Łódź 2016, p. 132.

Current expenditure of the budget of a local government unit including a city is understood as budget expenditure that is not expenditure on property. The current expenditure plan distinguishes planned amounts of current expenditure, in particular:

- 1) expenditure of budgetary units, including:
 - a) remuneration and contributions from them,
 - b) expenses related to the performance of their statutory tasks;
- 2) grants for current tasks;
- 3) benefits for individuals;
- 4) expenditure on programs financed with the participation of funds referred to in article 5 paragraph 1 points 2 and 3 (Act of 27 August 2009 on public finance), in part related to the implementation of tasks of the local government unit;
- 5) payments due to sureties and guarantees granted by the local government unit, to be repaid in a given budget year;
- 6) servicing the debt of a local government unit.

The plan of property expenditure distinguishes planned amounts of capital expenditure, which includes expenditure on:

- 1) investment and investment purchases, including programs financed with the participation of funds referred to in article 5 paragraph 1 points 2 and 3, in part related to the implementation of tasks of the local government unit;
- 2) purchase and assumption of stock and shares;
- 3) contribution to commercial law companies.

Opole is a city with county rights and, at the same time, the capital of the Opolskie Voivodeship which makes it the main city of the region. It is also an economic, administrative, cultural and education centre. By the decision of the Cabinet Council of 19 July 2016 and published in the form of a regulation (Regulation of the Cabinet Council of 19 July 2016 on establishing the boundaries of some communes and cities, granting some towns the status of a city and changing the name of a commune), from 1 January 2017 after joining the area from the neighbouring municipalities, Opole increased from 97 km² to 149 km² area. Before the change of administrative borders in Opole there were about 118 thousand residents and after the change, the number increased to over 128 thousand. Opole is a city with good road, rail and water connections. It is a key urban centre affecting the pace and dynamics of the development of the entire Opolskie Voivodeship.

This is reflected in the financial situation of the city, which is improving year by year. Based on the budget resolution, it can be stated that the city's income and expenses since 2014 show an increasing trend, as shown in Figure 3.

The budget resolution, in financial terms, is the basic document of city management. The City Council of Opole with resolutions and the President of the City with fiats may make the changes to the revenue and expenditure plan of the city budget plan because of overtaken activities.

As a result of the corrections made in the budget resolution of the city of Opole, the growing trend in individual areas of the city budget has been preserved since 2014. The most important is that, in December 31 of each year, budget implementation is being prepared, in which since 2015 budget surplus has been recorded at different levels, and so in 2015 the budget surplus amounted PLN 7 622 350.96, in 2016 it was PLN 3 036 099.16, and in 2017: PLN 2 886 225.92. The implementation of the budget for 2014-2017, on 31 December each year is presented in Figure 4.

The data presented in bot charts above show that the largest part of expenditures are current expenses amounting to approx. 87% of all expenditures, the remaining part is capital expenditure. In 2018, it is assumed that the expenses of the city of Opole will be respectively: current expenditure 69%, property expenditure 31%. In 2018, the city authorities plan to allocate the following financial resources to individual sectors. Figure 5 presents, in percentage terms, the funds spent for particular sectors.

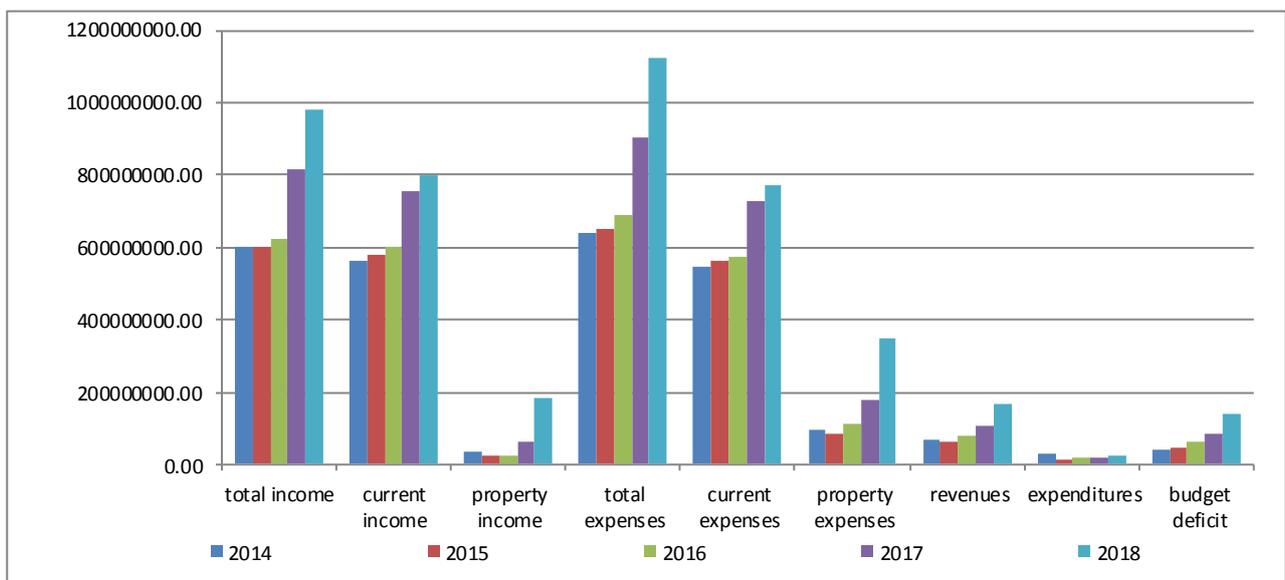

Figure 3. Planned income and expenditures as well as budget revenues and expenses in 2015-2018 based on adopted budget resolutions of the city of Opole

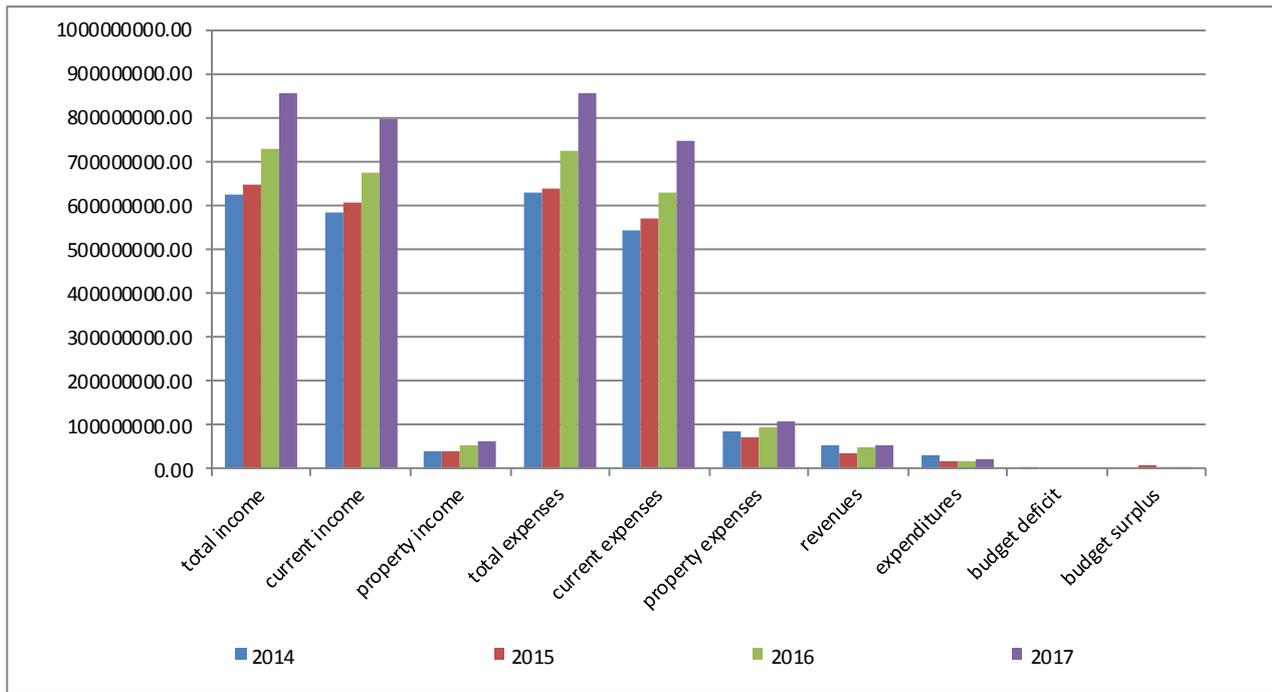

Figure 4. Implementation of the budget of the city of Opole for the years 2014-2017 on 31 December each year.

Source: own study based on the reports of the President of Opole on the implementation of the city budget of Opole for the years 2014-2017.

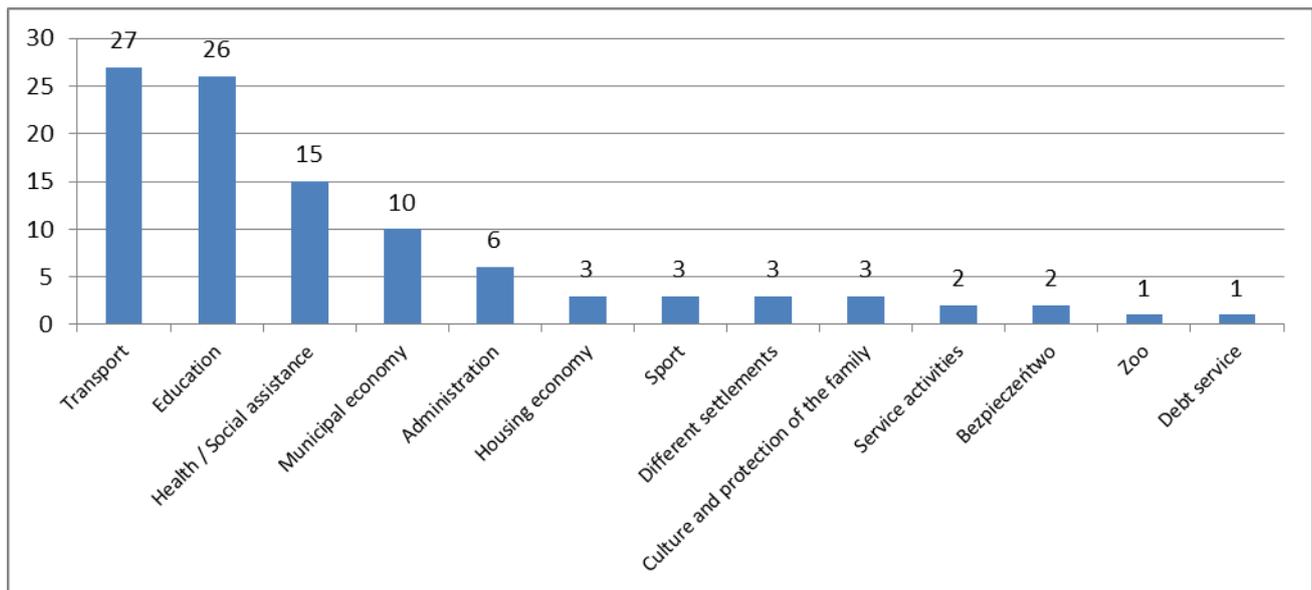

Figure 5. The most important expenses of the city of Opole in 2018, divided into areas

Source: R. Ćwirzeń-Szymańska, Skarbnik Miasta Opola, *Budżet miasta Opola w 2018 r.* [w:] *Budżet miasta Opola w 2018 r.*, A. Wiśniewski, Prezydent Miasta Opola, Urząd Miasta Opola z dnia 15 listopada 2017 r.

In accordance with the adopted budget resolution in 2018, the following financial resources are assumed for investment expenditures (Wiśniewski, 2017):

- culture - PLN 965 932 (modernization of cultural objects - value of the task: PLN 8 781 043),
- sport and recreation - PLN 10 260.28. (construction of sports fields and football pitches at schools - the value of the task: PLN 5 872 000 and PLN 200 000 were allocated to the competition concerning the concept of the new stadium),
- revitalization and monuments - PLN 11 876 330 (reconstruction of city squares - value of the task: PLN 8 065 632, revitalization of Krakowska street, two stages - value of the task: PLN 29 555 000. Former Opole - Upper Castle - value of the task: PLN 6 294 800),
- housing management - PLN 7 410 000. (purchase of land and real estate as well as construction of new apartments),
- service activity - PLN 15 840 000.
- reconstruction of roads and pavements - PLN 17 000 000.

- new bike paths - PLN 3 000 000.
- street lighting – 700 000 PLN.
- Opole East - PLN 20 320 000. (value of the task: PLN 182 620 624),
- Opole Zachód - PLN 17 033 305. (value of the task: 29 875 965 PLN),
- road in Żerkowice - PLN 7 957 195. (value of the task PLN 8 216 990),
- education - PLN 4 518 300. (support for vocational education - value of the task: PLN 5 429 047, reconstruction of the playground near the school - value of the task: PLN 50 000, purchase of computer equipment for schools – value of the task: PLN 500 000, modernization of the cloakroom and canteen at school - value tasks: PLN 220 000).

It is known that part of the investment is short-term and will end within one budget year, and some of them will require higher investment expenditures spread over time. Such investments include, for example, the reconstruction of the intersection of Oleska and Batalionów Chłopskich streets (Opole East), the cost of which is estimated at over PLN 180 million. The city office received as much as PLN 112 million for this investment from the governmental Operational Program Infrastructure and Environment 2014-2020. The project assumes:

- reconstruction of access roads to the intersection,
- creation of a double roundabout,
- construction of an underground passage for cars,
- construction of a flyover at the railway embankment and a tunnel in the embankment next to the Opole Wschodnie railway station,
- creation of a small bus station,
- creation of car parks and bike rentals.

The investment will be implemented in stages from 2018. Figure 6 presents the current state - before the implementation of the investment project (Guzik, 2018).

Figure 6. Intersection before the undertaking

Figure 7. Visualization of the intersection after completion of the investment

Source: Naszemiasto.pl, aktualizacja 23 lipca 2018 r. dostęp: <http://opole.naszemiasto.pl/artukul/centrum-przesiadkowe-przy-stacji-kolejowej-opole-wschodnie,4735717,artgal,34107785,t,id,tm,zid.html>

Previous significant investments in Opole include the demolition of the old bridge and the construction of a new bridge in its place with a footbridge and bicycle path, a comprehensive modernization of Niemodlińska street with infrastructure replacement, construction of new pavements, bicycle paths, modernization of the "Okraślak" Sports and Entertainment Centre, construction of the "Politechnika" roundabout, renovation of the Amphitheatre and creation of the Polish Song Museum, reconstruction of roads, construction of green areas, investments in educational facilities and many other important for the development of the city and improving the lives of residents.

The effect of the investments is to improve and create infrastructure in every area of economic, social, service etc ... city life. Rational investment of financial resources by the city authorities ensures efficient functioning and development of the city (communes). Each local government unit, pursuing a specific policy, strives to gain a competitive advantage in terms of investment attractiveness. Acquiring entrepreneurs and creating new investments results in increasing the budget revenue of the commune, especially own income, from which it is possible to finance tasks serving the development of the local community (Nargiełło, 2006). The growing budget income of the city of Opole and its skilful and rational spending contributes to making further investments and further improving the living conditions of residents and city investors.

A graduate of a secondary school on the labour market. Chances and threats

Anna Rajchel^{a*}

^aOpole University of Technology, Faculty Economics and Management, 45-758 Opole, Prószkowska 76, Poland

Abstract

Dynamic and changing job market requires professional experience from employees. In the Polish education system, vocational education is provided by technical and industry schools. General secondary schools educate mainly potential students. Young graduates of these schools have no professional preparation. The selected class profiles do not give them any rights. However, those young people have a large theoretical knowledge and that can be used in many industries consistent with their education and knowledge. When analyzing job offers for people with general secondary education, it often turns out that they are addressed to people who already have acquired some professional experience. Secondly, they are not always adequate to the education they ended.

Keywords: general secondary school, class profiles, job market, job offers

1. Introduction

Secondary schools are the ones that are very popular among young people. They prepare well for the secondary school-leaving exams and studies in specific directions. Students planning a professional career in such areas as medical, legal, pedagogical, etc. are choosing classes with profiles corresponding to their interests, further educational and professional plans. In 2018, the number of graduates of this type of schools amounted to 5367 people. In comparison to 2017, this number decreased by 610 people, and when compared to 2005 by 2964 people (Liczba absolwentów...). This situation may result from several reasons. One of them is demographic. Another reason is the change in the attitude of young people to education. Technical schools prepare for the school-leaving exam and performing a specific profession. During their education, students must complete compulsory placements which allow them to gain experience. General secondary schools, according to the assumptions in their curriculum do not offer such a chance. The emerging new class profiles, above all, tempt young people with high pass rate of school-leaving exams, cooperation with universities, the possibility of pursuing specific educational projects, participation in workshops that bring them closer to a particular profession. These schools offer a great number of development opportunities. Young people, depending on the chosen class profile, have classes in subjects that are most often introduced during studies. This is, for example, psychology, medicine, dietetics etc. Extra classes are being implemented in many areas, thanks to which young people can better prepare for the school-leaving exam. However, the situation of young graduates of general secondary schools in the labour market (especially those who have not passed the school-leaving exam) is not easy. These are young people without any experience and professional preparation. They are yet to get them. For them it is the beginning of their professional career.

The article presents profiles of education in selected general secondary schools in Opolskie Voivodeship and job offers offered to the graduates of these schools. There is an attempt undertaken to show that these offers are not always adequate for the education of job applicants. They are usually directed to people who already have certain skills and professional experience. Young people who have just graduated secondary school and have only secondary education, are open to acquiring new skills and improving their qualifications. They are good employees who can prove themselves in various fields, but adequate to their education and capabilities.

2. The structure of education in Poland

The education reform in force in Poland since 1 September 2017 introduced many changes in the education system for children and adolescents. According to art. 18 of the Act of December 14, 2016, *Prawo oświatowe*, public and non-public schools are divided into:

- 1) an eight-year primary school (previously 6-year primary school + 3-year lower secondary school),
- 2) post-primary schools:
 - a) four-year secondary school (previously 3-year)
 - b) a five-year technical college (previously 4-year)
 - c) three-year industry school of the first degree (previously 3-year basic vocational school)
 - d) a three-year special training school for employment,
 - e) a two-year industry school of the second degree,
 - f) post-secondary school for people with secondary or secondary industry education, with a teaching period of no more than 2.5 years (The Act of December 14, 2016 *Prawo oświatowe*).

Figure 1 shows the structure of education in Poland.

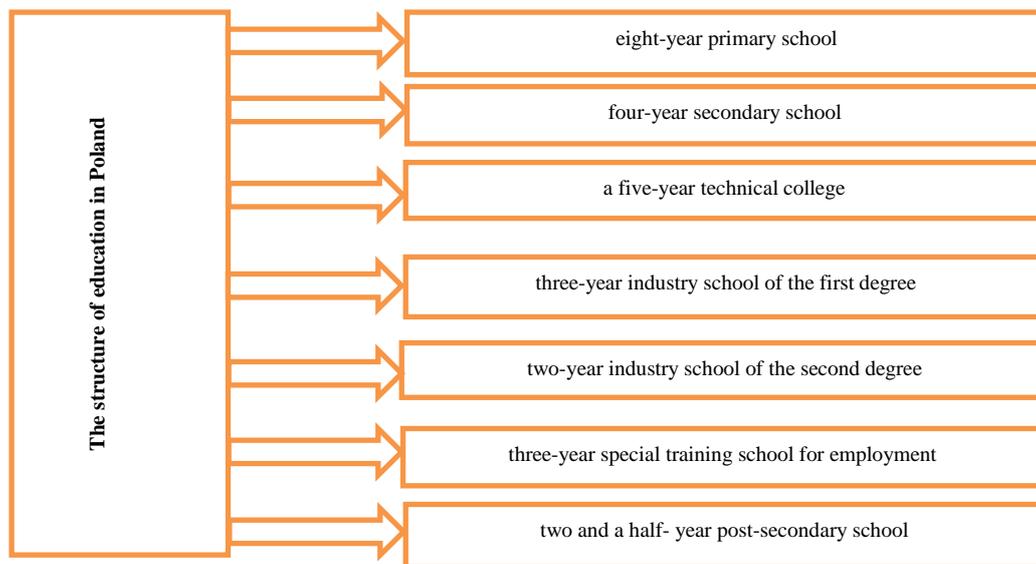

Figure 1. The structure of education in Poland

Source: Own study based on art. 18 acts from December 14, 2016. *Prawo oświatowe oraz Nowa struktura szkolnictwa w Polsce*, <https://www.nowaera.pl/strona-glowna/reforma-oswiaty-pod-lupa/nowy-ustroj-szkolny>

Children at the age of 7 start their education in a primary school. After completing education at this level of education, young people can choose a secondary school, technical college preparing for a school-leaving exam as well as for vocational exam, a 3-year industry first-degree school, which appeared in place of a basic vocational school. From September 1, 2020, the second-degree industry school will be launched, intended for graduates of the industry school of the first degree. In the first-degree industry school, young people will learn within one qualification (Regulation of the Minister of National Education of March 13, 2017 w sprawie klasyfikacji zawodów szkolnictwa zawodowego). Graduating the second-degree industry school allows its graduates to obtain the degree of a technician. The special education school is a special school designed exclusively for students with moderate or severe intellectual disabilities and for students with disabilities (Article 18 point 2 of the Education Law Act). According to art. 19 of the Act, the graduation of primary school enables students to educate in secondary schools. Graduating secondary school allows student to approach the secondary school-leaving exam and after passing, obtaining a certificate (the secondary school-leaving examination is not compulsory).

The technical school allows graduates not only to obtain a secondary school-leaving certificate after passing the exam but also obtaining a diploma confirming your professional qualifications after passing the examinations confirming the qualifications in a certain profession. Completing the first-degree industry school allows students to obtain a certificate confirming vocational qualifications after passing an exam confirming your qualifications in a given profession, as well as further education in a second-degree industry school in the profession, in which a common classification for the profession taught in the industry-level and second-cycle school has been separated. Graduates of first-degree industry school may also educate in secondary school for adults starting from year two. The second-level school industry gives the possibility to obtain a certificate confirming vocational qualifications in the profession taught at the technical level, in which the common qualifications for the profession taught in the industry school of first and second degree was separated, after passing the exam confirming the qualifications in a given profession and obtaining a certificate of secondary school-leaving exam.

Special training schools allow you to obtain a certificate confirming the preparation for work. Post-secondary schools enable obtaining a certificate confirming vocational qualifications after passing examinations confirming qualifications in a given profession (The Act of 14 December 2016. Prawo oświatowe). The person completing a 4-year general secondary school is about 18-19 years old, a graduate of technical secondary school, about 19-20 years old.

3. Characteristics of educational profiles on the example of selected secondary schools of the Opolskie Voivodeship

Young people choosing to study in a 4-year secondary school, have to fulfil several conditions. One of them is good results from the exam at the end of a primary school. Secondary schools as well as technical ones have a limited number of places that is why there is a point threshold from which schools can recruit students to particular classes.

This type of school prepares young people, mainly for the school-leaving exam, so that graduates can get to certain studies after graduation. Therefore, each secondary school introduced specific profiles of education corresponding to the interests of young people, the needs of universities and the labour market. In principle, all secondary schools in their educational offer have classic educational profiles such as:

- mathematics
- biology-chemistry
- humanist
- language

These profiles had to be varied with new elements corresponding to the directions emerging in higher schools (universities and technical universities). Therefore, in secondary schools, classes with the following profiles have been created. In the case of mathematical classes, these are branches, e.g.

- mathematics-IT
- mathematics-physics
- polytechnic (mathematics-physics-IT)
- polytechnic-economics
- engineering (mathematics and IT)
- business (mathematics-geography)

Schools with classes in biological and chemistry profile introduced such branches as:

- nature
- biology-chemistry with psychological inclinations
- medical
- healthcare profession(doctor)
- medical and pharmaceutical

Classes with a humanistic profile are primarily:

- social-legal
- humanistic-language
- humanistic-legal
- legal
- university social and humanistic class
- managerial - social
- history-social
- psychological
- geopolitical

In case of language classes these are:

- language-geography
- language-business
- linguistic
- tourist (geography-language) (Based on the websites of selected secondary schools of the Opolskie Voivodeship).

In addition, secondary schools also have sports, military and other. The choice is vast depending on the students' interests and their decisions related to the further path of education.

The main difference between a general secondary school and other secondary schools is that such school does not prepare young people for the profession. "General secondary school is an example of secondary school, which from the very beginning of its history has promoted a model of general education, not related to profession preparation" (Madalińska-Michalak, 2013). Young people can participate in projects implemented by the school aimed at, for example, equalizing their educational opportunities on the labour market by participating in monthly professional internships (Rajchel, 2015) in selected institutions, workshops and occupational counselling classes. However, not everyone can participate in them, secondly, internships as such are not mandatory, and thirdly they are not carried out cyclically. For students graduating this type of school which does not give any qualifications, further studying at university or post-secondary schools becomes a necessity.

These young people acquired theoretical knowledge, but not practical. The situation worsens when young people do not take the school-leaving exam or fail it (there is a possibility of retake) and after graduation, without skills and qualifications they are looking for employment.

4. Unemployed people in the Opolskie Voivodeship according to the level of education

On a national scale, the Opolskie Voivodeship is the smallest. On 31 December 2017, the number of residents amounted to 990069 people. Young people aged 15-19 are 45627 people (Ludność, ruch naturalny i migracje..., 2018).

At the end of July 2018, 22 152 people were registered in county labour offices. Compared to the end of June 2018, the number of unemployed increased by 41 people, or 0.2% (Informacja o sytuacji na rynku pracy...). Young people up to 25 years old constituted 2,489 and in comparison, to June 2018 it increased by 29 people (Informacja o sytuacji na rynku pracy...). Figure 2 presents the structure of the unemployed due to their education in the Opolskie Voivodeship. Status on the end of December 2017.

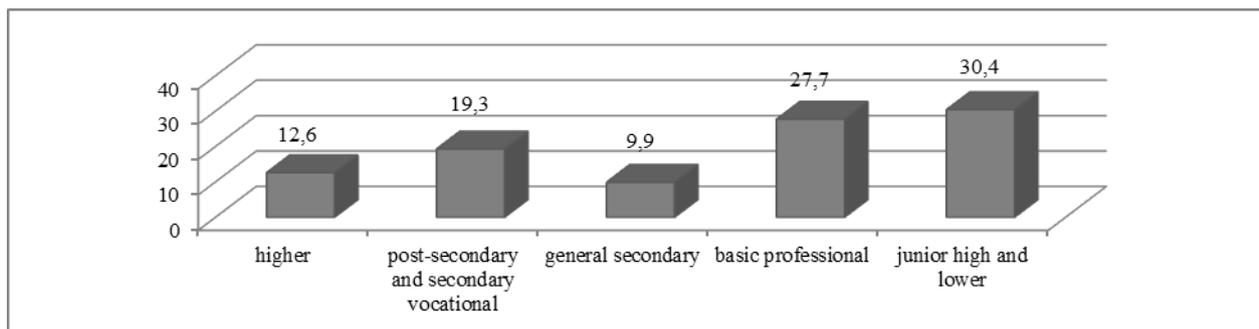

Figure 2. Structure of the unemployed due to education – status on the end of December 2017

Source: *Analiza sytuacji na rynku pracy województwa opolskiego w 2017 roku*, Wojewódzki Urząd Pracy w Opolu, pp. 20.

In the Opolskie Voivodeship at the end of 2017, the smallest number of unemployed had general secondary education (in statistical data it was not determined whether these persons obtained a secondary school-leaving certificate or graduated from school without a secondary school-leaving certificate). This situation may result from several reasons. Firstly, graduates of secondary schools do not have professional experience, therefore they can be taught to their profession. Secondly, young people of this type of school frequently take a holiday job. Thirdly, students also work as volunteers and thus, acquire skills (Raport z badania *Szkolne Kluby Wolontariatu*, 2016). Figure 3 presents the number of unemployed registered by the level of education.

The figures refer to the area of entire Poland.

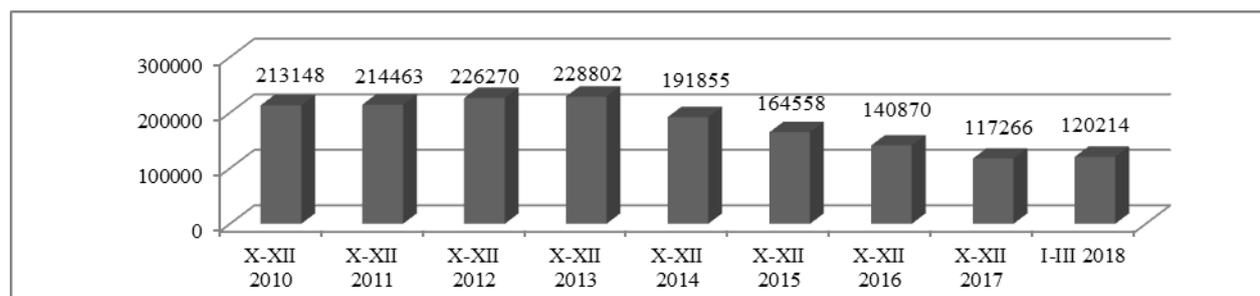

Figure 3. Number of unemployed in Poland according to the level of education

Source: *Bezrobotni zarejestrowani według czasu pozostawania bez pracy, wieku, poziomu wykształcenia*, http://swaid.stat.gov.pl/RynekPracy_dashboards/Raporty_predefiniowane/RAP_DBD_RPRA_16.aspx

Most unemployed people with general education were registered in the last quarter of 2013 (228802 people). This number was falling until the end of 2017. In the first quarter of 2018, compared to the last quarter of 2017, it increased by 2948 people. Young people do not always want to work at posts offered by County Labour Offices Since very often they do not correspond to their ambitions and interests. Table 1 presents selected job offers for people with general education reported to the County Labour Office in Opole. Status in August 19 and 20, 2018. Those interested could choose from 44 job offers.

Table 1. Selected job offers for people with general secondary education

Position	Required professional experience
Shop assistant Baby sitter	Lack of information Among others, experience in working with children in a nursery or kindergarten for a minimum of 2 years. Artistic and musical skills. A completed tutor course in a nursery or children's club.
Shop assistant – furniture department Office and administration employee	Ability to make contacts, experience in driving vehicles up to 3.5 tonnes Min. 2 years of experience in a similar position, availability, commitment, responsibility, practical knowledge of MS Office,
Office cleaner Secretary	Lack of information Experience in working in a similar position (secretary, reception), MS Office service, office equipment support, ability to work in a team
Coordinator of consultants for customer service	Minimum 3 months of experience in the customer service telephone industry, the ability to motivate employees supported by experience in managing a sales team
A specialist for logistics and office services	Computer skills, very good knowledge of English, willingness to work, knowledge of the construction industry,
Technical sales advisor	Experience in a similar position, min. 2 years, experience in driving a car, openness and ease in establishing contacts, good organization of work, ability to work in a team, knowledge of building and finishing materials
Warehouseman	Computer support, Office package, permissions to operate cranes, permission for a forklift driver
Fitness instructor	Conducting classes aerobics, pilates, yoga, healthy spine, permission to conduct fitness classes
HR, payroll and accounting clerk	Professional experience is welcome, knowledge of accounting and accounting rules (additional asset), very good work organization, independence, high communication and personal culture, willingness to learn.
Customer Advisor	Experience in a similar position is welcomed, communication skills, ease in acquiring knowledge, ability to conduct telephone conversations.
Blacksmith decorative products	Required 10 years of experience in a similar position, knowledge of Ukrainian in speech and writing, artistic skills, experience in forging artistic products, gas welding, TIG welding
The driver of the delivery truck	Category C driving license, 2 years of experience in a similar position, reliability, conscientiousness, ability to work in a team, knowledge of construction and finishing materials (additional asset)

Source: Job offers, County Labour Office in Opole, <http://pup.opole.pl/oferty> (19-20.08.2018).

When analysing job offers for people with general secondary education, several trends are easy to notice. First of all, people with basic or vocational education (e.g. cleaner) may be employed for some positions, and no secondary general education is necessary. Secondly, in job offers often the term "specialist" appears, assuming having specific knowledge, experience, special entitlements (e.g. permissions to run fitness classes, driving vehicles up to 3.5 tons, permissions to operate gantries etc.). Graduates of secondary schools after graduation are not specialists in any area and graduation of a profiled class does not mean the acquisition of certain rights desired by employers.

"Employers are (...) interested in both the quality of vocational education within the educational system as well as learning outcomes, that can guarantee a good adjustment of graduates to the needs - the most frequently mentioned in this context is the needs of the labour market" (Kozek, 2013).

Thirdly, experience in working in a similar position is generally required in all offers. Secondary school graduates are yet to get it. Fourthly, many job offers indicate the specific soft skills that an employee should have. "(...) soft skills belong to the so-called portable competencies that are indispensable for effective functioning in many diverse professional roles, and which, at the same time, greatly facilitate retraining, changing jobs and adapting to a new profession as well as new professional duties and tasks. Therefore, it is possible to combine the efficient functioning of the entity in the professional roles with the level of soft competences possessed" (Quote in: D. Fastnacht, 2006). The development of soft skills should take place at every lesson. A high school student who often has no professional experience should know what they are characterized by, how they can be developed and what role they play in the labour market. For a future employee, it can be an advantage when recruiting for a specific job.

5. Conclusion

Graduates of general secondary schools are specific employees on the labour market. Graduating the school does not give them any qualifications or eligibility. They do not have placement and most often professional experience. The school prepares them for the role of students, but not employees. A well-passed school-leaving exam allows them to take up studies in every subject and every university. The situation becomes problematic when a young person does not take the exam or does not pass it and therefore decides to look for a job. Job offers proposed by the County Labour

Offices in most cases do not take into account the fact that high school graduates, who have recently left the school walls, have never worked professionally. If they have already decided to take up a paid job, it usually did not give them specific rights or qualifications. The profile of the class they have completed does not mean acquisition of competences. It allows students to better understand what they can learn in a similar or related field, but at a higher education level. Where they can take up a job after graduation, what it will characterize with, what subjects should they choose at the school-leaving exam. These issues are introduced by teachers and school career counsellors. Graduates of secondary schools are, above all, theoreticians who can only increase their qualifications and gain professional experience. However, without employment opportunities, this is not possible. Employers, if they decide to accept a person with such education, most often require experience, specific skills and entitlements. Young graduates of secondary schools do not have these. Therefore, they undertake work on positions that can be performed by people with vocational and basic education or having no school-leaving certificate. Therefore, the lack of hard competences should be compensated by shaped soft competences. They are just as important as hard competencies, which a high school graduate can learn. Creativity, team work, the ability to resolve conflicts, willingness to learn and self-development, high personal culture - they most often appear in job offers and students can and must work on them. It is also important that young people do not give up their further education, even if they fail to pass the school-leaving exam at the time; they need to continue to study. "(...) there is a strong relationship between the level of education and the probability of unemployment. With the growing level of education, the probability of unemployment is clearly decreasing" (Polityka rynku pracy..., 2015).

The better education, the greater opportunities on the labour market, better earnings and opportunities to improve one's skills. Persons without work experience are in a very difficult situation on the labour market and often choose positions that do not correspond to their education. Graduates of a secondary school are good employees who can work in various professional disciplines but must be able to develop their skills and competences.

The Analysis of the content of newspapers: „Cronica Văii Jiului”, „Gazeta de Dimineață” and „Ziarul Văii Jiului”

Cosmin Sergiu Cremene

Vasile Alecsandri, nr.1B, Bl3C, Ap.25, Vulcan, jud.Hunedoara, Romania

Abstract

In order to create a clearer vision, more profound about the particularities of evolution or regression of written press, I have resorted to an analysis of it for a period of three years, namely 2011, 2012 respectively 2013. The newspapers on which the analysis was made were "Cronica Văii Jiului", "Gazeta de Dimineață" and "Ziarul Văii Jiului", the latter being the only publication that did not give me the papers for analysis.

The analysis of this three newspapers: "Cronica Văii Jiului", "Gazeta de Dimineață" and "Ziarul Văii Jiului" have been transposed in four dimensions namely: The demographic and social dimension, The economic dimension, The political dimension and The cultural dimension.

This analysis will show whether the press in Jiu Valley is ready to evolve from a media point of view.

Processing of newspapers was made with the help of programs such as soft-wear (QuarkXpress Version 8.2, A-PDF Merger, MaxQda 12).

1. Introduction

The written press often contributes to changing the importance of figures in order to give a certain perspective to a fact presented in the sociological report, depending on the specifics of the publication, or/and political partisanship (where appropriate). Simplifying, it is desired to manipulate the behavior of individuals in the sense of particular interest group that considers that a certain type of report that is presented to the general public will generate a favorable reaction on the part of it.

2. The demographic and social dimension

"The second component of demographic growth is international migration [...] Immigrations have the same meaning with births, emigrations represent losses..." Vladimir Trebici

A clear definition of "demography" is given by Vladimir Trebici in his demography (1979): "Demography is the social science that studies the human populations spatially delimited and burdened by social significance, their size and spatial distribution, their structure according to their demographic and socio-economic characteristics, their evolution, the direct factors that determine the evolution of the population - fertility, mortality, migration socio-economic factors that influence demographic phenomena in order to highlight the regularities they produce." This dimension, which is very important for the entire community studied as well as for society as a whole, has a decisive role in the daily existence of each of us.

Following the revision of the electoral lists of Vulcan Municipality on 21.10.2013, the population was 22,505 people. As we can observe, there is a discrepancy between the number registered by the County Directorate in 2011 (fig.1) and that found by the NIS (table no.1) of 27,998 people, the reason being one that can attract funds in this municipality (reporting a larger number than in reality).

"Lowering of the population poses a real threat to the sustainable development of the long-term, especially in conditions of ageing of the population, imposing measures is the creation of new jobs and to attract and maintain young people in the city ". (Development Plan of the Jiu Valley 2014-2020, p. 215).

For a clearer view of the evolution of the main demographic indicators registered at the level of Vulcan municipality during the period 2008 - 2012 is presented in table 1.

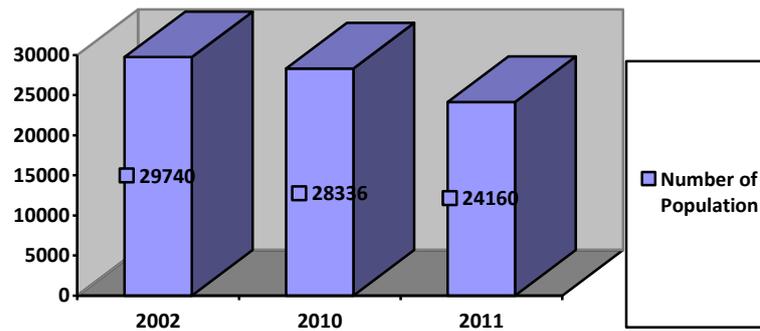

Fig.1 The population is stable in 2002, 2010 2011 respectively (source: Direction of statistics, Hunedoara County)

Table 1 The main demographic indicators registered at the level of Vulcan municipality during 2008 - 2012

Population	2008	2009	2010	2011	2012
Stable population - total on 1 July	28713	28413	28336	27998	27678
Stable population - women on 1 July	14513	14394	14372	14225	14065
Live births	229	280	244	215	206
Deceased - total	261	259	254	258	237
Deceased under one year	3	4	2	3	2
Marriages	179	191	132	114	127
Divorces	91	83	92	87	85
Establishments with domicile (including foreign migration)	301	300	452	-	-
Departures with domicile (including foreign migration)	589	441	664	-	-
Settlements of residence in the locality on 1 January	221	217	159	152	118
Departures from the locality on 1 January	342	415	363	291	310
Emigrants	4	4	4	-	-
Immigrants	3	1	3	-	-

3. The economic dimension

Senator PSD of the Jiu Valley, Nicula, appeals to politicians who have contributed to the politicians who have contributed to burial in the Jiu Valley mining to take over their work results and says that CNH was not devastated by the miners or their direct bosses keep on surprising him that those Ministers of Economy does not come out with statements in explaining how many moves were made in the Jiu Valley via CNH for cost price of coal that should be at the level of the one practiced in the EU declares Cosmin Nicula for the "Cronica Văii Jiului" in art. „Cosmin Nicula: The National Company of Black Coal is the mirror of the political incompetence of those who led the Ministry of Economy” - 5.10.2012.

An important article that awakens us from the state of lethargy is given in the daily Jiu Valley Chronicle where the researcher Dr. Eng. Valeriu Pleșea concerned about global energy issues, was kind and gave an exclusive interview in which he stated that 'Germany aims to give up nuclear power in favor of thermal power stations on coal. The crisis decides what attitude to take and being cheap... In these conditions and we need to do something because there is a fierce 'competition' for survival, and we have to be competitive, otherwise coal will be brought out. They keep their eyes on us...' (Valeriu Pleșea, 2013). The article specifies that ' in the year 2012, energy coal had the highest growth in the world. And to not buy this coal from countries that are not under sanction environmental protocols-such as the US and China, countries that have coal production manner that could bury a country like Romania: 997 million tonnes and 3,100 million- Canada has upset and announced its withdrawal from the Kyoto Protocol, a protocol that has no effect (instead of lowering emissions due to the measures imposed on accession countries, these noxes have increased) but it eats the money and kills them the economy...' (Cronica Văii Jiului, 2013)

Tourism what seemed to be an alternative to the Jiu Valley mining proved to be a real failure indicates Luiza Andronache (2013) in art. ' The Jiu Valley, without mining, without tourism, without the future ' reports that the Project envisaged the union of the resorts Pasul Vâlcău with Straja stepping on the spot, the development of the resort at Vulcan as Petrita, construction of the resort Dobraia is in the same phase for several years, to walk the papers and ask for approvals from the ministries invoking that there is no money to continue the work.

References should be added at the end of the paper, and its corresponding citation will be added in the order of their appearance in the text. Authors should ensure that every reference in the text appears in the list of references and vice versa. Indicate references by Clark et al., 1962 or Deal and Grove, 2009 or Fachinger, 2006 in the text. The actual authors can be referred to, but the reference citation(s) must always be given.

Some examples of how your references should be listed are given at the end of this template in the 'References' section, which will allow you to assemble your reference list according to the correct format and font size.

4. The political dimension

Vulcan Municipality has dressed up many 'political clothes' that have not given a good image to this city, such as the conservative party, the democratic party, and maybe this year it will wear 'the coat' of the national liberal party.

We observe a strange phenomenon in all three daily newspapers following their transformation and processing for 2011, namely that the „Cronica Văii Jiului" is presented to us only in November and December; Gazeta de dimineață also two months of October and December respectively and in Ziarul Văii Jiului the first months of the year, January and March. (fig. 2)

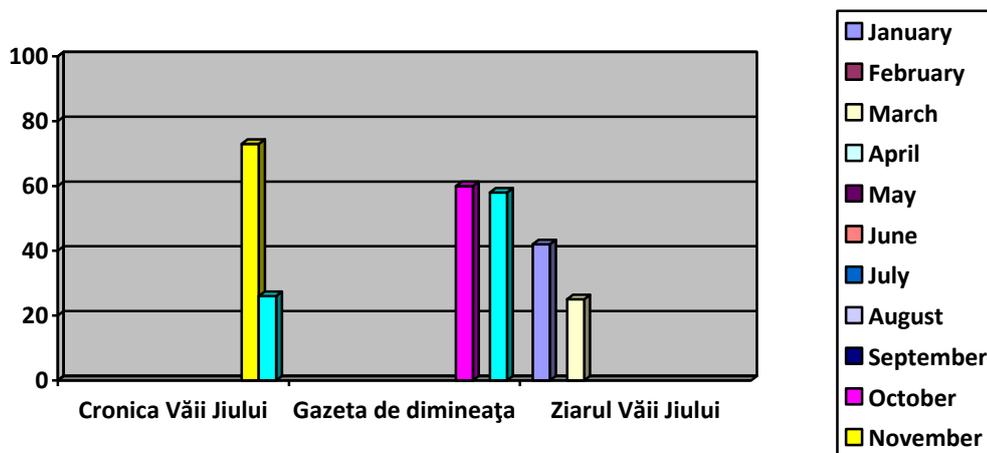

Fig. 2. The absolute frequency of the PNL party in the three newspapers analyzed for 2011

As we can see in the figure below (fig.3), the national liberal party has the most appearances, which are given by several articles circulated around the local council of Vulcan, namely 'PSD Councilors, PNL and PRM in Vulcan boycott the activity of all Mayors of the Jiu Valley' (Marius Mitrache, Gabriela Rizea, 2012); 'PNL and PSD Vulcan divorce from Dorel Șchiopu' (Anamaria Nedelcoff, 2012); 'Șchiopu tricked by' fox' (Diana Mitrache, 2012).

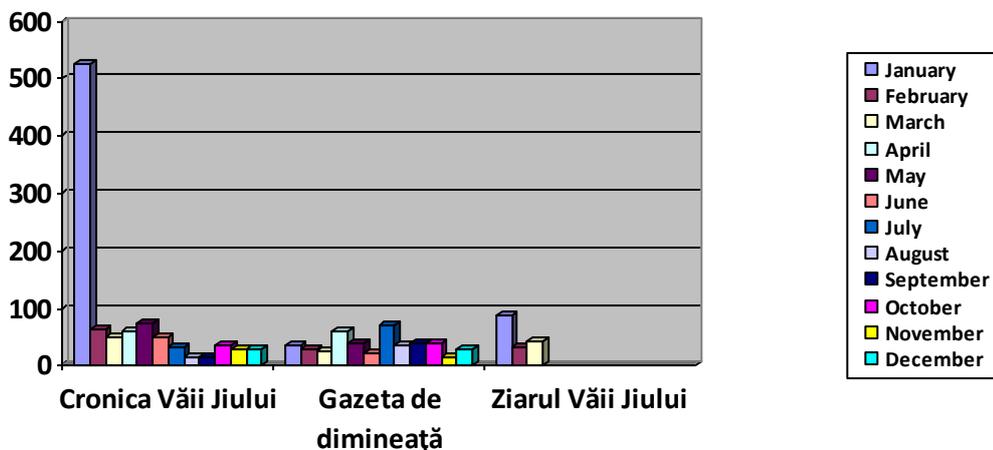

Fig. 3. The absolute frequency of the PNL party in the three daily newspapers analyzed for 2012

Making a comparison between the three daily newspapers on the emergence of the liberal national party in these, we noticed a more intense promotion of the party from the Cronici Văii Jiului which, as can be seen in (fig.4), October 120; April 107 times and 98 times in June 2013.

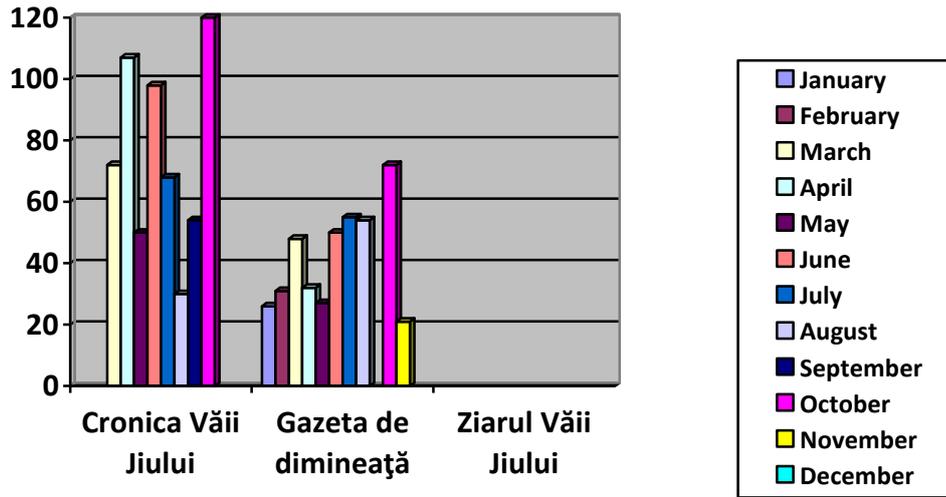

Fig. 4. The absolute frequency of the PNL party in the three daily newspapers analyzed for 2013

As I said, the Ziarul Văii Jiului was the only one who did not provide me with the papers for analysis, invoking different pretexts that do not have databases that are formed and cannot be transferred. Finally, a person whose name I do not want to disclose gave me the personal stick the so-called 'newspapers in pdf format.' Which turned out to be in another format and put several extensions to mask their presence on stick. Transforming Quark format files into pdf. and lipid them with the 'A-PDF Merge' program resulted in 13 newspapers (January) and 8 newspapers (March) of 2011.

Although I only had two months of daily newspaper 'Ziarul Văii Jiului', I wanted to see the frequency of the PNL and PSD appearing in it. We have seen a greater rise from the Social Democratic Party, which leads to the conclusion that this daily could be under the 'wing' of the PSD. (fig.5)

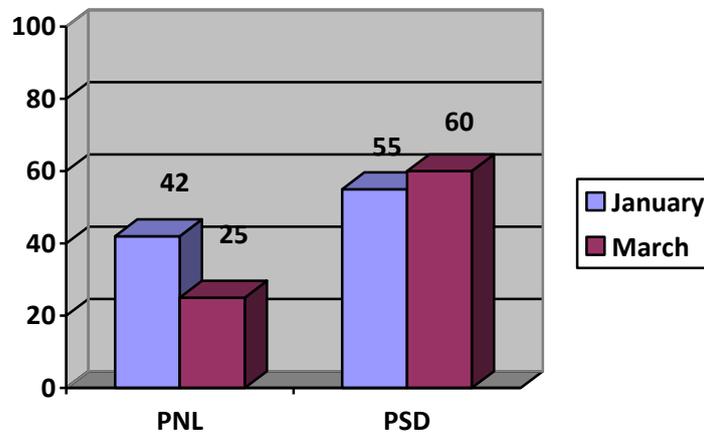

Fig. 5. The absolute frequency of the PNL party in the three daily newspapers analyzed for 2013

5. The cultural dimension

In Achim Mihu's view (2002), culture is the way of life of a group of people in the circumstances of a particular environment created by man and made up of material and non-material products transmitted from generation to generation.

Currently trying to rediscover and, although we are witnessing an ageing of the population and the decrease in young people.

Along the years, have formed numerous bands (vocal-instrumental groups) such as „Color” Group , „Stacatto” Group, „Astral” Group, Folklore Group „Doruleț” respectively „Flori de munte” that brought numerous awards and have given evidence that they know to keep alive the tradition of folk that were in various festivals in the country and abroad.

Few people know that in the JIU Valley School No. 2 in Uricani, a classroom was converted into a Museum, about the people and customs of the area. The idea belongs to a family of teachers, Petre and Violeta Udrea. Their passion for history and for the ancestral habits have made to gather data and objects that reflect past people in the JIU Valley. The Museum's story began in 1978, when Petre Udrea, then a teacher at the school at the Children's House in Uricani, he received the task to do a project about the history and customs of the JIU Valley. Since there was a database about the population in the area and had no real data about people, customs and history of the place, Petre Udrea He began to collect objects, documents, photographs, clothing, paintings and icons. (Anamaria Nedelcoff, 2011).

Considering the fact that in the 'Jiu Valley Chronicle' only two months were analyzed, namely November and December of 2011, the number of customs and traditions was limited. A feast was connected to the night ' Saint Andrew called in the folk tradition of the 'night of the undead (strigoi)' - the evil spirits that fill the earth and are stronger than the rest of the year. In Romanian mythology, the undead (strigoi) are the souls of the dead who are supposed to go out of the tomb night and take a ghost or animal form to cause trouble. In the village, as a rule, it is said of evil people, greedy, with a 'small and black' soul, that they will become (or have become) undecided (strigoi) after death. On the night preceding the celebration of Saint Andrew (November 29/30), especially in the countryside, strange rituals are practiced, believing that it is easier to find protection from all evils, well-being and even love. Most rituals are devoted to attracting love. By hiding under the pillow of a holy basil, it is believed that the image of the 'future husband' is dreamed up. Another method used to know the future is to look at midnight, between two fires, in a glass of untouched water, placed on ashes. In the center of the glass there is a wedding ring that has already been sanctified by the priest by the religious wedding, and it is believed that in the wedding ring the face of the 'future husband' appears, if it is intensely watched for a few minutes. All the night of St. Andrei are practiced and popular weather predictions for the coming year. Usually in the attic of his house are loaded on 12 healthy onions as big, that are left there until the Christmas evenings, when it is the result. Each onion is assigned the name of a month. Crows that ruined indicate rainy months or hail, and those that sprouted - months favorable to harvest. ' (Marius Mitrache, 2011).

According to Ion Ghinoiu, the author of the volume Days and Myths. The Romanian peasant's calendar, Nativity's legends invite us to the ethnographic landscape of a pastoral village, where Santa Claus and Santa Claus lived, with large houses and many stables. Suddenly an unknown woman appears in their lives who, feeling the time to give birth, asks for help. If the first one denies it, the second one stretches out a hand. But not knowing that the woman is the Mother of God, she does not receive her in the house and sends her to the cattle's stable. Santa's wife helps to give birth, without her husband's knowledge, but is then punished by cutting her elbows. When Christmas finds out that Jesus was born in his stable, he repents and asks for forgiveness to God, becoming 'the first Christian,' the 'oldest saint,' 'the husband of the woman who mourned Mary. It is said that he was so excited that the day he shared his whole fortune with the poor children, from where the tradition of making Christmas gifts, especially to the children. (23.12.2011 'A Happy Christmas!' - Chronicle Jiu Valley)

The written legend (volume 'Romanian Mythology' by M. Olinescu, p. 182, 'The Worstest') tells us that the mourners are three in number, three maids from the time of Emperor Alexander Macedon. On his journeys, he came to a spring of living water and filled a pot with the elixir of immortality. The three maids stole the living water, drank it, and became immortal. God decided then that they establish the course of life of every man on earth from then on. The legend tells us that they lived in a beautiful palace, where they burn as many candles as there are souls on the earth. From time to time to time turns off one light but it appears another instead, when a child is born. One of the mourners pours oil into the candle, and it will burn as long as he has his child to live.

Interesting is the ritual performed by the mockery. They go three times in the night at the house where a child was born, either a girl or a boy, to bruise them. The first of these, called the Mug, holds the fork and the throat and sets down to the smallest detail what is going to happen. The second is called Fate, it carries the quark (a bundle of wool in hemp or borangic) to life, and the third, most feared, is Death that has the power to curtail the thread of life. The third, most urgent, with the greatest power, dresses each other with other servants. If one day wears price clothes, all those born on that day will have wealth and happiness. On other days he's dressed in a merchant's or peasant's clothes, those who are born that day will earn their daily living hard. The brightest fate is those born on the day the bridegroom dresses in rags. They will not have much joy in life.

In order to attract the mercifulness of the mockers, the momarlans bring offerings whenever they have the occasion, but especially on the day of the great feasts (Pascal, Christmas, Saint Peter and Paul, St. Elias, etc.). This ritual was gathered from the omer of Tirici - Cimpa, Gărgan Ion (Ionică), at the wonderful sheepwalk of Poiana Muierii (or of the bride) led by the Tirici village shepherd Petrică Tiric. (Petru Bolog, 2013)

Residents' perception of the studied communities through a direct survey

Cosmin Sergiu Cremene *

Vasile Alecsandri, nr.1B, Bl3C, Ap.25, Vulcan,336200, jud.Hunedoara, Romania

Abstract

The direct survey was conducted on the basis of a questionnaire containing 45 items, in which they caught the types of questions starting with the opinions, factual, dihotomic as well as some questions taken from the Public Opinion Barometer in May 2006. The questionnaire was completed by the respondents, at their home, in the presence of the field operator.

The period of data collection (field phase) was March - April 2015.

This research was carried out in the municipality of Vulcan having as target population a number of 336 random people taken from different social backgrounds such as: Vulcan Town Hall, churches, schools, etc. of the total population of the Vulcan municipality of 22,505 people, their number was found in the following revisions of voter lists in 21.10.2013 by me at City Hall.

Keywords: written press, journalist; comunity, media;

1. Introduction

Direct surveys collect information about events, facts, happenings where the subjects are involved, and do not ask themselves about intimate facts. While the indirect ones require information about facts, events to which the subjects either participated or did not participate to protect the subject, they are asked to appreciate the behavior and attitudes of other people involved.

Both the definition of problems and the perception of their severity, urgency, and priorities differ from one social category to another. While young people are preoccupied with finding a job, retirees are concerned about the issue of medicines. Therefore, different social segments will propose different themes and priorities on the public agenda. Social issues differ depending on the type of community, region, county, city, neighborhood. The needs of the population in a commune differ significantly from those of the population in a mono-industrial city, as well as those of the inhabitants of major cities. The needs of the population in a floodplain area will be different from those of the inhabitants of a drought.

Bianca Radu (2015, pag.24), Specifies that Tonnies and Weber have identified four essential aspects of communities: (a) the interdependence between people; (b) a high degree of uniformity in relation to certain measures and norms shared in the community; (c) their presence more as highly internalized elements than as formally expressed elements; (d), and as such, as a whole of a common culture and way of life, the existence of a strong sentiment of engrossing with an outgroup (Amerio, 2003, pag. 32)

"The survey-in general-is one of the oldest, but also the complex methods (techniques) for investigation. This is supposed to lead to the clarifications needed, at a broad consensus on the content, features, advantages and its limitations. However - or perhaps precisely because of this - there are still many controversies and uncertainties, ambiguous appreciations and disputable meanings '. (Septimius Krausz, Irinel Stegar, 2007, pag. 121)

2. Community issues

Given the rather precarious situation of the entire Valley, the municipality of Vulcan was one of the few where public administration involvement in road infrastructure development was seen, although citizens' problems are quite different, namely: more than a quarter are afraid of health, a quarter of the future of children, 23.2% of prices, less than a quarter of the fact that they finish a school and remain unemployed, 5.4% others and 1.4% fear a possible strike. (fig.1)

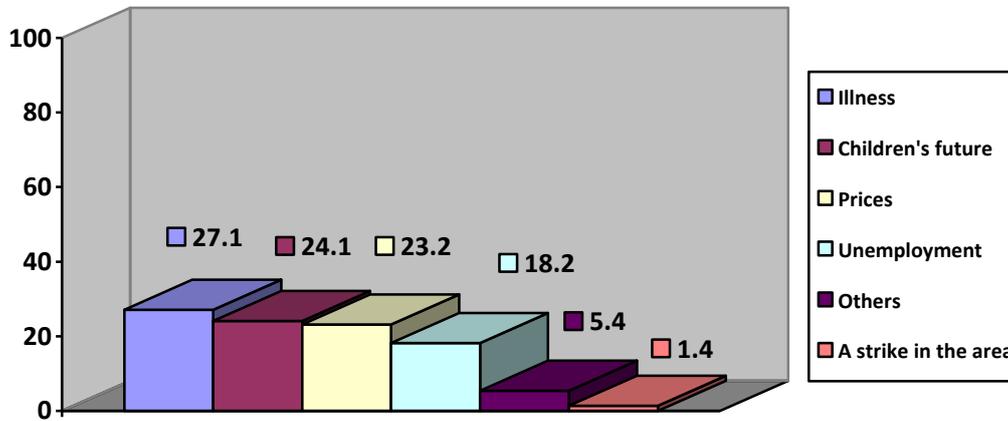

Fig.1 Things that induce a state of fear

Following the correlation between occupation and fears, we found that less than half of the household (40%) and those employed (33.3%) are afraid of a possible illness; 34.1% of pupils and students are afraid of their future (34.1%), while the unemployed have fears about prices and unemployment - 31.6% each (perhaps the fear of remaining unemployed) and, as far as pensioners are concerned, their fear is given by prices as well as an eventual 29% disease each of them. (fig..2)

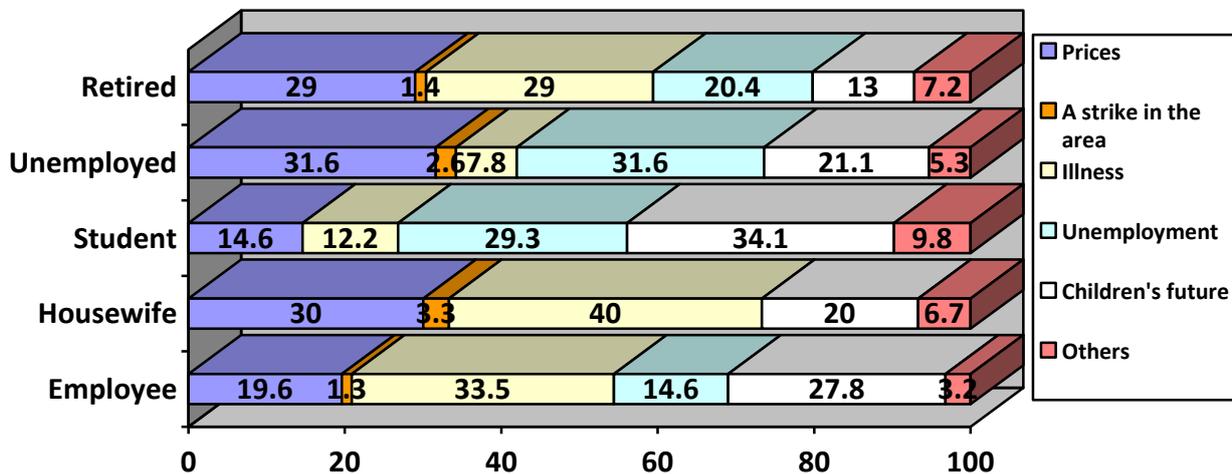

Fig. 2. The correlation between occupation and fears

Almost a quarter of those surveyed believe that the social reality and problems in the Jiu Valley are scattered by political parties through the press. (table 1)

Table 1. Covering social reality and issues by political parties through the press

	Yes, In what way?	No	I do not know	Total
Frequency	74	77	185	336
%	22	22,9	55,1	100

And the means used by them are multiple starting with 46%-by bribery; 20.2 percent through blackmail; 9.5% through promises; 8.1%-political interests; 6.8% against favors favors; 4%-affinities; 2.7 through concealment and lack of professionalism of journalists. (table 2)

Table 2. The means used by political parties to present another social reality and the real problems of the Jiu Valley

	Frequency	%
Bribery	34	46
Blackmail	15	20,2
promises	7	9,5
Political interests	6	8,1
Favors v. favors	5	6,8
Affinities	3	4
Concealment	2	2,7
The lack of professionalism of journalists	2	2,7
Total	74	100

The opinions of the interviewed persons about the period before the revolution and the current one from the administrative, demographic, economic, legislative, political and social point of view have many opinions, namely that from an administrative point of view one can notice an improvement of the system; demographically, we can see that the balance tends towards a negative natural increase, an aging population and declining birth rates; the economy is the only one in which almost half of the respondents say that this sector has turned around; at the intersection between good and evil; in terms of the political sector, we are dealing with a homogeneity of the direction in which this sector evolved, and in the latter there is a dissatisfaction on the part of the respondents in the social sector. (fig. 3)

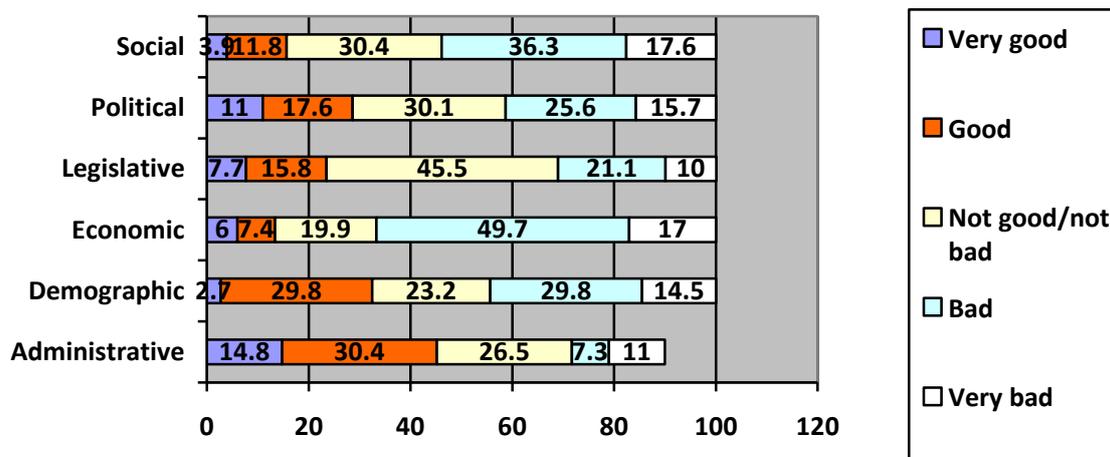

Fig. 3. Evolution of the Jiu Valley from an administrative, demographic, economic, legislative, political and social point of view

To see what age group and education level who have expressed their opinion on the degree of evolution have turned to relations between age, studies and developments in terms of administrative, demographic, economic, legal, political, respectively social as follows in the description below:

From the administrative point of view, people with mid-level (professional - 70.6%, post-secondary - 60%) respectively those with 54.1% higher education aged 18-44, said that this sector evolved for the better while those aged 65 years and over with gymnasium studies - 52.4%; professional - 50%; 80% of all high school graduates and all those without a study said that this sector has reversed.

From a demographic point of view, most of those with high school education and aged 65 years and over said that this sector has neither evolved nor deviated; nearly half of those aged 45-64 and middle school say that it has invaded; half (53.8%) of those aged 18-44 and gymnasiums are more positive saying that this sector is heading for the better.

Realizing the correlation between age, education and evolution of Jiu Valley from economic point of view, we note that all categories of age: between 18-44 years of age, between 45-64 years, 65 and over have stated that this sector decades a day when the reason is quite obvious when looking at the mining sector, it is the one that still supports the economic sector.

Most people aged 65 and over who have professional studies say that from a legislative point of view, Jiu Valley is at the intersection of evolution and regression. The same can be said when it comes to the political one for more than half of those with post-secondary studies and 18-44 years of age respectively for the majority of those aged 65 and over.

With regard to the social sector, for the majority of categories of age and with an average level of study have a neutral position toward the negative.

3. The interest manifested against mass media

More than a quarter of those questioned show interest in buying a newspaper several times a week. (table 3)

Table 3. Periodicity of buying a newspaper

	Daily	Several times a week	Several times a month	More rarely	Never	I do not answer	Total
Frequency	51	84	77	77	23	24	336
%	15,3	25	22,9	22,9	6,8	7,1	100

The vast majority of those interviewed stated that there are more points of sale of newspapers and magazines in the municipality. (fig. 4).

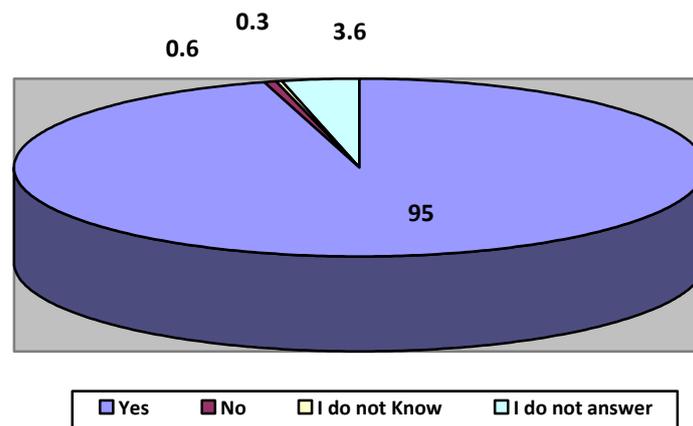

Fig. 4. The existence of points of purchase of newspapers

One-third of those questioned believe that the press should belong to both the State and the private environment; a quarter say they have to go into the state's attributions; less than a quarter are private and 22.3% abstain. (table 4)

Table 4. Media coverage

	State	Private	To exist and State and private	Don't know/no answer	Total
Frequency	79	59	123	75	336
%	23,5	17,6	36,6	22,3	100

A quarter of those who said they knew about the existence of the Romanian Press Club. (table 5)

Table 5. Media coverage

	Yes, go to question 30	No, go to question 31	Do not respond	Total
Frequency	90	123	123	336
%	26,8	36,6	36,6	100

And more than half of those who have expressed their opinion about CRP say they does anybody know; I do not know; do not answer, and less than a quarter have a good opinion and 8.8% have a bad opinion about its activity (table 6).

Table 6. The opinion on the activity of the Romanian Press Club

	Rather good	Rather bad	Does anybody know	do not know	Do not respond	Total
Frequency	12	8	20	13	37	90
%	13,3	8,8	22,3	14,4	41,2	100

I can say at the end of this article that after one year of my PhD thesis as stated therein and that the press is "dying", it has been confirmed that at present there is no longer any point of sale of newspapers.

A small part of today's journalists more respects the right to privacy and private life, as there is a continuous scurry after the show, we look at the television channels that are more interesting, more attractive, more spicy, one describes and brings before us as a private, intimate life. When they collide with each other what do they do? They penetrate one into the life of the other and brings out all the 'misery' everything, because he thinks this way it becomes interesting and it can 'knock down' the potential opponent, that is the world we live in.

Less than half of the subjects consider that a large number of journalists still show professionalism in this profession. (table 7)

Table 7. Professionalism on the part of journalists

	Almost all	A large part	A small part	Almost none	I do not know	Total
Frequency	62	138	87	33	16	336
%	18,5	41,1	25,8	9,8	4,8	100

Nearly half of respondents say that almost all journalists are influenced by their chiefs to pass on information. (table 8)

Table 8. Influence of journalists by the bosses when a news story

	Almost all	A large part	A small part	Almost none	I do not know	Total
Frequency	159	102	43	11	21	336
%	47,3	30,4	12,7	3,3	6,3	100

Of those questioned mentioned the fact that a large proportion of journalists give exaggerated importance with regard to the topics, which may be due to the fact that they gather many people in front of the tv (table 9).

Table 9. Exaggerated importance to some topics uninteresting

	Almost all	A large part	A small part	Almost none	I do not know	Total
Frequency	68	192	51	19	6	336
%	20,2	57,1	15,2	5,7	1,8	100

Nearly one-third of subjects considered that journalists are both presenting some topics that are not in the public interest and against them (table 10).

Table 10. Presenting some topics that are not in the public interest on the part of journalists

	Almost all	A large part	A small part	Almost none	I do not know	Total
Frequency	76	105	108	32	15	336
%	22,6	31,3	32,1	9,5	4,5	100

The organizational culture in junior High Schools in the Druze Sector

Nabila Kheir Faddul^{a*}, Nicolae Aurelian Bibu^a, Doina Dănăiață^a

^aWest University of Timisoara, Romania

Abstract

The present study examined the dominant organizational culture in the Druze schools in the High Galilee in Northern Israel. It examined the current organizational culture and the preferred organizational culture. The Organizational Culture Assessment Instrument (OCAI) developed by Cameron and Quinn (1999, 2006, and 2011) was used for the purpose of this study. 220 staff members from nine schools including principals, teachers, and workers were chosen as research samples. Research findings showed that the clan culture is the current dominant culture and is also the most preferred culture; whereas the hierarchy culture is the least current culture and the least preferred culture. The second current culture is the market culture; however, the second preferred culture is the adhocracy culture. The differences between the current cultures and the preferred cultures do not exceed 3.37 degrees. According to Cameron and Quinn (1999, 2006, 2011) there is congruency between the current culture and the preferred culture, so, there is no need for a change. Besides the OCAI, the participants were asked to answer three questions concerns the level of their satisfaction, motivation and the willingness to stay in the school. The answers were scales from 1-6. The average of the answers to the three questions concerns satisfaction, motivation, and the willingness to stay at school, was 5.09 out of 6 (SD 1.612517). This reinforces that the culture in the Druze schools is positive and strong and that there is no need for change. The results of this research can be beneficial for the schools. They will provide a clear picture to the principals and the teachers about their organizational culture. It may strengthen and urge them to put higher goals and visions. It can also urge the principals to make some changes to bridge the tiny gaps between the current and the preferred cultures.

Keywords: Organizational Culture; Junior High schools; the Druze sector

1. Introduction

The organizational culture is a prime instrument by which it is important to start when studying an organization (Fox, 2013). The results of the study help in getting a clearer understanding of the organizational culture. Studies on the organizational culture are needed to identify the kind of cultures and the values that govern the organization (Cameron and Quinn, 2011). Understanding the culture can guide the people to understand many things and can attribute in many processes. It helps to understand the leadership style (Bass, 1985; Mendel et al., 2002; DiPaola et al. 2004; MacNeil and Busch, 2009; Louis et al., 2010; Adeogun and Olisaemeka, 2011; Cameron and Quinn, 2011; Finnigan, 2012; Voight et al., 2013; Gülşen, and Gülenay; 2014; Beauchamp and Parsons, 2012; Herbert, 2011). It helps to predict the level of success in the organization (Voight et al., 2013). It can predict the level of student achievement (Bulach et al., 2011. Mudiwa and Scherz, 2013, Cobb, 2014). It helps to predict teachers job motivation (Freiberg and Stein, 1999) and job satisfaction, and how people feel concerns the organization (Beauchamp and Parsons, 2012; Herbert, 2011). It helps in understanding how things are being operated within the organization (Cameron and Quinn 2011). The organizational culture can provide a "conceptual framework" which accordingly the dynamics of their work can be predicted (Pettigrew, 1979).

2. Theoretical Framework

Druze people are a religious group of people that started in Egypt in the eleventh century. There are more than a million and a half Druze people in the world. They live mainly in Israel, Syria, and Lebanon. The religion of the Druze people is secret. They are conservative people. They have their own culture, beliefs, values, traditions, and ceremonies

* Corresponding author. E-mail address: nabila.fadul@gmail.com

(Hirsch and Cicurel, 2010). Lately, however, the Druze community in Israel is changing from a very conservative community into a much more modern one. They are giving up some of their traditions, keeping others (Falah, 2018). In today's modern world, where things are changing quickly in all areas of life including education, and in the Druze sector, it is imperative to revisit the organizational culture in the schools. We live in an age where things change (Anyim, Chidi, and Badejo, 2012). There are fast-growing companies, fast growth factors, practices of fast-growing firms (Bibu, Sala, and Alb, 2016). Knowing the organizational culture in the Druze schools is an essential step that can help the school leaders and teachers to put their visions and take actions in better and more explicit ways. There are about 120,000 Druze residents in Israel. They live mainly in three areas: in twelve villages in the north of Israel, in two villages in the Carmel Mountain and four villages in the Hormone Mountain. In Israel nowadays there are about 30,000 Druze students who study from kindergartens till the universities. About 2.3% of the total number of students in Israel, although the percentage of Druze out of the total population does not exceed 1.6% (Israeli Foreign Ministry website). This study took place in nine schools in northern Israel.

"Organizational culture may be considered as the shared way of being, thinking and acting in a collective of coordinated people with reciprocal expectations; it is shaped, disseminated, learned and changed over time, providing some predictability in every organization." (Serpa, 2016). "The Organizational culture is the shared values, beliefs, and norms that influence the ways employees think, feel and behave toward each other and toward people outside the organization (George and Jones, 2008)." "Organizational culture is a system of values held and conducted by members of an organization which distinguishes an organization from others" (McBain, 2007). The organizational culture indicates which beliefs and behaviors are acceptable and supported to be in the organization and which are not (Dyck and Neubert, 2007). The core components of the Organizational culture are the Shared values, beliefs, traditions, stories, myths, heroes, and the financial arrangements (Wahiba, 2012). The best organizational culture that can influence the employees positively contains values like trust, fairness, support, openness, and supportive communication between the organization and its employees (McBain, 2007). The culture influences the organization (Abrudan et al., 2010). The leaders and the organizational culture are reciprocally connected (Mendel et al., 2002). The Principals, who can motivate the teachers, and make them in alignment with their values and beliefs, are leaders who can create positive organizational cultures; a culture that can bring to the success of the organization (DiPaola et al. 2004). The organizational culture influences the manager's behavior and style (Abrudan et al., 2010). The organizational culture is of crucial importance that if two different organizations share the same organizational culture, they can work together efficiently (Bibu and Haş, 2011). Strong organizational culture can help in achieving cohesion (Bibu and Brancu, 2008). The Druze people have stuck together for a thousand year without having a country of their own. One of the things that helped the Druze people to stick together is their culture which makes the Druze people follow shared values, beliefs, and purpose (Hirsch and Cicurel, 2010). The school organizational culture is essential for achieving the goals of the schools, and it is essential that it is planned and cared for. "The image or reputation of the organization and organizational culture must be assessed, controlled and directed towards achieving goals" (Bibu and Mos, 2012).

3. Methodology

3.1. Method

To find out the current organizational culture of the schools, and to find out the preferred organizational culture, the OCAI was used. The OCAI is a practical, efficient, involving manageable, valid and a useful instrument that was used in many studies in education (e.g., Fralinger and Olson, 2007; Kalliath et al., 1999). The OCAI was designed to identify the dominant culture of an organization by profiling that organization across a quartet of organizational culture types: clan culture, adhocracy culture, market culture, and hierarchy culture (Cameron and Quinn, 2011. p. 75). The OCAI instrument is organized into "Now" and "Preferred" sections. Each of these two sections is formed of 6 items that demand the participants to rate their workplace along six organizational dimensions: (a) dominant characteristics, (b) organizational leadership, (c) management of employees, (d) organizational glue, (e) strategic emphasis, and (f) criteria of success. Each of these six items demands the participants to rank four descriptive statements regarding the applicability of that statement to the participants' workplace. Participants must arrive at a total of 100 points for these four descriptors before moving on to the next question. The "Now" section shows the current dominant organizational culture while the "Preferred" section of the instrument expresses how the employees would like their school to function 5 years later. If the difference between "Now" and "Preferred" is 10 points or more, in any of the four organizational culture types: the clan, adhocracy, market, and hierarchy cultures, urgent action is required (Cameron and Quinn, 1999, 2006, 2011).

3.2. Subjects

The study was conducted in the year 2018 in the Junior High School in the Druze sector in the Upper Galilee in northern Israel. Its purpose was to examine the organizational culture of the schools. For this purpose, the "Organizational Culture Assessment Instrument" (OCAI), developed by Cameron and Quinn (1999, 2006, 2011) was used. The sample size for this study consisted of 220 staff members. They were from 9 different Junior High schools. Subjects for the OCAI pilot study were schools staff: principals, vices, coordinators, homeroom teachers, counsellors, teachers with no other roles, integration teachers, secretaries, librarians and other staff members. The questionnaires

were distributed to most of the staff who attended at the days when the researcher went to the schools to distribute the questionnaires. Some people did not agree to fill it in, others took the questionnaires and did not hand it back. 300 copies were distributed. 220 copies were collected.

3.3. Measures

The survey included demographic and empirical items. It had three sections. Section one: the demographic items which included: (a) gender (b) religion (c) subject of teaching (d) years of teaching (e) role in the school (principal, vice, coordinator, homeroom teacher, counsellor, teacher with no other roles, secretary, librarian, integration teacher, another subject, other) (f) being or not being a management member (g) certificates (matriculation, BA, MA, PhD, or other) (h) latest studies (i) classes the teacher teaches. Section two: three questions concern the level of satisfaction, the level of motivation and the willingness to stay in the school. These three questions were scaled from 1-6. Section three: the Organizational Culture Assessment Instrument (OCAI) Cameron and Quinn's (1999, 2006, 2011).

4. Discussion of the OCAI Results

Concerns the current culture, the school staff rated the clan culture as the dominant culture that they have now, and also gave considerable points to the other cultures as follows: (Mclan = 27.74 , SDclan = 6.86; Madhocracy = 24.20, SDadhocracy = 3.89; Mmarket = 24.55, SDmarket = 5.92; Mhierarchy = 23.45, SDhierarchy = 4.85). The difference across the ratings is highly significant $\chi^2(3, N = 220)=99.89, p<0.001$. Concerns the preferred culture, the school staff also rated the clan culture as the culture that they prefer to have in five years, but also gave considerable points to the other cultures as follows: (Mclan = 31.11, SDclan = 7.72; Madhocracy = 25.81, SDadhocracy = 4.94; Mmarket = 21.74, SDmarket = 5.61; Mhierarchy = 21.47, SDhierarchy = 4.87). The difference across the ratings is highly significant $\chi^2(3, N = 220)=312.109, p<0.001$. The results are clarified in the table and figure below.

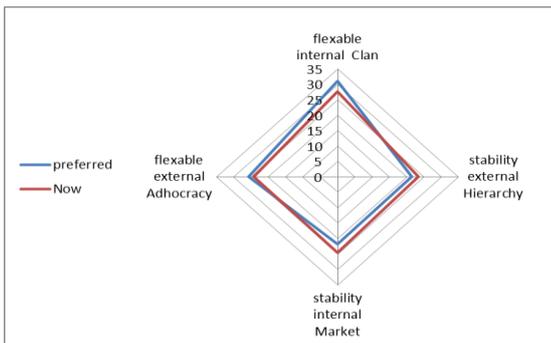

Figure 1. The organizational culture in the Druze sector

	current	Preferred	Difference
Clan	27.74	31.11	3.37
Adhocracy	24.20	25.81	1.61
Market	24.55	21.74	-2.81
Hierarchy	23.46	21.47	-1.98914
	100	100	

Figure 2. The organizational culture in the Druze sector

Figure 1 and Figure 2 show the findings for the organizational culture in the Druze Junior High schools in Northern Israel. The current dominant organizational culture is the clan culture (Mclan = 27.74) whereas market (Mmarket = 24.55) and adhocracy (Madhocracy = 24.20) come next with a very small difference between them which is 0.35 for the advantage of the market. And after that, the last one which is the hierarchy (Mhierarchy = 23.45) with a difference of 0.75 point from the adhocracy. In other words, the clan culture seems to be the most dominant culture with the difference of 3.19 from the market, which is considered a slight difference (Cameron and Quinn, 1999, 2006, 2011). As it appears, the other three cultures, the market, adhocracy and the hierarchy cultures are almost equal with the differences of a fraction of a number. So, and as it seems, the current school culture is a mixture of all the four cultures.

By looking at the expected culture in the Druze schools in five years, it appears that the clan culture is the most dominant culture (Mclan = 31.11). The difference in average between the current and expected for the clan culture is 3.37. The difference between the preferred clan culture and the least wanted culture which is the hierarchy culture is 9.64 degrees. The findings also show that there is an increase in adhocracy (Madhocracy = 25.81) which is the second desired culture by teachers and employees in their schools. However teachers and employees in the Druze sector want to reduce the hierarchy culture (Mhierarchy = 21.47) and the market culture (Mmarket = 21.74). They want to reduce the market with 2.81 degrees and the hierarchy with 1.98 degrees.

Figure 1 adds the flexibility versus stability and the external versus internal dimensions mentioned in Cameron and Quinn (1999, 2006, 2011). The findings show that the expectations of the school staff for organizational internal focus and external focus are balanced whereby the clan and the adhocracy cultures are the dominant cultures expected by teachers. They also want a flexible and carefree culture but still stable and under control.

4.1. The dominant values in the Druze schools according to OCAI

According to the results, the clan culture is the current dominant culture with also measurable rates for the other cultures. In other words, the Druze current dominant school culture is the clan culture, while the other three cultures appear to exist in the schools. This implies that the Druze organizational culture includes values from the four cultures but with different proportions. When looking at the values that each culture supports according to Cameron and Quinn (2011), the following values that express the clan culture appear to be dominant in the Druze culture: loyalty, commitment, cohesion, morale and being friendly. The leaders are considered to be mentors and parent figures. As it appears, the clan culture is the current dominant and the preferred culture. So, the participants are happy with the current organizational culture, and they have the clan values, and they want to strengthen them more. The participants also perceived that their schools have market culture, which is the second current culture. According to the market values mentioned in Cameron and Quinn, (2011), the Druze culture is also goal/results-oriented. People are competitive. The leaders, besides of being mentors, are also hard drivers, producers, competitors and demanding. They give significant importance to winning, reputation and success. The results that they are demanding are the high student achievement. They are competitive with other schools which are: the other Druze schools, the Arab schools, and the Jewish schools. According to the preferred results, it seems that the participants want to reduce the market culture. The Adhocracy Culture appears to exist in the schools with close proportion to the market culture. The adhocracy values that appear to be in the Druze organizational culture are: commitment, innovation, creativity, growth, and being dynamic. The organizations encourage individual initiative and freedom. According to the preferred results, the Adhocracy Culture is the second preferred culture after the clan culture. The least culture that they have and they want to have less of it is the Hierarchy Culture: according to the results, the schools are governed by procedures, stability; formal rules and policies. The leaders are perceived to a certain extent, as coordinators and organizers (M23.46); however, in less proportion to the other three cultures. Moreover, also, according to the preferred, the participants want to reduce this culture to (M21.47).

4.2. Discussion of the Demographic Data

Concerns the age of the teachers and the employees, almost half of them are more than 40 years old. The average age of the teachers and the employees is 39.7, SD=9.25. Also, the average seniority is 14.9, SD=9.8. Most of the respondents have teaching and working experience of 16 years or more which is 39.55% of the respondents. Riordan, Griffith, and Weatherly, 2003 (as cited by Badawy et al., 2017) suggested that the age and the seniority influence the organizational culture. He explained that older workers or those with longer tenure are more likely to become "emotionally attached" to their organizations. Wofford, 2003 (as cited by Badawy et al., 2017) suggested that there is a positive correlation between age, tenure and job satisfaction. The results of this research strengthen his suggestion. So it can be suggested that one reason for the similarities in the current and the preferred culture (the clan culture) is the percentage of the teachers who are older than 40 years and have seniority more than 16 years.

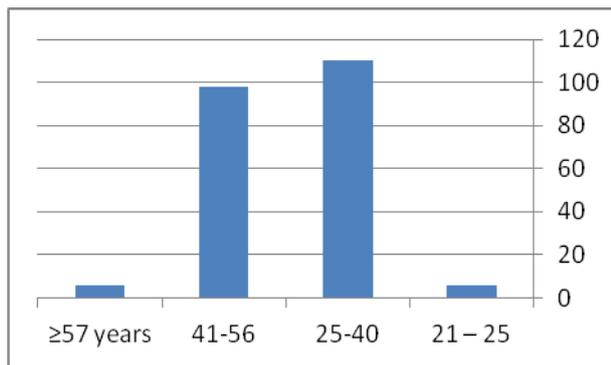

Figure 3. Age of employees

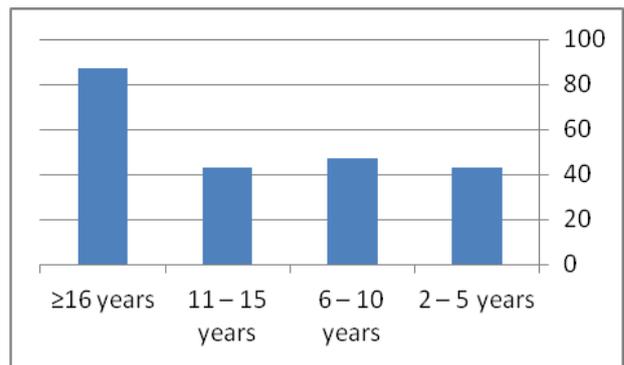

Figure 4. Years of seniority

Out of 220 teachers, 88.18% were reported to be females, and the remaining 11.82% were males. Sempane et al. 2002, Romaine, 1999 and Wofford, 2003 (as cited by Badawy et al., 2017) found that the gender does not affect the organizational culture. The three questions concerns satisfaction, motivation, and the willingness to stay at school were scaled from 1-6. The average of satisfaction is 4.97, SD= 1.24. The average of motivation is 5, SD= 2.02. The average of willingness to stay at the same school is 5.3, SD=1.57. There were no differences among religion.

The Following is a table that includes all the demographic analysis.

Characteristic	Number	%			
Gender			Teaching Experience		
Male	26	11.82%	2 – 5 years	43	19.55%
Female	194	88.18%	6 – 10 years	47	21.36%
Total	220	100.00%	11 – 15 years	43	19.55%
Age			≥16 years	87	39.55%
21 – 25	6	2.73%	Total	220	100.00%
25-40	110	50.00%	management member		
41-56	98	44.55%	Yes	35	15.91%
≥57 years	6	2.73%	No	185	0.840909
Total	220	100.00%	Total	220	100.00%
Religion			Certificates		
Druze	188	87.27%	Matriculation	10	4.55%
Christian	26	10.00%	BA	127	57.73%
Muslim	6	2.73%	MA	81	36.82%
Total	220	100.00%	PhD	1	0.45%
			other	1	0.45%
			Total	220	100.00%

Figure 5. Demographic Profile of Respondents

5. Conclusions

In the light of the empirical analysis data regarding the structural validity of the research scale, it is possible to judge that the OCAI is a highly credible tool that can be applied to the Druze Junior high schools. The current and the preferred culture in the Druze schools is the clan culture, the second current culture is the market, which is not the preferred. The third current culture is the adhocracy culture, and it is the second preferred culture. The hierarchical culture is the least existing culture, and it is also the least preferred one. The results show that the following values are apparent in the organizational culture and are also preferred: loyalty, commitment, cohesion, morale, competitiveness, innovation, creativity, growth, being friendly, results-oriented, initiative, and dynamic. The results indicate that the human development resource is apparent within the values and the culture of the schools. The works are carried out within the spirit of a team, consensus, and participation; the individuals have the commitment, mutual respect, and high trust. The differences between the cultures are not very significant. According to Cameron and Quinn (2011), these differences do not require changes. According to the findings, the participants who filled out the questionnaires are satisfied and motivated. There are two evidence that indicate that the organizational culture is positive: first, the results of the OCAI questionnaire, and second, the results of the answers on the three questions concerns satisfaction, motivation, and the willingness to stay at school. The average of the three questions was 5.09 out of 6.

Recommendations

A strong organizational culture where the members are satisfied with what they have can be motivating and inspiring. The leaders can arrive at higher levels of excellence and uniqueness, and can enable the schools to think of higher goals and visions which achieving them can be more comfortable than in an organization where the organizational culture is weak. The results of this research are significant for the schools. They can give the principles a more precise picture about how the teacher and the workers perceive their organizational culture and how they prefer it to be. Because there are only slight differences between the current and the preferred culture, the principals can learn these results; think what they can do to bridge the gaps and improve the organizational culture, which is very strong and encouraging. It is true that according to Cameron and Quinn (2011), there is no need for changing the organizational culture when the differences are less than 10, but, because the results are very encouraging, the leaders can think of specific ways to implement some changes that can improve the culture in their school. The leaders can bring their employees to work harder and harder. Also, understanding the organizational culture can be the basis for developing various programs that can help to achieve the organizational goals for better quality. Studies on the organizational culture can be used as a reference in the future studies. A recommendation for a future study is to make interviews with the principals of the schools that the OCAI was held on concerns their leadership styles. The need of this is to find out which leadership styles are used by the principals and that make the teachers perceive that the current culture is the clan culture and it is also the preferred.

Population ageing, a consequence of transition

Mihaela-Camelia Schmidt*

University of Petrosani, 20, University Street, 332006, Romania

Abstract

The paper contains a statistical analysis of data provided by literature in the field regarding the demographic phenomenon of population ageing and the multiple implications of this demographic tendency that represents a challenge for all the states of the world.

Keywords: old age, ageing process, demographic ageing

1. Old age and the ageing process

Ageing is a process that turns a vigorous adult into a fragile individual, vulnerable to most diseases and even to the risk of death (Prada, 2001, pag. 11). For the majority of specialists in demography, ageing means the growth of the ratio of old population in the total population.

Ageing is a process that generates a series of functional disturbances and deviations, associated with numerous structural alterations. It is not synonymous with old age, the latter being an age span (60/65 years old and over) characterized by profound degradation and involution of the main functions of the human body, among which the decline of physical and mental capacities, the decrease of resistance to diseases, the diminishing of the adaptation capacity, etc. (Rădulescu, 2002, pp. 63-64).

The issue of the vulnerability of the elderly is dealt with in most research in the field, mainly from the perspective of the biological/physiological, psychological and social changes brought about by ageing. Apart from the problems generated by these changes, elderly persons also face financial, material, and medical difficulties. The main biological (organic) alterations characteristic of ageing affect primarily the nervous system, followed by the locomotor, the cardiovascular, the respiratory, the renal and the reproductive systems. There are also skin changes, (aspect and color), sensory deteriorations (sight, hearing, etc.), reduction of the muscular tonus, of the effort capacity, digestive disorders, etc. Psychological changes become obvious with old age, manifesting themselves from the elementary mental processes (on a sensory level) to the most complex that define the human being (language, thought, attention, etc.). (Bucur & Maciovan, in Neamțu, 2003, pag. 914-916) from a social point of view, old age is equivalent with disengagement from active social roles, withdrawal from professional life and adoption of other social roles (Rădulescu, 2002, pag. 66).

2. The demographic ageing of population

Population ageing is a phenomenon that appeared as early as the last century, as a result of the decrease of mortality, the control of infectious diseases the improvement of the sanitary system and the progress of medicine, the higher living standard and better nutrition (Curaj, în Neamțu, 2010, pag. 281). The increase of the elderly population is a challenge for all the states of the world when it comes to managing the issues pertaining to old age. Although Romania has a population with a relatively balanced group structure, the increase of the elderly population follows the same international demographic trend. Literature in the field consider people of 60, 65, and over to be part of the elderly population.

In order to understand the evolution of the demographic ageing phenomenon in time, it is important to analyze the researchers' opinions regarding Romania's demographic projection for the next decades. Numerous studies analyze the demographic evolution of Romania's population (in the present, the past, and the future).

*Tel 0040722255366, E-mail: schmidtcamelia@yahoo.com

In this context, Cornelia Mureşan’s study divides the population into homogeneous age and gender sub-groups. This projection reveals a constant decrease of Romania’s population on account of decreasing birth rate, (and consequently, decreasing young and adult population) and of increasing number of elderly persons aged 60 and over (see table 1).

Table 1: Projection of Romania’s population (and of its demographic structures) until 2030

Population*	1990	2000	2010	2016	2030**
Total population (thousands)	23,207	22,435	20,247	19,703	18,671
Percentage compared with 1990	100	96.67	87.24	84.90	80.45
Births during the year (thousands)	314	234	212	188	137
Young between 0-19 years old (thousands)	7,348	5,760	4,322	4,139	3,236
Percentage of young between 0-19 years old	31.66	25.67	21.35	21.01	17.33
Adults between 20-59 years old (thousands)	12,226	12,455	11,417	10,747	10,974
Percentage of adults between 20-59 years old	52.68	55.52	56.39	54.54	58.77
Elderly aged 60 and over (thousand)	3,633	4,220	4,508	4,817	4,460
Percentage of elderly aged 60 and over	15.65	18.81	22.26	24.45	23.89
Percentage of females	50.7	51.10	51.30	51.2	52.20
Percentage of males	49.3	48.90	48.70	40.8	47.80

* Population on July 1 of the respective year

Sources: Mureşan, 1999, pag. 2012

NIS (National Institute of Statistics), Romania’s Statistical Yearbook, 2017

The group of elderly population, aged 60 and over, increases in Romania especially after the Second World War, doubling its ratio between the 1930’s and the beginning of the 70’s. Then, there is a stagnation of increase until the beginning of the 90’s, when the ageing rate accelerates again (Mureşan ş.a., 2009, pag.5).

The ratio of elderly persons in the total population increases constantly over the past decades from 15.65% in 1990 to 24.45% in 2016 (table 1). In the same period, the number of young decreases from 7,348,000 individuals to 4,139,000 in 2016, whereas the ratio of adult populations in the total population follows an ascending trend until 2010 (when it reaches the level of 56.39%, to undergo a later decrease to 54.54% in 2016).

Thus, the growth of the ratio of the elderly population (demographic ageing) is determined not only by the increase of the number of elderly, but also by the change of the proportion between different age segments of the population, always alongside with other evolutions, such as: the decrease of the percentage of young, the increase of the number of adult population, etc.

Apart from the size of the elderly population, the structure of the elderly population according to several variables (gender, residence environment, level of training, etc.), the degree of ageing, etc., there are also other indicators of ageing that can induce different classifications, namely the demographic ageing index and the parental support index.

The parental support index is meant to reveal the impact of population ageing on the family. Starting from the premise that the elderly need permanent care, and the responsibility of this care is attributed to the direct descendants, the parental support index expresses the ratio between the number of elderly persons aged 80 and over, and the number of “elderly adults” in the age group 55-64 years old. According to this index, on a national level there are approximately 23 elderly persons for every 100 “elderly adults” (op. cit., pag. 21).

Having a universal character, population ageing affects societies on every level, Romania being no exception, and the social and economic consequences of this process are difficult to assess.

Some of the major consequences of population ageing are the following: the challenge for the welfare services by increasing the expenses necessary for the social programs for the elderly to the detriment of other expenses allocated to other age segments of the population; the financial overloading of the pension system by the increased number of beneficiaries and the decrease of the number of contributors to the pension fund; increasing expenses in the health system, which generally grow with the number and the age of the elderly; the decline of the modern society of western type by loss of dynamism, of the capacity for innovation and progress; the decline in the number of population, etc. (op. cit., pag. 7).

The implications of the demographic ageing tendency are multiple and have consequence on different levels (Curaj, in Neamțu, 2010, pp. 294-296):

1. On a financial level. It is known that the number of elderly persons does not coincide with that of pensioners, the latter representing the larger proportion, the explanation being that the category of pensioners also includes persons who acquire this status earlier than the beginning of old age (for example: employees in the mining industry, in the military or the police force, etc.). Financial issues occur due to the fact that the ratio of pensioners grows gradually and the ratio of the employed decreases, so that every employed person must pay higher and higher contributions to the pension fund. On the other hand, it is known that, in the families headed by persons of 60 or over, income is lower than in the families headed by adult persons. This is explained by its source, since it primarily comes from social services (mainly pensions), whereas the adults get their income from salaries, the difference being obvious if we take into account the difference between the value of pensions and that of salaries. In close correlation with the income level, the expenses of the households headed by elderly persons are lower than with those headed by adults. Most of the consumption expenses of the elderly is represented by expenses for food and non-alcoholic beverages, followed by household related expenses (water, electricity, gas). These two categories of expenses, alongside with those dedicated to health issues, represent a higher ratio with the elderly than with the adults;
2. On a health level. Romania's economic and social evolution in the transition period had a strong impact on the demographic and health status of the population. Although there has been preoccupation for improving the population's health and the providing of suitable medical services, the health status of the Romanian population is still precarious in certain respects. On the other hand, due to higher life expectancy, the number of elderly persons grows, which leads to an increasing number of ill persons, especially suffering from chronic diseases (heart and respiratory diseases, diabetes, osteoporosis, etc.) and mental conditions (dementia, depressions, anxiety, etc), old age being known to be characterized by poly pathology;
3. On a social welfare level. Having in view the increasing number of elderly, with their specific problems, the number of persons in need of support from social welfare services increases. The lower the healthy life expectancy, the heavier the 'burden' for the health services and the pension system, and the political decision-makers should be prepared to take adequate measures in order to deal with the needs of elderly persons. On the other hand, although most of the elderly live independently or are taken care of by their family, an increase in the number of elderly persons committed to specialized institutions has increased over the past years. Among the social services provided to the institutionalized elderly there are: support for household cleaning, juridical and administrative counseling, ways of preventing social marginalization and social reintegration according to the psycho-affective capacity.

Consequently, population ageing has an objective and virtually irreversible character, being one of the consequences of demographic transition, that is of the shift from traditional high fertility and mortality regimes to modern low fertility and mortality regimes. It is a steady and long process, both present and future, still not completed in any country in the world. However, the rate of ageing can be slower or faster depending on the evolution of its major determining factors – fertility and migration. It is a universal phenomenon which affects everybody. The growth of the number of elderly in comparison with the working population has direct repercussions on the equity and solidarity between generations. Ageing involves the increase not only in the ratio, but also in the absolute number of elderly.

A combinatorial gray wolf optimization algorithm for finding 2D protein conformation

Ioan Sima^a *

^a“Babes-Bolyai” University, str. M. Kogalniceanu, nr. 1, Cluj-Napoca, nr. 1 RO-400084, Romania

Abstract

Protein folding problem is one of the exciting subjects in the bioinformatics field. It consists in finding tertiary or quaternary structure from an amino acid sequence. Gray Wolf Optimization (GWO) algorithm is a new meta-heuristic method dedicated to solving optimization problems with continuous functions. In this paper, we propose a novel variant of Gray Wolf Optimization algorithm for finding the optimum of combinatorial functions (cGWO). This variant includes crossover operation taken from evolutionary methods. In our proposal, it is applied for solving protein folding in HP 2D model, which is a combinatorial problem. Furthermore, Protein Folding is NP-complete problem. Results of experiments have shown that the proposed cGWO has a weak convergence. However, the best known energy in the literature was reached in this study. Energy conformations close to optimum are obtained from the first iteration if the size population is large enough.

Keywords: Grey Wolf Optimisation; Combinatorial optimization; Protein Folding; 2D HP Model; Crossover; Bioinformatics;

1. Introduction

The proteins are one of the most important constituents of living matter. They are epigenetic expression of the cellular genome (Dinu et al, 2006). They perform and control the essential functions in living cells and organisms. Therefore, the knowledge of the structure and their functions is essential to understanding the functioning of the living.

The tertiary or quaternary structure (also called native conformation or folded protein) is difficult to predict because the space of the possible conformations is huge and complex. This is known as *protein folding problem*.

At the molecular level, the proteins are linear polymers formed from 20 types of α -amino acids (aa), called proteinogenic amino acids. The length of the proteins varies from a few tens to a few thousand, even tens of thousands of aa. Thus, the molecular mass varies from hundreds to millions of u.a (Dalton).

Amino acids have similar chemical structures. These differ by the degree of hydrophobicity, charge and size.

Levinthal outlines the principle according to which the native conformation can be predicted only from their linear sequences (Levinthal, 1969).

Over time, several models have been created for the representation of protein conformations. One of the simplest and coarser models, but one that still captures the essence of the folding phenomenon, was proposed by Lau and Dill, 1989. It has two simple forms: square or 2D - used in this paper - and cubic or 3D type, closer to the real protein.

To solve protein folding on this model, so far, it has been proposed a lot of computational methods. In Unger and Moulton, 1993, it was applied a genetic algorithm (GA) with a form of simulated annealing (SA) and Turabieh used a hybridized GA with a form of local search (LS) called Great Deluge Algorithm (Turabieh, 2016).

It was also proposed an Ant Colony Optimization Algorithm (ACO) with the 2D and 3D Model (Shmygelska and Hoos, 2003, 2005). In the same way, it has been proposed an improved hybrid algorithm which is a mix between particle swarm optimizer (PSO) and tabu search (TS) and it is used for prediction protein structure for 3D HP lattice (Zhou et al, 2013). In Czibula et al, 2011, it is found a Q-learning approach for solving the 2D HP lattice.

The Grey Wolf Optimization (GWO), a new inspired of nature algorithm, was proposed by Mirjalili et al, 2014. Initial, it was created for solving continuous functions. Madadi and Motlagh, 2014, used it for optimal tuning of proportional-integral-derivative (PID) controller parameters for DC Motor drive to find the global optimum solution in search space and Yassien applied the GWO to the 0/1 Knapsack Problem (Yassien et al, 2017).

E-mail address: sima.ioan@cs.ubbcluj.ro.

Lu et al, 2016, changed the GWO for the approach of combinatorial issues. This variant, named by them, MODGWO, is a multi-objective discrete grey wolf optimizer used for scheduling problem in welding production. The authors modified the search operator developed in originally GWO for solving continuous optimization problems, with a mutation shift variant. Also, the GWO has been modified for approach the binary problem for feature selection (Emary et al, 2016).

After this state of the art, we can say that the GWO algorithm has not yet been applied for solving the protein folding problem.

This paper is organized as below. After this introduction, the next Section presents briefly the protein folding problem. In Section 3, we will describe in very short details the Grey Wolf Optimization (GWO) algorithm for continuous function. Then a modified GWO algorithm, adapted for combinatorial function, that we called cGWO, is proposed in this paper for solving the 2D HP model. This model will be explained in Section 4. In Section 5, we will analyze the results of our experiments. The last section contains the conclusions and further work.

2. Protein folding problem

There are 20 proteins genic (protein-building) amino acids (aa), which differ one from another by the nature of side chain R. Biochemical notation uses three letters, while bioinformatics uses a single English letter for its representation.

The proteins (also called protein sequences) are linear chains of α -amino acids. The proteic macromolecule has four levels of organization: primary structure, secondary structure, tertiary structure, and quaternary structure (Mihalaş, 2011).

Primary structure is the amino-acid sequence, poly-peptide chain being represented as an ASCII string in bioinformatics.

Secondary structure is made of by regularly repeating local substructures (α -helix, β -sheet, turns) stabilized by hydrogen bonds.

Tertiary structure is the overall shape of a single protein macromolecule, representing the spatial (3-D) relationships of the secondary structures to one another. A synonym term to tertiary structure is fold – it enables the basic function of a protein.

Quaternary structure is sometimes formed by several protein molecules (called protein subunits) which function as a single protein complex.

Protein folding is the physical process through which their uni-dimensional primary structure becomes three-dimensional tertiary (or quaternary) one, by means of a sequence of twists, bends, and bundles. Most proteins fold into unique 3-dimensional structures and the shape of the natural folding process is called native conformation. In the case of small proteins, the folding process acts spontaneously, both in vivo and in vitro.

Native (or folded) protein conformation is difficult to predict.

Due to its numerous applications in genetic engineering and medicine, the prediction protein structure folded, starting from its primary structure is one of the greatest challenges of current bioinformatics research.

To solve it, this problem has been addressed from the perspective of several algorithms applied on series simple or more complex models.

3. HP 2D Lattice Model

One of the most popular considered models is HP model, which was proposed by Lau and Dill in 1989. This model introduces a series of simplifications.

First, HP being a coarse model, the units that are represented on lattice are the amino acids, not atoms.

Second, the 20 proteinogenic amino acids are classified only into 2 classes: H (hydrophobic) and P (polar, or hydrophilic). The H amino acids reject the water and P amino acids attract the water. Due to the fact that the globular proteins are submerged in an aqueous internal environment of living organisms, they will form a hydrophobic core, as can be seen in fig 3. Thus, it will have an alphabet composed by 2 letters, {H, P}, between which it can form up to 4 types of contacts: H..H, H..P, P..H and P..P.

The third, the space is discretized in very simple lattices. For bi-dimensional lattices, the simplest space is the square and for tri-dimensional lattices a simple space is the cube. In these spaces, amino acids can be rotate with exactly 90 degrees. The encoding of directions of amino acids can be absolute or relative. In our work, we are focused on experimenting in 2D space, where amino acids can be rotate with 90, 180 or 270 degrees and it was used the absolute encoding of directions. In this way, the directions are: Right – R(0), Down – D(1) Left – L (2), and Up – U(3). For 2D HP model and absolute encoding, it will have an alphabet of directions composed by 4 letters: {L; R; U; D}.

The fourth, the energy of the HP model is a convention which reflects the fact that H aa to form a hydrophobic core. Thus, for each pair of non-consecutive H (H..H) aa in the protein sequence, but which are adjacent on the lattices (topological neighbors), the energy of conformations decreases with a value, e , equal to -1. For the other three types of contacts (H..P, P..H, P..P), the value of e is considered equal to 0. In fact, the energy of conformation is the number of contacts between H...H aa that are not consecutive in sequence (see fig. 3).

These being given, the folding protein problem, in HP models, can be defined as a problem of combinatorial optimization.

The HP sequence is given as: $s=s_1s_2s_3..s_i..s_n$, where: n – no of aa; $s_i \in \{H, P\}$; the native conformation is the conformation which has the minimum energy, c_m , of sequence s , where $c_m \in C(s)$, and $C(s)$ - the set of feasible conformations of the sequence s .

The energy of conformation $c_m, E(c_m)$, is:

$$E(c_m) = \min\{ E(c) \mid c \in C(s) \}, \text{ where } E(c) \text{ - energy of conformation } c \tag{1}$$

$E(c)$ is:

$$E(c) = - \sum_{i,j=1}^n a_{si} \cdot b_{sj} \tag{2}$$

where: $a_{si}, b_{sj} = 1$ if s_i is H aa, and $a_{si}, b_{sj} = 0$, otherwise
and a_{si} and b_{sj} are topological neighbors, but are not sequence neighbors

4. Gray Wolf Optimization (GWO) Algorithm

Grey Wolf Optimization (GWO) is one of the newest meta-heuristics proposed by Mirjalili et al, 2014. It is a Swarm Intelligence algorithm which imitate the social hierarchy and hunting behavior of grey wolves.

The grey wolves are divided into four categories: alpha-wolf (α) is the highest; beta-wolf (β) is the second, obedient only to α -wolf; and delta-wolf (δ) is the third in hierarchy. The others are omega-wolves (ω). During the rush, ω -wolves follow the three leaders.

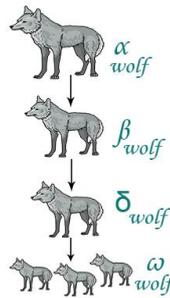

Fig. 1. The social hierarchy of the grey wolves.

The encircling and hunting of the victim can be mathematically formulated by (3)-(6).

$$D = |C \cdot X_p(t) - X(t)| \tag{3}$$

$$X(t+1) = X(t) - A \cdot D \tag{4}$$

$$A = 2a \cdot r_1 - 1 \tag{5}$$

$$C = 2r_2 \tag{6}$$

where the components of r_1 and r_2 are uniform random vectors in $[0,1]$ and the components of vector a decrease uniformly from 2 to 0 over iterations. X_p is the position vector of the prey, t is the current iteration, and X represents the position vector of a current grey wolf.

The standard GWO was created to find the optimum of continuous functions.

The prey represents the solution that should be found. As this solution is not known, it is considered that an intermediate position of the first three wolves could be very close to the place of the **prey** (the optimal solution).

Since the optimum position (prey) is not known, the optimization process consists in capturing the prey, which is presumed to find in the positions of the three wolves dominated (α, β and δ). Finally, the optimal value is the best position of the α -wolf.

The equations are:

$$D_\alpha = |C_1 \cdot X_\alpha - X|, \quad D_\beta = |C_2 \cdot X_\beta - X|, \quad D_\delta = |C_3 \cdot X_\delta - X| \tag{7}$$

$$X_1 = X_\alpha - A_1 \cdot D_\alpha, \quad X_2 = X_\beta - A_2 \cdot D_\beta, \quad X_3 = X_\delta - A_3 \cdot D_\delta \tag{8}$$

$$X_{(t+1)} = \frac{X_1 + X_2 + X_3}{3} \tag{9}$$

Advantages of algorithm:

- Few parameters required by the algorithm
- There is no need for mutation or crossover probabilities like Genetic Algorithms.
- It is easier to implement.

The downside is that GWO was created to solve continuous optimization problems. As the Protein Folding Problem is a combinatorial optimization problem, in this situation the GWO cannot be applied in its classical form.

5. Gray Wolf Optimization combinatorial (cGWO) Algorithm

In order to be applied the GWO for combinatorial optimization problems, our work consist in adding a crossover type, so that in this way the GWO can be applied to problems that involve discrete or combinatorial functions.

Thus, the modified search operator is replaced with crossover operation. From the GWO algorithm it is retained the idea of going through the entire wolf population that makes crossover with one of three dominant wolves:

$$c_i(t+1) = \begin{cases} crossover(c_\alpha(t), c_i(t)), & \text{if } rnd < 1/3 \\ crossover(c_\beta(t), c_i(t)), & \text{elseif } rnd < 2/3 \\ crossover(c_\delta(t), c_i(t)), & \text{otherwise} \end{cases} \tag{10}$$

where $c_i(t+1)$ is the conformation resulting from the application of the crossover operator, $c_i(t)$ is the current wolf of current iteration, and $c_\alpha(t)$, $c_\beta(t)$, $c_\delta(t)$ is the conformation of the α -wolf, β -wolf, δ -wolf, respectively. Rnd is a uniform random value between [0,1].

In this work, we used single-point crossover. The place, where the string is cut, varies linearly with number of iteration. In the first generations, the location where will be the cutting is close to 1, so that towards the end of the algorithm it reaches close to n-1, where n is the length of the protein sequence. Therefore, at the beginning is encouraged exploration, but finally, exploitation. This is because, at first, the resulted conformations from the crossover have big sequences from ω -wolves, and to the end, they have a large portions of one of three dominant wolves, which are conformation with high energy.

For example, for a structure by 8 aa, in below image can see how the first half of α -wolf is concatenate with the second half of the current wolf (an ω -wolf). Note that, not all conformations results crossover operation are feasible.

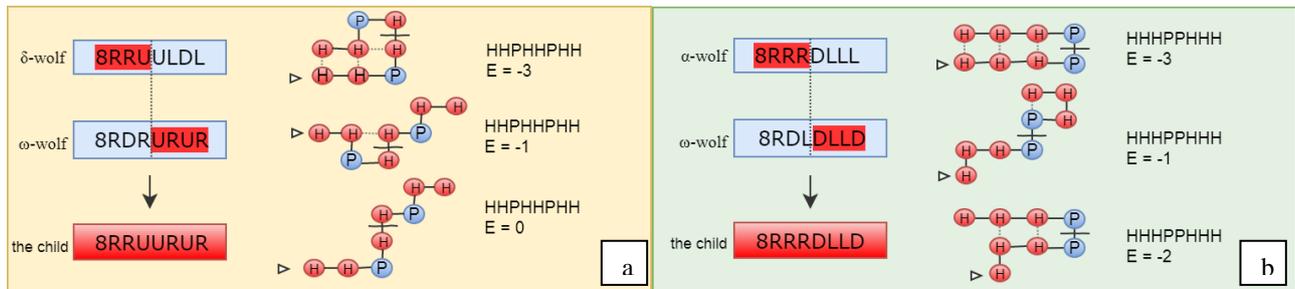

Fig. 2. The crossover operation. (a) the resulting conformation is weaker than parents. (b) the resulting has o intermediate energy. The red is Hydrophobic aa and the blue is Polar aa.

In the above picture it can be seen that after crossover operation it is obtained the following cases:

- the resulting conformation is weaker than the initial conformations. See fig. 2 (a).
- the resulting conformation is better than the initial conformations
- the energy of the resulting has an intermediate value between the energies of the initial conformations. See fig. 2 (b).

6. Experiments (Simulation results)

The aim of this paper was to experimentally evaluating in our proposed combinatorial Grey Wolf Optimization algorithm (cGWO). The cGWO was implemented using C# programming language and tested on one standard benchmark HP protein. The parameters of the cGWO algorithm are: number of grey wolf (population size): 10 – 100,000; number of runs for every population size: 10, number of iterations: 1,000.

The sequence tested in this paper is: HPHPPHHPHPPHPPHPPH, a sequence which contains 20 aa. This sequence is well-known structure. It was taken from Unger and Moulton, 1993. In its case, it is known that there are 83,779,155 feasible conformations of which only 4 conformations have the lowest energy level, -9. Note that an optimal conformation is very difficult to achieve. The fraction of the optimal conformations from the total number of conformations is extremely small, only 4.77×10^{-8} .

Below, in table are presented the best result from the 10th runs for every population size. It can be observed that our approach has a weak convergence and that the lowest energy was reached in the case of big population size (the cGWO is not able to increase significantly the initial solutions). It can also be seen that the minimum energy was obtained in all cases in the first 100 iterations. In the other 900 iterations, is not significant evolution which took place. From this, it can be deduced that the size of the population is more important than the number of iteration. This means that the crossover operator in this form is not the best solution.

In this experiments the α -wolf it is not conserved from one iteration to another.

Table 1 Results of our proposed cGWO

Population size	Energy from first iteration	Best energy (solution)	No of iteration where the best energy was reached
10	-3	-7	87
50	-4	-6	93
100	-4	-6	68
200	-4	-6	24
500	-5	-8	62
1,000	-6	-8	68
5,000	-8	-9	62
10,000	-7	-9	49
50,000	-7	-9	43
100,000	-8	-9	37

It can be seen that our algorithm is able to obtain the conformations with the best energy. One of the conformation found (energy is -9), is represented in fig below:

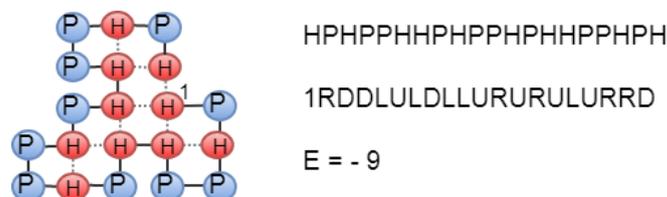

Fig. 3. The best conformation finding the cGWO. The red is Hydrophobic aa and the blue is Polar aa. It can see that H aa forms a hydrophobic core.

In below figure is represented the convergence of cGWO for protein folding on 2D HP lattice for population size = 10,000. In the same picture, it was represented only the first 100 iterations.

Since the first iteration a low energy conformation has been generated (-7). For 42 iterations there was no evolution. In iteration 43, a-wolf reaches the energy -8, so after another six iterations reaches the minimum energy (-9)

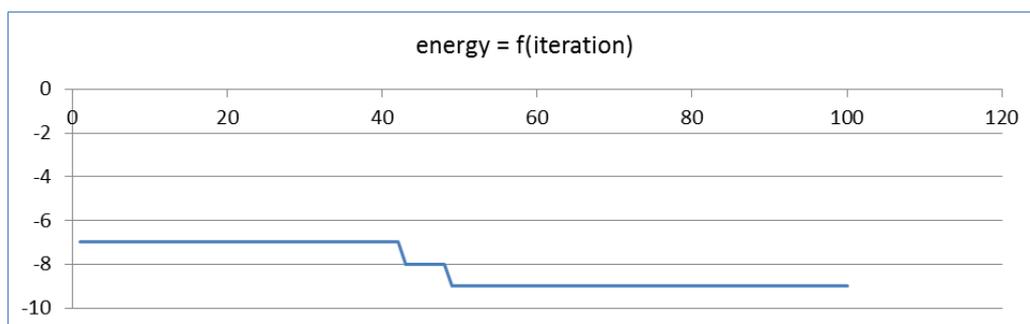

Fig. 4. The convergence of cGWO

7. Conclusion and further work

In this work, we proposed a Gray Wolf Optimization Algorithm for solving of protein folding problem on the bi-dimensional Hydrophobic-Polar Model. Due to the fact that the GWO is a meta-heuristic for finding the optimum for continuous functions, and protein folding is a combinatorial function, in this paper was presented a modified GWO Algorithm (cGWO) adapted to search for solutions in combinatorial spaces. This includes the crossover, a known evolutionary operator.

This algorithm is simple and shows a good result on the tested sequence on 2D HP lattice model. But the convergence of the algorithm is weak.

The further work will consist in the improvement of our algorithm including mutation and finding ideas for increasing convergence. Then, our research can be extended to other large HP protein sequences and the 3D HP Models.

Using film to interpret literature: Charles Dickens’ “A Christmas Carol”

Esther Andraş^{a*}

^a Colegiul Tehnic “Dimitrie Leonida” Petroşani, Department of Foreign Languages, str. 22 Decembrie, nr.6, Petroşani, 332020

Abstract

It is argued within this paper that film is becoming an important educational tool in the English classroom, that it enlivens and enriches classes and it facilitates students' understanding of course materials. Although students may still treat film chiefly as passive entertainment, with the appropriate teaching methods and strategies they can become sophisticated interpreters of the interplay of sound and image. Film should not be regarded as a guilty pleasure or the "reward" at the end of the semester but a legitimate means of enhancing literacy.

Keywords: Dickens, A Christmas Carol, literature, film, technology

1. Introduction

The development of technology and the rise of digital revolution have changed language teachers' perception on promoting the students' English proficiency. The way in which teachers can stimulate the language development of their students is by providing what is known as an acquisition-rich classroom. Foreign language teachers are intrigued to discover the effectiveness of a “different” teaching and learning environment that is supported by multimedia technologies. The main focus of this paper resides in the teaching of literature with innovative methods and multimedia resources. It is a venture that enables teachers who have little or no experience of the use of multimedia to benefit from its numerous virtues. Teaching literature with technology aims to encourage students to think creatively and independently, to appreciate not only the stimulation but also the enjoyment derived from the study of literature.

Authentic films should not be considered additional resources in a literature class; on the contrary, this type of content ought to be integrated in the curriculum. The acquisition of receptive skills becomes a vital prerequisite of good productive abilities. Movies provide exposure to the real language uttered in authentic settings and the culture in which the foreign language is spoken (Stempleski, 1992, Telatnik and Kruse, 1982). Selecting the appropriate literary text – “A Christmas Carol” by Charles Dickens, animated by the video production, may encourage students to achieve a new kind of confidence in reading and overcome their sense of insecurity, experiencing the feeling of success. The modern method of teaching literature is learner-centred, focusing on the student's response and creativity.

A further aim of this study is to explore to what extent films can assist students to engage in interactive activities that offer opportunities to read, to write, to listen to, to watch and to discuss oral and written English texts expressed in a variety of ways. Technology also represents an escape from the rigid learning patterns encountered in the traditional settings. The use of technology has assisted for many years with the goal of reaching students. Multimedia addresses various learning styles typically neglected by traditional teaching methods, positively impacting on the learning experience. The numerous and extensive opportunities for natural communication provided by multimedia allow for the complete integration of language skills. Furthermore, research on second language acquisition suggests that more efficient learning takes place when students are engaged in relevant tasks within a dynamic learning environment rather than in traditional teacher-led classes. Working successfully in groups fosters the development of transferable skills, enhancing social skills and interaction. Dickens' work is a landmark in the comic literature of the world. His genius has created an enormous variety of eccentric and highly colourful characters described with a vividness which gives the stamp of his fictional art. The poetic structure of his novels, the descriptions of places charged with a high symbolic

E-mail address: esther_peter2004@yahoo.com

meaning point to Dickens' allegiance to the great Romantics of world literature. The reader is convinced through rhetorical devices which rely on the effect of laughter, suspense, sympathy and pathos. One reason for the great popularity which he enjoyed at the time when he wrote his novels was the fact that Charles Dickens identified himself with the public and shared common experience with it. He performed public readings from his novels in England and America which established an even closer intimacy between himself and the readers. Besides, in his youth, Dickens had wanted to become an actor and one of his hobbies was to act in plays with amateur actors. This theatrical inclination influenced the nature of his fiction. Because of its specific dynamism, its evocative quality and strong visual appeal, his fiction could be acted.

"A Christmas Carol" is one of the most popular stories in English literature. With its numerous literary, stage, radio and film adaptations, the tale has become a holiday classic and the character, Ebenezer Scrooge, has become a cultural icon. Each year during the Christmas season, this famous story is revived once again, teaching life lessons and morals. It is interesting to note that, rather than chapters, Charles Dickens has divided his novella into five staves. Staves are normally associated with music, dividing the music into verses, much like a poem. Dickens has done this in order to give his story a lyrical feel, providing him with another opportunity to create sentiment and emotion. Holiday tradition gives people a sense of comfort and purpose. Perhaps Dickens chose Christmas time as the time frame for his story because he truly believed in the power of Christmas to unite fellow men. Revisiting "A Christmas Carol" by Charles Dickens seems like a good practice as the story is timeless and appropriate for all age levels. It teaches students to look past the moment to see what their actions will reap, and illustrates essential morals like compassion, kindness, generosity. The novella encourages self-direction by teaching students how to use their feelings and sense of responsibility to decide whether something is right or wrong and decide on the course of action. It creates several hypothetical circumstances which allow students to assess their feelings and choices as a chance to reinforce their values. It also demonstrates how English literature can be used to teach character education. Character education is a vital aspect of students' learning because it teaches them different social and moral lessons with impact on their future development.

As written texts, the classics are often inaccessible to students. The setting and historical background can prove challenging, the complex language can interfere with fluent reading and complete understanding of the text. Using film is a way to ensure comprehension, whether with the whole filmed version of the story or fragments that complement the themes, characters, setting or plot of the story. Like the words in a novel, everything students see and hear on screen contributes to the overall meaning. A critical viewer can predict, make connections, infer, ask questions and interpret. In both written texts and films, meaning is made through the details of character, theme, plot, mood and symbols. It is the teacher's task to act as organizer and guide students to become active interpreters. Nearly all the works of classic literature students study in high school have been adapted for film, some of them in multiple versions. The major difference between the film and the book is that visual images stimulate our perceptions directly, while written words perform this indirectly.

Film is a more direct sensory experience than reading and adds colour, movement and sound. But the film is also limited. Whereas there are no time restrictions on a novel, the film must compress events into approximately two hours. Film does not offer the same amount of freedom a novel does - to imagine the characters, the setting and the plot. And, above all, the filmmakers adapt a literary work to film using their own vision and tools, thus altering the original spirit of the story. It is also a common practice for filmmakers to make changes in order to emphasise traits of character or add explanations. Substitutions of language can be made to be recognizable to a modern audience. To what extent can a film be "faithful" to a work of literature? Is the film intended to capture the novel literally or to capture its spirit?

There have been more than fifty adaptations of Charles Dickens' "A Christmas Carol" for movies and television. In 1908 a fifteen-minute silent film production of Dickens' story, in 1938 MGM presented "A Christmas Carol" starring Lionel Barrymore. The 1999 film version of the novel, starring Patrick Stewart as the famous Scrooge, is considered one of the most convincing and faithful to Dickens' story. Patrick Stewart is a classically-trained actor and thus is perfect for a literary character like Ebenezer Scrooge. This adaptation has all the qualities of a very well-done period costume drama. The script is practically a scene by scene transcription of the novella to screen. No scenes are missing and very few are added. It represents an appropriate version for use in an English literature class as it is probably the most accurate representation.

Although setting is often taken for granted by viewers, there is a great deal of work behind the creation of sets, costumes and makeup which remain faithful to the description in the narration. A filmmaker's use of setting reveals important aspects of the people and the society the story depicts. It can include social, cultural, political and historical aspects (the details of everyday existence, work, class, gender, politics, customs) that define a time and a place (for example, Victorian England). The setting of a film can emphasise the symbolic role of a place or highlight themes and ideas. Establishing shots often go unnoticed by viewers but are key elements of the plot. It is interesting to note how the filmmakers portray the grounds and house in Dickens' novels.

Simple things like a close-up of the actor's face or camera angles can express a character's feelings and personality. Elements such as a character's age, dress, speech, facial expression can also influence the viewers' understanding. The music playing in the background or a darkened light on the actor's face enhances the students' perception of a character. Also the choice of costumes can provide more information than we are aware of.

Film and literature have their own tools for organizing narrative structure. In a novel, a new chapter might take the reader back to a different time and place in the narrative whereas in films the director can make use of flashbacks or a crosscut. Even sounds can substitute a narrative sequence in a novel. Films reveal theme in extremely subtle ways and everything from the lighting to the makeup must enhance it. Directors try to find images to represent metaphors for a theme, usually something visual and dramatic that conveys the overall message. When an image or sound is repeated, it becomes a motif or symbol in the film, reminding the viewer of an important idea. The opening scenes in both film and literature announce the theme to be established. In film, point of view can change rapidly. Multiple techniques have been invented to inform the viewer when the point of view changes. Besides the eye-line match, there are techniques such as the voice-over, the flashback, slow motion, distorting lenses and even special sound effects to tell us we are in a character's imagination, not reality. The camera might show a character at first, then move to another, intercept looks and reactions, then feature a new character in the film. A combination of music, lighting and camera angles can create the tone and mood employed by the author of the novel. The director can manipulate the viewer's emotions by generating suspense and obtaining sympathy and pathos. In Dickens' novels tragedy and comedy constantly play off each other and the elements of filmmaking work together to illustrate the author's attitude towards the characters and events. The use of specific colours carries a symbolic message and deliberately enhances the mood.

2. From viewing to producing video

In the following section I aim to explore how bringing new technology into foreign language classes can activate students and determine them to interact and cooperate. The focus is on digital video devices and current approaches to video production as tools for language learning.

Nowadays most teachers integrate the communicative approach within their teaching and regard communication as the main goal of the lesson. The use of video enables students to observe interaction in an authentic setting. Moreover learners have the unique opportunity to witness different gestures and other paralinguistic features of languages which add further meaning to the text. Many language methodologists argue that most video-watching activities aim at the form and structure of the target language and less on meaning. They must also be considered passive as they do not generate communication and thus watching video becomes time consuming and non-motivational.

Watching a video can be successfully turned into a video production project in which communication will facilitate language acquisition. Today digital technology encourages teachers to produce and edit video in a classroom setting. The new generation of students can perhaps fulfil the task of simplifying the production process. Much of the technology already exists on the students' computers, even mobile phones and tablets and editing software can be downloaded for free on the Internet. Enabling students to work with video production is considered a beneficial tool that makes use of both the target language and the new technology. It is suggested that video productions be created as part of an optional course or project as it is impossible to involve the class as a whole. It is often better to divide the class into groups and assign different types of tasks regarding research, script work, and technical issues. The preparatory work should include techniques and activities that enable the entire group to participate in the planning of the video.

An essential part of video production refers to script developing. In this context the teacher plays the part of getting the students started by supplying ideas, speech patterns and examples. The language level of the script should be appropriate for the students' age and linguistic abilities. It is a new experience to use video production as a teaching aid with literary works. After having studied a novel or a play, the students can display or reinforce the acquired critical and analytical skills through a video-producing activity. At this point they should decide how they can portray the content of the literary text using video. As the length of the recorded material will be obviously reduced as compared to the book or the adapted film, it is of great importance to guide students through the script writing stage. A relevant choice of dialogues will ensure the meaning and message of the short film.

Also during the preparatory stage, it is important to decide on the location of the recording, the actors in front of the camera and the students behind the camera who sustain the technical process. Having established the role of each member of the production group, it is high time for the "actors" to start rehearsals. Students are required to learn their lines by heart and follow the instructions in the script when displaying attitudes and feelings. This is a unique opportunity to portray characters and illustrate the tone and style of the production. Once the equipment is prepared and checked, the recording proceedings may begin. Digital video technology makes it very easy to record a large number of sequences without the challenges of a real scale studio. It is a good idea to try to reduce mistakes when recording otherwise the editing process will prove long and discouraging. The next stage implies editing the recorder material by importing it to a computer. There are editing programmes such as Microsoft Movie Maker, Virtual Dub, WAX, which can be downloaded for free. These programmes allow users to remove dissatisfying scenes and work only with the best recordings. Music or pictures can be added into the video, titles, notes, visual and sound effects. The final product should appear in a compressed format such as divx, mpeg, avi, mkv etc.

Having completed the video production it is essential to present it to the students so that they may reflect on various aspects: performance, use of language, pronunciation, diction, accurate illustration of plot, theme and characters. This post-task activity will enable students to assess critically their own work and improve it in the future. The teacher plays the key role in language teaching. Traditionally the main task of the teacher was to transmit information and check students acquired knowledge. Today the role of the teacher has dramatically changed. A teacher in the technology era

must go beyond knowledge transmission. Along with the development and implementation of new technology in the classroom, a new dimension is added to the role of the teacher, that of facilitator and manager. It is the teacher who can add the power to videos and create a successful learning environment. As Lonergan (1995) states, the use of videos is not to “replace, rival or overshadow the teacher” but to ensure fruitful language acquisition. This type of multidimensional environment is student-centred, very active and requires careful planning and students’ cooperation.

Within the classroom one of the most important roles that teachers have to assume is that of organising students to do various activities. This involves presenting the information, explaining clearly the activities students are expected to perform, dividing them into pairs or groups, offering feedback when the lesson has come to an end. J. Harmer (2001:59) summarises the teacher’s role of organiser as follows: engage > instruct (demonstrate) > initiate > organise feedback. Often students find themselves unable to fulfil the required tasks, they become confused or are unable to proceed for lack of vocabulary. In such situations the teacher should act as a “prompter” and help students in a discreet and encouraging manner by offering suggestions, words, ideas. Students may also need information during an activity and turn to their teacher as the most available and helpful resource. When acting as resource it is difficult to prevent students from becoming over reliant on their teacher. Offering guidance as to where to look for information could encourage students to use resource material for themselves and become more independent learners.

3. Conclusions

This paper has presented and discussed the use of multimedia in a learning environment to facilitate the successful study of literature, to equip students with creative and critical thinking skills and to enable them to experience technology-supported learning situations.

As evidenced by this study, movie videos can be an invaluable teaching tool in literature classes if teachers can incorporate their use in effective pedagogy. The teacher plays the key role in language and literature teaching by creating a successful learning environment. The teacher acts as organizer and initiates the activities, provides instructions, clarifies questions, leads the transitions from one activity to another, stops the activity and gives proper feedback. Many students who are uninspired by the traditional methods of teaching are motivated and stimulated by the vivid images, appealing videos, the rich and contextualized language. As a result, the efficient acquisition of receptive skills generates comprehensible learner output.

Sport - An inexpensive way of treatment for poor people

Laura Marica^a, Cristian Siminic Ilioni^a

^a University of Petrosani, Department of Social and Human Sciences, str. Universităţii 20, Petroşani, 332006

Abstract

Inactivity is described by the Department of Health as a “silent killer”. Evidence is emerging that sedentary behaviour, such as sitting or lying down for long periods, is bad for your health. I say this because even poor people have come to have in the priority list TV and computer. Many parents who live with bad neighbors do not let their children play outside for fear that something bad might happen to their children and therefore prefer to keep them in the house where they sit and watch TV or play on the computer. This makes them sick mind and body.

Keywords: Sport, people, priority, poverty, statistics;

1. Introduction

Thinking about it, sometimes compassionate, sometimes just watch them and try to discern their intimate mechanisms of functioning, their inner dynamics that make them to be so petty, limited, partly naked, unable to receive and even less to give.

“Previous generations were active more naturally through work and manual labour, but today we have to find ways of integrating activity into our daily lives,” says Dr Cavill .

They are poor people. I do not care for their money and no matter how many materials have checked on the priority of my list, I'm just curious how many acres lies in their heart and how tall they ideals fly ?

2. What does poverty mean ?

- Poverty is about struggling to meet basic necessities such as food, shelter and clothing;
- It also means not being able to access the following to ensure a comfortable quality of life;
- Essential goods and services;
- Meaningful employment and decent earnings;
- Adequate and affordable housing;
- Safe neighbourhoods with public amenities;
- Health and well-being;
- Social networks;
- Basic human rights.

3. Exactly how “poor” do you have to be to be poor ?

- Statistics can suggest aspects of poverty - such as, income levels, educational attainmen, or employment;
- From these numbers, an assumption about quality of life may be made;
- But statistics do not reflect the *experience of living in poverty*;
- To look deeper at the issue of poverty, one may consider two important issues.

4. Depth of Poverty and Populations Affected by Poverty

Poverty is experienced differently by different people. Even though one may be employed full-time, they may still experience poverty. Poverty is experienced differently by:

Those at-risk of poverty – people who are one or two pay detts away from poverty or whose employment is insecure;

The working (waged) poor – people working close to minimum wage and trying to make ends meet

The temporarily unemployed – individuals facing short-turn employment due to layoffs or other reasons

The persistently unemployed – people who face barriers in finding and maintaining employment

The dependent – individuals on a fixed income (i.e. retired people, people with work limiting disabilities)
The homeless – people living without proper housing.

Fig. 1. Poor people

First i should tell you that many people consider poverty as a disease. Why? The poor peoples lifestyle leads to increased stress levels and the stress of not having anything can reflect on the human body.

No matter how much you want to help these people closed in themselves, living only from day to day, without caring what leave behind, which teaches pass those who are supposed to help them get out of this miserable situation in which they are, poverty.

I started thinking that if we want to help these people we need to focus our attention in order to teach their children not to be like them.

Fig. 2. Very poor children

For children, stress that they live in some dirty house, eat very little and unhealthy living around some parents who are stressed as well and they are uninterested in what happens to their children, of some neighbors with the same level of poverty, affects both mentally and physically.

Although are very poor, I noticed that most of them smokes a lot, and drowns his sorrows in several glasses of drink and that makes them aggressive with their families and unfortunately their children who grow up in such environments do nothing but use the same behavior, they are not integrate into society and become addicted to alcohol and drugs.

All this leads to many health problems, which due to lack of money and education not solve them, reaching the death rate increases significantly.

Stress can lower the potential to focus on teaching, the behavior change.

By including children in sports activities in schools or sports clubs, decrease the level of illness because of the environment in which they live, reduce stress, and increase their adaptation to their social environment and the opportunity to develop physical harmony.

Returning to the factors that influence poor human health, they are very numerous: from misery to poor eating habits, stress of being poor, cold winter and so on, all these factors affect both the human psyche and the muscular system, articular, nervous, circulatory, cardiovascular, etc.

5. Study on practicing physical exercise by people with health problems

Studies show that only 10% of the population is sport frequently, which means that the remaining 90% are ideal candidates of heart disease.

In some studies the results show that in patients with heart problems and prediabetes both physical and medications reduce the risk of death. Among patients who have suffered an accident stroke, physical activity appears to be more efficient than drug therapy.

Fig.3. Those poor children

Regular physical activity using large muscle groups, such as walking, running, or swimming, produces cardiovascular adaptations that increase exercise capacity, endurance, and skeletal muscle strength. Habitual physical activity also prevents the development of coronary artery disease (CAD) and reduces symptoms in patients with established cardiovascular disease. There is also evidence that exercise reduces the risk of other chronic diseases, including type 2 diabetes, osteoporosis, obesity, depression, and cancer of the breast and colon.

This American Heart Association (AHA) Scientific Statement for health professionals summarizes the evidence for the benefits of physical activity in the prevention and treatment of cardiovascular disease, provides suggestions to healthcare professionals for implementing physical activity programs for their patients, and identifies areas for future investigation. This statement focuses on aerobic physical activity and does not directly evaluate resistance exercises, such as weight lifting, because most of the research linking physical activity and cardiovascular disease has evaluated aerobic activity. Whenever possible, the writing group has cited summary articles or meta-analyses to support conclusions and recommendations. This evidence supports the recommendation from the Centers for Disease Control and Prevention (CDC) and the American College of Sports Medicine (ACSM) that individuals should engage in 30 minutes or more of moderate-intensity physical activity on most (preferably all) days of the week.

Let's talk about depression. In Romania, people suffering from depression rises to the top limit of the European Community, that means over 3 million Romanian – that means 15% of the population of the country.

Since the early twentieth century until today have done hundreds of studies demonstrating the immense benefits to the mental health of regular exercise. The results of research, which involved hundreds of thousands of people cannot be challenged by any member of the scientific community, therefore it is and prefer keeping silence about this therapy in medical protocols taught in medical schools. So, as the area moves a lot of money, enough to be purchased research institutes, politicians and psychiatrists, the world suffer and suffer increasingly more diverse mental disorders, although the improvement and even cure can be so close. Research proves the positive effects of exercise for most mental disorders: anxiety, depression, panic, schizophrenia, Alzheimer's dementia, etc.

In recent years, studies have focused on the benefits of exercise on mental and emotional health. Both youth and adults who practice exercise regularly have better mental and emotional health compared with the inactive, sedentary and "exercise reduces symptoms of depression and anxiety and improves disposition " (World Health Organization-WHO).

Therefore, WHO recommends exercise as a way of reducing the risk of depression or anxiety. Lifestyle changes and, in particular, the practice of regular physical exercise has become an alternative or complementary intervention as psychotherapy and drug therapy.

6. Conclusions

Physical exercise is an effective way of regulating or controlling the negative emotional states (depression, anger, anxiety, worry); improves quality of sleep; reduce the tension, fatigue and negative impact of daily stress.

Planned involvement in physical activity also increases the frequency of social interactions which has as consequences that strengthening social support and increase the positive feedback received. The consequence of this is to improve wellness and reduce anxieties or depression.

Although poor some people are more open to learn what is right and accept some advice, which often lead to changing conceptions of life.

If exercise were a pill, it would be one of the most cost-effective drugs ever invented," says Dr Nick Cavill, a health promotion consultant.

Research shows that physical activity can also boost self-esteem, mood, sleep quality and energy, as well as reducing your risk of stress, depression, dementia and Alzheimer's disease.

People are less active nowadays, partly because technology has made our lives easier. We drive cars or take public transport. Machines wash our clothes. We entertain ourselves in front of a TV or computer screen. Fewer people are doing manual work, and most of us have jobs that involve little physical effort. Work, house chores, shopping and other necessary activities are far less demanding than for previous generations.

We move around less and burn off less energy than people used to. Research suggests that many adults spend more than seven hours a day sitting down, at work, on transport or in their leisure time. People aged over 65 spend 10 hours or more each day sitting or lying down, making them the most sedentary age group.
